SEKE 2011 Foreword

On behalf of the Program Committee Co-Chairs and the Program Committee of the 2011 International Conference on Software Engineering and Knowledge Engineering (SEKE2011), we sincerely welcome you to contribute and attend SEKE-2011 in Miami Beach, Florida, USA.

The International Conference on Software Engineering and Knowledge Engineering has entered its 23rd year. In the past twenty-two years, the International Conference on Software Engineering and Knowledge Engineering has provided a unique and important forum for academic and industrial researchers and practitioners to exchange research ideas, results and application experience in software engineering and knowledge engineering.

This year's technical program is prepared and organized by a great team of Program Co-Chairs, who are listed below.

Program Co-Chairs:
Du Zhang, California State University Sacramento, USA
Marek Reformat, University of Alberta, Canada
Swapna Gokhale, University of Connecticut, USA

It has been my great honor and pleasure to serve as the SEKE2011 Program Committee Chair and work with this great team and the program committee members to prepare a rich and solid technical program as well as the high quality conference proceedings. The published conference proceedings contain the papers accepted and selected for presentation at SEKE2011 based on a rigorous review process. I hope it will serve as a valuable reference for the research community in the coming years.

We received 224 submissions from 33 countries. The acceptance rate for full papers is 33%, and that for short papers is 29%. This year, 150 authors from 30 countries (Australia, Austria, Brazil, Canada, China, Cyprus, Denmark, Egypt, England, France, Germany, India, Italy, Japan, Korea, Malaysia, Mexico, New Zealand, Peru, Portugal, Scotland, Senegal, Singapore, Spain, Sweden, Switzerland, Tunisia, Turkey, UK, and USA) will present 75 regular papers, 65 short papers, and 5 demo posters at the conference.

As the Program Chair for this Conference, I am very grateful to have this opportunity to work with three distinguished SEKE2011 Program Committee Co-Chairs and the committed program committee members. Their excellent support and prompt review efforts led to the successful organization of SEKE2011 technical program. I want to extend my sincere and deepest thanks to Dr. Shihong Huang and Dr. Xiaoying Bai as the Publicity Co-Chairs, Dr. Hironori Washizaki as the Asia Liaison, Dr. Jose Carlos Maldonado as the South America Liaison. My appreciation also goes to the keynote speakers and special address presenter for sharing their visions, insights, and experiences with the conference attendee about emergent technologies and trends, research topics and issues in both academic research and industry applications. Moreover, I like to express my appreciation to the organizers of the new poster/demo session, namely, Dr. Farshad Samimi, Dr. Ming Zhao, and Dr. Raul Garcia Castro for their great contributions. In addition, I would like to thank Dr. S. K. Chang, the Steering Committee Chair, and Dr. Jerry Gao, the Conference Chair, for their excellent guidance throughout the conference preparation process. Last but not the least, I owe a special gratitude to the staff members of Knowledge Systems Institute, specially, to David Huang and Rachel Lu, for their great efforts and timely support.

Finally, I truly hope you will enjoy the technical program of SEKE2011, have productive discussion, great presentation and networking. Of course, I sincerely hope you will all explore and enjoy the sunshine state of Florida and various attractions in Miami Beach area.

Masoud Sadjadi
SEKE2011 Program Chair

Keynote I
Sustainable Software Systems for Real Time Applications

Dr. S. Sitharama Iyengar
Ryder Professor of Computer Science
Director of School of Computing and Information Sciences
Florida International University
and
Roy Paul Daniels Professor and Chairman
Department of Computer Science
Louisiana State University

Abstract

Development of software systems for Real Time Applications is at a critical juncture. Investments in software developments for these sytems will require transformative changes in the context of science, design and policies. This talk provides an overview in achieving sustainable software systems for sensor based real time applications. It will also focus on the consumer demand and policy incentives of these applications.

About the Speaker

Dr. Iyengar is a Member of the European Academy of Sciences, a Fellow of the Institute of Electrical and Electronics Engineers (IEEE), a Fellow of the Association of Computing Machinery (ACM), a Fellow of the American Association for the Advancement of Science (AAAS), and a Fellow of the Society for Design and Process Science (SDPS). He has received the Distinguished Alumnus Award of the Indian Institute of Science, the IEEE Computer Society's Technical Achievement Award, and the IEEE Golden Core Member award. Dr. Iyengar has published over 400 research papers in journals and conferences and has authored, co-authored, or edited 14 texts in the areas of parallel algorithms, sensor networks, wavelets, robotics, and computer modeling of complex biological systems. Cited well over 4,500 times, his research has been funded by DARPA, NSF, ONR, DOE, MURI, NRL, ARO, NASA, and state governments and the industry. Dr. Iyengar has graduated 42 Ph.D. students. He is the founding Editor-In-Chief of the International Journal of Distributed Sensor Networks and has been an Associate Editor for IEEE Transaction on Computers, IEEE Transactions on Data and Knowledge Engineering, and guest Editor of IEEE Computer Magazine. Dr. Iyengar is a pioneer in the field of distributed sensor networks, computational aspects of robotics, and oceanographic applications. He is best known for introducing novel data structures and algorithmic techniques for large scale computations in sensor technologies and image processing applications. His work has had significant impacts in buy-at-bulk network design problems which further affect a wide range of practical applications including the areas of communication and transportation networks. He has also pioneered a universal technique for finding the Price of Anarchy of every bottleneck congestion game, extending the game theory to applications in network routing, scheduling and cloud computing.

Keynote II
Applications & Services Exploration for the Broadband Mobile Systems

Bao-Shuh Lin, Director
Microelectronics and Information Systems Research Center (MIRC)
National Chiao Tung University, Taiwan

Abstract

The system characteristics of future broadband mobile systems are high throughput (data rate), low latency (delay), high mobility (km/hr), and high capacity. The current recognized broadband mobile systems should meet the requirements specified by IMT-Advanced. Those broadband mobile systems include 3GPP-LTE/LTE-advanced and IEEE-802.16e/802.16m (Mobile WiMAX 1.0/ Mobile WiMAX 2.0). In the mean time, the smart phones with powerful embedded CPU/GPU, high-resolution digital camera, GPS, various sensors and digital compass are becoming popular. With the combination of the deployment of broadband mobile systems and the usage of smart mobile phones, there are many potential appealing applications & services can be creating. In this talk, we will explore several software intensive applications and services include mobile augmented reality, mobile healthcare, and high speed rail.

About the Speaker

Prof. Bao-shuh P. Lin, an IEEE Fellow, is a Chair Professor of Department of Computer Science and the Chief Director of Microelectronics and Information Systems Research Center (MIRC), National Chiao Tung University (NCTU) in Hsinchu, Taiwan since September 2009. He was the Vice President of Industrial Technology Research Institute (ITRI) and the General Director of the Information & Communications Research Laboratories (ICL) of ITRI from 2001 to 2009. During the same period, he was also the Director of Committee of Communication Industry Development (CoCID), Ministry of Economic Affairs (MOEA) in Taiwan. He obtained his Ph.D. in Computer Science from the University of Illinois at Chicago, USA, and has published more than 130 technical papers and reports in ICT fields. In his long professional career, Dr. Lin has won numerous significant awards, has been actively involved in science and technology policy formulation, and helped initiate national programs on System on Chip, Broadband and Wireless Communications, All-IP Networking and Services, and Mobile Digital Life technologies. All these efforts have exerted tremendous impacts on economic and social benefits in Taiwan.

Visual Specification of Component-based Slow Intelligence Systems

Shi-Kuo Chang[1], Yingze Wang[1] and Yao Sun[1]
[1]Department of Computer Science, University of Pittsburgh, Pittsburgh, PA 15260, USA
{chang, yingzewang, yaosun}@cs.pitt.edu

Abstract

A new approach for the visual specification of component-based software systems is proposed. The main idea is to employ two visual representations - the I-card (information card) and the C-card (control card) - together to specify a component-based software system. This approach is especially useful in the specification and design of component-based slow intelligence systems. This approach is currently being applied to the design of slow intelligence system for social influence analysis.

Keywords

Visual specification, component-based software system, slow intelligence system, super component

1 Introduction

In the specification of component-based software systems, control and timing information is often unclear or even lost. If a formal, mathematical approach is used, control and timing information could be buried in the details and become unclear to the designer/programmer. If a less formal approach is used, such information could be lost.

In this paper, a new approach for the visual specification of component-based software systems is proposed. The main idea is to employ two visual representations - the *I-card (information card)* and the *C-card (control card)* - together to specify a component-based software system. This approach is seemingly simple, but actually quite powerful. This approach is also especially applicable to the specification and design of slow intelligence systems where *super components* are employed to search for solutions.

A slow intelligence system (SIS) is a general-purpose system characterized by being able to improve performance over time through a process involving *enumeration, propagation, adaptation, elimination and concentration* [Chang2010]. A SIS is a component-based software system, but it differs from ordinary component-based systems by employing super components, in the sense that multiple, similar components can be activated either sequentially or in parallel to search for solutions. The proposed visual specification approach is especially suitable for the specification and design of such systems with super components.

The paper is organized as follows: Section 2 explains in detail this visual specification approach using dual visual representations. In Section 3, we describe the user interface design to produce and manage the dual visual representations for the generic SIS system. Finally, Section 4 discusses future works.

As described in [Chang2011b], we are applying this approach to design the slow intelligence system for social influence analysis (SIA).

2 Visual Specification of Component-based Software Systems

2.1. Dual Visual Representations

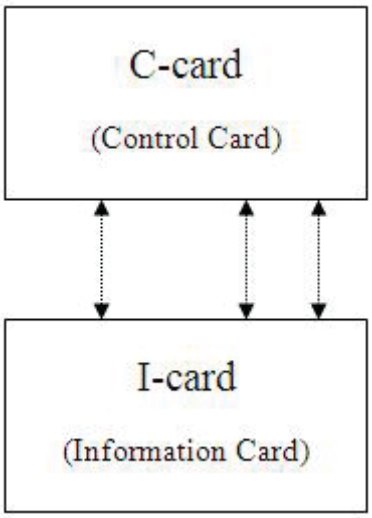

Figure 2.1. Dual visual representations.

The main idea is to employ two visual representations - the *I-card (information card)* and the *C-card (control card)* - together to specify a component-based software system. A generic example is illustrated in Figure 2.1. The I-card specifies the logical relationships among the components, and the C-card specifies the control and timing relationships among the components. Their inter-relationships are represented by bi-directional arcs (the dotted lines) connecting components, or other entities, in the I-card and the C-card.

2.2. An Example

In the following example, the two components X1 and X2 can be either simple components or super components. We will first give an example involving only simple components. Suppose there are two components X1 and X2. The component X1 is invoked first, followed by the invocation of component X2.

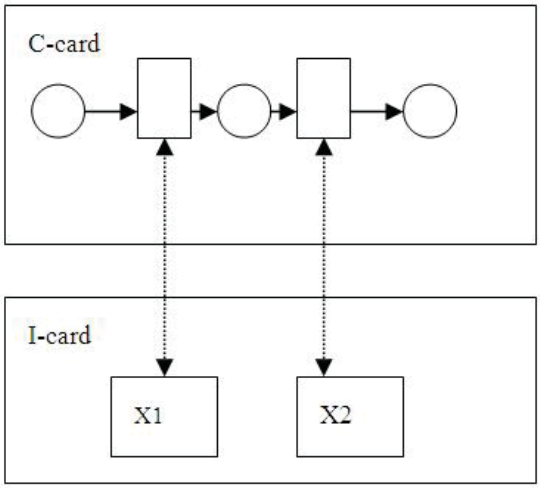

Figure 2.2. Dual visual representations by components and Petri net.

As shown in Figure 2.2, the two components are specified in the I-card as two rectangles. This specification for components can be further refined. For instance each component can be described by a detailed class diagram in UML. The timing relationships among the two components are specified by the Petri net in the C-card, where places are represented by small circles, and transitions by vertical rectangles. The Petri net's transitions in the C-card correspond to the components in the I-Card, therefore they are linked by dotted lines.

Although a Petri net is used in the above example, we can also replace the Petri net by other kinds of timing diagrams such as the sequence diagram or the activity diagram in UML. We can now give another example as illustrated by Figure 2.3. This example illustrates the simplicity, flexibility and versatility of this approach. We can use different diagrams in the I-card and the C-card to present different views of the component-based software system.

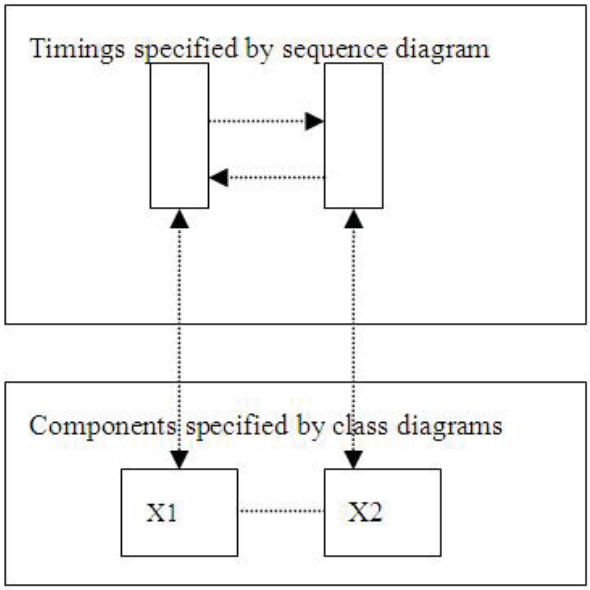

Figure 2.3. Dual visual representations by class diagram and sequence diagram.

It is also possible to associate multiple diagrams for multiple views of a component-based software system. However our primary interest in this paper is to introduce the notation for super components so that we can specify and design slow intelligence systems using this extended notation. Multiple view visualization and consistency checking will be the topic for a subsequent paper.

2.3. Super Components

As mentioned before, in the above example the two components X1 and X2 can be either simple components or super components. A *super component* X1 is a collection of similar components x_1^1, x_1^2, …, x_1^j, retrieved from some component database or generated by some algorithm. As shown in Figure 2.4 the visual representation of a super component is a box with double-edged border.

With super components, the Petri net in the C-card is actually a concise representation of a much larger underlying Petri net, such as the one shown in Figure 2.5. It should be pointed out this is by no means the only possible expanded Petri net. As noted above, depending upon the meaning of the association between the I-card and the C-card, different expanded Petri nets can be generated.

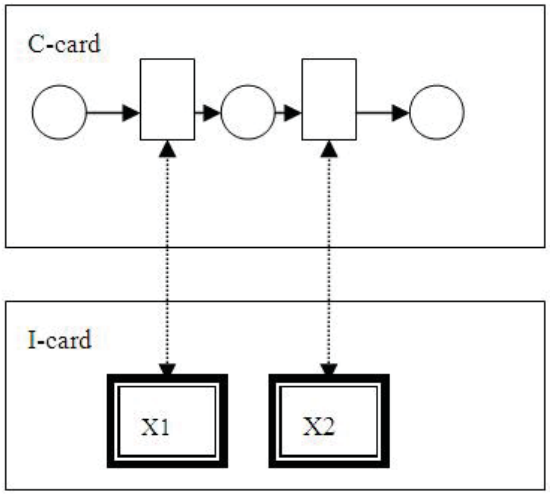

Figure 2.4. Super Components.

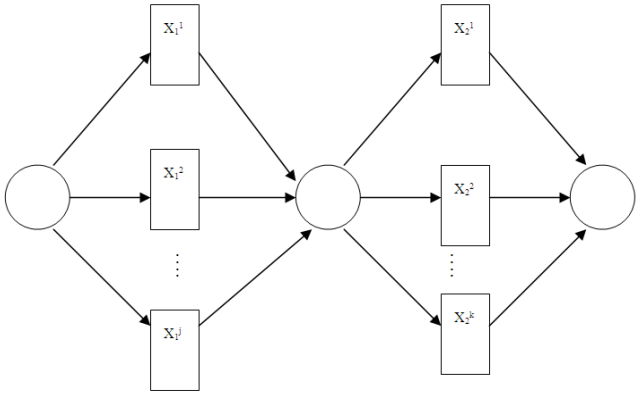

Figure 2.5. Expanded Petri net based upon super components.

With different visual diagrams embedded in the C-card, the interpretations could be different in each case. For instance if sequence diagrams are used instead, we can envision for each super component, a subsidiary sequence diagram could be generated to render a precise and detailed specification of the entire system.

2.4. SIS Design using Super Components

The super component can also be further refined. A super component is essentially a concise representation of a collection of components. Therefore we can employ a generic design pattern or a *component generator* to specify such a super component.

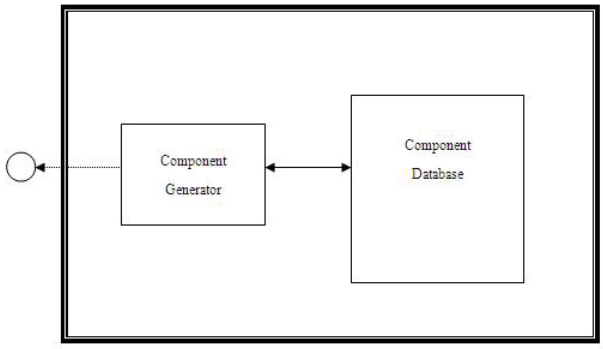

Figure 2.6. A component generator for super components.

In Figure 2.6 the small circle indicates the sub-system interface. The component generator produces customized components by accessing the component database. In practice, the component database could contain the parameters to generate customized components. In some cases the components can be algorithmically generated without referring to a component database. In which case, Figure 2.6 can be further simplified by eliminating the component database.

As noted in [Chang2010] a slow intelligence system can be designed based upon five SIS primitives (or five SIS design patterns): *enumerator*, *adaptor*, *eliminator*, *concentrator* and *propagator*. They can also be specified using the notation of super components. Therefore, with the notation of super components, and the dual visual representations using I-card and C-card, we can visually design a slow intelligence system. In the following sections, we will describe the design of a versatile user interface supporting visual design using the dual visual representations.

3 User Interface for SIS System

In this section we describe the user interface design to create and manage the dual visual representations for the SIS system. Based on SIS system framework, the user interface can be designed for three specific tasks: (1) Interface for designing control card. In our generic SIS system, control card (C-Card) can define functional dependency repertoire. (2) Interface for designing information card (I-Card). For SIS system, I-card can define candidate functions repertoire. (3) Interface for designing testing data, which in our SIS system is stored in test data repertoire.

3.1. User Interface for designing C-card

Each functional component is a super component or a simple component that can be represented by a transition in a Petri Net. Here super component is a collection of components; while simple component is a single component. We need to define the dependencies between

different functional components. User interface is used to draw Petri Net as shown in Figure 3.1.

We developed our user interface based on [Bonet 2007] PIPE tool, which is a powerful software for editing Petri Net. In Figure 3.1, particularly, unfilled rectangle represents transition for defining simple component. Filled rectangle represents super component. Circles represent the places. User can utilize the Petri-net to define the sequence and dependency among functional components. Moreover, we extend the meaning of Petri Net that places can represent the messages sending from one transition to another, as shown in Figure 3.2. Since slow intelligence system uses messages to communicate among each component. Thus, in message editor, user can define a list of messages related to the particular place, which enhance the power of Petri Net. Note that messages can be automatically mapped to MsgID defined in system, so that users don't need to know the exact MsgID. After designing the Petri-net for a specific system, user can save the diagram in xml format, such as the Petri Net Markup Language (PNML), which is an XML-based syntax for high-level Petri nets designed as a standard interchange format for Petri net tools [Weber2003].

We give an example as shown in Figure 3.1. This is a simple Petri Net with two transitions named "Enumerator" and "Diffusion Model". Enumerator represents a simple component while "Diffusion Model" represents a super component. This Petri Net shows that Diffusion Model depends on Enumerator. Such dependency relationship indicates that super component Diffusion Model should execute after Enumerator's execution. Also Enumerator can send message "Enumeration Notify" to Diffusion Model edited by place P1. The saved xml file of this Petri Net in PNML format is:

```

3.2. User Interface for designing I-card

After designing the dependencies among functional components for SIS generic system, the user needs to devise the information card for each component (super component and/or simple component). For a super component containing a number of candidate components, we need to use I-Card to add each candidate component from database or from the template algorithm with different parameters to this super component. For a simple component in Petri-net, although there is only one component, we still need to add it from database or specific algorithm. In slow intelligence system, there are two types of functional components: system components like enumerator, eliminator, etc; algorithm components like diffusion model for social influence analysis. Each type of component can be simple or super. Usually system component is simple one while algorithm component is super one. The user interface design is shown in Figure 3.3.

When user right clicks on transition, the transition editor

will pop up. User can define the component type in comb box and edit the corresponding component I-Card. If it is the existing one, the user can load it. The system component I-Card editor interface contains a comb box to define name of component. Each type of system component has specified Key. When user selects one, the corresponding key will shown on table. The user only needs to define the value of the Key. Figure 3.3 gives an example. The system component I-Card is saved as a .txt file using format:

$$BEGIN and END are keywords
BEGIN ConcurrentComps
5
END ConCurrentComps

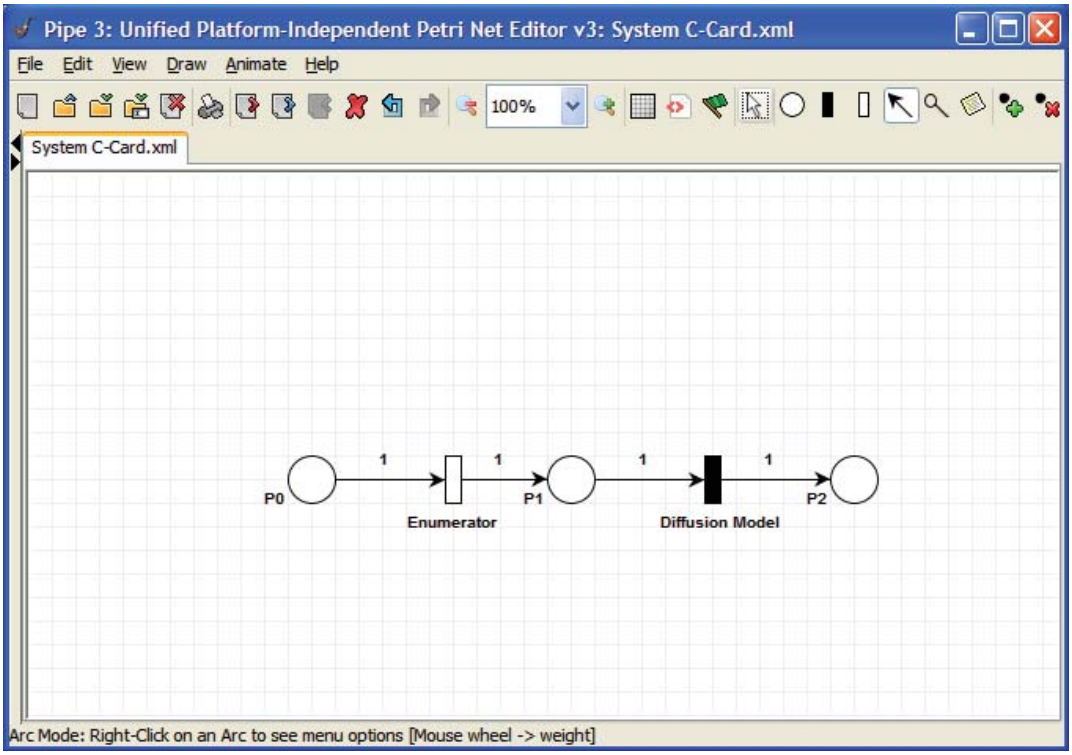

Figure 3.1. Screenshot for C-card Design.

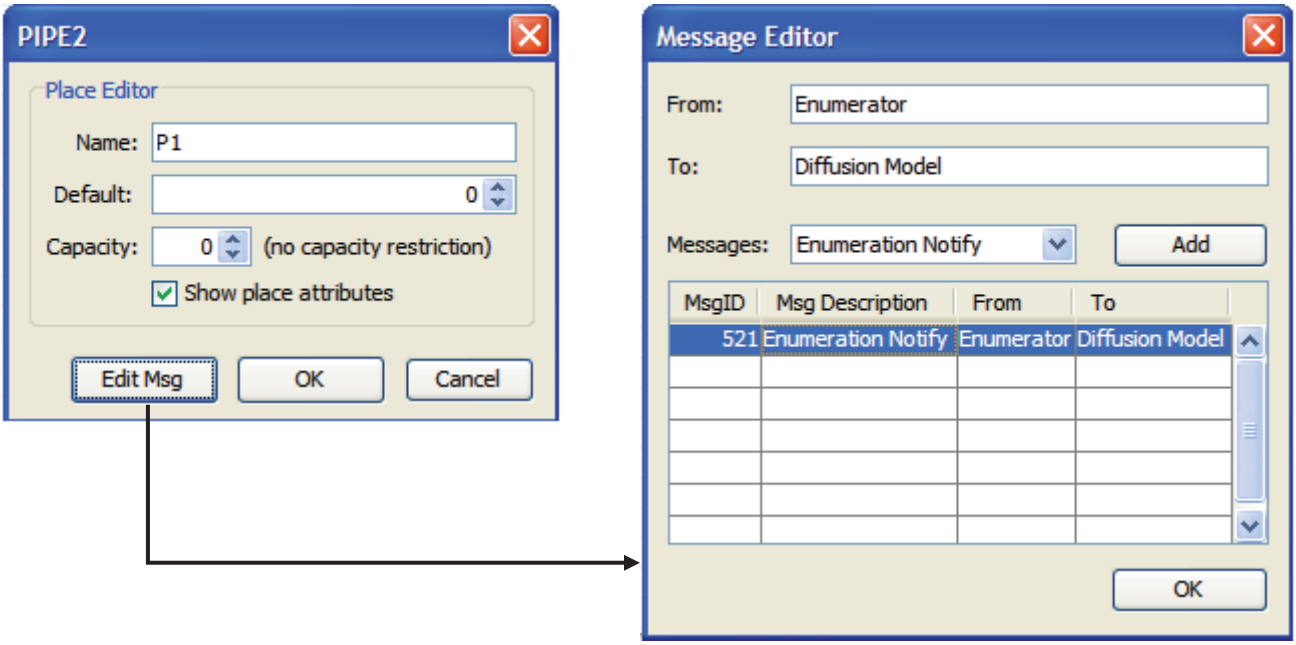

Figure 3.2. Screenshot for place editor and message editor design.

Algorithm component I-Card editor contains three Panels. In panel "property", if the transition is filled rectangle, the type should be super component and the user can add each candidate component to this super set. If the transition is unfilled rectangle, the type should be simple component and the user only needs to add one candidate component. Since the candidate (simple or super) components in each functional block do the same job using different algorithms, thus in the interface, "Functions" edit box describes the job of this functional block. User should choose the way that enumerator of SIS system (Component generator) performs, using all the candidate components or using only one of them. If user chooses "one candidate component", he/she should input the default candidate ID number that will be utilized. The list on right shows the name of "Candidate components" that user added. Also user can click "details" tab to see the details of each candidate component in a table. For each algorithm functional component (I-Card), there is a test data set for testing each candidate component in this block. Thus in panel "Testing Data", user can edit the dataset by T-Card editor in next subsection. This algorithm component I-Card can be saved as xml format.

We give a simple example as shown in Figure 3.3. This I-card corresponds to transition "Diffusion Model" in Figure 3.1, which is a super component containing two candidate components. The candidates are from template algorithm with different parameters. Thus the user can load the template and set different parameters as shown in Figure 3.3. Since the user defines by enumerating all candidate components, thus there is no default one. The saved xml file of this Petri Net could follow the format:

```
<Msg>
  <Head>
    <Name>
    </Name>
    <Description>
    </Description>
  </Head>
 <Body>
<Item>
      <Key>
      </Key>
    <Value>
    </Value>
  </Item>
 <Body>
</Msg>
```

Tab <Name> shows the name of I-Card. Tab <Description> shows brief description of this I-Card. Tab <Key> indicates the key text such as: Type, Candidate Name, etc. Tab <Value> indicates the value of user's input in textbox. Thus, <key> and <value> should be pairs. For example, some pairs as shown in Figure 3.3 are:

```
  <Item>
   <Key>Candidate Name
   </Key>
  <Value>Diffusion Model 2
  </Value>
 </Item>
  <Item>
   <Key>ID Number
   </Key>
  <Value>2
  </Value>
 </Item>
  <Item>
   <Key>Template
   </Key>
  <Value>Yes
  </Value>
 </Item>
  <Item>
   <Key>Parameter
   </Key>
  <Value>3.0
  </Value>
 </Item>
```

3.3.User interface for designing test data

Figure 3.4 shows the interface of designing testing data for testing each candidate component in algorithm functional component block. This split panel includes two parts. The left part is used to load testing data from existing files and to specify the output results property. User can browse existing file and define the place to store the result. The right part is designed for the purpose of simple testing and debugging. User can manually edit the data on the table. The input data could be any value including number, string, boolean variable. The output data is the correct result corresponding to input. Then user can compare their algorithm's results to these standard results.

We give an example as shown in Figure 3.4. This T-card corresponds to algorithm component I-Card defined in Figure 3.3. The T-Card is saved as a .txt file using format:

```
$$BEGIN and END are keywords
BEGIN InputDataList
/*List test data files*/
Twitter.txt          D:\SIS\Data\Twitter.txt
END InputDataList

BEGIN OutputPro
/*List output results property*/
txt        D:\SIS\Result
END OutputPro
```

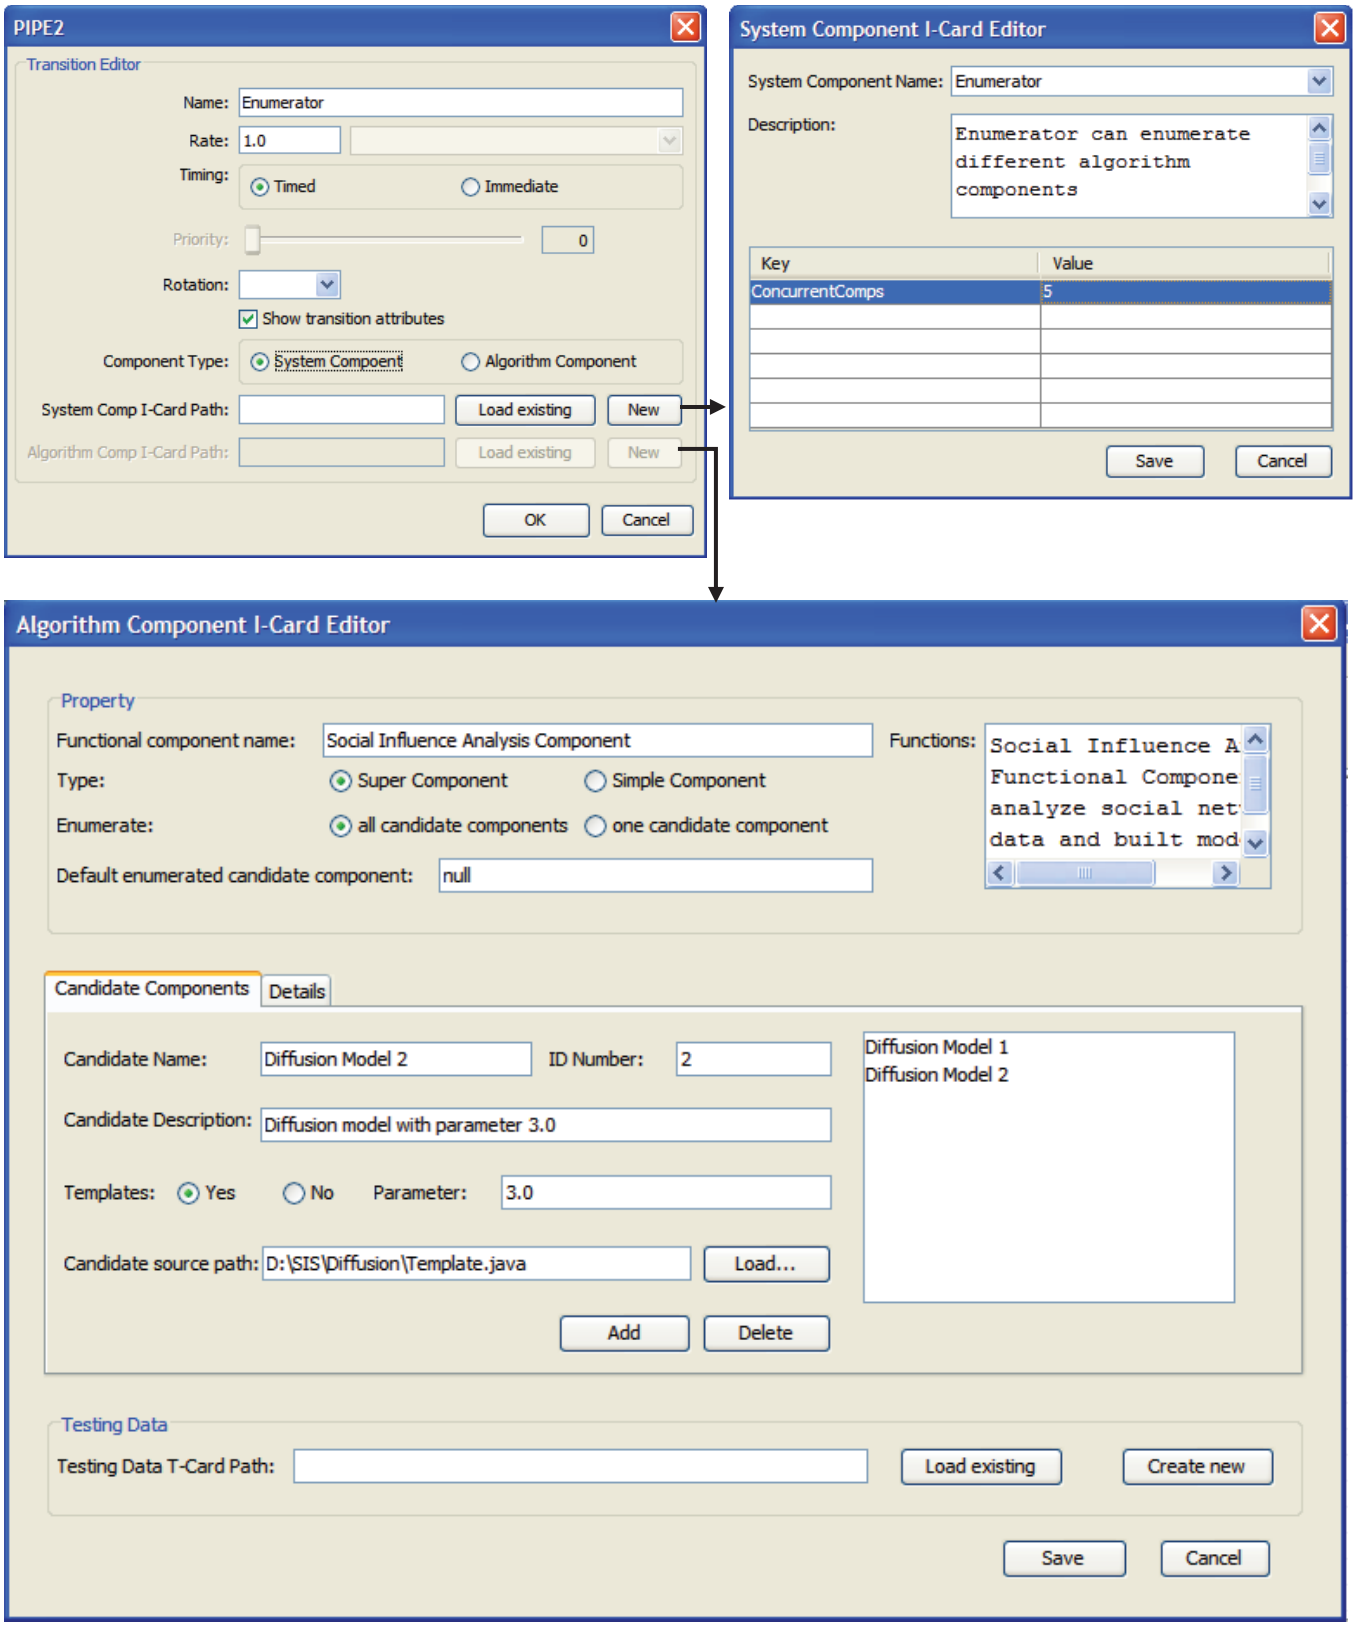

Figure 3.3. Screenshot for I-Card design.

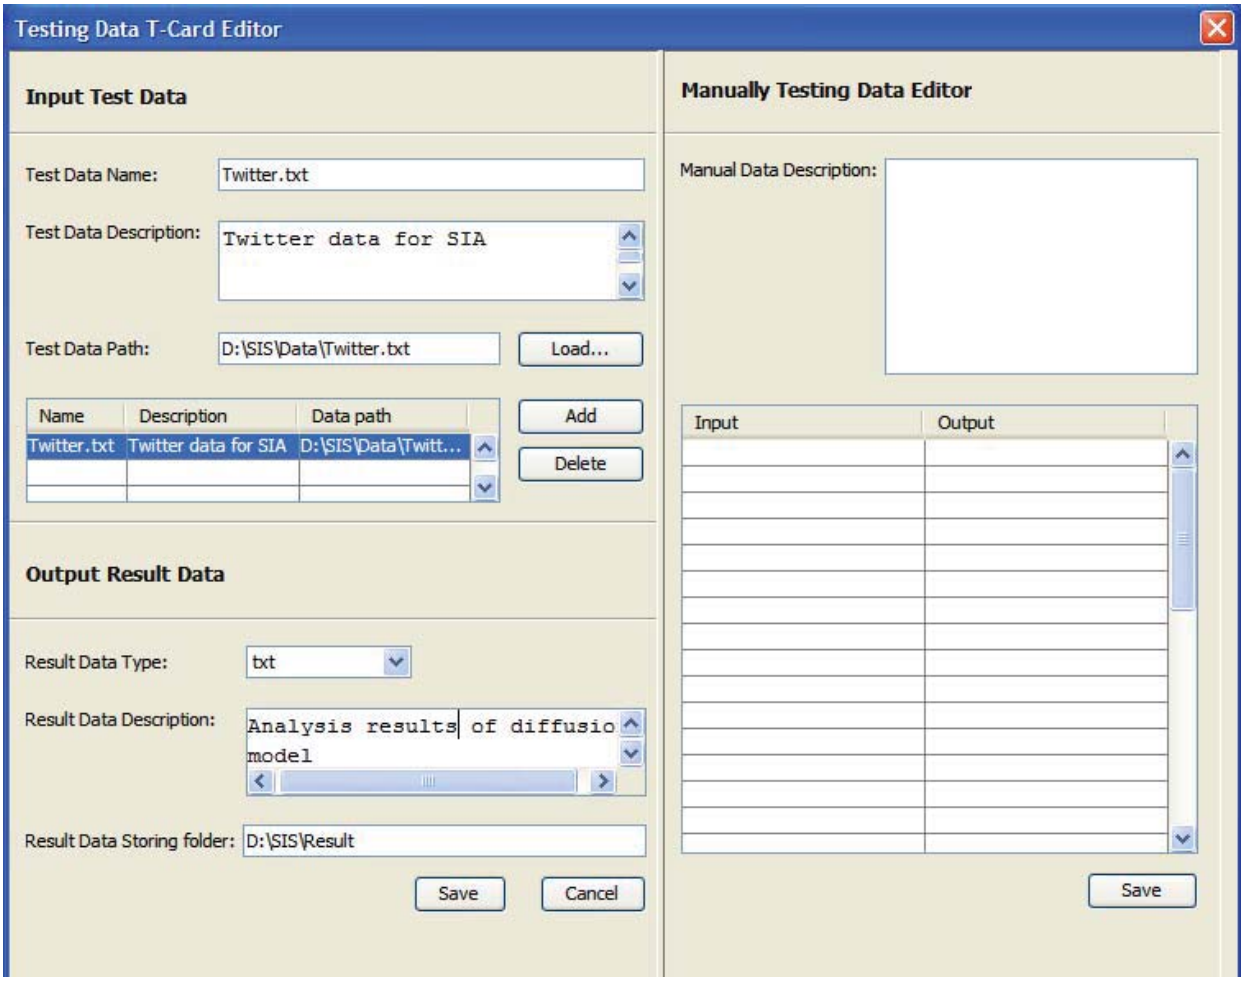

Figure 3.4. Screenshot for Testing Data design.

4 Discussion

In this paper we described a new approach for the visual specification of component-based software systems by employing two visual representations - the *I-card (information card)* and the *C-card (control card)*. The user interface for visual specification of component-based software system is currently being developed. For practical convenience, a *T-card* can be used to specify test data.

We can use different diagrams in the I-card and the C-card to present different views of the component-based software system. It is also possible to associate multiple diagrams for multiple views. Furthermore, the bi-directional arcs between the two visual representations can be labeled to specify the meaning of the associations so that different interpretations can be generated from the visual specification. How to check the consistency of multiple views, and how to synthesize a consistent spec from multiple views, will be topics for further research.

Abstract

We present the architecture and operational characteristics of a generic SIS system. To design the SIS system we also provide the data structures and operating procedures to describe each system component. We are applying this approach to design the Slow Intelligence System for Social Influence Analysis. Some initial experimental results are also reported.

Keywords

Component-based software system, slow intelligence system, super component, social influence analysis

1 Introduction

A slow intelligence system (SIS) [Chang2010] is a general-purpose system characterized by being able to improve performance over time through a process involving *enumeration, propagation, adaptation, elimination and concentration*. A SIS continuously learns, searches for new solutions and propagates and shares its experience with other peers. A SIS is a system with multiple decision cycles such that actions of slow decision cycle(s) may override actions of quick decision cycle(s), resulting in poorer performance in the short run but better performance in the long-run.

A SIS is characterized by employing super components, in the sense that multiple components can be activated either sequentially or in parallel to search for solutions. In [Chang2011a] we explained in detail a visual specification approach using dual visual representations, and described the user interface design to produce and manage the dual visual representations for the generic SIS system. In this paper we further present the design of component-based slow intelligence systems, and the application of SIS to social influence analysis. Some initial experimental results are also reported.

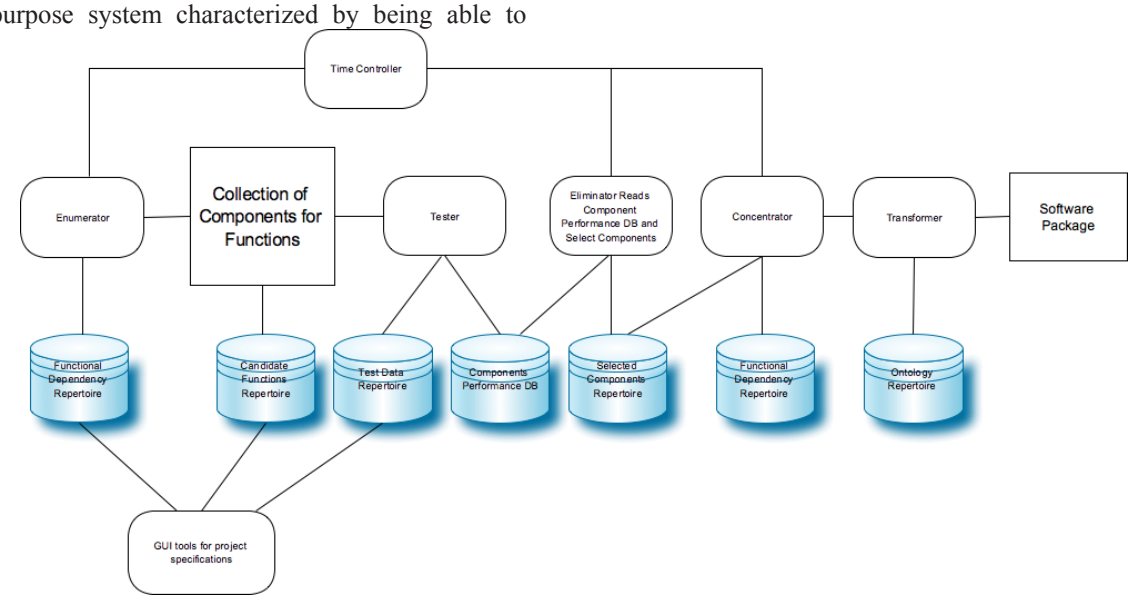

Figure 2.1. System architecture of Component-based Slow Intelligence System.

The paper is organized as follows: In Section 2 we present the architecture and operational characteristics of a generic SIS system. To design the SIS system we also provide the data structures (Section 3) and operating procedures (Section 4) to describe each key system component. In Section 5 we apply this approach to design the Slow Intelligence System for Social Influence Analysis (SIA).

2 A Generic Component-based SIS

2.1. System Architecture

Figure 2.1 illustrates the system architecture comprising the key components of the SIS system. The slow intelligence components are Enumerator, Eliminator, Concentrator and Time Controller. In addition, a customized Tester and a Transformer are included to provide more functionalities.

The system works as follows. The Enumerator reads in the specification of functional blocks and creates multiple candidate components for each functional block. The Tester tests all the functional blocks and records their performance in the DB. The Eliminator selects the best candidate components based upon their performance. The Concentrator packs the selected candidate components based on dependency specifications and generates a generic software package. When there are terminological and/or conceptual differences within the software package, Transformer is used to transform the Concentrator-generated software package to target software package that serves specific purpose. The Time Controller is sort of like an automatic system manager, it controls all the above mentioned components, telling them when to perform actions. That is to say, Enumerator, Eliminator and Concentrator perform their tasks multiple times upon Time Controller's instructions.

2.2. Specification

Specification is the very first phase of the system. As shown in Figure 2.2, a GUI program is used to specify a certain system. The GUI can be divided into three different parts. One for specifying functional blocks dependency, one for specifying pools of candidate components for functional blocks, and the other for specifying test data for functional blocks.

All the three specifications are stored in three different repertoires. *Functional blocks dependency repertoire* stores the dependencies between different functional blocks, for example, which functional block's output is which functional block's input. As what their names imply, *candidate functions repertoire* stores all the candidate components for functional blocks, and *test data repertoire* stores all the test data for use of testing candidate components for functional blocks.

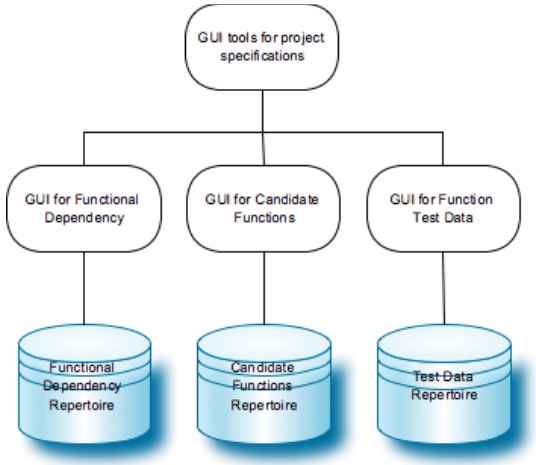

Figure 2.2. Specification of Component-based Slow Intelligence System.

In practice, we will use the dual visual representation method described in [Chang2011a] to design the GUI for our component-based Slow Intelligence System. We can use C-card to specify the functional block dependency, I-card to specify pools of candidate components for functional blocks, and T-card to specify test data.

2.3. Initial Run

In this phase, Enumerator first reads in the functional blocks dependencies from the functional blocks dependency repertoire and creates multiple candidate components for each functional block. The candidate components are selected from candidate functions repertoire. In Figure 2.3, we show in detail what is called *components for functions* in the whole system diagram. In the components for functions, all candidate components are classified into different *functional blocks*, which are actually what we have introduced as *super components* in [Chang2011a]. We use the same double-edged notation as in [Chang2011a] to depict the super components in Figure 2.3. And within each functional block, the candidate components do the same job using different algorithms or different parameters. We will discuss how the candidate components are generated in Section 4.1. Tester starts running in this phase and keeps running for ever until the system halts. Tester tests each candidate component with test data from test data repertoire and record their performance into components performance DB.

2.4. Multiple Runs

In this phase, Time Controller takes over the manager role of the system. The system goes into its main cycle of life. The system may go through multiple runs of Enumeration

and Elimination. Time Controller notifies Enumerator when to create new candidate components from candidate function repertoire and notifies Eliminator when to eliminate some candidate components based upon their performances recorded in components performance DB and store the results into selected components repertoire.

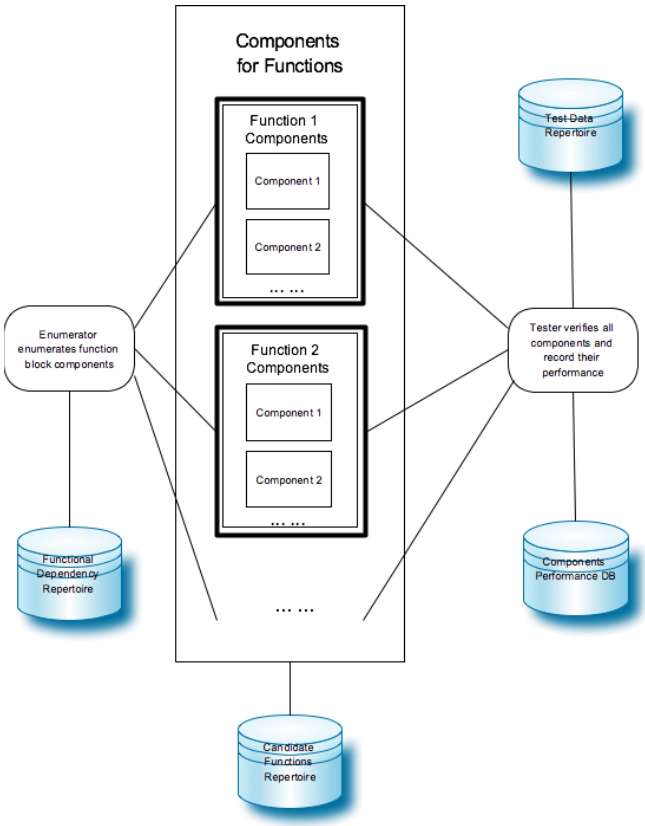

Figure 2.3. Initial Run of Component-based Slow Intelligence System.

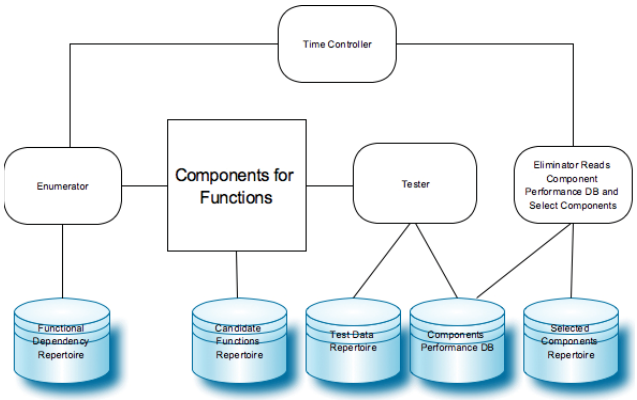

Figure 2.4. Multiple Runs of Component-based Slow Intelligence System.

2.5. Software Package Generation

This is the last phase of the system. The Concentrator reads in functional blocks dependencies from functional blocks dependency repertoire to determine the software package structure and generate a generic software package using the candidate components from selected components repertoire. Concentrator is also under control of Time Controller. When there are terminological and/or conceptual differences within the software package, Time Controller can notify Concentrator to generate intermediate software package from currently selected components and send it to the Transformer, which accesses an ontology repertoire storing the terminological and/or conceptual relations to map the intermediate software package to the target software package for specific applications.

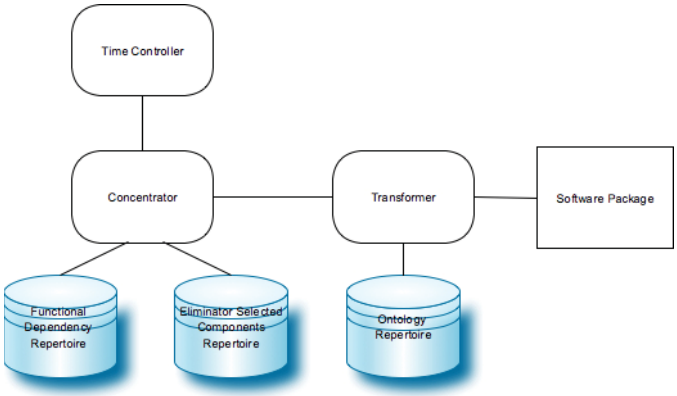

Figure 2.5. Generate Software Package.

3 Data Structures

In this section we will discuss the data structure for each repository mentioned in previous section.

3.1.Functional Blocks Dependency Repertoire

Functional blocks dependency repertoire stores the functional blocks dependencies specified by GUI tools for C-card interface described in [Chang2011a]. And it is used by Enumerator for creating functional blocks (super components)that is to be filled with candidate components. And it is also used by Concentrator to determine the functional blocks dependencies within a software package.

For functional blocks dependency repertoire, since it stores the precedence and dependencies between functional blocks, we can use structures very similar to a directed graph to store the information. We treat functional blocks as nodes and use edges to denote functional dependencies. Thus we can design the data structure as follows:

FunctionalBlockName1
FunctionalBlockName2
FunctionalBlockName3
... ...
FunctionalBlockName1->FunctionalBlockName2
FunctionalBlockName1-> FunctionalBlockName2
... ...

The first part of the data structure lists all the functional blocks that will appear in the system, and the second part lists all the functional blocks dependencies between functional blocks.

3.2. Candidate Functions Repertoire

Candidate functions repertoire stores all the candidate components specified using GUI tools for I-card interface described in [Chang2011a]. And it is used by Enumerator to generate candidate components to fill in the super components (functional blocks).

For candidate functions repertoire, we design its data structure as follows:

FunctionalBlockName1:[All or One]
Candidate1;Default;Generic
Candidate2;NonDefault;Specialized
... ...
FunctionalBlockName2:[All or One]
Candidate1;Default;Generic
Candidate2;NonDefault;Specialized
... ...

Basically, we store the candidate components by their functional block type followed by several different attributes. Here candidates denotes the address where the candidate components stores. Functional blocks can have an attribute called All or One. All means when Enumerator is generating candidate components for this functional block, it creates instances of all candidate components. One means when Enumerator is generating candidate components for this functional block, it creates only one instance of the default candidate component. Candidate components can also have different attributes. Default or Non-Default denotes whether this candidate component should be selected when the functional block has the attribute One in enumeration process. Generic or Specialized denotes whether this candidate component can have multiple instances. Generic means we can pass in different parameters to this candidate component to generate different instances. Specialized means this candidate component does not accept parameters and its instance is determined. We can have different attributes attached to candidate components when necessary.

3.3.Test Data Repertoire

Test data repertoire stores test data information for each functional block, these test data are specified by what is called T-card described in [Chang2011a]. It is used by Tester to retrieve the test data when testing different candidate components. For each functional block(super component), all its candidate components share the same test data.

For test data repertoire, the data structure is designed as follows:

FunctionalBlockName1:
Input1;Output1
Input2;Output2
... ...
FunctionalBlockName2:
Input1;Output1
Input2;Output2
... ...

3.4. Components Performance DB

Components performance DB stores all the candidate components' performance evaluated by Tester. And it is used by the Eliminator to select best or eligible candidate components. For Component performance DB, the data structure is designed as follows:

FunctionalBlockName1
CandidateName1: CorrectCount;IncorrectCount
Input1;Output1;Correctness;ResponseTime
Input2;Output2;Correctness;ResponseTime
... ...
CandidateName2: CorrectCount;IncorrectCount
Input1;Output1;Correctness;ResponseTime
Input2;Output2;Correctness;ResponseTime
... ...
... ...
FunctionalBlockName2
... ...

This means we use a list to store functional blocks, and for each functional block, we use a sub-list to store its candidate components and the candidate components' overall performance, and for each candidate component, we use another sub-list to store the candidate component's performance on certain inputs and outputs.

3.5. Selected Components Repertoire

Selected components repertoire stores all the eligible candidate components selected by Eliminator, and it is used by Concentrator to constitute a generic software package.

For component performance DB, the data structure is designed as follows:

FunctionalBlockName1:BestCandidate1
Candidate1
Candidate2
... ...
FunctionalBlockName2:BestCandidate2
Candidate1
Candidate2
... ...

This means we use a list to store functional blocks together with its best candidate component, and for each functional block, we use a sub-list to store its eligible candidate components that pass Eliminator's elimination criteria.

4 Operating Procedures for SIS System Components

In this section, we describe the operating procedures of key system components to show their functions.

4.1. Enumerator

The input to the Enumerator are functional blocks dependencies from functional blocks dependency repertoire and candidate components from candidate components repertoire. The output from Enumerator are multiple instances of candidate components for all functional blocks.

First the Enumerator reads in the functional blocks dependency specifications, retrieves all functional block names and generate a super component for each functional block. These super components are empty components that are to be filled with instances of corresponding candidate components in the next step. Next the Enumerator reads in information stored in candidate components repertoire. It checks each functional block if it needs only one candidate component instance or multiple candidate component instances. If it needs only one candidate component instance, it directly instantiate the default candidate component and fill in the super component. If it needs all candidate component instances, it instantiate all candidate component instances and fill them into the super component. There are also two ways to instantiate a candidate component. If a candidate component is generic, then we may pass in different parameters to generate multiple instances of one candidate component. If a candidate component is specialized, then only one determined instance is created for that candidate component.

4.2.Tester

The input to the Tester is all test data stored in the test data repertoire, the output of the Tester is each candidate component instance's performance, and these performances are recorded in the components performance DB.

First, the Tester reads in the test data information and classifies them by functional blocks (super components). Then it retrieves from the test data the inputs by functional block and sends the inputs to corresponding candidate components, then it checks the results returned from candidate components and compares them with the correct outputs. Finally Tester records the corresponding candidate components' performance into components performance DB. These performances are structured as described in section 3.4 in components performance DB. Tester should maintain the structure. It stores each candidate component's response time and correctness on each test input. It also maintains each candidate component's overall performance, like correctness rate and average response time.

4.3. Eliminator

The input to the Eliminator is candidate components' performance information stored in components performance DB and the output of Eliminator is eligible candidate components and best candidate component for each functional block(super component). The output is stored in selected components repertoire.

First, the Eliminator reads in all candidate components' performance information classified by functional block. Then the Eliminator eliminates unqualified candidate components by some threshold on correctness rate, i.e. eliminate candidate components whose correctness rate is below some value. The Eliminator stores the surviving qualified candidate components in selected components repertoire. We store these qualified candidate components information for next round of Enumeration and Elimination. Next, the Eliminator selects the candidate component with highest correctness rate as the best candidate for the corresponding functional block. If the correctness rates are the same for multiple candidate components, the Eliminator selects the one with shortest average response time. The best candidate component information is also stored in selected components repertoire. We may also introduce weights for different test data in the future to further evaluate candidate components.

4.4. Concentrator

The input to the Concentrator is the best candidate component information in selected components repertoire and the functional blocks dependency information in functional blocks dependency repertoire. The output is a generic software package.

First, the Concentrator reads in the functional blocks dependency information from the functional blocks dependency repertoire, then it reconstructs the functional blocks dependency graph from these information, that is a graph with functional blocks(super components) as nodes. Then the Concentrator retrieves the best candidate component from the selected components repertoire for each functional block and replace the functional blocks with their best candidate components. Finally the

Concentrator packs all best candidate components and generate a generic software package. When there are terminological and/or conceptual relations within the software package stored in an ontology repertoire, the Transformer can take this generic software package as the input and transform it into target software package to serve different specific purposes.

5 Application to Social Influence Analysis

In this section we describe how to apply this approach to the specification and design of Social Influence Analysis System. In large social networks, nodes (users, entities) are influenced by others for different reasons. How to model the diffusion processes over social network and how to predict which node will influence which other nodes in network have been an active research topic recently. Many researchers proposed various methods [Goval2010], [Yang2010], [Tang2009] in this area. How to utilize these algorithms and evolutionarily select the best one with the most appropriate parameters to do social influence analysis is our objective in applying the generic SIS system.

5.1. System Design and Implementation

First, we can utilize dual visual representations approach [Chang2011a] to design the system's control-card and information-card for the social influence analysis application. The generic SIS system architecture is shown in Figure 2.1. Omitting the details, the partial visual representations for SIA are shown in Figure 5.1.

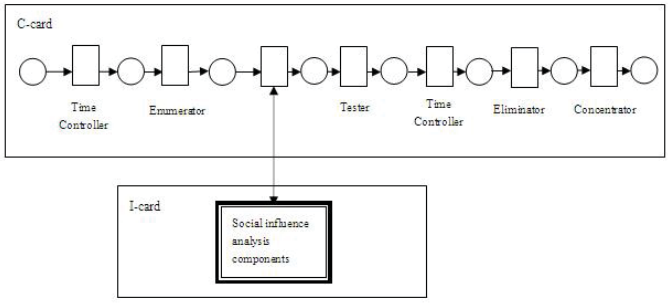

Figure 5.1. Partial visual representations for SIA system.

In this SIA system, there is only one functional block (super component) containing different candidate components for social influence analysis. All the candidate components in this super component are the different specified algorithms or the generic algorithm with different parameters doing the same job for analyzing social influence. In realization and implementation, we apply the algorithm proposed in [Yang2010], in which the authors developed a linear influence model (LIM) to analyze global influence a node has on the rate of diffusion through the implicit network. In its model, there are two parameters to control the performance. Thus we design the information card containing this generic algorithm with different parameters as the candidate components to build the super component for social influence analysis. Then our SIS system can test each parameterized algorithm and eliminate the worse ones and concentrate on the best one based on relative reduction in error.

As described in Section 2, an SIS system is a component based software system. In implementation, we use Java language. First a SIS server is implemented. The SIS server deals with all the messages between components. Messages are the only way components could communicate with each other and all the messages within the SIS system are routed through the SIS server. Components could be classified into two classes: system components and candidate components. Enumerator, Eliminator, etc. could all be treated as system components. They are responsible for initializing and managing the SIS system. And all the social influence analysis algorithms could be wrapped as candidate components in this case and provide a service to analyze social network data. They start running and wait to receive data message from the SIS server. Upon receiving the data message, they will work on the dataset and return the analysis results to SIS server. The SIS server could route the results to corresponding components such as Eliminator. Unless Eliminator closes a certain candidate component, candidate components are always running and servicing.

In social influence analysis case, the SIS system runs in the following manner. Enumerator sends initialization messages to SIS server and starts candidate components with different parameters. A data sender sends data to SIS server, SIS server routes the data to candidate components and wait for their response. When SIS server receives the response messages containing results from candidate components, the results are routed to Verifier and Eliminator for selection. After one round of elimination, the next round of enumeration starts.

We use Key/Value pairs to constitute a message. A message contains at least two Key/Value pairs, they are MsgID and Description. Customized Key/Value pairs could be added into messages. For instance, a Key/Value pair for dataset file could be added to data message. Fig. 5.2 and Fig. 5.3 provide examples of messages captured from the administrator tool of SIS system.

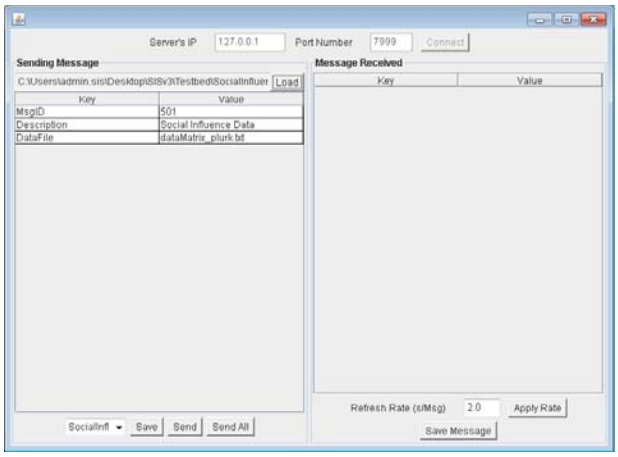

Figure 5.2. Data Message.

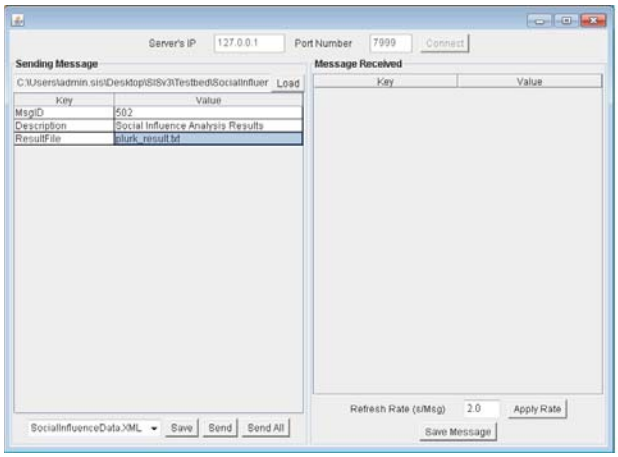

Figure 5.3. Result Message.

5.2. Experimental Setup and Initial Results

We did initial experiments on two different datasets. First, we collect the posts and responses over the Facebook between January 25th to April 22nd 2011. We choose five concepts of interest that related to some commercial products. All the concepts are in Chinese. Top 1000 active users are selected based on the number of posts in historical data. We use the model in [Yang2010] based on the influence of these 1000 users. We set the time interval unit to 3 hours. To form the matrix M, we give a number either 1 if the user u mentions the concept k in time interval t and 0 otherwise. To form the volume vector V, we count the number of users who mention/relate_to each concept k at each time t. Second, similarly we use the same scheme to collect the posts and response over Plurk between February 23rd, 2009 to April 21st, 2011. We use the same concepts of interest as facebook dataset and select 1000 active users over Plurk as well.

In [Yang2010], LIM model has a parameter L (i.e. influence of a node decays to zero after L time units). In solving the constrained linear least-squares problem:

$$\min \ \| V - M \cdot I \|_2^2 + \lambda \| I \|_2^2$$

there is a regularized parameter λ. Thus, two parameters in the model can be modified. Different combinations of these two parameters lead to different performance of the model. The SIS system can select the algorithm with the best combination. In Fig. 5.4 and Fig. 5.5, we show the comparison between the ground-truth volume V of a concept and the predicted volume by LIM with different parameters for the concept in each sub-figure. Due to the limited space, we only report the results of two concepts in both datasets with two different combinations of parameters L and λ. In practice, our SIS system can enumerate generic algorithm LIM with lots of combinations of different parameters, eliminate the worse ones, and concentrate on the best one based on the least error between the real volume and the predicted volume.

e-mail: {*fcolace, desanto*}*@ unisa.it*

***Abstract* — The last decade has witnessed an intense spread of computer networks that has been further accelerated with the introduction of wireless networks: this growth has increased significantly the problems of network management. Especially in small companies the management of such networks is often complex and faults have significant impacts on their businesses. A possible solution is the adoption of the Simple Network Management Network administrators can manage network performance, find and solve network problems, and plan for network growth by the use of the SNMP. Over the past years much efforts has been given to make more effective the Simple Network Management Protocol and new approaches has been developed. In particular a promising approach involves the use of Ontology. The ontology based network management has recently evolved from a theoretical proposal to a more mature technology and this is the starting point of this paper where a novel approach to the network management based on the use of the Slow Intelligence System methodologies and Ontology based techniques is proposed. The Slow Intelligence System is a general-purpose system characterized by being able to improve performance over time through a process involving various phases as enumeration, propagation, adaptation, elimination and concentration. Therefore, the proposed approach aims to develop a system able to acquire, according to the Simple Network Management Protocol, information from the various hosts that are in the managed networks and apply actions in order to solve problems. To check the feasibility of this approach and its performance an experimental campaign in a real scenario has been designed and the first experimental results in a real scenario are showed.**

***Index Terms*— Ontology – Network Management – Slow Intelligence System**

I. INTRODUCTION

Networks and distributed computing systems are becoming increasingly important. This rash spread, however, resulted in increased difficulty in configuring and managing computer networks. The concept of network management is quite articulated. It involves activities such as the identification and management of various devices, monitoring their performance and much more. So efficient and intelligent configuration management techniques are to reach an automatic or semi-automatic configuration for these devices [1]. A solution for this problem can be the adoption of the Simple Network Management Protocol (SNMP). The SNMP is not only a protocol but can be considered as a general framework for the network management. This framework provide the following components [18][19]:

- network management objects known as MIB objects. In fact in the framework management information is represented as a collection of managed objects that together form a virtual information store, known as the Management Information Base (MIB)
- a data definition language known as SMI (Structure of Management Information) that defines the data types, an object model and rules for writing and revising management information
- a protocol SNMP for conveying information and commands between a managing entity and an agent executing on behalf of that entity within a managed network device
- security and administration capabilities

In literature ontology is considered a good way for supporting the network management and many papers deal with ontology based methodologies for network management [2]. Ontology based network management, in fact, has recently evolved from a theoretical proposal to a more mature technology. The main reason of this is in the significant role that ontology plays in the information model harmonization [3]. In the network management there are many management information models and a harmonization is needed. This harmonization can not be made just as a syntactic translation but a semantic translation is needed. Many papers deal with this approach: in [4] ontologies are used to provide this harmonized information model with an approach to map and merge different information model definitions, taking into account their semantics in a common ontology based model. A similar approach is in [5] where the management information is merged from several sources. Other works in recent years have also included related proposals about using ontologies for different aspects of

network management. For instance [6] proposed using ontologies for the integration of network management policies. That previously showed is the starting point of this paper. In fact it introduces a novel approach to the network management based on the use of the Slow Intelligence System methodologies [7] and ontology. The Slow Intelligence System is a general-purpose systems characterized by being able to improve performance over time through a process involving enumeration, propagation, adaptation, elimination and concentration phases. This approach works at its best when adopts the ontology for the representation of its knowledge base. So the proposed approach aims to develop a system able to acquire information from the various devices that are in the managed networks and apply solutions in order to solve problems. In particular the proposed system can handle multiple networks and adopt solutions that have proved successful in some other context. By the use of ontologies the system will be able to choose the right action to take when some hosts send alerts. The use of the Slow Intelligence System approach will allow the system to automatically infer the actions to take. In order to test the effectiveness of the proposed approach, it has been applied to various LANs that adopt the SNMP protocol for the network management. This paper is organized as follows. The next section introduces the proposed approach and describes the Slow Intelligence System and the ontology approach. The third section gives more details on the proposed approach and describes its operative workflow while the fourth section shows the experimental results. Finally some conclusions are provided.

II. A NETWORK MANAGEMENT FRAMEWORK BASED ON THE SIS APPROACH

In this section we will describe the architecture of the proposed Network Management tool through the description of its main components. In particular it will be showed how the framework works according to the Slow Intelligence System approach and by the use of the ontological formalism for the management of the knowledge base. The architecture of the proposed system is described in figure 1.

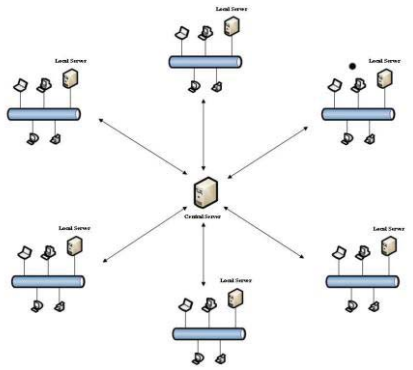

Figure 1 A possible working scenario

Each server manages a computer network and works according to the principles of the Slow Intelligence System.

II.1 The Slow Intelligence System

A Slow Intelligence System is a general-purpose system characterized by being able to improve performance over time [7]. A Slow Intelligence System continuously learns, searches for new solutions and propagates and shares its experience with other peers. It differs from expert systems in that the learning is implicit and not always obvious. A Slow Intelligence System seems to be a slow learner because it analyzes the environmental changes and absorbs that into its knowledge base while maintaining synergy with the environment. Usually a Slow Intelligence System solves problems by trying different solutions, is context-aware to adapt to different situations and to propagate knowledge and may not perform well in the short run but continuously learns to improve its performance over time [7]. A Slow Intelligence System workflow is typically composed by the following phases:

- Enumeration: In problem solving, different solutions are enumerated until the appropriate solution or solutions can be found.
- Propagation: The system is aware of its environment and constantly exchanges information with the environment. Through this constant information exchange, one SIS may propagate information to other (logically or physically adjacent) SISs.
- Adaptation: Solutions are enumerated and adapted to the environment. Sometimes adapted solutions are mutations that transcend enumerated solutions of the past.
- Elimination: Unsuitable solutions are eliminated, so that only suitable solutions are further considered.
- Concentration: Among the suitable solutions left, resources are further concentrated to only one (or at most a few) of the suitable solutions.

The sixth one, on the other hand, is rather unique for a Slow Intelligence System:

- Slow decision cycle(s) to complement quick decision cycle(s): SIS possesses at least two decision cycles. The first one, defined as the quick decision cycle, provides an instantaneous response to the environment. The second one, defined as the slow decision cycle, tries to follow the gradual changes in the environment and analyze the information acquired by experts and past experiences. The two decision cycles enable the SIS to both cope with the environment and meet long-term goals. Sophisticated SIS may possess multiple slow decision cycles and multiple quick decision cycles. Most importantly, actions of slow decision cycle(s) may override actions of quick decision cycle(s), resulting in poorer performance in the short run but better performance in the long run. The structure of a Slow intelligence System by the introduction of the basic building block and advanced building block.

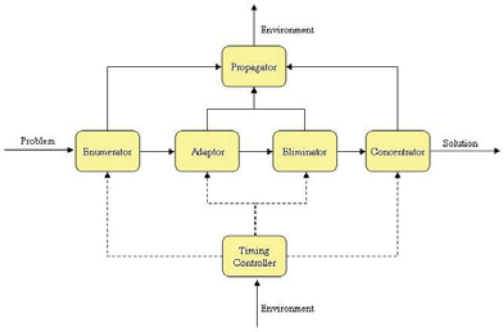

Figure 2 A basic building block BBB

Problem and solution are both functions of time, thus we can represent the time function for problem as x(t)problem, and the time function for solution as y(t)solution. The timing controller is also a time function timing-control(t). For the two-decision-cycle SIS, the basic building block BBB can be expressed as follows:

```
if timing-control(t) == 'slow'
then /* timing-control(t) is 'slow' */
        y(t)solution = gconcentrate (geliminate (gadapt
(genumerate(x(t)problem))))
else /* timing-control(t) is not 'slow' */
        y(t)solution = fconcentrate (feliminate (fadapt
(fenumerate(x(t)problem))))
```

where $g_{enumerate}$, g_{adapt}, $g_{eliminate}$, $g_{concentrate}$ are the transform functions for enumeration, adaptation, elimination and concentration respectively during slow decision cycles, and $f_{enumerate}$, f_{adapt}, $f_{eliminate}$, $f_{concentrate}$ are the transform functions for enumeration, adaptation, elimination and concentration respectively during quick decision cycles. An Advanced Building Block can be a stand-alone system as shown in Figure 3. The major difference between an ABB and a BBB is the inclusion of a knowledge base, further improving the SIS's problem solving abilities.

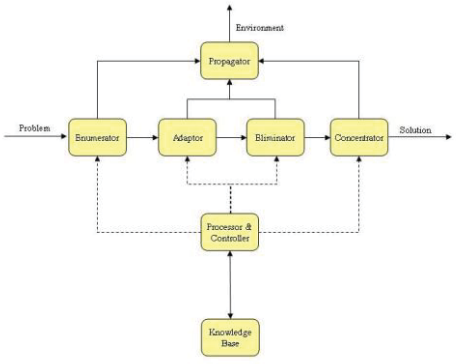

Figure 3 The advanced building block ABB

As showed in figure 3 the advanced building block works using a Knowledge Domain that contains all the information that the ABB needs in order to manage the various problems. Each ABB works with a well defined Knowledge Domain that can change through the interaction with the other peers. An effective way for the representation of the Knowledge Domain is the adoption of the ontology formalism. In the next paragraph more details on the Ontology formalism will be given.

II.2 The role of the Ontology in a Slow Intelligence System

The definition of ontology is still a challenging task [8]. The term 'ontology' has its origin in the Greek word 'ontos', which means 'being'. So in this sense ontology could be defined as a branch of philosophy dealing with the order and structure of reality. In the 1970s ontology came to be of interest in the computer science field. In particular the artificial intelligence community started to use the concept in order to create a domain of knowledge and establish formal relationships among the items of knowledge in that domain for performing some processes of automated reasoning, especially as a means for establishing explicit formal vocabulary to be shared among applications. The term 'ontology' was first used in the computer science field by Gruber who used the term to refer to an explicit specification of a conceptualization [9]. The use of this term is rapidly growing due to the significant role it plays in information systems, semantic web and knowledge-based systems, where the term 'ontology' refers to "the representation of meaning of terms in vocabularies and the relationships between those terms" [10]. Also this kind of definition is still satisfactory for each field where ontology can be applied and so perhaps a good practical definition would be this: "an ontology is a method of representing items of knowledge (ideas, facts, things) in a way that defines the relationships and classification of concepts within a specified domain of knowledge" [8]. Following this point of view, ontologies are "content theories", since their principal contribution lies in identifying specific classes of objects and the relations that exist in some knowledge domains [11][12]. Ontologies are usually classified into lightweight and heavyweight ontologies [12]. Lightweight ontologies include concepts, simple relationships among concepts (such as specialization is_a) and properties that describe concepts. Heavyweight ontologies add axioms and constraints to lightweight ontologies. Axioms and constraints clarify the intended meaning of the terms gathered in the ontology. Heavyweight and lightweight ontologies can be modelled by the use of different knowledge modelling techniques and they can be implemented in various kinds of languages which are usually divided in two groups: classical and ontology mark-up language [13]. The ontology mark-up languages, mainly used in the context of semantic web and of which the most important is OWL [10], have their own syntax, their own expressiveness, different knowledge representation paradigms and their own reasoning capabilities provided by different inference engines [13]. It is important to underline how database community as well as the object oriented design community build models using concept, relations and properties but they usually impose less semantic constraints. Ontologies are typically not static entities and so in recent years ontology evolution processes have drawn considerable attention of the researchers. The ontology evolution can be considered as the

"timely adaptation of an ontology to the arisen changes and the consistent management of these changes" [14]. This definition suggests that a successful evolution can only be achieved by having both "adaptation" and "change management". In the literature there aren't many approaches capable of handling these two tasks within one framework. Another core aspect of ontology evolution is how to guarantee the consistency of the ontology and the dependent applications [14][15]. In this sense many papers are introducing approaches and methodologies for the ontology evolution management and its change requirement description. In particular frameworks for the management of atomic and complex changes have been introduced [16]. A particular aspect of ontology application is in the analysis and comparison of particular ontologies that could be used to derive information beyond operational data. In this case ontologies could be for management support. This is a very interesting application field but some critical problems remain to be solved. In fact usually the lightweight ontology furnishes a very simple and generic representation of a context and so is not able to well manage a system or supporting users in the interactions with it. In particular if it represents the services and components of a system probably its computational and functional optimization could be not reached. However heavyweight ontology could be very difficult to define and includes some aspects that are not all the time useful and the risk of wasting system's resources to maintain heavyweight ontology is quite high. With the aim to avoid the above described problems, in this paper a lightweight plus ontology is proposed, which can be defined as $O = \{C, A, R_H, R\}$ where C is the concept set, A is the concept attributes set, R_H expresses the hierarchical relationships among the concepts and R is the set of non-hierarchical relations. By the introduction of the non-hierarchical relations, a lightweight plus ontology is more complex and semantically richer than the lightweight ontology, but is not as complex as heavyweight ontology because there are no axioms to consider. The lightweight plus ontology will be the starting point for the representation of the knowledge domain that is involved in the ABB.

III. The Proposed Network Management approach

The aim of this paper is the design and the implementation of a network management tool based upon the slow intelligence system approach. The system follows the architecture showed in figure 1 and in this paragraph more details on the operative workflow will be given. First of all the local server is described: it has the role to collect the information about the faults that are happening in the network and to solve them according the slow intelligence approach. At this aim each local server needs a knowledge domain represented by the following lightweight plus ontologies:

- O_{SNMP_i} $\{C_{SNMP\_i}, A_{SNMP\_i}, R_{HSNMP\_i}, R_{SNMP\_i}\}$: this ontology defines the entire structure of SNMP protocol events' signals that the local server "i" can manage. This ontology is part of a more general ontology O_{SNMP} developed by the analysis of SNMP standard (RFC 1157) and of the related Structure of Managed Information (RFC 2578)
- $O_{Fault\_i} = \{C_{Fault\_i}, A_{Fault\_i}, R_{HFault\_i}, R_{Fault\_i}\}$: this ontology describes each kind of possible errors that can occur within a LAN. This ontology is part of a more general ontology O_{Fault} developed by network manager experts that express also the relationships with the events that are in the O_{SNMP} ontology
- $O_{Cause\_i} = \{C_{Cause\_i}, A_{Cause\_i}, R_{HCause\_i}, R_{Cause\_i}\}$: this ontology defines the causes of the faults that may occur in a LAN. This ontology is part of a more general ontology O_{Cause} developed by network manager experts that express also the relationships with the faults that are in the O_{Fault} ontology
- $O_{Solution\_i} = \{C_{Solution\_i}, A_{Solution\_i}, R_{HSolution\_i}, R_{Solution\_i}\}$: this ontology defines the solutions that can be taken to recover from fault situations which occurred within a LAN. This ontology is part of a more general ontology $O_{Solution}$ developed by network manager experts that express also the relationships with the faults that are in the O_{Fault} ontology
- $O_{Action\_i} = \{C_{Action\_i}, A_{Action\_i}, H_{Action\_i}, R_{HAction\_i}, R_{Action\_i}\}$: this ontology aims to identify the actions to be taken in order to recover from fault's situations. This ontology is part of a more general ontology O_{Action} developed by network manager experts that express also the relationships with the faults that are in the $O_{Solution}$ ontology
- $O_{Component\_i} = \{C_{Component\_i}, A_{Component\_i}, R_{HComponent\_i}, R_{Component\_i}\}$: this ontology describes the components that are within the LAN "i". This ontology has to be developed by the network administrator of LAN "i" that defined also the relationships among the components and the SNMP events.
- $O_{Environment\_i} = \{C_{Environment\_i}, A_{Environment\_i}, R_{HEnvironment\_i}, R_{Environment\_i}\}$: this ontology describes the operative context where the LAN "i" works. This ontology has to be developed by the network administrator of LAN "i" that defined also the relationships among the environment and the SNMP events.

These ontologies represent the knowledge base of each advanced building block. The local server works as depicted in figure y and it acts like a slow intelligence and follows the following phases:

Enumeration Phase: in this phase the Local server tries to find all the actions that can be adopted in order to solve a fault. In particular the input of this stage is the SNMP event and the outputs are the actions that can be adopted. If the event has been managed in the past, the system adopts the previous actions and passes in the concentration phase. If the SNMP event has not been ever managed the enumeration module adopts the following functions:

$$F_{Enumeration}: E \times O_{SNMP\_i} \times O_{Fault\_i} \times O_{Solution\_i} \times O_{Action\_i} \rightarrow A^N$$

where E is the space of SNMP events and A is the space of the actions. In other words this function accepts as input the SNMP event that could be in the O_{SNMP_i} ontology. In this way it is possible, analyzing the ontologies, to find the actions that can lead to the solution of the fault. In general this function gives more than one actions that can be adopted and each of them has an effectiveness grade established by experts. At this point the system can evolve in the adaptation phase. If the function is not able to find an action the propagation phase has to be invoked.

Propagation Phase: in this phase the local server sends the SNMP event to the central server that tries to calculate the actions by the use of the function:

$F_{Enumeration}: E \times O_{SNMP\_CS} \times O_{Fault\_CS} \times O_{Solution\_CS} \times O_{Action\_CS} \rightarrow A^N$

If the central server is able to find the actions, it will send them to the local server "i" and it will send also the parts of ontologies that are needed for the event's resolution. In particular the following function will be invoked:

$S_{Propagation}: E \times O_{SNMP\_CS} \times O_{Fault\_CS} \times O_{Solution\_CS} \times O_{Action\_CS} \rightarrow O^N$

This function sends to the local server "i" the following ontologies

$O'_{SNMP\_CS} \subset O_{SNMP\_CS}$
$O'_{Fault\_CS} \subset O_{Fault\_CS}$
$O'_{Solution\_CS} \subset O_{Solution\_CS}$
$O'_{Action\_CS} \subset O_{Action\_CS}$

these ontologies have to be merged to the ontologies that are in the local server "i" in the following way

$O_{SNMP\_i} = O_{SNMP\_i} \cup O'_{SNMP\_CS}$
$O_{Fault\_i} = O_{Fault\_i} \cup O'_{Fault\_CS}$
$O_{Solution\_i} = O_{Solution\_i} \cup O'_{Solution\_CS}$
$O_{Action\_i} = O_{Action\_i} \cup O'_{Action\_CS}$

If the central server is not able to infer the actions the SNMP event has to be send to the other local servers in order to infer the actions. Also in this case each local server "j" calculates the actions by the use of the following function:

$F_{Enumeration}: E \times O_{SNMP\_j} \times O_{Fault\_j} \times O_{Solution\_j} \times O_{Action\_j} \rightarrow A^N$

and send to the central server the parts of ontologies that need for the actions' inference by the use of the function:

$S_{Propagation}: E \times O_{SNMP\_j} \times O_{Fault\_j} \times O_{Solution\_j} \times O_{Action\_j} \rightarrow O^N$

The central server collects the actions and updates its ontologies according to the previous described method. It sends the actions and the ontologies to the local server "i". If both the central server both the various local servers are not able to infer actions, the local server "i" has to send an error signal to the network administrator. The local server "i" collects the actions and the ontologies from the central server and invokes the adaptation phase.

Adaptation Phase: in this phase the inferred actions has to be customized according to the components that are in the LAN and the environment where the LAN works. In particular for each action the following function is invoked:

$A_{Adaptation}: A \times O_{SNMP\_j} \times O_{Fault\_j} \rightarrow A$

At the end of this phase the system obtains a list of adapted actions. Obviously not all the actions can be adapted and so for each adapted action an improvement for its effectiveness grade is set.

Elimination Phase: the system collects all the actions inferred in the previous phases ranking them according to this function:

$F_{Elimination}: A^N \rightarrow A$

This function can be implemented in various ways according to predefined strategy. In this case the adopted approach is the following:

$F_{Elimination} = \max_{i=1\ldots N}$ effectiveness grade (A_i)

At the end of this phase the concentration phase can be invoked

Concentration Phase: In this phase the local server "i" adopts the selected action. If this action leads to the problem's resolution and comes from the central server the local server "i" updates its ontologies. If the action does not lead to the problem's resolution a message is send to the network administrator that can decide both to adopt one of the other actions retrieved in the other phases both to solve the fault in a manual way.

Summarizing the operational workflow of the system can be described as follows:

Step 1: a SNMP message as result of a fault generated by a LAN's device is sent to a local server "i"

Step 2: The local server "i" receives the SNMP message. This is the beginning of the enumeration phase.

Step 3: The local server "i" tries to identify the problem through analysis of various ontologies that describe its knowledge base. If the SNMP event was managed in the past the concentration phase can start (step 9). Otherwise the system infers a list of actions that can applied for the resolution of the problem and generates the solutions and the actions that the various hosts in the LAN have to be apply. At this point the adaptation phase can start (step 7). If the local server "i" is not able to infer any actions the request is sent to the local server. In this way the propagation phase (step 4) can start.

Step 4: The central server tries to infer the actions that can solve the faults that the SNMP event sent by local server "i" represents. If it is able to find actions the central server sends them and the ontologies parts that are needed for the event management. In this way the adaptation phase (step) can start. Otherwise the central server sends the SNMP events to the other local servers

Step 5: The various local servers try to infer the actions from the received SNMP event. If actions are retrieved each local server sends them and the parts of ontologies needed for their inference.

Step 6: The central server collects the various answers from the local servers and send them local server "i" and the adaptation phase (step 7) can start. If no answers from local servers are received an empty action is sent to the local server.
Step 7: The local server "i" starts to adapt the actions according to the environment and components LAN's ontologies. After this phase the elimination phase can start. If in this phase no actions have been inferred a message to the network administrator have to be sent.
Step 8: The local server "i" selects the action to apply from the other ones collected in the other phases according to a predefined rule.
Step 9: The local server "i" can apply the action in order to recover the fault situation and update, if needed, its ontologies

IV. Experimental Results

In order to test the performance of the proposed system an experimental campaign has been designed. First of all the working scenario has been set: the system has to manage three laboratories during their normal working time. These laboratories are equipped in the following way:

First Laboratory
- **1 Cisco Router Cisco**
- **3 Cisco Catalyst Switches**
- **56 Personal Computers equipped with heterogeneous operative systems and applications**
- **2 Network Printers**

Second Laboratory
- **1 Cisco Router**
- **2 Nortel Switches**
- **40 Personal Computers equipped with heterogeneous operative systems and applications**
- **2 Network Printers**

Third Laboratory
- **1 Cisco Router Cisco**
- **2 Cisco Catalyst Switches**
- **42 Personal Computers equipped with heterogeneous operative systems and applications**
- **1 Network Printers**

In each of these laboratories a local server was settled and the system monitored the three LANs for one week collecting the various SNMP signal and managing the various faults. The local servers have been furnished by the various ontologies and in particular they adopted an O_{SNMP_i} covering about the 60% of concepts of the full O_{SNMP} that can manage about 250 events. Starting from the O_{SNMP_i} the experts has built the others ontologies. The system's performances have been evaluated according various approaches. The first parameter is the following:

$$CA = \frac{SolvedFaults}{Events}$$

The aim of this index is the evaluation of the effectiveness of the system in the resolution of the faults. For the evaluation also the precision and recall parameters has been introduced. The precision is defined in the following way:

$$precision = \frac{TruePositive}{TruePositive + FalsePositive} \qquad recall = \frac{TruePositive}{TruePositive + FalseNegative}$$

These parameters are typically used in information retrieval where a perfect precision score of 1.0 means that every result retrieved by a search was relevant whereas a perfect recall score of 1.0 means that all relevant documents were retrieved by the search. In our case the precision means how many events have been resolved in the correct way (the true positive) respect the number of events that system tried to solve. So in this case a false positive is a fault that the system managed in a wrong way. The recall represents how many events have been resolved in the correct way (the true positive) respect the number of events that system could solve. For the evaluation of the propagation phase the following parameters has been introduced:

$$RCA = \frac{Solved\_Faults\_After\_Central\_Server\_request}{SolvedFaults}$$

In order to evaluate the capacity of the system to share knowledge among the various local servers also the following ontological parameters [17] has been introduced:
- NOC: Number of Concepts in the ontology
- NOL: Number of Leaf Concepts in the ontology
- NONHR: Number of "non-hierarchical" relationships
- NOF: Number of Fanouts
- AF-C: Average Fanout per Class
- MaxDIT: Maximum Depth of Inheritance Tree

All these parameters have been evaluated each 24 hours for each local server "i" and an average value has been expressed for the evaluation of the system. The obtained CA, Precision, Recall and RCA are depicted in the appendix of this paper as the ontological parameters for the full O_{SNMP} ontology and the various O_{SNMP_i} ontologies. The obtained results confirm the effectiveness of the proposed approach. The system allows an effective sharing of knowledge among the various servers as the ontological parameters show. In fact after about the 30% of the managed events each system reaches good results in their management and the local servers improve their knowledge domains. The system shows a very good CA result and more in general after a first training phase achieves very good performances both from the precision both from the recall point of view. It is important to underline that the various local ontologies show a less complex structure of the full ontology and so, in this way, it is easier to manage them.

V. Conclusion

In this paper a novel method for network management has been introduced. This method is based on Ontology and Slow Intelligence System approach. It has been tested in an operative scenario and the first experimental seems to be good. In particular the proposed approach showed how an ontology based interoperability framework can help to improve several tasks in the network management value chain. The proposed approach introduces a powerful way for the improvement of the information model interoperability and allows the introduction of services for the automatic resolution of networks fault. The opportunity to continuosly upgrade the knowledge base allows to continuosly upgrade the capacity of the system to manage new faults. In particular network administrators will not only benefit from more powerful

applications, but they can transfer their expert knowledge into the management applications and in this way automating more and more network management tasks. The future works aim to improve the system by the use of new and effective methodologies for the ontology management and the use of some artificial intelligence approach for the automatic inference of action when the system is not able to find anyone.

***Abstract*—In order to correctly evaluate semantic technologies, which have become widely adopted in recent years, we need to put evaluations under the scope of a unique software quality model. This paper presents a quality model for semantic technologies. First, some well-known software quality models are described, together with methods for extending them. Afterwards, a new method for extending quality models is proposed and it is then used to define a quality model for semantic technologies by extending the ISO 9126 quality model. Finally, the proposed model is validated by analyzing existing semantic technology evaluations.**

I. Introduction

Software product quality has become an important concern in almost every domain or technology, and the specification and evaluation of quality during the software development process is of crucial importance for obtaining high quality software [1].

Quality models provide the basis for software evaluation and give a better insight of the characteristics that influence software quality by specifying a consistent terminology for software quality and by providing guidance for its measurement. Nevertheless, in order to use a quality model in a specific domain, it usually has to be extended to include the particularities of such domain.

Various methods for extending quality models have been proposed in the literature. They all follow a top-down approach, starting from general characteristics to concrete measures; for some cases, however, a bottom-up approach would be more effective as is the case of those which have many of evaluations to extract the quality model.

An example of this occurs in the semantic technology field. Semantic technologies provide new ways to express in machine processable formats knowledge and data that can be exploited by software agents. We have seen an exponential growth of semantic technologies in recent years and multiple evaluations of such technologies have been proposed, from general evaluation frameworks [2] to tool-specific evaluations [3], [4] and even characteristic-specific evaluations [5].

However, it is very difficult to compare semantic technologies because of the different evaluation characteristics used. Furthermore, there is no consistent terminology for describing the quality of semantic technologies, and available software quality models do not specify the quality characteristics specific to them.

This paper describes a bottom-up approach for specifying a software quality model by extending an existing one. Using this approach, we have defined a quality model for semantic technologies, starting from real semantic technology evaluations and extending the ISO 9126 quality model.

Clearly, during the definition of the quality model not every available evaluation can be taken into account. To validate and complete the quality model, we have performed a literature review over those semantic technology evaluations presented in the most relevant conferences in the semantic research field.

The reminder of this paper is organized as follows. Section II gives an overview of existing software quality models. Section III describes top-down methods for extending software quality models, while Section IV presents the bottom-up method that we have defined. Section V describes how we have applied such method to define a quality model for semantic technologies. Section VI presents the validation of the quality model and, finally, Section VII draws some conclusions and includes ideas for future work.

II. Review of Software Quality Models

Various software quality models have been described in the literature: McCall's model, Boehm's model, ISO 9126 model, and SQuaRE model. This section describes the models most used and identifies their main elements.

ISO 9126's Model. The International Organization for Standardization (ISO) identified the need for a unique and complete software quality standard and, therefore, produced the ISO 9126 standard for software quality [6]. The ISO 9126 standard defines three types of quality: internal quality, external quality, and quality in use.

Six main software quality characteristics for external and internal quality are specified: functionality, reliability, usability, efficiency, maintainability, and portability, all of which are further decomposed into sub-characteristics that are manifested externally when the software is used and are the result of internal software attributes [6]. The standard also provides the internal and external measures for sub-characteristics.

Regarding quality in use, the model proposes four characteristics: effectiveness, productivity, safety, and satisfaction.

The ISO 9126 standard gives a complete view of software quality with evaluation criteria and definitions of every software characteristic and sub-characteristic. Some authors also suggest that according to the nature of the product itself some new sub-characteristics can be added, the definitions of existing ones changed, or some sub-characteristics can be eliminated from the model [7].

However, as pointed out in [8], some practical problems with ISO 9126 arise, namely, the ambiguity in metric definitions and usability interpretation. Furthermore, the authors argue that the number of attributes and measures are missing, that some characteristics are too abstract, and that the standard itself is open to interpretations, which, according to the authors, questions its purpose.

SQuaRE's Model. Because of advances in technologies and changes of users' needs over time, some problems and issues have arisen with the ISO 9126 standard. Therefore, it is currently being redesigned and has been renamed SQuaRE (System and software Quality Requirements and Evaluation). At the time of writing this paper, the parts of the SQuaRE standard related to the quality model and evaluations are still under development (ISO 25010 and ISO 25040 respectively) and their final versions will be published during 2011.

As a summary of this section, Table I presents the elements of the quality models mentioned. In our work, and in the rest of the paper, we have adopted the terminology of the ISO 9126 standard.

TABLE I: Elements of mentioned quality models.

Structure/Model	McCall	Boehm	ISO 9126
First level	Factor	High level characteristic	Characteristic
Second level	Criteria	Primitive characteristic	Sub-characteristic
Third level	Metrics	Metrics	Measures
Relationships between entities	Factor-Metric	/	Measure-Measure

III. Approaches for Extending Software Quality Models

Existing software quality models (e.g., the ISO 9126 one) provide insight into characteristics that are general and common for almost every type of software. However, different types of software products have characteristics which are specific to them and, therefore, the actual application of software quality models usually requires reusing an existing quality model and extending it for a specific software product or domain.

To this end, starting from a certain quality model, its quality characteristics and sub-characteristics should be adapted according to the nature of the domain by excluding those out of scope, redefining others, and introducing new ones.

Some authors have proposed software quality models for various types of applications: B2B [1], mail servers [9], web-based applications [10], e-learning systems [11], and ERP systems [7]. All those authors have used the ISO 9126 standard as the basis software quality model, and have extended it to fit their particular domain.

Software quality model extensions can be performed following two main approaches [12]:

- A **top-down** approach that starts from the quality characteristics and continues towards the quality measures.
- A **bottom-up** approach that starts from the quality measures and defines the quality sub-characteristics that are related to each specific measure.

Franch and Carvallo proposed a method based on a top-down approach for customizing the ISO 9126 quality model [13]. After defining and analyzing the domain, their method proposes six steps:

1) *To determine quality sub-characteristics*. In this first step, according to the domain, some new quality sub-characteristics are added while other are excluded, or their definitions are changed.
2) *To define a hierarchy of sub-characteristics*. If needed, sub-characteristics are further decomposed according to some criteria.
3) *To decompose sub-characteristics into attributes*. In this step, abstract sub-characteristics are decomposed into more concrete concepts that refer to some particular software attribute (i.e., observable feature).
4) *Decomposing derived attributes into basic ones*. Attributes not directly measurable are further decomposed into basic ones.
5) *To state relationships between quality entities*. Relationships between quality entities are explicitly defined. Three possible types of relationships are identified: a) *collaboration* means that increasing the value of one entity implies increasing the value of another entity; b) *damage* means that increasing the value of one entity implies decreasing the value of another entity; and c) *dependency* implies that some values of one entity require that another entity fulfills some conditions.
6) *To determine metrics for attributes*. To be able to compare and evaluate quality, it is necessary to define metrics for all attributes in the model.

In building their quality model for B2B applications, Behkamal et al. proposed a method to customize the ISO 9126 quality model in five steps [1]. The main difference with the previous method is that in Behkamal's approach the quality characteristics are ranked by experts; thus, the experts should provide weights for all quality characteristics and sub-characteristics and these weights are later used to establish their importance, which can be time consuming and resource demanding. Besides, Behkamal's approach does not contemplate defining relationships between quality entities.

IV. A Bottom-Up Approach For Extending Software Quality Models

The approaches presented in the previous section follow a top-down approach and, at the time of writing this paper,

we have not found any example of a bottom-up approach in the literature. However, there are scenarios where it would be convenient to base on real practices the extension of the quality model because of the existence of a significant body of software evaluations and evaluation results (as in the case of the semantic technology field).

In our approach, evaluation results are used as the starting point from which the quality measures, sub-characteristics, and characteristics are specified.

The method for extending a software quality model consists in performing the following six consecutive steps:

1) *To identify basic measures*. The output of evaluating a software product with some input data (i.e., executing a test case) allows identifying the basic measures of a certain evaluation execution.
2) *To identify derived measures*. Basic measures can be combined to obtain derived ones, which are also related to one particular evaluation execution (i.e., test case).
3) *To identify quality measures.* Quality measures are measures related to a whole evaluation (i.e., multiple test cases using different input data) and are obtained by the aggregation of basic and derived measures.
4) *To specify relationships between measures*. In this step, which can be performed in parallel with the previous ones, relationships between measures are expressed either in an informal way (e.g., the collaboration, damage and dependency categories proposed in [13]) or more formally (e.g., with the formulas used for obtaining the measures, as proposed in [14]). For any derived measure defined it is recommendable to specify the function (or set of functions) that allows obtaining such derived measure from the basic ones. Similarly, for any quality measure it is also recommendable to identify the function that defines it based on other measures.
5) *To define domain-specific quality sub-characteristics*. Every software product from a particular domain has some sub-characteristics that are different from other software products and those sub-characteristics, together with more generic ones, should be identified and precisely defined. Every quality measure provides some information about one or several software sub-characteristics; therefore, based on the software quality measures defined in the previous step, software quality sub-characteristics are specified. Furthermore, it is not necessary that every quality sub-characteristic has only one measure that determines it, but rather a set of measures. Finally, if needed, some quality sub-characteristics can be combined into more general ones.
6) *To align quality sub-characteristics with a quality model*. In this step, the alignment with an existing quality model is established; i.e., the software quality sub-characteristics that have been previously defined are related to others already specified in the existing model. Depending on the domain and nature of the software product, some new quality characteristics can be specified, or existing ones can be modified or excluded.

V. Defining A Quality Model For Semantic Technologies

This section describes the definition of a software quality model in the domain of semantic technologies by following the bottom-up method presented in the previous section.

A. Identifying Basic Measures

The starting point for defining software quality measures has been the set of evaluation results obtained in the SEALS project[1], which has produced evaluation results for different types of semantic technologies (ontology engineering tools [15], reasoning systems [16], ontology matching tools [17], semantic search tools [18], and semantic web service tools [19]).

For each type of technology, different evaluation scenarios were defined, using in each of them different test data as input. In this step we identified the basic measures of each evaluation scenario (i.e., those outputs directly produced by the software during the evaluation).

Due to space reasons, we cannot present details about all evaluation scenarios. Therefore, we just present the outcomes of each step for one concrete scenario, that of evaluating the conformance of ontology engineering tools.

Different test suites are used for evaluating the conformance of ontology engineering tools, which are composed of different test cases each containing

- *Origin ontology*. The ontology to be used as input.

A test case execution consists in importing the file containing an origin ontology (O_i) into the tool, and then exporting the imported ontology to another ontology file (O_i^{II}), as shown in Fig 1.

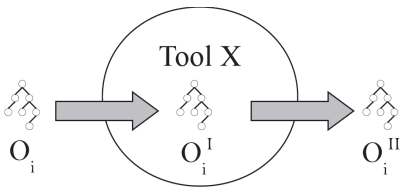

Fig. 1: Steps of a conformance test execution.

The basic measures obtained after a test case execution are

- *Final ontology*. The ontology that is produced by the tool when importing and exporting the origin ontology.
- *Execution Problem*. Whether there were any execution problems in the tool when importing and exporting the origin ontology.

B. Identifying Derived Measures

Based on the test data and the basic measures of one test execution, the following derived measures were specified:

- *Information added*. The information added to the origin ontology after importing and exporting it.
- *Information lost*. The information lost from the origin ontology after importing and exporting it.

[1] http://www.seals-project.eu

- *Structurally equivalent*. Whether the origin ontology and the final one are structurally equivalent.
- *Semantically equivalent*. Whether the origin ontology and the final one are semantically equivalent.
- *Conformance*. Whether the ontology has been imported and exported correctly with no addition or loss of information.

C. Identifying Quality Measures

From the derived measures in the conformance scenario, the following quality measures were obtained:

- *Ontology language component support*. Whether the tool fully supports an ontology language component.
- *Ontology language component coverage*. The ratio of ontology components that are shared by a tool internal model and an ontology language model.
- *Ontology information persistence*. The ratio of information additions or losses when importing and exporting ontologies.
- *Execution errors*. The ratio of tool execution errors when importing and exporting ontologies.

Similarly to the example of the conformance evaluation presented above, we have defined measures for the other types of tools. Table II summarizes the results obtained.

TABLE II: Number of measures obtained for semantic technologies.

Tool\Measures	Basic	Derived	Quality
Ontology engineering tools	7	20	8
Ontology matching tools	1	3	4
Reasoning systems	7	0	8
Semantic search tools	12	11	21
Semantic web service tools	5	10	11
Total	27	40	50

D. Specifying Relationships Between Measures

We have identified the relationships between measures in a formal way by defining the formulas used for obtaining derived and quality measures.

For example, the formula for the *Information added* derived measure calculates the structural difference between the origin and final ontologies:

$$\text{Final ontology} - \text{Origin ontology}$$

Similarly, the formula for the *Execution errors* quality measure calculates the percentage of tests with execution problems:

$$\frac{\text{\# tests where Execution problem = true}}{\text{\# tests}} \times 100$$

E. Defining Domain-Specific Quality Sub-characteristics

In this step, from the quality measures previously identified, we defined the set of quality sub-characteristics that are affected by those measures. In some cases we were able to reuse existing quality sub-characteristics but, in others, we had to define domain-specific ones.

In the conformance evaluation scenario, based on the measures and analysis presented above, we have identified three quality sub-characteristics:

- *Ontology language model conformance*. The degree to which the knowledge representation model of a software product adheres to the knowledge representation model of an ontology language. It can be measured with two different quality measures: *Ontology language component coverage*, and *Ontology language component support*.
- *Ontology processing accuracy*. The accuracy of the process of importing and exporting ontologies. It can be measured with *Ontology information persistence*.
- *Ontology processing robustness*. The ability of the software product to process ontologies correctly in the presence of invalid inputs or stressful environmental conditions. It can be measured with *Execution errors*.

Fig. 2 presents the basic measures, derived measures, quality measures, and quality characteristics of the conformance evaluation for ontology engineering tools.

In total, we have identified twelve semantic quality sub-characteristics. Three of them are those described for the conformance evaluation and the others are the following:

- *Ontology language interoperability*. The degree to which the software product can interchange ontologies and use the ontologies that have been interchanged.
- *Reasoning accuracy*. The accuracy of the reasoning process.
- *Ontology alignment accuracy*. The accuracy of the matching process.
- *Semantic search accuracy*. The accuracy of the semantic search process.
- *Semantic web service discovery accuracy*. The accuracy of the process of finding services that can be used to fulfill a given requirement from the service requester.
- *Ontology interchange accuracy*. The accuracy of the interchange of ontologies between tools.
- *Ontology processing time behaviour*. The capability of the software product to provide appropriate response and processing times when working with ontologies.
- *Reasoning time behaviour*. The capability of the software product to provide appropriate response and processing times when performing reasoning tasks.
- *Semantic search time behaviour*. The capability of the software product to provide appropriate response and processing times when performing search tasks.

Apart from these domain-specific quality sub-characteristics, we have identified the following general ones: *Operability*, *Productivity*, and *Satisfaction*.

Finally, we have also identified those sub-characteristics that are contained into others (e.g., *Reasoning time behaviour* is a sub-characteristic of *Ontology processing time behaviour*).

F. Aligning Quality Sub-Characteristics with a Quality Model

As ISO 9126 has been used by a number of authors, as mentioned in Section III, we have also adopted it for constructing the quality model for semantic technologies.

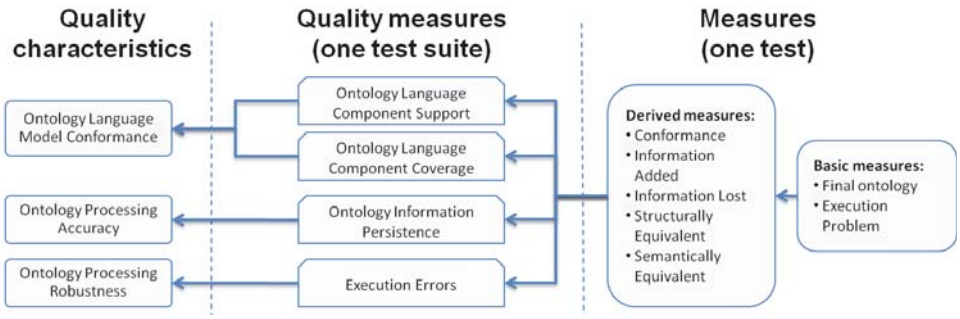

Fig. 2: Entities in the conformance scenario for ontology engineering tools.

In the previous step we have identified the set of quality sub-characteristics specific for semantic technologies. In this step, all the identified sub-characteristics were properly assigned to the ones that already existed in the ISO 9126 quality model.

For instance, *Ontology language model conformance* is defined as a sub-characteristic of *Functionality compliance* (i.e., the capability of the software product to adhere to standards, conventions or regulations in laws and similar prescriptions relating to functionality).

VI. Quality Model Validation

Since we started from a specific set of evaluations in order to define the quality model for semantic technologies, we performed a literature review to validate the quality model and to complete it if needed. The review was performed according to the procedures described in [20] and, due to space reasons, we will only present the final results.

We have analysed the proceedings of the two most relevant conferences in the semantic area: the International Semantic Web Conference (nine editions) and the European Semantic Web Conference (seven editions) to identify those publications that deal with semantic technology evaluation. We focused on publications that describe evaluation methods or suggest measures for evaluation as well as on publications that suggest new algorithms (e.g., for reasoning or semantic web service discovery) that are also evaluated.

In total, we have analysed fifty seven publications. Table III shows an overview of this analysis including, for each type of semantic technology, the evaluation measures used. Every evaluation measure is classified according to the quality sub-characteristics that our model describes and the number of occurrences is shown in brackets.

From the analysis we can observe that the quality model that we have proposed is quite complete regarding current semantic technology evaluations. Almost all the measures described in the publications fit the quality characteristics that our model describes. However, some measures found did not fit our model, and therefore we have defined new quality characteristics for them. These are

- *Semantic web service time behaviour*. The capability of the software product to provide appropriate response and processing times when performing semantic web service discovery tasks.

TABLE III: Measures used in conference publications.

Ontology engineering tools (2)
Ontology processing robustness: execution (1) *Ontology processing time behaviour*: execution time (1) *Ontology import/export accuracy*: information added/lost (1)
Ontology matching tools (21)
Ontology alignment accuracy: precision (19), recall (19), f-measure (13), measure at cut-off point (1)
Reasoning and storage systems (18)
Reasoning time behaviour: classification time (5), execution time (5), reasoning time (5), entailment time (1), labeling time (1), lattice operation time (1), justification time (1) *Ontology processing time behaviour*: loading time (4) *Reasoning accuracy*: reasoner errors (1), correct results (7), wrong classifications (1), fitness value (1)
Semantic search tools (5)
Semantic search time behaviour: query execution time (2), speed (1) *Semantic search accuracy*: recall (4), precision (3), reciprocal rank (1), f-measure (1), relevance (1) *Ontology processing time behaviour*: loading time (1) *Operability*: usability (2)
Semantic web service tools (11)
Semantic web service discovery accuracy: precision (12), recall (8), f-measure (1), returned sources (1), bpref (1), reciprocal rank (1)

- *Matching time behaviour*. The capability of the software product to provide appropriate response and processing times when performing matching tasks.

Fig. 3 shows an overview of the quality model for semantic technologies after completing it during the validation.

VII. Conclusions and Future Work

This paper presents a new method for extending software quality models, which is based on a bottom-up approach. It starts from existing evaluations and continues defining quality measures and quality sub-characteristics, which are aligned with an existing quality model.

In practice, the quality model to be extended is taken into account from the beginning of the method, even if the alignment to such quality model is the last step of the method. Therefore, it seems natural to follow a hybrid approach, which combines the bottom-up and top-down approaches, and a future extension of the method should also cover this approach.

We have used the method for defining a quality model for semantic technologies, which extends the ISO 9126 software quality model. Such quality model can provide a framework for the evaluation and comparison of semantic technologies.

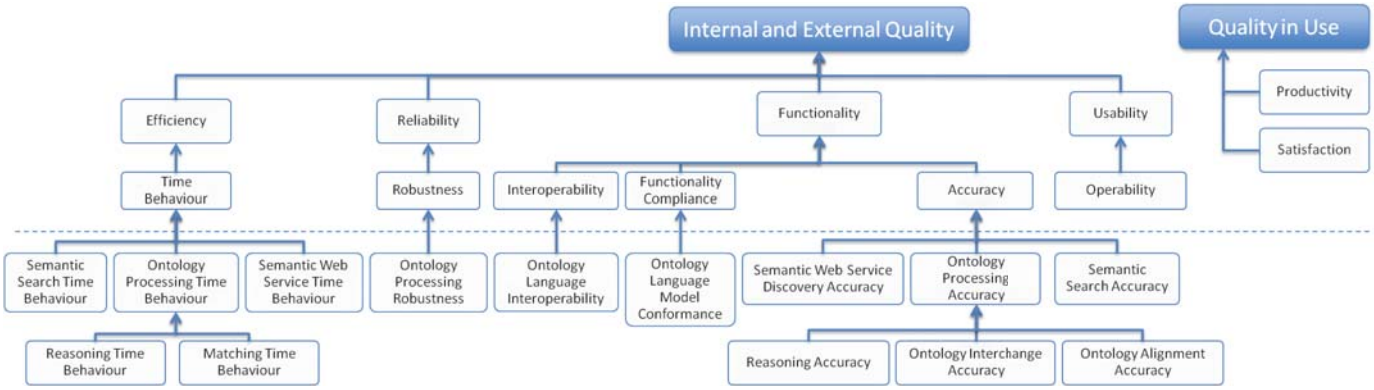

Fig. 3: External and internal quality characteristics for semantic technologies.

Although some problems with ISO 9126 have been identified (as described in [8]), we have introduced quality measures specific to semantic technologies, and we have also specified functions for all derived and quality measures, which result in reducing ambiguities in our model.

Furthermore, we can note that our quality model is easily extensible and that new quality measures or characteristics can be easily introduced and categorized, as shown during the validation process.

During such validation, we have concentrated only on the most relevant conferences in the semantic field. In order to get more complete results, we plan to extend our analysis to other conferences, as well as to relevant journals. This will help us to further extend and validate the model.

The ISO 9126 standard is being replaced by the SQuaRE standard; when the SQuaRE software quality model becomes available, the proposed quality model for semantic technologies will be adapted to it.

A future use of the proposed quality model, based on the evaluation results that are being obtained in the SEALS project, is to build a recommendation system for semantic technologies that will allow extracting semantic technology roadmaps. Such a system will provide users with guidance and recommendation of the semantic technologies that better suit their needs.

Abstract

This paper presents a novel approach (called PIP) for profiling inter-procedural paths, which makes extensions of previous work to inter-procedural situations. An inter-procedural profiling model, PCCG (Polymorphic Cluster Call Graph), is presented, which describes polymorphism, divides procedures into clusters, and improves profiling efficiencies. Theoretical analysis and experimental results show that different clustering strategies of PCCG have different advantages (lower cost in instrumentation or in execution) can meet custom needs. Compared with existing work, PIP is more practical as it profiles more cyclic paths, deals with polymorphism, and is totally accurate.

***Keywords*—Path profiling; inter-procedural paths; polymorphism; dynamic analysis;**

I. Introduction

Path profiling records the frequency of each executed path. It was introduced by Ball and Larus [1] in *Efficient Path Profiling* (EPP), which could enable the collection of profiles for acyclic intra-procedural paths at a reasonable cost. Since then, path profiles have been extensively used in a wide variety of areas such as computer architecture, compilers, debugging, program testing, and software maintenance. But same as EPP, most of these extensions work in single-procedure situations, that is, with inter-procedural paths still untreated. However, it is often desirable to obtain frequency counts of paths that extend across procedure boundaries [2].

Supported partially by the National Natural Science Foundation of China under Grant No. 60773105 and no. 60973149, and partially Supported by Doctoral Fund of Ministry of Education of China under Grant No. 20100092110022, and partially by National High Technology Research and Development Program under Grant No.2008AA01Z113.

Melski et al. have proposed an approach for profiling inter-procedural paths. They connect the flows of all procedures together and use EPP to enumerate the paths in this combined flow graph [3]. But this method can only profile paths without any backedges in any procedures.

Tallam et al. propose an approximate profiling which can deal with backedges, and extend this approach to profile inter-procedural paths [2]. But this method is not completely accurate and has severe restrictions on loops.

So in a word, existing inter-procedural profiling methods can only profile paths without backedges accurately, or profile certain cyclic paths inaccurately. In this paper, we gives an extension of PAP (*Profiling All Paths*) [4] to address the problem of collecting accurate profiles for inter-procedural paths (including loop iterations and procedure calls), which is called PIP (*Profiling Inter-procedural Paths*). PIP algorithm is based on an inter-procedural control flow model, PCCG (*Polymorphic Cluster Call Graph*), which describes polymorphic relations.

The rest of this paper is organized as follows: Section II illustrates the preliminaries; Section III discusses the details of PIP; Section IV gives experimental evaluations; Section V summarizes related work and Section VI concludes the paper.

II. Preliminaries

This section gives necessary basis. First EPP is used to explain the basic methodology of path profiling, then PAP is illustrated in details since PIP is quite related to it.

A. EPP

In order to collect path profiles, existing techniques use probe variable(s), that is, they instrument probe statements for the variable(s) into the program under profiling, and these statements are executed as the program runs. When

an execution is over, the value of the variable(s) (so called *pathid*) will determine the path of the execution. This profiling process requires a unique *pathid* for each path to make profiles correct and accurate.

EPP uses one integer variable r, and its probes are in the form of "$r := r + i$", where "i" is the edge **weight**, computed by BL algorithm [1]. Fig.1(a) shows how EPP computes the edge weights in a DAG (*Directed Acyclic Graph*, "N_a" means the number of paths from node "a"). EPP gives each acyclic path a unique *pathid*, so that the probe value of variant "r" can identify the corresponding path after the execution.

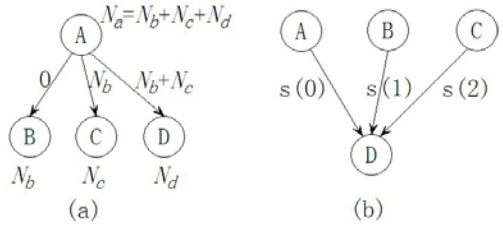

Fig. 1. Probes of EPP and PAP

B. PAP

In order to profile all paths (especially cyclic paths), we have presented PAP algorithm, which instruments probes in the form of "$r := r * s + i$" ("$s(i)$" for short, s is called **weight** and i is called **remainder**) on the inedges of each CFG node N, where s is the indegree of N, and i is the serial number of the inedge, as Fig.1(b) shows (single-inedge nodes don't need probes). After executions, using the probe value of r we can acquire the whole path by iteratively finding out the former node and restoring the former probe value (this phase is called *backwalk*).

Different from EPP, PAP does not need to change backedges, and can accurately profile both acyclic and cyclic paths.

In order to deal with the probe-value overflowing that may happen during executions, a *breakpoint* mechanism is devised to use more storage to handle longer paths, i.e., when overflowing occurs, the position and probe value before overflowing (called a *breakpoint*, which contains an integer and a node), are recorded, and then the probe variable is reset and current execution is continued. As studied in [4], with several *breakpoints* for each path, PAP can profile paths that are much longer and with more loops.

III. Inter-procedural Profiling

PIP's steps can be briefly shown in Fig.2: code splitting is used to handle polymorphism, as discussed in Section III.A; procedure clustering and PCCG is used to reduce the cost of code splitting, as discussed in Section III.B; instrumentation and optimization of probes are discussed in Section III.C; program execution and *backwalking* in PIP make no differences to those in PAP, and are not specially discussed here. For convenient explanation, intra-procedural structures is ignored for PIP, since those can be handled by PAP.

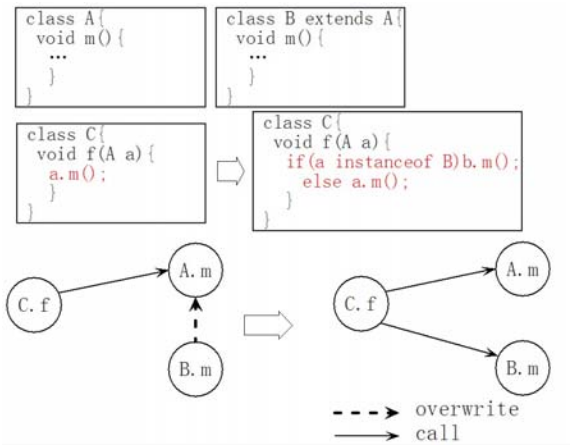

Fig. 3. An example of code splitting

A. Code Splitting

In polymorphic situations, every call edge, where polymorphism may happen, can be equally replaced by several edges, which each stands for an actual call relation that possibly occurs in some executions. By such replacement, a polymorphic inter-procedural CFG can be transferred into the same form of an intra-procedural CFG. As Fig.3 shows, class B extends class A, and overwrites A.m(). C.f() calls A.m(), and in dynamic scenarios, B.m() may be called instead of A.m(). To deal with such a polymorphic call, we can simply split the call statement. As shown in Fig.3, in the code of C.f(), the input parameter is verified and the target callee procedure can be precisely fixed. And correspondingly, the call edge is divided into two ones.

B. PCCG and Procedure Clustering

Though code splitting can handle polymorphic relations, it is still hard to perform when the inheritance relations are very complicated, as one call may need to be replaced by many calls. It is thought to make procedures classified into clusters, and some code splitting may be saved if the callees fall into one cluster.

In order to describe the polymorphic information which uses one procedure to replace another in executions, this

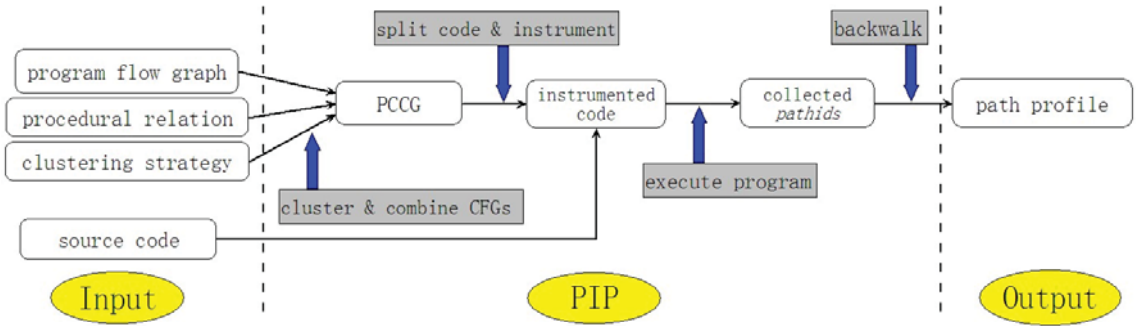

Fig. 2. Framework of PIP

paper presents a new method-call model, PCCG, which is a directed graph, and consists of three sets, CS, PS and CE:

- CS is the cluster set, where each cluster consists of at least one procedure;
- PS is the procedure set, where each procedure is contained by one cluster;
- CE is the set of call edges (including return edges), where each edge points from a procedure to a cluster.

PCCG can be generated based on a call graph and PE (polymorphic edges), according to following steps: first, the potential call edges are added to PCCG based on PE (like how Fig.3 does); then the procedures with polymorphic relations are clustered and redundant edges are removed; at last, corresponding return edges are added to the graph.

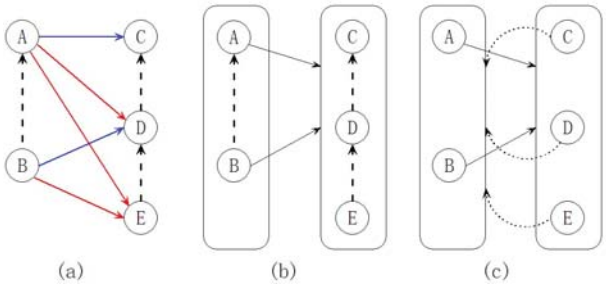

Fig. 4. A PCCG example

Fig.4 shows an example of how to generate a PCCG. Fig.4(a) has five procedures (each is a single-procedure cluster), and originally, there are only two calls, (A, C) and (B, D). Based on three polymorphic relations (described as dotted arrows) in it, three potential call edges are put on the graph, (A, D), (A, E) and (B, E). Fig.4(b) classifies all five procedures into two clusters, and removes redundant call edges. After that, Fig.4(c) adds return edges on the graph.

Based on PCCG, procedure clustering can be performed, which leads to less code splitting because calling procedures in one cluster does not need to be split.

C. Instrumentation and Optimization

1) Instrumentation: As given in [4], PAP instruments all inedges of each CFG node sequentially. Here on PCCG, PIP instruments all inedges of each cluster in the same way, which also ensures a unique *pathid* for each inter-procedural path. The difference is, in PAP, paths consist of edges from node to node in CFG; while in PIP, paths consist of edges from procedure to cluster in PCCG. Such a difference does not affect the accuracy, because the latter path representation can precisely identify the former one.

2) Optimization: In a PCCG, each call edge points from a procedure to a cluster, so does each return edge. For a procedure in the callee cluster, if all its return edges have the same probe on them, then these probes can be replaced by only one probe, which is at the end of the procedure instead of on return edges. This replacement does not influence the execution of probes along any path, but reduces the probe amount and makes instrumentation easier to perform.

To make more probes replaceable, if a callee cluster has multi return edges, the weight of probes on these edges is increased, then the remainders of them could be reassigned same if possible.

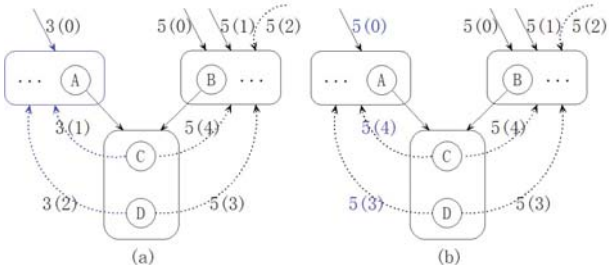

Fig. 5. An example of optimization

An example is shown in Fig.5 to explain such an optimization. Fig.5(a) displays three clusters, and the callee

cluster contains two procedures, C and D, which are called by A and B. The cluster of A has one other inedge, and the cluster of B has three other inedges (call edges and return edges). Since C and D return into both A and B, A has three inedges in all and the weight of probes on them is 3, while B has five and the weight is 5. The probe on the return edge (C, A) is 3(1), and the probe on (C, B) is 5(4). To make the probes on (C, A) and (C, B) same, 5 is used as the uniform weight, and the probes can be reassigned as Fig.5(b) shows, where all return edges from C has the same probe 5(4). After that, this probe can be put to the end of C, and only one probe is needed instead of two. So does procedure D. By such a process, weights "spread" along the return edges from a procedure, and the amount of probes gets reduced.

From all discussed above, PIP algorithm is given in Algorithm 1.

Input: PS : the set of procedures
CE : call edges
PE : polymorphic edges
sc : the cluster strategy
Output: ps : the probe set
/* generate the PCCG */
use sc to cluster procedures and get CS;
initialize a PCCG with CS, PS and CE;
remove redundant call edges and add return edges to the PCCG;
/* compute probes */
foreach *cluster* c *in* CS **do**
    int $weight$ = c.fanIn(); //the indegree of c
    int i = 0;
    foreach *inedge* $e \rightarrow c$ **do**
        ps.addProbe(e, $weight$, i++);
    end
end
/* optimize probes on return edges */
foreach *procedure* p *in* PS **do**
    if p *returns into more than one cluster and can be optimized* **then**
        spread the weight to make return edges from p have the same probe, assumed to be (w, i);
        foreach *return edge* e *from* p **do**
            ps.remove(e);
        end
        ps.add($p.exit$, w, i);
    end
end

Algorithm 1: PIP

D. The Trade-Off

From former parts of this section, PIP has been presented, which works on PCCGs, combines procedures into clusters, and brings following benefits.

First, it reduces probes by optimizing their placements; second, it saves code splitting when polymorphic calls exist; third, it generates a chance of custom selection: the bigger the clusters are, the easier instrumentation is; but on the other hand, the more storage is needed since the *pathids* get bigger as the weights grow.

So in clustering there is a trade-off between the convenience of instrumentation and the storage cost of executions: fewer probes bring more storage.

IV. Experiment

As Fig.2 shows, for a program under profiling, PIP needs the clustering strategy to perform. So here experiments are carried out to watch the performances of different strategies.

A. Measured Aspects

PIP's overhead be classified into three categories, *static cost* (the cost for instrumentation), *storage cost* (the cost for storing *pathids*), and *dynamic cost* (mainly influenced by the *backwalk* cost). Section III.D displays a trade-off between *static cost* and *storage cost*. Here we explore the relationship between *static cost* and *dynamic cost*.

For a strategy used by PIP, its *static cost* can be measured by the probe number (which also represents the *storage cost*) and code splitting; its *dynamic cost* can be measured by the number of unique *breakpoints* since fewer unique *breakpoints* lead to less *backwalk* cost since duplicate *breakpoints* only need to be *backwalked* once.

So in order to test the efficiencies of different strategies, we collect their probe amounts on the same PCCG and the number of unique *breakpoints* on the same paths.

B. Tested Strategies

Some clustering strategies are presented and measured in experiments:

- sa: each cluster contains a single procedure;
- sb: two procedures in one cluster if they have polymorphic relations;
- sc: all procedures are in one cluster;
- $s(n)$: two procedures are in one cluster if they are commonly called by n or more procedures.

Obviously, $s(1)$, sb and sc can avoid code splitting, and $s(k)$ needs no more code splitting than $s(k+1)$.

sa, $s(2)$, $s(3)$, $s(4)$, $s(5)$, sb, sc are chosen to be experimentally inspected on probe numbers.

C. Experimental Results

To perform these strategies, we randomly generate PCCGs (sized of 100 procedures) and paths based on three parameters:

- RP: the ratio of calls between each two procedures;
- NR: the number of polymorphic relations;
- APL: the average length of random paths.

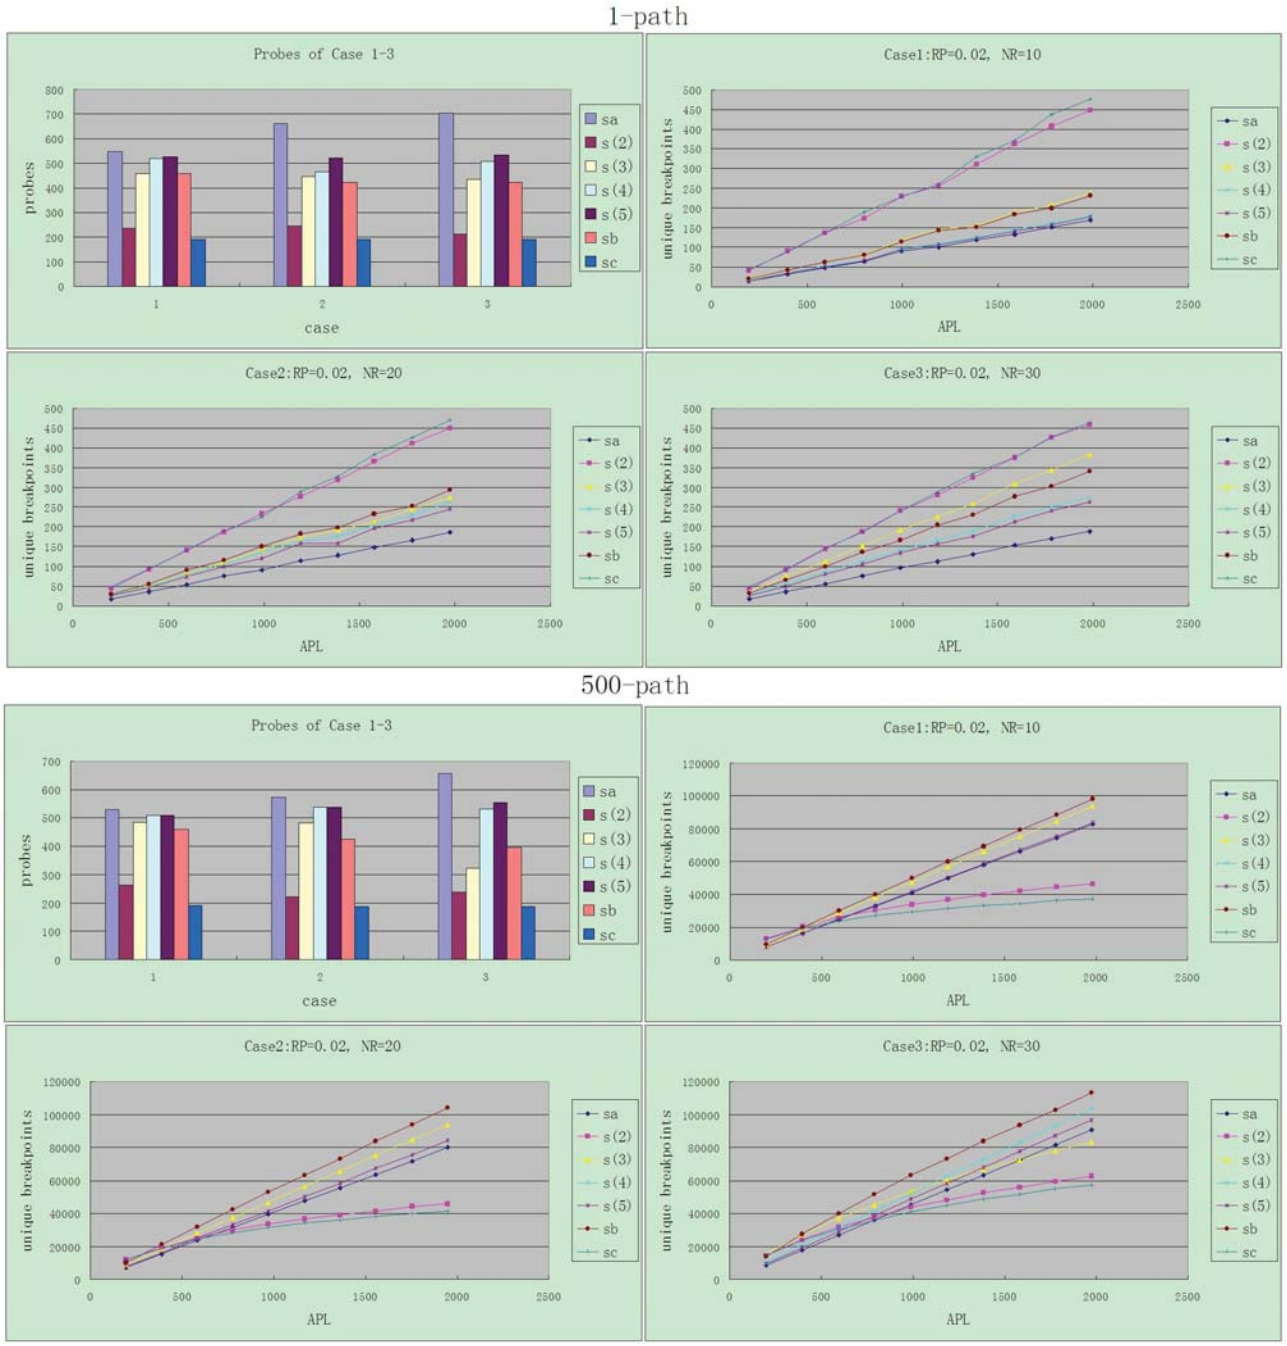

Fig. 6. Experimental results of breakpoints with 1 path and 500 unique paths

Based on random PCCGs and random paths, we count the probes needed by each strategy given above, and collect the unique *breakpoints* of the paths.

With different assignments of parameters, the experimental results of probe numbers and unique *breakpoints* are shown in Fig.6, which contains two parts, each deals with one path and 500 unique paths.

D. Analysis

From the results in Fig.6, we can draw following observations and conclusions.

First, as in 1-path situation, the number of unique *breakpoints* increases almost linearly as the path lengths grow;

TABLE I. Comparison of related work

Techniques	[3]	[2]	PIP
Cyclic	no	yes	yes
Completely accurate	yes	no	yes
Polymorphism handled	no	no	yes
Overflowing handled	no	no	yes

Second, generally in 1-path cases, if a strategy needs fewer probes, then it needs more unique *breakpoints*; but in case 3 of 1-path situation, compared with $s(3)$, sb uses fewer probes and still fewer unique *breakpoints*, which means it is possible to find a strategy which performs well in both aspects;

Third, as in 500-path situation, the growths of unique *breakpoints* of some strategies, such as sc, show obvious nonlinearity. So it is known sc is more efficient than others in both *static cost* and *dynamic cost*. Furthermore, it is inferred that with longer unique paths executed, PIP can use less average *dynamic cost* on a certain length; and compared with 1-path situation, with more paths executed, less average *dynamic cost* on each path.

V. Related work

As we know, during various profiling techniques, only three papers [2, 3, 5] involve inter-procedural profiling.

Ammons et al. present *Flow Sensitive Profiling* and *Context Sensitive Profiling*, which are combined together to provide an efficient approximation for inter-procedural path profiling [5].

Different from [5], [3] truly profiles paths with call and return edges. It also makes an optimization on "multi calls" to avoid profiling on some invalid paths.

In [2], Tallam et al. have extended their profiling into inter-procedure scenarios, which can profile *overlapping paths*. But though with high precision, their method is approximate, and still has limitations on loops. On the storage cost, a four-dimensional array is used to represent inter-procedural overlapping paths, so it may cost much space in complicated scenarios.

Moreover, neither of them consider polymorphic relations.

PIP extends PAP into inter-procedural situations, and can profile all paths with finite loops accurately (with enough storage). It divides procedures into clusters, and perform an optimization in instrumentation, which can reduce the amount of probes and improve the efficiency.

As shown in Table.I, PIP is compared with the approaches of [2, 3] in details. On one hand, PIP' ability is higher than other two techniques, i.e., PIP can profile longer paths as well as paths with more loop iterations; On the other hand, profiling longer paths leads to bigger cost, as bigger *pathids* need more storages.

VI. Conclusion

Focused on profiling inter-procedural paths, this paper has presented a profiling model PCCG and the PIP algorithm. PIP can handle paths with loops, across procedural boundaries, and under polymorphic situations, i.e., it gives an accurately profiling for cyclic inter-procedural paths, which would be useful in program understanding, profile-directed optimizations, and so on. By optimizations on procedure clustering and probe locations, it is easier to perform and achieves higher efficiency.

From theoretical analysis and experimental results based on random PCCGs and paths, we can draw following conclusions:

- Bigger clusters, which need less code splitting and fewer probes, result in less *static cost*;
- A trade-off exists between *static cost* and *storage cost*;
- With certain strategies used, PIP's *dynamic cost* is more efficient as more and longer paths are executed: its growth is obviously sublinear as the number of unique path and the average path length increase;
- Different clustering strategies for clustering give different benefits.

Furthermore, as discussed in Section IV.D, a proper strategy needs to be chosen based on the three types of cost. Although four types of strategies are tested in experiments, it is still a further problem to inspect more types, and to explore an algorithm for searching optimal strategies.

***Abstract*— The use of the Internet as a means of ensuring greater visibility for products, services and information offered by companies is gaining strength in recent decades. However, it is known that to ensure satisfaction and subsequent virtual customer loyalty, it is necessary to guarantee the quality of the websites, allowing indiscriminate access regardless of the resources used, as well as rapid responses to possible requests. In order to assist this process, this paper presents a set of guidelines for the development of websites having quality characteristics, efficiency and portability as per ISO 9126 norms. An observational analysis of e-commerce websites was done which showed that they are inadequate as to the proposed guidelines, making them difficult to access available content. Therefore, the adoption of the proposed guidelines can greatly contribute to increasing the quality of websites and, consequently, enable quick and effective access regardless of the resources used.**

Keywords - websites quality assurance; websites development guidelines; efficiency and portability characteristics

I. INTRODUCTION

Internet use has grown amazingly and is increasing in the number of new users. This has encouraged many companies to migrate the publicity of their products and services to the Internet, seeking access to a larger public. However, this entails the need to guarantee the users indiscriminate access to documents, products and services, regardless of where they are and the device used. With this scenario, it is necessary to develop new techniques to help the process of quality assurance, since the websites have unique features not offered by traditional software engineering.

This article then presents a set of guidelines that contributes to the creation of websites with emphasis on quality characteristics of efficiency and portability, as defined in ISO / IEC 9126 [1], including the need to ensure agility and indiscriminate access to information.

This article is organized as follows: section 2 presents related work in software quality; section 3 presents the guidelines established in this work; section 4 presents the results of an observational analysis undertaken in the context of Brazilian e-commerce websites in relation to proposed guidelines; and finally section 5 presents the conclusion.

II. RELATED WORK

Quality is an important factor for any software, regardless of their characteristics and restrictions. The ISO / IEC 9126 [1] established a standard of quality characteristics to be measured against during the development of software systems. However, the Web environment is an even greater challenge because of its unique characteristics, spawning various works ([2] [3] [4] [5] [6] [7]) which seek to establish elements that will ensure the quality of a website project. In this context, it is observed that quality efficiency and portability represent key aspects in websites, since their quality and interaction experience may be jeopardized by various factors, such as access device, means of access and implementation of specific features present in websites.

Works related to efficiency usually focus on usability, i.e., although important, efficiency is often not dealt with explicitly in works that cover the quality theme in websites ([8] [9] [10], [11]). The use of mobile devices to access websites makes it necessary to adapt the websites to the hardware characteristics of those devices [10]. Thus, the work related to portability seeks to minimize such problems ([12], [13], [14],[15]), often caused by lack of concern for quality when websites are developed.

Because of the above, this paper focuses on providing a set of guidelines in order to direct the development of quality websites, with emphasis on efficiency and portability characteristics, as defined in ISO / IEC 9126 [1]. With this, it is possible to improve the quality of websites, helping to ensure user satisfaction and guarantee indiscriminate access to information.

III. GUIDELINES FOR DEVELOPING WEBSITES

Creating quality websites is a challenge to designers and developers. To define the guidelines presented in this study, current information regarding the use of websites was gathered in order to assist the developers in the creation, with available resources, of a website with quality that meets today's demands. In this context, we emphasize that today, although it is possible to access the Web through various types of networks and different connection speeds, the Internet speed available to most of the population is less than 56 Kbps [9]. In Brazil, the newest CETIC [16] research points out that about 34% of the population has an Internet connection of up to 256 Kbps, a fact that causes a number of problems to access some websites, because it can create a barrier between the user and application, substantially hindering access to useful information. Against this scenario, in establishing guidelines, this study considered only three speed levels: below 256 kbps; from 256 kbps to 1 Mbps; and above 1Mbps.

The presentation of each of the proposed guidelines was conducted according to a defined set of relevant information in

order to facilitate their understanding and use. This combination is shown schematically in Figure 1 and detailed below. It should be noted that for a given category, different guidelines can be established.

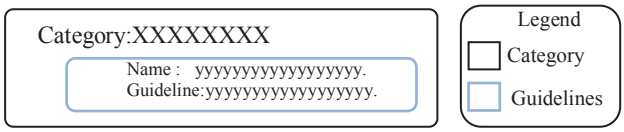

Figure 1 Structure of the guidelines.

Category: reflects the group that belongs to the established guideline(s).

Name: assigns a unique identifier for the corresponding guideline, based on the context of the metric considered as a basis [3].

Guideline: defines rules to guide the design of websites as a way to contribute to the production of results that meet the requirements of portability and efficiency.

In the following subsections, the guidelines established to aid in the development of websites following the proposed structure are presented.

3.1 Category: Media

The use of media to interact with the user in the form of tutorials or newsletters has been an element used in websites as a means of assisting users in the performance of a task.

a) Name: Duration.

Guideline: Due to the high volatility of Internet users, videos should not be too long, i.e., the recommended duration should be between two and ten minutes [17], to ensure effective execution and portability to different access devices.

b) Name: Response time.

Guideline: As to efficiency, the size of the videos and audios can be defined by taking into account three factors: the first is that a user needs to receive a response from the website up to one second after the click [6], i.e., the user must be able initiate the execution of video or audio until one second; the second factor is the use of streaming data, which is the ability to play media while downloading the rest of the file; finally, the last factor is to consider the connection speed of the user. Thus, in order to provide a satisfactory interaction with the user, it is necessary that the download of a new second of media be possible for each second done. Therefore, the media size is defined by the equation 1:

$$Average\ size = download\ per\ second\ X\ display\ time \quad (1)$$

In this context, based on a time range of two to ten minutes from the previous guideline and the proposed levels of access speed considered in this work, you can establish the following maximum size of videos and audios described in Table 1. In the item portability, it should be noted that most mobile devices that are used to access videos and audios do not have great processing power and storage capacity. Cell phones, for instance, seldom have an internal memory size greater than 100 MB. Thus, the adoption of media to support the use of a website should be done with caution so as to always consider the size of such media related to desired portability.

Table 1. Maximum size of videos and audios

	Media	
Speed	2 minutes	10 Minutes
up to 256 kbps	up to 3,840 KB	up to 19,200 KB
between 256 kbps and 1 Mbps	between 3,840 KB and 17,520 KB	between 19,200 KB and 87,600 KB
above 1 Mbps	from 17,520 KB	from 87,600 KB

c) Name: Image.

Guideline: Whereas a user can access information from a website from a mobile device, more precisely with less processing power such as cell phones, some precautions should be taken in relation to the use of images. Therefore, to improve the portability of the website, we suggest the preferred use of JPEG and GIF in an attempt to ensure a better user experience. To improve efficiency, we recommend that the resolution be set correctly inside the tags, specifying the value of the image that is loaded by the browser to prevent the resizing of images loaded by the browser [17]. As an example of the effectiveness of this policy, considering the use of HTML, the implementation could be done by adding the width and height attributes within the HTML image tag, as follows:

<img src="img.gif" width="28" height="21" >

The use of actual image values of width and height helps the browser to build the page properly, improving aspects of portability and efficiency of websites related to different devices and thus improving user experience.

3.2 Category: Maximum access time

The access time to a website represents an element that will be part of the quality evaluation of the user, directly influencing the user's decision about whether or not to continue using that website.

Name: Loading rate

Guideline: The metrics considered in this guideline are heavily dependent on the maximum download time that the user is willing to wait to see the website or any additional element. An additional feature is defined as being any external component from the page the user wants to see, for example, downloading a text file, an image with higher resolution, etc. Nielsen [11] defines ten seconds as being the maximum time users will wait before they decide to choose another page. Taking into account this time and the download speed, it is possible to calculate what the recommended size of a page or additional element of the website should be. The page size is the sum of all the sizes of each element that composes it, or is the sum of all images, texts, scripts, animations, and other elements that make up the website page. You can calculate the maximum size with the following equation 2:

$$Maximum\ Size = download\ speed\ X\ maximum\ waiting\ time \quad (2)$$

There are videos that do not need a complete loading when opening a page, since the total size of the video can be accessed by streaming if the user so wishes. Therefore, the size of the videos only represents the size of the application that will play them. In developing websites focused entirely on

mobile phones, it is recommended that pages have sizes of up to 20 KB [15]. As for the other devices, based on levels of access speed considered in this work, you can establish the following maximum sizes for a page described on Table 2:

Table 2. Maximum size for a page

Speed	Size
up to 256 kbps	up to 320 KB
between 256 kbps and 1 Mbps	between 320 KB and 1,280 KB
above 1 Mbps	from 1,280 KB

3.3 Category: Interface

The quality of the interface of a website aims to facilitate its use by the user through the organization of its established features.

a) Name: Text.

Guideline: It is recommended that websites be developed to make available a version where the images are not loaded by the browser whenever the user so wishes. This guideline is motivated by two factors: the first is the inability of some browsers to display the images and the second is to reduce the amount of downloaded data, thus reducing the access time to websites [18]. Moreover, it is necessary to allow the user to browse the page without any loss, even without viewing the images. As an example of how to put this guideline into effect, considering the use of HTML, the implementation of a text-only version could be done by adding the alt image tag within the HTML, as follows:

< img alt=”Name of the picture” ...>

With this, instead of viewing the image, the user will only see the information according to the tag. This is a feature that provides benefits to access websites via mobile devices, since it reduces the amount of information to be accessed, and consequently stored, without affecting the usability of the website.

b) Name: Title.

Guideline: The use of titles for all images of the website helps the overall readability of the site and its use is recommended.

c) Name: Reading.

Guideline: The overall reading of the site is the user's ability to understand the information contained in it. The overall readability of the site, even when it is not displaying images, should remain unchanged. Therefore, the guidelines related to the text-only version and inclusion of titles in the images must be implemented, so that the user has no trouble in understanding the information even when not viewing the images.

d) Name: Compactness.

Guideline: The navigation map is a representation in the form of a tree structure of possible paths to be followed in a website. Map compacting considers the number of levels required to gain access to pages that have the desired information. It is known that the less effort made by the user to access the information he wants, better will be the compactness of the navigational map. Therefore, the amount of levels established in this guideline for the maximum size of the navigational map, takes into account that the pages have used the maximum loading rate proposed in the maximum access time guideline. In addition, three other facts were considered: 1) studies show that users should be able to perform simple tasks within a website in one minute [10], 2) the time visiting a website lasts from one to two minutes, so the user must be able to reach the target website within that time or he will give up [19], 3) a user would spend, on more than 50% of the times, at least ten seconds to see each page of the website [19]. Therefore, considering that of the two minutes (average maximum time of one visit) the user can use up to one minute to perform the proposed task, we can then calculate the maximum amount of pages that can be visited before reaching the last one through the following equation 3:

$$Number\ of\ pages = \frac{Downlod\ Time + Reading\ Time}{Remaining\ time\ of\ the\ visit.} \quad (3)$$

The remaining time is the time of the visit less the time spent performing the task the user wants to accomplish. With that, the maximum use of up to three pages is indicated for the desired task to be accomplished. The high compactness of the navigational map contributes to the ease of access to websites through mobile devices, since they do not always have elements of interaction, such as mouse or keyboard.

e) Name: Scroll**.**

Guideline: The need for scrolling or rolling of the website page should be avoided. Studies show that the user will choose, in more than 75% of the times, a link which is available on the interface after the loading time. Therefore, the developer should avoid the use of long pages. Mainly for cell phones, this should be done due to the small size of their screens.

f) Name: Words.

Guideline: Users of websites tend to read only a little of the information contained on a page, and the more information available, the less will the user read. Studies show that users read at least 50% of the information contained on page that has 111 words or less [8]. Above this amount, the percentage of words read falls. Therefore, the use of short texts, with an option to expand them if the reader so desires, is recommended [8]. The use of few words improves visualization of websites when accessed by mobile devices, since they have very small screens.

g) Nome: Scripts and flash.

Guideline: The use of scripts and flash on websites influences the user’s experience in different ways, depending on the means of access used. The use of scripts can be very useful to developers, providing a powerful tool which can often improve elements related to the usability of websites. However, the use of scripts and the use of flash animation must be seen through a different perspective when developing an application that will be accessed via mobile devices. The different browsers used to access websites do not always have today’s technologies so can cause serious problems, preventing the user from accessing the desired information. Therefore, one should avoid incorporating scripts and flash on items considered essential in the website.

h) Name: Map.

Guideline: The use of a navigational map, when downloading several pages of the website, helps the user to quickly locate the desired information without the need for extensive searching. Accessing the website through networks that have a low speed or high cost per KB, the use of the navigational map can reduce the time needed to reach the desired information.

i) Name: Dimension.

Guideline: Setting the size of the resolution established for a monitor may affect the experience that the user will have with the website. According to a study conducted by Market net share[1], about 21% of Internet users use a 1024x768 resolution and 17% a 1280x800. Due to this, the use of one of the two aforementioned resolutions is recommended to better serve users. In the category of mobile devices, specifically for mobile phones, the instruction is to use pages having a width of at least 120 pixels. Currently most mobile browsers implement functions that facilitate the viewing of websites with resolutions greater than this value [19].

j) Name: Frame.

Guideline: A frameset is a tag used in the HTML that gives the developer the division of the website in multiple frames, including the loading of other pages within each of these frames. When the Web started, the use of frames to create sites was very common, but due to problems related to navigation and location of pages by search engines, frames were gradually forgotten and currently only a few websites still use them. Therefore, it is recommended not to use frames in a website.

k) Name: Search.

Guideline: It is recommended that a search engine on the website be created for users to be able to quickly look for the content they want without the need for an exhaustive search through the site.

IV. WEBSITES ANALISIS

The Internet has changed the way how companies conduct their business; it has become increasingly vital to their success. In recent years, e-commerce has grown and now moves billions of dollars in the global economy. In Brazil, e-commerce profit grew 30% in 2009 and peaked at 6.3 billion dollars[2]. According to [20], 33% of the people already use mobile phones to buy goods over the Web and 47% to compare prices of products before purchasing. Another important fact is that users prefer to access the websites available on www instead of applications developed specifically for mobile phones.

Given the importance of the use of Internet for dissemination of company products and the need to develop quality websites accessible through any device, which are decisive factors for customer satisfaction, this article examined five Brazilian e-commerce websites: Americanas.com (www.americanas.com.br); Submarino (www.submarino.com.br) ; NetShoes (www.netshoes.com.br); Compra Fácil (www.comprafacil.com.br); Saraiva (www.saraiva.com.br). The purpose of this analysis was to verify the impact of the adequacy, or not, to guidelines which aim to ensure indiscriminate access to information on websites, thus increasing the visibility of products and services and ensuring user satisfaction.

The analysis was done to rate total adequacy (T), partial (P) or inadequacy (I) of websites regarding the proposed guidelines, using the following access devices: a desktop, a laptop and a smartphone. To do this, we adopted that for the guidelines that have a set of values that vary according to the provided resources, we analyze the narrower range of values. Thus, the established connection speed for analysis was up to 256 kbps, which is the most used in Brazil. Moreover, it was observed that the browser used by smartphones and notebooks did not display images. Results are shown in Table 3.

Table 3. Web Site Analysis

Guidelines	Analyzed Websites				
	Americanas	Subamrino	Netshoes	Compra Fácil	Saraiva
Media					
01- Length	T	T	T	T	-
02- Size	I	I	I	I	-
03- Images	P	I	I	T	I
Maximun access time					
04- Loading Rate	I	I	I	I	I
Interface					
05- Text	P	P	P	P	P
06- Title	T	T	T	T	T
07- Reading	T	P	P	T	T
08- Compactness	I	I	I	I	I
09- Scroll	I	I	I	I	I
10- Word	I	I	I	I	I
11- Scripts and flash	I	I	I	I	I
12- Map	I	I	I	I	T
13- Dimension	I	I	I	I	I
14- Frame	T	T	T	T	T
15- Search	T	T	T	T	T

4.1 Media

For this category, we found that this feature is beginning to be explored by Brazilian e-commerce websites as a way to demonstrate the benefits offered by their products. Furthermore, we observed that, generally, video viewing is done through a video portal available on the Internet, which makes access via smartphone difficult. Among the five analyzed websites, four had videos which only rated total adequacy for the "Length" guideline. Moreover, the guideline "Size" was not followed in any of the analyzed cases so, consequently, the efficiency of devices used for accessing was lacking. As for the "Images", only one of the websites had total adequacy to the guideline. The remaining images had been resized or without its actual size defined in the tag, which resulted in a partial rate for one site and inadequacy for the other three. This deficiency has led to problems related to portability and efficiency during the analysis, reducing the

[1] http://marketshare.hitslink.com/report.aspx?qprid=17

[2] http://www.e-bit.com.br

quality of user experience when accessing the site and causing the unnecessary loading of information and poor design of the page by the browser to a smartphone or notebook.

4.2 Maximum access time

In the guideline "Loading Rate" all websites examined had pages that exceeded the size limit to the speed selected. As a result, there were difficulties in accessing information through different devices, significantly jeopardizing desired efficiency.

4.3 Interface

In this category it was possible to observe some critical points regarding the efficiency and portability of analyzed websites. The guideline "Text" had been partially followed in the five analyzed websites as it was found that none of the websites provided a function that allowed the user to not access the images. This led to serious problems because the purchase button disappeared and was not easily found.

During the use of a smartphone, it became evident that the deficiency in this category was because guidelines were not followed, endangering, in many cases, the use of the website and causing a loss of quality. The guideline "Title" was fully met in all websites. The guideline "Reading" was met in part in two websites, jeopardizing the quality of interaction with websites when it was not possible to view images.

The guideline "Compactness" could be considered as met only in situations where you used the search as way to find the desired product. However, we found that when this feature was not used, the amount of levels needed to access the page with the desired information went beyond the limit with three pages. Moreover, the guidelines "Scroll", "Word" and "Dimension" were not met in any of the analyzed websites, making it difficult to visualize the information shown. The inadequacy of websites in relation to the "Scripts and flash" guideline caused a big problem when accessed via smartphone as this device does not support these technologies.

Thus, during tests with smartphones, the use with scripts that were not supported by the device prevented the access to links and thus denied access to various areas of the websites. The guideline "Map", rated total adequacy in only one of the analyzed websites. This made it difficult to search for information in the other websites. Finally, we observed that the guidelines "Frame" and "Search" were fully met on all websites. The guideline "Search" is used as a tool to aid navigation in all analyzed websites, which could not be otherwise when it comes to e-commerce.

V. CONCLUSION

It is undeniable that the search for websites that satisfactorily meet the needs of users is a requirement of the market and becomes a factor influencing customer loyalty and consequently the visibility of organizations. This paper therefore presented a set of guidelines that can help with the construction of websites that allow indiscriminate access to information regardless of resources.

Towards this end, the priority is for quality characteristics, portability and efficiency. In e-commerce websites, availability and easy access for users is an important element for the success of the enterprise. As a result of the validation performed on five Brazilian e-commerce websites, we observed that the ones that only partially met the guidelines established in this work, or simply did not follow them, had their access to information jeopardized by low efficiency and lack of portability. Therefore, we conclude that more attention is needed to the design quality of a website as a way of ensuring greater availability and ease of access, regardless of the devices and network used.

Abstract— **This paper presents a model-driven approach that aims at monitoring the software development processes, through the adoption of workflow management systems in order to allow the automatic collection of quantitative measures during software development project execution. Our approach provides support to the definition, deployment, execution and monitoring of software processes. It has been designed and implemented using existing model-driven technologies, which promote the transformation of process descriptions, specified using the Eclipse Process Framework (EPF), to workflow specifications that can be installed in the jBPM workflow engine.**

Keywords: Software Processes, Model-Driven Development, Process Metrics

I. INTRODUCTION

The increasing scale and complexity of software systems requires the definition and application of systematic methods, techniques and tools along the software life cycle. Large and medium software projects demand the definition and continuous improvement of software processes in order to promote the productive development of high-quality software. Over the last decades, the software engineering community has proposed many methods and techniques for the definition and improvement of software processes, such as: process models [1], process productivity metrics [6], maturity models, and process methodologies. All of them contribute to provide a more systematics process definition, execution, measurement and improvement. As a consequence, they contribute to the quality and productivity of the software development process.

Recent research work has proposed notations and formalisms to the process definition [1, 2]. Rational Method Composer (RMC) [1] consists of a suite of commercial tools for editing, modeling, viewing, configuration and publishing specifications of software processes. The Eclipse Process Framework (EPF) [2] is an open-source framework used for process definition based on the Unified Modeling Architecture (UMA) metamodel. In addition, there are many recent studies that investigate the integration of approaches and languages for process modeling and execution [3] [4] [5].

Despite the recent advances in the software process research area, little effort has been made to integrate techniques and tools that allow the definition, execution and monitoring of software processes. The integration of such techniques and tools can support the automated monitoring of software processes, thus contributing to the process activity estimation, quality control, productivity assessment, and project management. Moreover, current research work has not explored: (i) the adoption of existing and modern workflow systems to execute software processes specified in workflow languages; and (ii) the modeling, specification and integration of process metrics with software processes, and their respective deployment in workflow systems.

In this context, this paper presents a model-driven approach to the definition, execution and monitoring of software processes. The approach allows: (i) the modeling and specification of software processes with their respective productivity metrics; (ii) the automatic transformation of software process specifications to workflow specifications; (iii) the deployment and execution of these workflow specifications that represent software processes in workflow engines; and (iv) the monitoring of the process execution through a set of specific metrics automatically collected.

Our approach has been implemented using existing model-driven technologies. Software processes are specified using the Eclipse Process Framework (EPF) and automatically transformed to a specification written in the jPDL workflow language, which can then be deployed and executed in the jBPM workflow engine. QVTO and Accelleo languages are used to support the model-to-model and model-to-text transformations, respectively.

In addition to the support of automatic mapping of process elements to workflow abstractions, our approach still addresses: (i) the automatic weaving of metric collection actions inside process model elements that are subsequently refined to workflow actions or events - which will be responsible to gather information used to quantify each process productivity metric; and (ii) the process specification is also refined to customize Java Server Faces (JSF) web pages, which are used during the workflow execution to collect valuable information about the current status of the software process.

The remainder of this paper is organized as follows. Section II presents our model-driven approach for the definition, execution and monitoring of software processes. Section III details its current implementation and illustrates its application

to a software process instantiated from the OpenUP framework. Section IV presents related works. Finally, Section V presents the conclusions and points out future work directions.

II. AUTOMATIC EXECUTION AND MONITORING OF SOFTWARE DEVELOPMENT PROCESSES

This section gives an overview of our model-driven approach that provides support to the definition, deployment, execution and monitoring of software processes. Next, we describe the main systematic activities that define our approach.

1. Process Modeling and Specification. The first activity of our approach is the modeling and specification of a software process. The EPF framework and associated tools are used to support the process definition. Existing process frameworks, such as OpenUP (available in the EPF repository), can be reused and customized in this activity. The main responsible for this activity is the process engineer, who produces EPF process specifications (output artifact of this activity).

2. Metric Integration with Software Processes. After the modeling and specification of the software process, our approach allows process engineers to select and specify the metrics that will be automatically monitored and collected during the process execution. A pre-defined set of process metrics is already available to be selected and composed with the software process. The metrics integration involves the definition of the start and the end activities of the monitored software process. In order to support the metrics inclusion, we defined a new metamodel which helps the definition and integration of the metrics with EPF specifications. The output of the metrics inclusion is the EPF process specification refined with activities related to the automatic collection of the metrics.

3. Process to Workflow Transformation. In this activity, the refined EPF process specification is automatically transformed to a workflow description. To do so, we apply model-to-model and model-to-text transformations to automatically map abstractions from the process domain to the workflow domain, thus enabling the instantiation and deployment of the software process in a workflow engine. In the current implementation of our approach, the EPF process is transformed to a workflow specification described in the jPDL language, which is used by the jBPM workflow system.

4. Workflow Deployment and Execution. The final activity of our approach aims at deploying and executing the workflow specification which represents a software process in the target workflow engine. It allows monitoring the software process activities, including the quantification of specific process metrics related to the team and project productivity. Team members of the software project under development must interact with the workflow system in order to maintain updated the progress of the process activities.

III. OUR APPROACH IN ACTION

In this section, we detail the implementation our approach for process definition, customization and execution, using the EPF framework and the jBPM workflow engine. In addition, we illustrate the application of our approach to the OpenUP software process through three different stages. Next subsections describe how each activity of the proposed approach was applied in order to define a software process based on the OpenUP framework.

A. Process Modeling and Specification

The first activity of our approach is the process modeling and specification. The Eclipse Process Framework (EPF) and associated tools are used to support this activity. Existing process frameworks, such as OpenUP, can be used as a base to define the elements (activities, roles, artifacts, iterations) of the development process to be modeled. Fig. 2 (Step 1) shows a fragment of a process derived from the OpenUP. It models an iteration of OpenUp Elaboration phase, with the following activities highlighted: *Identify and Refine Requirements*, *Develop Solution Increment* and *Test Solution*. Such activities will be subject to be monitored during the execution of the software processes.

The processes from the EPF framework are specified according to the Unified Metamodel Architecture (UMA), which is a subset of the Software Process Engineering Metamodel (SPEM) defined by OMG. The UMA is specified as an Ecore metamodel using the Eclipse Modeling Framework (EMF). This brings facilities to the subsequent activities of our approach, which requires the EPF model transformation with different purposes. In addition, there are many existing model-driven platforms and technologies that were developed based on the EMF. We have also extended our approach to support the specification and integration of metrics for the process defined. After the process specification is necessary to define the metrics that have to be intercalated with the process tasks. Next subsection describes how this extension is implemented.

B. Metrics Integration in Software Processes

The metrics integration activity starts when the process engineer selects and specifies the metrics from a pre-defined set of process metrics, already available. In our current approach implementation, we have initially focused in metrics that quantify the duration of significant project tasks, such as process tasks, activities, steps and iterations.

During the modeling of an OpenUP based process, we have selected 2 project metrics: "*Duration of UC requirements tasks*" and "*Duration of UC development tasks*". The first one is defined to intercept the process activities to count the time interval required to accomplish activities related to the specification of use cases. The last one is responsible to intercept the process activities to count the time interval related to activities for developing use cases (UC).

In order to promote the metric modeling and integration with an EPF process model, it was necessary to define a separate metric model. Fig. 1 shows the metamodel for composing metrics in software processes. It allows specifying where the metric will be quantified in the workflow that represents the process execution. It supports process activities and tasks like intervention points for the metrics collection. Therefore, it is necessary to specify for each metric which activities or tasks it must operate through a simplified metric model. The metric metamodel defines several abstractions related to a metric plan for a development process. The

MetricPlanModel element aggregates the set of metrics defined for the process (Fig. 1).

The central model element is the *Metric*. It is used to describe all metrics defined for the process. Each metric has a unique identifier (*id* attribute), and a *name* and *description* that provide information about the metric. The *type* parameter of the *Metric* abstraction contains the metric type that can be one of the following: *hardData*, *softData* and *normalizedData*. It is specified as an enumeration named *MetricType*. This classification identifies the kind of information used in measurement [6]. The hard data information can be quantified with little or no subjectivity. The soft data information refers to the kind of information in which human opinions must be evaluated or, in other words, information where precision is not possible. Finally, the normalized data is used to more fairly evaluate projects that have different characteristics. They represent standard metrics for comparative purpose. Our approach focuses currently only on the hard data measurements.

The *form* property represents the type of event (task) quantified by the metric. The *continuous ColectType* means that the task cannot be paused and the metric value is computed as the interval from start until the end of the task or activity under measurement. The *intercalated ColectType* means that the task can be paused and the metric value is the sum of each timeslice spent on it. Finally, the *unit* property is used for indicating the unit of the metric. For the metrics modeled for our case study, we have the following option for the *MetricUnit* enumeration: *minutes* or UC.

While modeling a metric plan, we have to choose a base process model element that is used for the metric monitoring. These model elements can be currently process activities (*ActivityMetric*) or tasks (*TaskMetric*). The *ActivityMetric* element is used to define that a metric must intercept processes elements of the activity type. It adds two attributes for the metric. The "*activityBegin*" and "*activityEnd*" attributes store, respectively, the begin and end activity names that this metric will intercept, thus representing a sequence of tasks to be monitored. If the metric is intended to intercept only one activity, the *activityEnd* attribute must be blank. If there is not a direct flow between the activities, only these two activities will be considered. Finally, the *TaskMetric* element adds only one new attribute, named *tasksBase*, that must contain the names of all tasks affected by the metric being defined.

Fig. 2 illustrates a metric model for our OpenUp based process. It specifies two metrics for activities interceptions: *Duration of UC development tasks* and *Duration of UC requirements tasks*. The *Duration of UC development tasks* metric, for example, is defined to intercept and count the time spent the process activities related to the development of a use case (UC). The model exemplified in Fig. 2 (Step 2) sets activities from "develop_solution" activity to "test_solution" activity. It means that all activities between them have to be monitored. The value *continuous* setting to the form attribute implies that the time measured by this metric is the time interval between the start and the end of each activity specified.

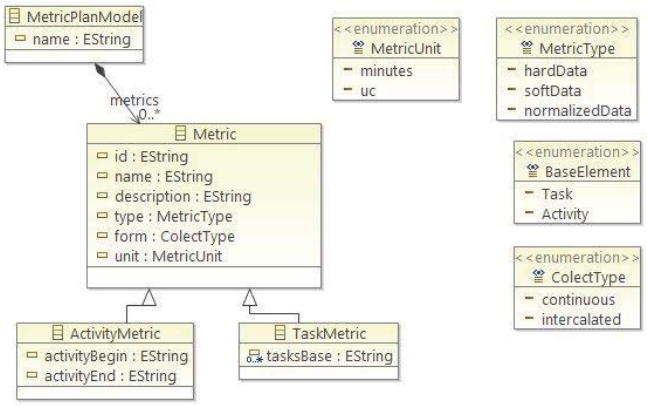

Figure 1 Metric Metamodel

C. *Process to Workflow Transformation*

After the modeling of a software process and the respective metrics that must be collected during its execution, our approach focuses on the model-to-model and model-to-text transformations of the process model to a workflow specification, which can be deployed in a workflow engine.

1) *Model to Model Transformation*

The M2M transformation is responsible for both: (i) realizing the process and metrics integration; and (ii) transforming the process model to a workflow specification. When applying this transformation, all process activities and tasks specified in the metric model must derivate new elements that will be responsible for the automatic collection of the productivity metrics. In addition, the transformation also maps all the process abstractions modeled using the UMA metamodel to workflow abstractions modeled using the jPDL language, which is adopted by the jBPM workflow system.

Table 1 shows the mapping from the process abstractions from the UMA metamodel to their respective jPDL workflow element produced by the M2M transformation. As you can see, there is a direct mapping between existing Activity elements in the UMA process models to specific node elements from the jPDL language. For example, the "Activity without predecessor" is mapped to the "start-node", and the "Activity with more and one successor" is mapped to the "fork-node".

TABLE I. MAPPINGS FOR JPDL ELEMENTS

UMA or Metric Element	JPDL Element
Activity	task-node
Worker-order	transition
Activity without predecessor	start-node
Activity without successor	end-node
Activities with more than one successor	fork-node
Activities with more than one predecessor	join-node
Task	task
Metric	event and action

On the other hand, each metric is associated with JPDL actions elements that are triggered by JPDL event elements at the end of each task execution. These actions elements are responsible for the data collection through their association with existing Java classes. Fig. 2 (Stage B), for example, shows the result of the process-to-workflow transformation. As we can see, there are two jPDL event elements responsible to quantify the use case productivity metric for the different.

The integration between the UMA process model and our metric model can be seen as a transversal composition. The integration is performed using the QVTO transformation language, which receives a UMA process model and a metric model as input, and it produces as output a jPDL process execution model (workflow model). Fig. 2 presents the metric and process input models in the Stage A, as well as the jPDL source code output in the Stage B. At the end of this stage, we have a workflow model that is produced as the weaving of the process and metrics models. Every measurement event can be seen as an aspect advice that acts on the task execution. We must consider that the jPDL elements that enable the measurements (actions and events) are not mapped visually to the workflow definition, but they are represented as elements that can be triggered and processed in background during the workflow execution. The task-node *Test Solution*, for example, has an event of "*task-end*" type which contains an action named *UCDevTime* that is associated with the *UCDevActionHandler* class responsible for the metric calculation.

2) Model to Text Transformation:

The model-to-text transformation is used in our approach to map and refine the resulting jPDL specification – produced as output from the model-to-model transformation – to workflow code assets that will be deployed in the jBPM engine to tracking and monitoring the software process execution. This transformation has been written in Acceleo template language. The jBPM workflow engine used in our approach enables the creation of web forms implemented in Java Server Faces (JSF) framework, from a jPDL workflow model definition. Such forms can be used to track the process workflow with the aim of storing information about the tasks and/or decisions taken during its execution. The transformation was created for the composition of the JSF dynamic web pages that will collect additional information for the tasks of our workflow. Specific jBPM taglibs are used in these JSF pages to indicate to the workflow engine to run the form and associate it with the process.

The model-to-text transformation is also responsible for generating a configuration file (forms.xml) that associates each task of our workflow to a JSF form and Java classes that represent the custom actions responsible to quantify the specified measurements.

The following code assets are produced as result of the transformation: (i) process-definition.xml – the jPDL specification that represents the process workflow; (ii) forms.xml – a configuration file that associates the JSF pages to the jPDL model generated by M2M transformation; (iii) JSF web pages with forms for each process task; and (iv) Java classes associated with each existing metric that will be executed after the conclusion of specific workflow tasks as described in the jPDL workflow specification. Due to space restriction, these code assets are not presented in this paper, but they can be found at [7].

D. Workflow Deployment and Execution

All code assets generated from the process-to-workflow transformation are organized and stored in a jPDL project in Eclipse IDE. Through simple manual settings, the jPDL project and associated code assets can be easily deployed and run on the jBPM workflow engine.

Fig. 2 (Stage C) shows the process execution after the deployment of workflow code and configuration assets in the jBPM engine. The execution can be monitored in the engine console deployed as a web application in the JBoss application server. After the deployment of the process workflow, the user can run a new process instance. Step 4 of Fig. 2 shows a process instance summary where links are displayed for viewing information about the process execution, such as start date, status, tasks instances, process image, process variables, among other information.

Step 5 shows the *Test_Solution* task form during execution. When performing each task, the software engineer (or project manager) informs required information in the task execution interface (JSF form), and she/he can end the task after its completion by using the transition button. The process instance can be checked for tracking issues at any time. All information from the process workflow and process instances is stored in a database.

Step 7 presents the task form during its execution. It shows the *id*, *name*, *status*, *start date*, *end date* and *actions* regarding the tasks that belong to the execution of the process workflow instance. As you can see, the "*Identify and Refine Requirements"* and "*Develop Solution"* tasks are running. Step 6 shows the values of process variables after the end of their associated tasks. The form displays the value 1265 for the variable *UCDevTime*, and the value 608 for the variable *UCReqTime*. The values of these variables were quantified in *minutes* and they are associated with the metrics responsible for the measurement of time spent in the use cases requirements specification and development during an iteration of the OpenUP Elaboration phase. These metrics are collected for each process iteration.

IV. RELATED WORK

Recent studies have promoted the integration of approaches and languages for modeling the process execution. However, these research works mainly emphasize the modeling of processes using new proposed modeling languages. None of them focuses monitoring software processes with automatic metric gathering in workflow systems.

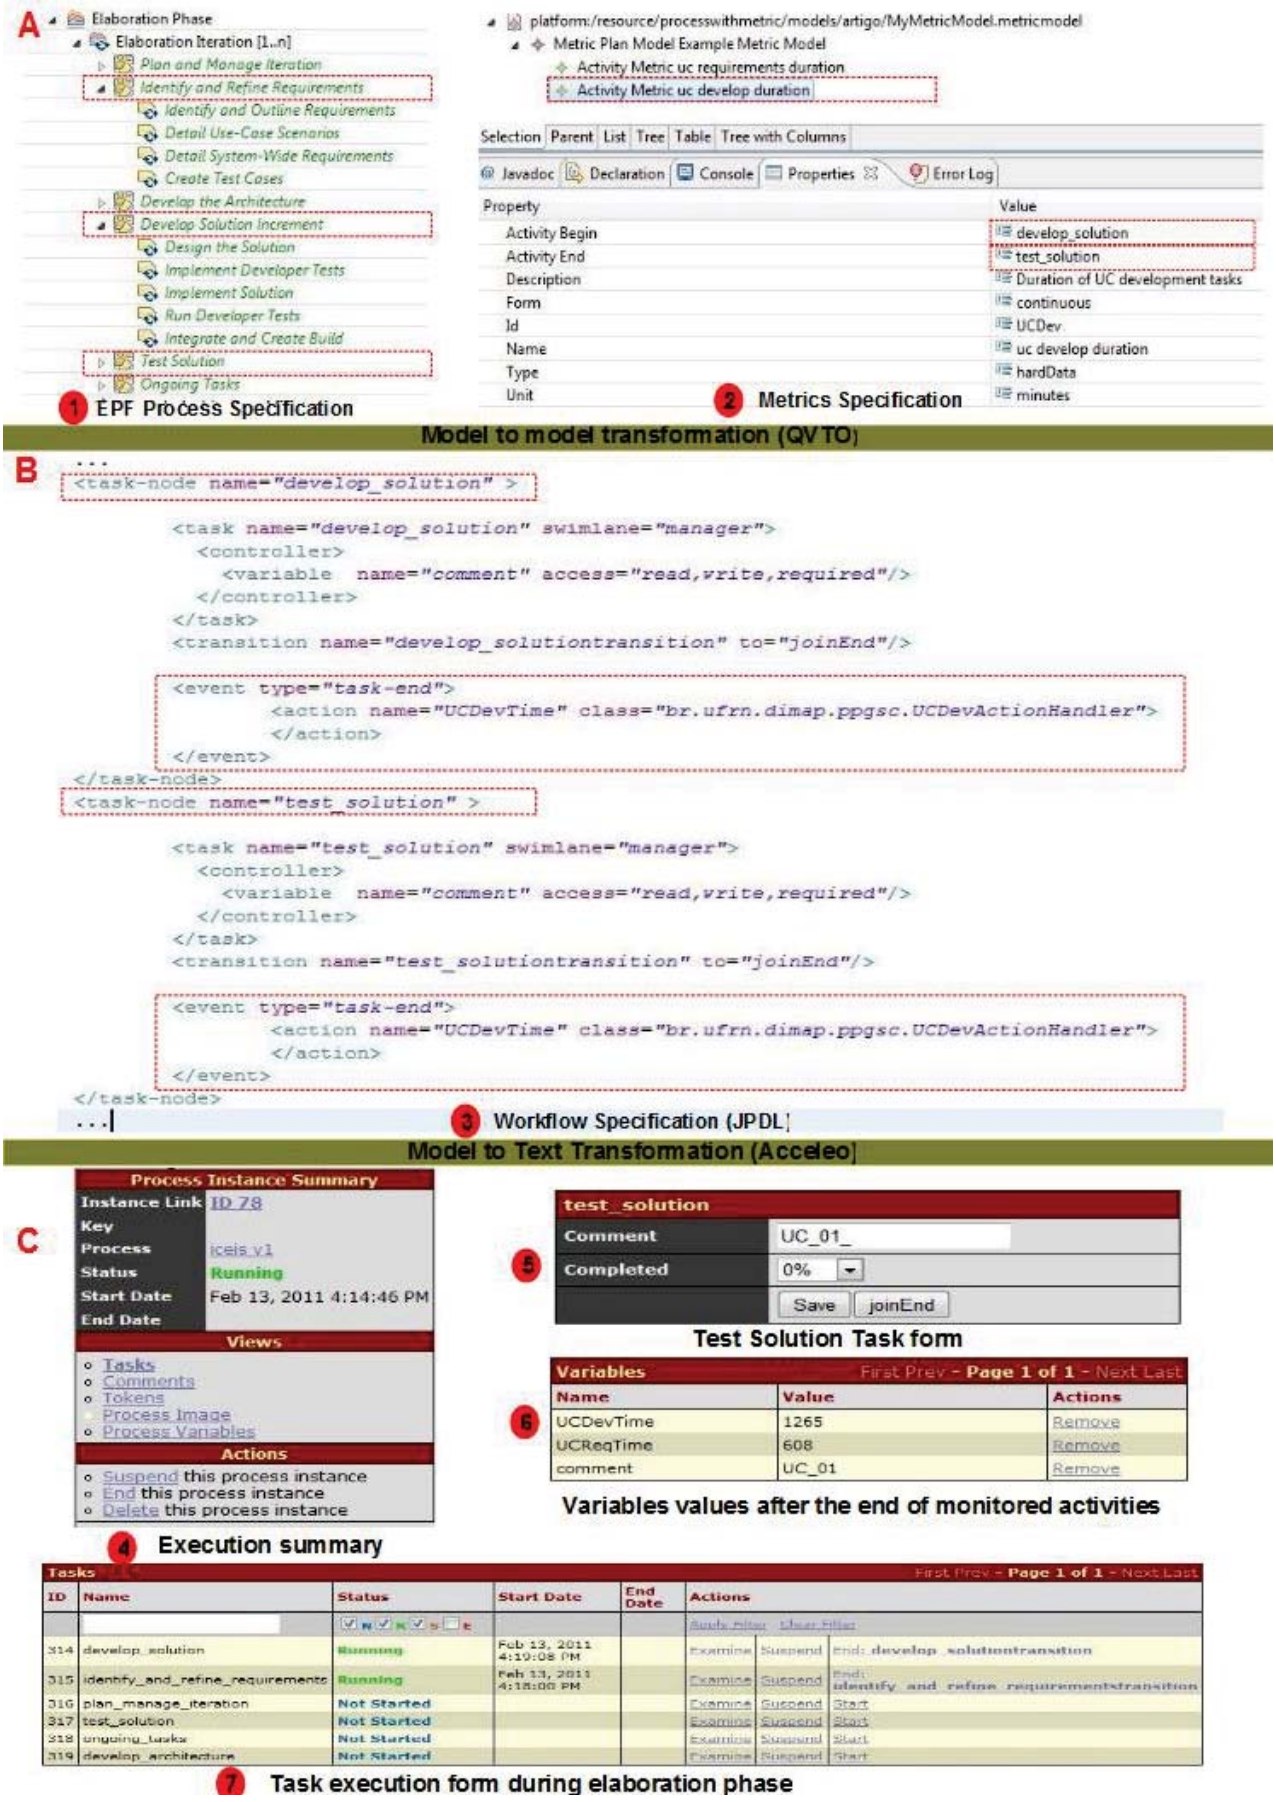

Figure 2 Approach in Action

Bendraou et al [3] presents a model-driven approach that includes the mapping between UML4SPM and WS-BPEL languages. Each language operates in a different domain: software process definition and process execution, respectively. The rationale for this choice was that both languages have their strengths in both the modeling and execution purposes. The transformation from process to workflow models has been defined by a program written directly in the Java language.

Maciel et al [5] also defines a model-based approach to software process modeling using MDA. The authors mention that the approach is totally based on OMG standards, such as SPEM 2.0, UML 2.0, MDA. However, the main focus of this work is on the specification of processes elements. The approach does not propose a complete transformation of software processes specification in order to enable their execution in workflow systems.

The approach proposed in this paper has in common with the works mentioned above the aim of addressing the process execution from existing process specification. However, our work differs from the most research carried out because: (i) our approach proposes automated model transformations between technologies of process definition (EPF) and execution (jBPM) widely used in industry and academia; (ii) it promotes the generation of workflow code assets (configuration files, JSF components and Java classes) that provides support to the effective processes execution and monitoring in workflow systems; and, last but not least, (iii) it enables the automatic collection of metrics during the execution of the process while minimizing the cost and cultural issues traditionally involved in manual collection of measures in software projects.

V. CONCLUSIONS

This paper presented an approach to the definition, deployment, execution and monitoring of software development processes that supports the automatic collection of quantitative measures during project execution. The approach was implemented and evaluated using existing model-driven technologies and platforms. Our implementation enables the transformation of process specifications from the Eclipse Process Framework (EPF) to jBPM workflow specifications.

Our approach also proposes extensions to the process modeling in order to support the collection of productivity metrics during the process workflow execution. Each new metric to be adopted in a software project must be specified in a specific model. When modeling each process metric, it is necessary to specify its points of intersection in the process. These join points can be the beginning and end of tasks/activities execution, or even the tasks/activities creation and deletion. The task and activity model elements from the process model act as join points, which can be intercepted to collect information of interest to be stored for the metrics. As described in the paper, the model-to-model transformation from the process and metric models to a jPDL workflow specification can be seen as a weaver that produces as output a process execution description with a set of actions responsible to automatically collect information during the process execution.

As future and ongoing work, several refinements of the approach can be done and some of them are already under development. Currently, an industrial case study in applying new metrics to measure productivity of a project is being modeled and implemented. New measures are being explored to extend our approach, such as the effort spent by team members on project tasks or activities, and the number of bugs or defects found, reported and corrected. In addition, we are integrating the approach proposed in this paper with variability management techniques and mechanisms previously proposed [8]. The main goal is to provide support to the variability modeling of process lines [9] and the automatic derivation, deployment and monitoring of software processes in workflow systems.

***Abstract*—FBD (Function Block Diagram) is one of the widely used PLC (Programmable Logic Controller) programming languages in plant automation industry. Many vendors and products have their own forms and formats, which are not compatible with others. Formal verification techniques and tools for FBDs should have provided vendor- and product-specific versions. PLCopen, a vendor/product independent worldwide association, provides a standardized way to define FBDs in an XML format. This paper proposes a CASE tool, FBDtoVerilog, which translates the PLCopen-FBDs into Verilog programs. Verilog is an input programming language for formal verification tools such as VIS (Verification with Interaction and Synthesis). It had been efficiently used as an input front-end of formal verifications, when developing software controllers of nuclear power plants in Korea. We demonstrate its usefulness and effectiveness with a prototype version of FBDs which had developed for APR-1400 nuclear power reactor in Korea.**

Keywords-Translation; PLCopen; FBD; Verilog; CASE

I. INTRODUCTION

FBD is one of the five widely used PLC programming languages defined by International Electrotechnical Commission (IEC) [1]. It visually expresses PLC controller's behavior as sequentially interconnected function blocks. The KINCS project [2] developed a new RPS (Reactor Protection System) for Korean nuclear power plants and implemented its software in FBDs. Rigorous quality demonstration of RPS software was also required by the regulation agency (e.g., KINS [3] in Korea) prior to issuing operational approval. Automated and formal verification techniques such as model checking [4, 5] and equivalence checking [6] was applied to the FBDs in order to ensure adequate quality assurance.

Formal verification techniques have their own input front-ends. For example, the VIS verification system [7] needs Verilog program, while the SMV [8] model checker does SMV input program or Verilog program. Translation from FBDs into these front-ends is therefore the first step to applying various formal verification techniques into FBD programs. Our former researches on FBD verifications, '*FBD Verifier'* and '*PLC Verifier'* [9, 10] had to use a FBD format specific to POSCO ICT [11], which generated from its PLC engineering tool '*pSET*' [12]. Some changes in the format, however, made us difficult to keep consistency and correctness of the automatic translators and verification tools. This paper proposes a CASE tool, '*FBDtoVerilog*' translating FBDs into Verilog programs, but uses a de facto standard XML format of FBD, proposed by PLCopen [13]. PLCopen is a vendor- and product-independent worldwide association. *FBDtoVerilog* can translate into Verilog programs FBDs from any vendors complying with the association's standard.

We demonstrated correctness and effectiveness of the proposed translator through a case study, formal verification of FBD programs using the SMV and the VIS. We used a prototype version [14] of FBD programs which had developed for a nuclear reactor protection system in Korea. The remainder of the paper is as follows. Section 2 introduces the FBD and PLC open association briefly. It also introduces relevant features of Verilog programming language, which are pertinent to our discussion. Section 3 introduces the CASE tool *FBDtoVerilog*. Section 4 explains a case study of formal verification using the proposed tool. Section 5 concludes the paper.

II. BACKGROUND

A. Function Block Diagram

An FBD (Function Block Diagram) consists of an arbitrary number of function blocks, '*wired'* together in a manner similar to a circuit diagram. The international standard IEC 61131-3 defined 10 categories and all function blocks. For example, the function block ADD performs arithmetic addition of n+1 IN values and stores the result in OUT variable. Others are interpreted in a similar way.

Fig.1 shows a part of preliminary FBD programs for the KNICS RPS BP (Bistable Processor) logic. The former was generated mechanically [15] from a formal requirements specification [14], while the latter was developed by domain experts. Even though they look different in appearance, they show the same behavior. We used these FBDs as examples to keep consistent with our former work and aid understanding of FBD programs. These FBDs both creates a warning signal '*th_X_Pretrip*' when the pre-trip condition (i.e., reactor shutdown) remains true for *k_Trip_Delay* time units as implemented in the TOF function block. The number in parenthesis above each function block denotes its execution

order. The output '*th_Prev_X_Pretrip'* from MOVE stores current value of '*th_X_Pretrip'* in order to use in the next execution cycle. A large number of FBDs similar to Fig.1 and Fig.2 are assembled hierarchically and executed according to a predefined sequential execution order.

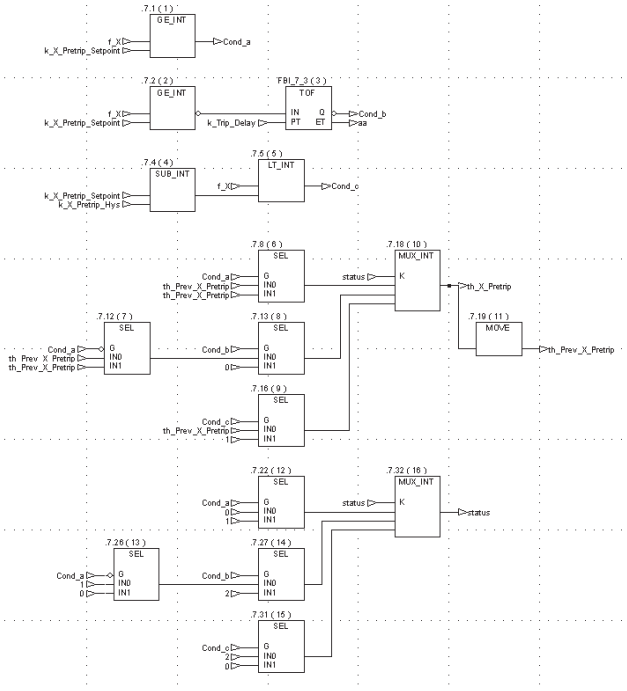

Figure 1. An FBD for *th_X_Pretrip* logic, generated mechanically

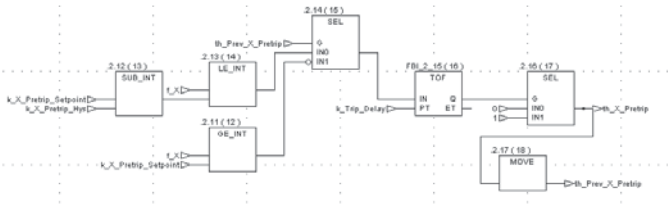

Figure 2. An FBD for *th_X_Pretrip* logic, developed by domain experts

B. PLC open

PLCopen [13] is a vendor- and product-independent worldwide association, aiming to resolve topics related to control programming and to support the use of international standards IEC 61131-3 [1]. A working group named TC6 for XML (eXtended Markup Language) in PLCopen has defined an open interface between all different kinds of software tools, which provides the ability to transfer one's information to other platforms. This paper used the XML specification defining FBD programming languages. The format unfortunately does not include all items which we need to translate FBDs into Verilog programs, so we used a few items in the specification for our specific purpose. The details will be introduced in Section 4.

C. Verilog Programming

Verilog is one of the most common Hardware Description Languages (HDLs) used by Integrated Circuit (IC) designers. Many verification and analysis techniques and tools widely use Verilog as an input programming language.

Fig.3 shows a Verilog program translated from the FBD described in Fig.2 according to the translation rules [15]. There are two inputs and two outputs. As input prefixes "*k_*" indicate constants variables. *th_Prev_X_Pretrip* is used as both input and output. Since it stores the value of *th_X_Pretrip* using the MOVE function block, we defined it as a *reg* variable in lines (8) and (32). The FBD's output is produced in the *assign* statements (12) ~ (18) by composing several function blocks in the FBD. It also uses the variable *timer* to emulate the TOF function block, which we emulate with *procedural* assignments using *always* statements (19) ~ (31). We restricted the number of TOF internal states to six in this example as defined in (1). In addition, we used the *clk* variable, reserved for simulation purposes in the VIS verification system, to simulate cyclic executions of PLCs.

```
(1)  typedef enum {T0, T1, T2, T3, T4, T5} timer_state;
(2)  `define k_X_Pretrip_Setpoint 30;
(3)  `define k_X_Pretrip_Hys 30;

(4)  module th_X_Pretrip(clk, f_X, th_X_Pretrip);
(5)      input clk;
(6)      input [0:6] f_X;
(7)      output th_X_Pretrip;

(8)      reg th_prev_X_Pretrip;
(9)      timer_state reg timer;

(10)     initial th_prev_X_Pretrip = 1;
(11)     initial timer = T0;

(12)     assign th_X_Pretrip =
(13)             ((th_prev_X_Pretrip == 0) && (f_X <= (k_X_Pretrip_Setpoint - k_X_Pretrip_Hys))) ? 1 :
(14)             ((th_prev_X_Pretrip == 0) && (f_X > (k_X_Pretrip_Setpoint - k_X_Pretrip_Hys)) && (timer == T5)) ? 0 :
(15)             ((th_prev_X_Pretrip == 0) && (f_X > (k_X_Pretrip_Setpoint - k_X_Pretrip_Hys)) && (timer != T5)) ? 1 :
(16)             ((th_prev_X_Pretrip == 1) && (f_X < k_X_Pretrip_Setpoint)) ? 1 :
(17)             ((th_prev_X_Pretrip == 1) && (f_X >= k_X_Pretrip_Setpoint) && (timer == T5)) ? 0 :
(18)             ((th_prev_X_Pretrip == 1) && (f_X >= k_X_Pretrip_Setpoint) && (timer != T5)) ? 1 : 0;

(19)     always @(posedge clk) begin
(20)             if(f_X >= k_X_Pretrip_Setpoint) begin
(21)                     case(timer)
(22)                             T0: timer = T1;
(23)                             T1: timer = T2;
(24)                             T2: timer = T3;
(25)                             T3: timer = T4;
(26)                             T4: timer = T5;
(27)                             T5: timer = T5;
(28)                     endcase
(29)             end
(30)             else
(31)                     timer = T0;

(32)             th_prev_X_Pretrip = th_X_Pretrip;
(33)     end

(34)  endmodule
```

Figure 3. A Verilog program translated from the FBD in Fig.3

III. FBDTOVERILOG

We have used the proposed, but not fully refined, FBD definition and translation rules [16] to formally verify FBD programs in the KNICS project. Fig.4 briefly shows how we have used them to verify the FBD programs with various verification techniques and tools. It is a part of PLC-based software development framework we proposed in [15]. We planned to apply two formal verification techniques into the FBDs, the model checking and the equivalence checking. While the former can prove mathematically whether the FBD satisfies important properties, the latter can conclude whether two different FBDs show the same behavior or not.

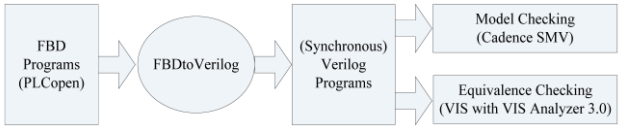

Figure 4. The use of the proposed translator in formal verifications

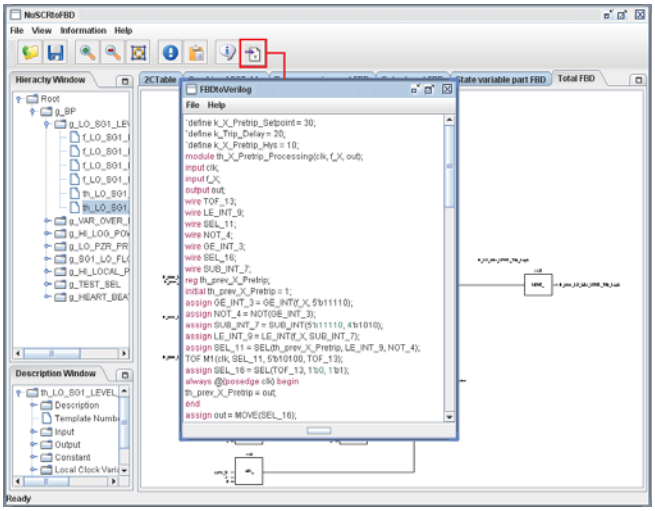

Figure 5. FBDtoVerilog v1.0 Screen-dump

We had developed automatic translator and verification assisting tool *FBD Verifier* [9], and applied them into the KNICS project in part [17]. However, our former work started with a specific version of FBDs specialized for POSCON ICT. In order to apply useful formal verification techniques with no hindrance from the compatibility problem, we decided to separate the translator from the specific FBD and used standard XML format of FBD. Fig.5 depicts a screen-dump of *FBDtoVerilog 1.0* CASE tool which we have developed. It is embedded in *NuSCRtoFBD 3.0* and reads standard FBDs of PLCopen and produces (synchronous) Verilog programs.

FBDtoVerilog used an *addData*, general-purpose element of the PLCopen XML specification [13]. *NuSCRtoFBD 3.0* generates PLCopen specific XML that every single function block element belongs to an externally visible output which *addData* element stores its name. Fig.6 shows *LE_INT* block cooperate with computing output *th_X_Pretrip*. *FBDtoVerilog* uses the information to translate an FBD's flat structure into a Verilog module's hierarchy structure.

```
<block instanceName="LE_INT" localId="9" typeName="LE_INT" exectionOrderId="15">
        <inputVariables>
                ...
        </inputVariables>
        <outputVariables>
                ...
        </outputVariables>
        <addData>
                <data name="th_X_Pretrip" handleUnknown="discard">
                        <BOOL/>
                </data>
        </addData>
</block>
```

Figure 6. Usage of *addData* element in *th_X_Pretrip* FBD specification

The current version of *FBDtoVerilog 1.0* has some room to improve. First, it produces incomplete Verilog code that requires manual post-process to supply variable size in bit vectors. Performing formal verification activities such as equivalence checking and model checking require complete size determination. Second, it translates every function block, even though they are too simple to be defined as a Verilog function. We suggest practically possible translation option in Table 1. These aspects will implement in next version of *FBDtoVerilog*.

Table 1. Alternative optimized function block translation rule

	Current rule	Optimized rule

SEL	var = SEL(a, b, c);
	…
	function SEL;
	  input in1;
	  input in2;
	  input in3;
	  begin
	  SEL = (in1 == 1) ? in3 :
	  in2;
	  end
	endfunction
		var = (a == 1) ? b : c;

ADD	var = ADD(a, b);
	…
	function [0:6] SUB_INT;
	  input [0:6] in1;
	  input [0:6] in2;
	  begin
	  SUB_INT = (in1 - in2);
	  end
	endfunction
		var = a + b;

IV. CASE STUDY

We performed a case study as described in Fig.7 to validate correctness of *FBDtoVerilog 1.0*. We translated the system FBD *g_LO_SG1_Level* depicted abstractly in Fig.1 and Fig.2 into Verilog programs. And we applied manual post-processing on the translated code with preserving its original semantic as we mentioned in Section 3 (see Fig.8). We had plan performing Cadence SMV model checking and the VIS equivalence checking against the Verilog program. When preparing the case study, we only focused on checking the validity of the CASE tool.

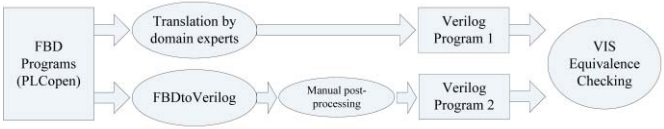

Figure 7. Case study plan

The VIS equivalence checking result shows "sequentially equivalent" message as we can see in Fig.9, which means two Verilog programs have same output behavior against same inputs. We also conducted flawless examination of two source codes to validate our tool's correctness, since source codes have quite different coding style. For example, original domain expert generated code doesn't contain user-define functions that our code has.

Cadence SMV model checker cannot read the Verilog program which the current version of *FBDtoVerilog* produced. We found out that the model checker forbid the reuse of functions such as *SEL* or *ADD* in our code. We are working on this issue with more refined translation rules. From the results, we can say that our proto-type *FBDtoVerilog* archived its main purpose at minimum that the translated Verilog code has same behavior with the original code developed and certified by domain experts.

```
module main(clk, f_X, th_X_Pretrip);
input clk;
input [0:6] f_X;
output th_X_Pretrip;

//wires and regs
wire tof_out;
wire Sel1;
wire Sel2;
…

reg th_prev_X_Pretrip;
initial th_prev_X_Pretrip = 1;

// assign temp wire varialbes
assign Ge_int = GE_INT(f_X, 7'b0011110);
assign Sel1 = SEL(th_prev_X_Pretrip, Le_int, Not);
…
TOF M1(clk, Sel1, 7'b0000101, tof_out);
assign th_X_Pretrip = MOVE(Sel2);

always @(posedge clk) begin
th_prev_X_Pretrip = th_X_Pretrip;
end

//function blocks
function GE_INT;
input [0:6] in1;
…
```

Figure 8. Translated Verilog code from the FBD in Fig.3

```

Warning: Some variables are unused in model LE_INT.
vis> init_verify
vis> seq_verify ./th_X_Pretrip_custom_v3.mv
Networks are sequentially equivalent.
```

Figure 9. VIS equivalence checking result

Our future work will focus on implementing next version of *FBDtoVerilog*. First issue is fully automatic Verilog code generation feature that includes variable size determination algorithm. Second issue is Cadence SMV compatible code generation feature. And we will plan the case study that verifies further correctness of the *FBDtoVerilog* through VIS equivalence checking and Cadence SMV model checker using all FBDs used in the KNICS project.

V. CONCLUSION

As safety critical systems are using FBD as standard representation of software design, software verification on FBDs becomes indispensable. Our former researches on FBD verifications used a vendor-specific format of FBD, and it made us difficult to keep consistency and correctness of the automatic translator and verification tools. This paper proposes a CASE tool, '*FBDtoVerilog*' translating FBDs into Verilog programs, but uses a de facto standard XML format of FBD, proposed by PLCopen. We demonstrated correctness and effectiveness of the assisting tool through a case study, formal verification of FBD programs using the VIS. We used a prototype version of FBD programs developed for a nuclear reactor protection system in Korea. The case study demonstrated that the CASE tool, *FBDtoVerilog* translates standard FBDs into Verilog programs correctly and efficiently.

Abstract

Policy-based management is a flexible approach for the management of complex systems as policies make context-sensitive and automated decisions. For their effective development it is desired to specify policies at a high level of abstraction initially and to refine them until they are represented in a machine-executable way. We present an approach for the modeling of event-condition-action (ECA) policies at different levels of abstraction. A relational algebra is used to formally specify and validate the models at each level. Finally, executable policy code is generated from the low-level models. The approach is generic as it can be applied to any domain and supports a flexible number of abstraction layers. It is applied to the network management domain and demonstrated with policies for coverage optimization in a mobile network.

Keywords–policy-based management; model-driven engineering; network management

1. Introduction

Increasing complexity of information systems complicates their development and management. This evolution calls for changes in the way those systems are built. The aspect of development is addressed by the model-driven engineering (MDE) approach, which moves the focus from a code-centric to a model-centric point of view [1]. Models raise the level of abstraction and reduce complexity by separating different concerns of a system from each other. Models in MDE are no longer used for discussion and documentation purposes only, but they are used as primary artifacts from which implementations are generated [2]. Increasing complexity also affects the management of information systems at runtime. This issue is addressed by the idea of self-organizing systems. One example is the Autonomic Computing Initiative (ACI) by IBM, which proposes self-manageable systems in order to reduce human intervention necessary for performing administrative tasks [3].

Policies represent a promising technique for realizing autonomic capabilities within managed objects as they allow for a high level of automation and abstraction. Policy-based management has gained attention in research and industry as a management paradigm as it allows administrators to adapt the behavior of a system without changing source code or considering technical details. A system can continuously be adjusted to externally imposed constraints by changing the determining policies [4]. A well-known application domain is network management, where policies are widely used for performing configuration processes. The usage of policy-based systems for the management of mobile networks was recently considered in [5–10].

The event-condition-action (ECA) model is a common way to specify policies. ECA policies represent reaction rules that specify the reactive behavior of a system. An ECA policy correlates a set of events, a set of conditions, and a set of actions to specify the reaction to a certain situation. The conditions are evaluated on the occurrence of an event and determine whether the policy is applicable or not in that particular situation. The actions are only executed if the conditions are met. Multiple policy frameworks share this model as for example Ponder2 [11].

Policy-based management is a layered approach where policies exist at different levels of abstraction. The number of abstraction layers depends on the system to manage. Strassner defines a flexible number of abstraction layers as the Policy Continuum [5]. The idea is to specify and manage policies at each level in a domain-specific terminology, and to refine them from a business level down to a technical level. To support this we present a generic approach for the modeling of domain-specific ECA policies at different levels of abstraction. Policies are specified at the highest level initially and iteratively refined by re-writing them with the means of the lower levels until they are represented in a machine-executable way.

This paper is structured as follows. Section 2 describes how domain-specific policies are modeled at different levels of abstraction before executable code is generated. Section 3 provides an example from a case study. Related work is discussed in section 4. The paper concludes with a summary and future work in section 5.

2. Modeling

We use different models at different abstraction layers in order to specify policies as indicated in [12] and illustrated in figure 1. The domain model allows domain experts to specify concepts of a domain or system. The policy model allows policy experts to specify policies that are used to manage the system. The linking model allows policy and domain experts to link the policy model to the domain model in order to use the domain-specific concepts within the policies. These models are actually parts of one large model. For each of them a metamodel exists that defines the structure of the model. Two layers *i* and *j* are shown exemplarily in figure 1 with layer *i* providing a higher level and layer *j* providing a lower level of abstraction. Actually, the approach supports a flexible number of abstraction layers. The lowest layer represents the models such that executable policy code can be generated from them.

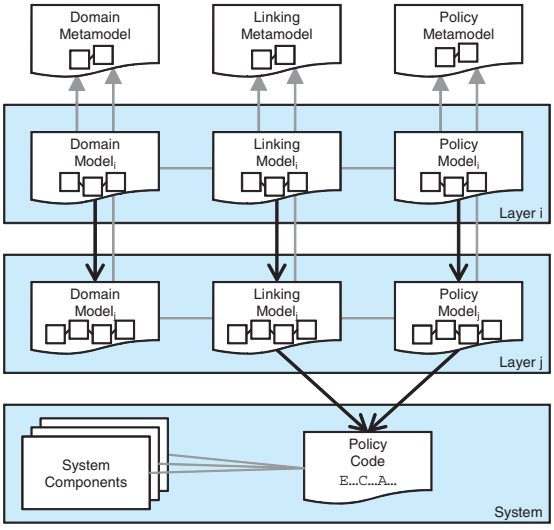

Figure 1. Overview

We are develpoing a relational algebra to formally specify the domain, policy, and linking metamodels, i.e. the abstract syntax of the models. The algebra will be used to validate whether model instances conform to the respective metamodel. For this purpose, a concrete syntax should provide a transformation into the relational algebra. Excerpts of the algebra are presented in this paper.

2.1. Domain Modeling

Different expert groups are involved in the management of a system such as business managers or system administrators. Depending on their focus and their background, members of an expert group have a particular view on the system and they use special terminology to describe their knowledge. The *domain* represents a common understanding of those expert groups and covers the context of a system at the different layers.

Any relevant information about the domain is covered by the *domain model*. The domain model covers the domain-specific concepts across all layers and specifies which concepts are available. Its purpose is to specify domain knowledge independently from any policies, which will later control a system in that domain. Thus it represents the basis for building policies, which will then use domain-specific concepts in their event, condition, and action parts. The domain model offers a particular view at any layer, which only contains the part of the domain model that is relevant at the respective layer. The domain model is an instance of the *domain metamodel*, which allows to specify domain models in a way that is more expressive than just a domain-specific vocabulary and close to the structure of an ontology. For this purpose, the metamodel represents domain-specific knowledge as shown in figure 2. It represents the abstract syntax of the domain, i.e. it defines the structure of the domain model.

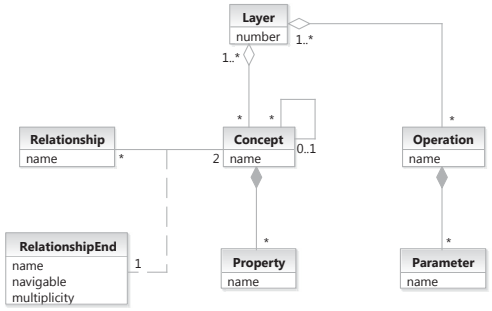

Figure 2. Domain metamodel

The domain metamodel contains the following entities. *Concepts* and *operations* in the domain metamodel have a name and are assigned to *layers*. The layers specify at which levels of abstraction concepts and operations are available. Each layer contains an arbitrary number of concepts and operations. Each concept and operation is assigned to one layer at least. A concept may have named *properties* assigned and each property belongs to one concept. An operation may have named *parameters* assigned and each parameter belongs to one operation. Any two concepts may be assigned to each other by named *relationships*.

The connection points between a relationship and a concept are called *relationship ends* and have a name, a navigability, and a multiplicity.

The domain metamodel allows to build a tree-like hierarchy of concepts. A concept may be assigned other concepts as subconcepts and is called their superconcept in this case. A subconcept inherits the properties and relationships from its superconcept. Thus any property and relationship of a superconcept is also available at its subconcepts. Of course, a subconcept may be assigned additional properties and relationships which are not assigned to its superconcept. A subconcept does not interit the layers from its superconcept. This allows to extend the concept hierarchy by specifying additional subconcepts at lower layers. If subconcepts also inherited the layers from their superconcept, they would be available at the higer layer as well, which is not intended.

2.2. Policy Modeling

Any information about the policies is covered by the *policy model*. The policy model offers a particular view at any layer, which only contains the part of the policy model that is relevant at the respective layer. The policy model is an instance of the *policy metamodel*, which contains the essential aspects required to specify ECA policies. It is shown in figure 3 and represents the abstract syntax of policies, i.e. it defines the structure of the policy model.

Various policy languages are available for different domains and application areas. A policy language usually provides some structured notation for policies and can be interpreted by an execution engine. Typically, such engines provide means to cope with priorities and conflict resolution, which reduces complexity for the developer. When developing a policy-based system, a decision for a policy language has to be made at some point. Unfortunately, no policy language is general and powerful enough to meet the requirements of any system in any domain. It is desired to specify policies independently from a particular policy language and to generate code for a particular language. For this purpose, we analyzed some well-known policy languages such as PonderTalk [11], KAoS [13], and Rei [14] and integrated them into the policy metamodel.

The policy metamodel contains the following entities. *Policies* in the policy metamodel have a name and are active or not. They are assigned to *layers* to specify at which levels of abstraction they are available. Each layer contains an arbitrary number of policies. A policy is assigned to one layer at least. A policy has at least one named *event* assigned. A policy optionally has a named *condition* assigned. A condition is one out of the following boolean expressions. A *binary expression* performs a comparison, which is one out of *equal*, *greater*, *greater or equal*, *lower*, and *lower or equal*. A *negation expression* negates another expression.

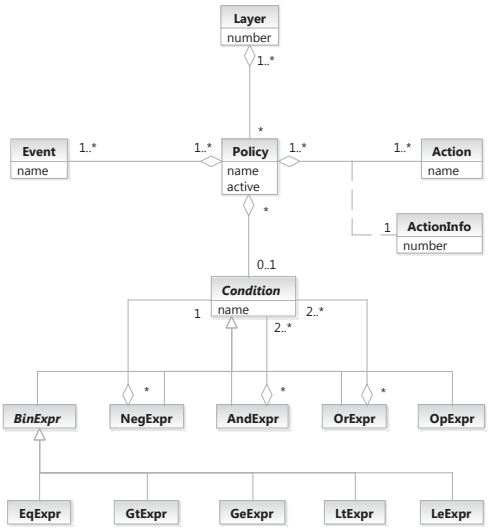

Figure 3. Policy metamodel

An *and expression* combines two other expressions as conjunction. An *or expression* combines two other expressions as disjunction. A special type of expression is the *operational expression*, which refers to some operation and uses its return value as the result of the expression. A policy also has at least one named *action* assigned. The sequence of action execution within that policy is specified by assigning a *number* to each action within that policy.

2.3. Domain-Specific Policy Modeling

Any information about how domain-specific information is used within the policies is covered by the *linking model*. It specifies how the domain and the policy model are linked to each other. For this purpose, it allows to create links from the entities in the policy model to the entities in the domain model at the respective layers. The linking model offers a particular view at any layer, which only contains the links that are relevant at the respective layer. The linking model is an instance of the *linking metamodel*, which provides means to create links from the policy model to the domain model as shown in figure 4. It represents the abstract syntax of the links, i.e. it defines the structure of the linking model.

An event in the policy metamodel corresponds to a concept in the domain metamodel that is used as event. The properties of that concept are regarded as the properties of the event. Multiple events may correspond to the same concept. A binary expression in the policy metamodel compares two arguments with each other. The simplest form of an argument is a literal value. A property in the domain metamodel whose concept is used as event of the respective policy may also be used as argument. This allows to use contextual information within the policy that was passed as

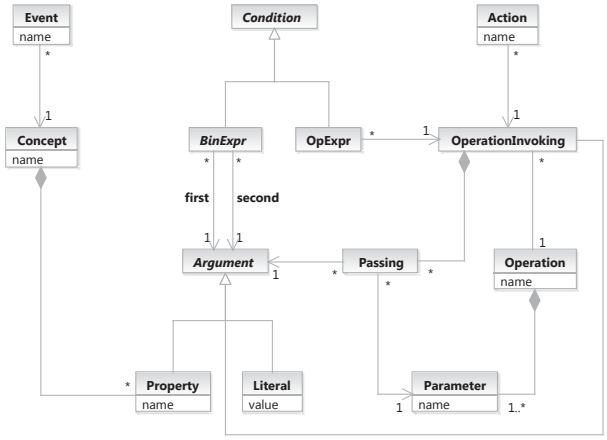

Figure 4. Linking metamodel

event parameter. Another form of an argument is the return value of an invoked operation in the domain metamodel. When invoking an operation, one argument may be passed to each parameter of the operation again. An operational expression in the policy metamodel invokes an operation in the domain metamodel and uses the return value of that operation as value of the expression. An action in the policy metamodel also invokes an operation in the domain metamodel.

The relational algebra imposes some restrictions on the models. One example is the usage of contextual information within a policy. Contextual information is usually passed to a policy via its events. The event properties contain information to be used within the policy and can be referenced in the policy condition and action. It is important that only properties are used within a policy that are visible for that policy. A property is visible for a policy if its concept is used as event of that policy. This restriction is covered by (1) to (3) in the relational algebra.

$$arg \in argumentsOfCondition(cd) \Rightarrow (arg \notin Properties \vee \forall po \in policiesOfCondition(cd). arg \in visibleProperties(po)) \quad (1)$$

$$arg \in argumentsOfAction(ac) \Rightarrow (arg \notin Properties \vee \forall po \in policiesOfAction(ac). arg \in visibleProperties(po)) \quad (2)$$

$$visibleProperties : Id_{Po} \rightarrow \mathcal{P}(Id_{Pr}) \quad po \mapsto \bigcup_{co \in visibleConcepts} propertiesOfConcept(co) \quad \text{with } visibleConcepts = \bigcup_{ev \in eventsOfPolicy(po)} conceptOfEvent(ev) \quad (3)$$

2.4. Code Generation

Refinement is performed by subsequently providing the models at the lower layers until they are represented in a machine-executable way. The domain model then represents the necessary concepts of the underlying system components and the policy and linking models represent policies that control the behavior of those components. Executable code in a policy language can now be generated from the models. This applies to any language that is able to express ECA policies as defined by the policy metamodel.

For this purpose, model transformations generate the policy code in a fully automated way. This involves model-to-model and model-to-text transformations, which first transform the policy and linking models into an intermediate model representation of the target language and then into executable policy code. Transformation is realized as proof of concept for the Ponder2 policy framework [11], which was developed at Imperial College over a number of years. Details of the transformation are presented in [15].

3. Case Study

Management of information systems is a complex task especially in the management of mobile networks. Complexity arises from the distributed architecture of the underlying cellular network with its high number of network elements (NEs) to be deployed and managed and from interdependencies between their configurations.

Operation, administration, and maintenance (OAM) of a mobile network is usually based on a centralized information system which is organized in different management domains. Configuration management (CM) deals with a consistent configuration of all NEs, performance management (PM) analyzes the efficiency of the current network configuration and seeks a more efficient one, and fault management (FM) detects and resolves errors that occur in the network. Any management domain focusses on different aspects and has a special view onto the network and the configurations of the NEs.

3.1. Policy-Based Coverage Optimization

One important management task within any cellular network is coverage optimization. The cells of the network should always provide a complete coverage without areas having no coverage at all. The detection and resolution of converage holes is a complex task as any of the CM, PM, and FM domains are affected. The coverage area of each cell is determined through multiple factors.

- **Position**: Location and direction of an antenna are the main determining factors for the coverage area of a cell. These parameters are preplanned and are almost

not adjustable after deployment as this would require expensive human on-site intervention.

- **Transmission power**: Later adaptations of the transmission power (TXP) have a direct impact on the size of a cell's coverage area. Adaptations can be performed remotely through the operation and maintenance system.
- **Antenna tilt**: The tilt describes the angle between the antenna and the ground. A rough mechanical adjustment is done when the antenna is deployed. Adaptations of the antenna tilt are performed through remote electrical tilt changes (RET) within the antenna.

In order to optimize coverage within the network, usually a sequence of power and tilt adaptations is used since they can be performed remotely. After each change the situation is re-evaluated by analysis of measurement reports. The results of this evaluation are used to determine whether additional adaptions are required or not. Due to the cellular structure of the network, power and tilt adaptations have a strong impact. Adaptions at a single cell may have impact on adjacent cells and may result in a conflict and thus undesired state of the network.

The dependencies between power and tilt adaptions require subsequent adaptions to be coordinated with each other in order to ensure that no logical errors, oscillations, or even deadlocks occur in the configuration. For this purpose, a policy-based coordination mechanism was developed that takes decisions in an automated way [9, 10]. The coordination policies express the decision logic to determine if a change request should be acknowledged, rejected, or rescheduled, and if previously executed requests should be rolled back. The policies are represented at multiple abstraction layers. The highest layer represents a management point-of-view whereas the lowest layer represents a specific implementation for the underlying management system [16] that uses Ponder2 [11] as policy framework.

3.2. Policy Modeling and Code Generation

The behavior of coverage optimization is controlled by a set of ECA coordination policies. For this purpose, a domain model is specified that covers the relevant concepts for coverage optimization. This happens at a high layer, i.e. from a functional point of view initially. At the same layer the necessary coordination policies are specified as a policy model and they are linked to the domain model with a linking model. Figure 5 shows a coordination policy that reschedules tilt change requests if a power change is already active. A simplified graphical notation with UML models and textual annotations is used as concrete syntax.

In order to enable a technical view, a refined domain model is specified at a lower layer that represents the underlying management system. A refined policy and a refined linking model is specified at the same layer in accordance with the refined domain model. Figure 6 shows the refined coordination policy, which provides the same functionality but uses the technical concepts of the underlying management system. Through refinement, some high-level entities must be replaced with the respective low-level ones, e.g. the *powerChangeRequest* and *tiltChangeRequest* concepts with the *reconfRequest* one or the *isPowerChangeActive.cell* and *isTiltChangeActive.cell* parameters with the *isReconfActive.property* one. Furthermore, information is added by means of the additional parameter *isReconfActive.type* and the passed value *"TXP"* in the invoking of the *isReconfActive* operation. The policy is now represented in a machine-executable way.

Finally, the refined models are automatically transformed into the executable Ponder2 code shown in listing 1. The respective model transformations are provided in [15]. The resulting code is directly used in the underlying management system.

```
1 policy := root/factory/ecapolicy create.
2 policy event: root/event/reconfRequest;
3        condition: [ :reconfRequest.id :reconfRequest.
              type :reconfRequest.property :reconfRequest.
              changeValue | root/op isReconfActive:"TXP"
              property:reconfRequest.property ];
4        action: [ :reconfRequest.id :reconfRequest.type :
              reconfRequest.property :reconfRequest.
              changeValue | root/op
              rescheduleReconfRequest:reconfRequest.id ].
5 root/policy at:"coordinationPolicy" put:policy.
6 policy active: true.
```

4. Related Work

This section summarizes comparable approaches for the modeling of policies. All approaches are compared to each other with regard to their features and outlined in table 1. A + in the table indicates that a feature is available in an approach, a *o* indicates a limited feature, and a - indicates that a feature is not available at all.

The authors of [17] present a model-driven approach to design policies and integrate them into the software development process. The approach is based on MDE concepts and uses a UML profile for modeling policies. The general policy modeling language (GPML) supports ECA policies amongst different types of policy. The ability to define a particular vocabulary allows to adapt policies to different domains. Policies are modeled at a low level of abstraction and cannot be refined. Model transformations are used to map GPML policies via an interchange format to existing policy languages. No formal specification is provided.

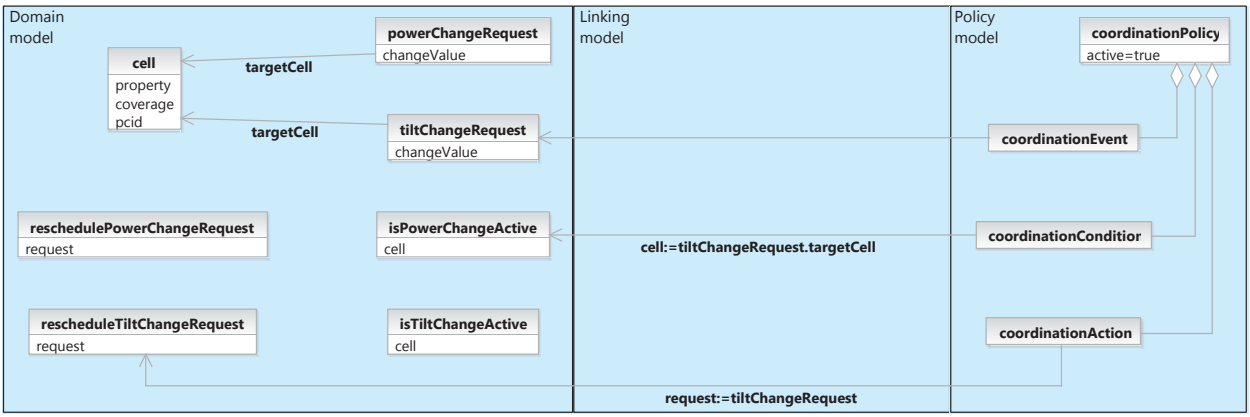

Figure 5. High-level model (excerpt)

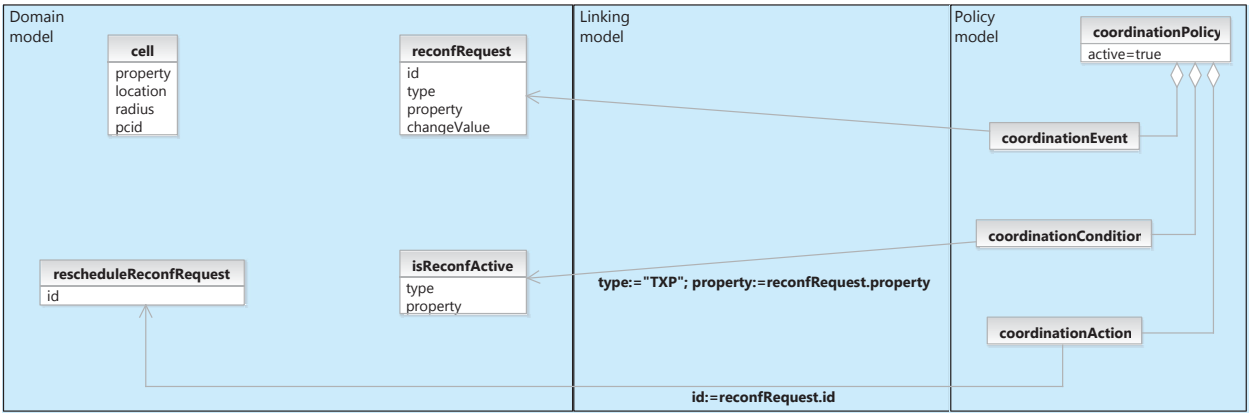

Figure 6. Low-level model (excerpt)

The CIM Policy Model [18] by the Distributed Management Task Force (DMTF) addresses the management of complex multi-vendor environments with a huge number of heterogeneous devices. Policies are specified in a language-independent way and abstract from hardware characteristics. A UML profile is provided for the graphical representation of policies. The CIM Policy Model is a domain-specific model with a focus on network management. Different abstraction levels and policy refinement are not supported. The approach does not address code generation for existing policy languages. A formal specification is not provided.

DEN-ng [6] by the TM Forum provides an information model for system entities and policies to manage those entities. It allows entities and policies to be modeled in an implementation-independent way while omitting technical details. ECA policies are modeled in a UML diagram. DEN-ng allows to specify a domain and resources within that domain on which policies operate. DEN-ng is based on the Policy Continuum and considers policies at different levels of abstraction. Specification of policies is addressed but policies cannot be refined automatically into a lower level of abstraction, nor transformed into an existing language. No formal specification is provided.

5. Conclusion

A model-based approach to the specification of ECA policies was presented in this paper. The usage of models allows to specify policies at a high level of abstraction initially and avoids the direct implementation of policies at a technical level. The approach is novel as it is generic with respect to the domain, to the language, and to the number of abstraction levels and nevertheless allows to generate executable code. The separation of knowledge into different models or model parts allows for an effective collaboration of domain and policy experts. The usage of different abstraction layers faciliates the collaboration of business and technical experts. A relational algebra is being developed to precisely define the abstract syntax of the models and allow

	GPML [17]	CIM Policy Model [18]	DEN-ng [6]	Modeling of Domain-Specific ECA Policies
ECA policies	+	o	+	+
Graphical modeling	+	+	+	+
Language-independent	+	+	+	+
Customizable domain	+	-	+	+
Abstraction levels	-	-	+	+
Formal specification	-	-	-	o
Automated refinement	-	-	-	-
Code generation	+	-	-	+

Table 1. Comparison of related work

for their validation, which is a prerequisite for the transformation into executable code.

The possibility to generate code eliminates the dependency from a particular policy language as the same models can be used to generate code for various languages. A prototype of a graphical policy editor that supports code generation for Ponder2 has already been developed [19]. The case study showed that a purely graphical syntax for the models might be confusing as diagrams take a lot of space in complex scenarios. An effective textual syntax is subject to future work. A representation of the models in the relational algebra for purposes of validation should be generated automatically. Automation of the refinement process is also subject to future work. Currently, the lower-level models are created manually based on the higher-level ones. However, it should be sufficient to specify the refinement of the domain model once and then apply that refinement to the policy and linking models in order to generate their refined representation whenever they are created or modified. In the end the objective is to automatically reflect changes of the high-level models in their low-level implementation.

***Abstract*—**
The smart grid has been proposed as the panacea to address systemic challenges of the over fifty year old legacy electrical grid, the single largest machine on the planet. A core component central to realizing the smart grid concept is the *microgrid*. The microgrid is a self-sustaining entity, capable of data interchange and real-time monitoring and control of its distributed generation, storage and load components.

In this paper we introduce ongoing research that uses a software engineering approach to user-driven control of the microgrid. Our approach uses a domain-specific modeling language (DSML), *MGridML*, and a virtual machine, *MGridVM*, which interprets user-defined models representing domain-level abstractions of the microgrid. MGridML captures high-level representations of pertinent domain features, based on a centralized hierarchical model of demand side energy management. A metamodel for MGridML and a prototype of the MGridVM are presented to show the feasibility and practicality of our approach.

***Index Terms*—Smart Grid, Microgrid, Domain-Specific Modeling Languages, Model-Driven Engineering.**

I. Introduction

The changes in energy consumption patterns are being dictated by rising energy costs and higher demand while increasingly being aware that thes unsustainable energy sources near depletion. These changes manifest themselves as additional requirements of the legacy electrical grid. The United States Department of Energy and similar entities across the globe have been tasked to upgrade the single largest interconnected machine on the planet, the electrical grid [1]. The existing grid, heavily reliant on fossil fuels, has effectively remained unchanged since the early twentieth century and is reaching its functional limits. The *smart grid* is seen as the successor to the lagacy grid and a core component central to realizing the smart grid concept is the *microgrid*. The microgrid is a self-sustaining entity, capable of data interchange and real-time monitoring and control of its distributed generation, storage and load components.

This paper introduces ongoing research that uses a software engineering approach to user-driven control of the microgrid. Our approach uses a domain-specific modeling language (DSML), *MGridML*, and a virtual machine, *MGridVM*, which interprets user-defined models representing domain-level abstractions of the microgrid. A metamodel for MGridML was developed based on a feature analysis of the microgrid and will be briefly described in the paper. To demonstrate the feasibility and practicality of our software engineering approach to energy management within the microgrid we provide a discussion of our prototype. The prototype includes the MGridML modeling environment, the MGridVM and a low voltage laboratory testbed which captures the essence of the microgrid.

This paper is organized as follows: Background technologies to provide context are reviewed in the next section. Section III provides our motivation for embarking on this research direction. The modeling language and virtual machines are described in Sections IV and V respectively. We place this work in perspective by presenting related work in Section VII. Finally we discuss future directions of this work and conclude in Section VIII.

II. Background

In this section we introduce the concepts and technologies required for our research. This background material include energy management within the microgrid and the use of domain-specific modeling languages (DSMLs) to model and realize applications in a specific domain.

A. The Microgrid Concept

The smart grid is the conceptualized solution to the ailing aspects of our existing grid infrastructure. The smart grid is challenged with balancing demand and supply through real-time communication and distributed generation accommodating renewable sources with self-healing capabilities [2]. All of this while reducing the carbon footprint and still maintaining the affordability of energy to the consumer [2]. It is expected that the smart grid will achieve much of the proposed goals through the integration of the microgrid concept.

Lasseter et al. [3] define the Consortium for Electric Reliability Technology Solutions (CERTS) concept of a *microgrid* as an aggregation of loads and microsources operating as a single system providing both power and heat. It is further stated that the majority of the microsources must be power electronic based. The key features of the microgrid include power electronics, control and communications capabilities that allows it to function as a semi-autonomous power system. The microgrid is expected to maintain stable operation and perform as a good citizen of the grid [4].

The production of electrical energy within the current electrical grid is demand based whereby the energy consumed drives the amount of energy being generated as storage is generally infeasible. Additionally, the means of energy production is centralized and far removed from the area of demand leading to heavy energy losses [5]. The microgrid advantage is in the proliferation of distributed energy resources (DERs) and energy storage and is the focus of our research. To further assist readers who maybe unfamiliar with the microgrid concept, we define the following terms:

- *Islanding* - In this state the microgrid operates independently of an external source.
- *Load* - A device which consumes electrical power.
- *Point of Common Coupling (PCC)* - The point at which the utility may be disconnected from the microgrid.
- *MGCC* - The Microgrid Central Controller, responsible for centrally directing energy flow within the microgrid.

B. Domain Specific Modeling Languages

Domain specific languages (DSL's) or little languages [6], are so called as they are usually small with well focused expressive power. The benefits of the DSL approach has been extensively researched. Sirer et al. [7], states that DSLs bring the solution domain closer to the problem domain, improve testability and simplifies maintenance. Empirical data from [8] suggests that the use of DSL's increases reliability, usability and flexibility. Bell Labs using the Family-Oriented Abstraction, Specification and Translation (FAST) approach to domain engineering reports at least a factor of four increase in productivity. [9]. DSLs were originally text-based, however there has been an increase focus on graphical DSLs or *domain-specific modeling languages* (DSMLs) since there are now tools to easily create modeling environments for DSMLs [10].

In order for this solution to apply, the problem domain has to be suitably qualified. According to [11], candidate domains should be reasonably stable and economically viable. We argue that the scope of our domain, microgrid energy management, falls within these parameters due to its maturity and its relevance within the global energy vision. Stahl et al. [12] outline the steps required to create a DSML, these include (1) an analysis of the domain, (2) the creation of a meta-model consisting of the abstract syntax of the language and the static semantics, (3) the concrete syntax for the language, (4) the dynamic semantics of the language. We applied Stahl et al. approach to define and design the MGridML language.

III. Motivation

The motivation for initially developing the MGridML and MGridVM was partially the result of observing the shortcomings of implementing a distributed generation and storage functionality within a local single family dwelling to facilitate islanding. We observed several issues which plague the realization of a robust microgrid capable of responding to instability in power distribution or the users economic preference. State of the art control systems typically require domain expertise far beyond that of the end-user of the system and are not programmable by the end-user. In the sequel we describe a scenario that typifies the challenges of an end-user faces when implementing a mircogrid.

A. Motivating Scenario

The primary actor in the scenario is Mary and the equipment in the microgrid comprises of distributed generation in the form of a photovoltaic generator, a storage system (batteries), and three loads, one of which is considered to be critical. The microgrid is connected to the local utility via a point of common coupling (PCC) which is capable of isolating or islanding the microgrid.

Microgrid Scenario: Our scenario begins when the utility grid is experiencing power fluctuations as observed in Mary's flickering lights and the erratic behavior of her appliances. Mary is not aware of how long this situation will last and is afraid of damage to costly equipment so she decides to remove herself from the grid and use stored energy. Mary is unsure of how long her energy storage will last. Mary, using a hardware solution, manually disconnects the microgrid at the PCC then engages the storage. Power is restored but Mary is left with an uneasy feeling. How long before she will have to switch to her batteries and how long will those last? Maybe she should turn off the non-critical appliances. She looks worryingly at the window at her neighbors house to see if power is restored.

Although this scenario is based on a manual approach, it raises critical questions as to the base requirements and issues yet to be addressed by alternate approaches in the context of user facilitated energy management. Our methodology conceives the solution as a black box then describe its core functionality and desired qualities. We postulate that the black-box requires realtime data and component state information from sources internal and external to the microgrid. It should conceptually describe Mary's directives in an intuitive manner and act accordingly within a reasonable time-frame, keeping her updated of the systems current state and near future projections.

Storage depletion estimates at current usage levels during islanding would assist the user, Mary, in modifying her load profile in the short term. It should alert her whenever the utility power level is stable as defined by some threshold and have the ability to automate a sequential restoration to pre-islanding operation. There is the need for a planning mechanism to optimize performance; the blackbox should be capable planning according to load and source forecasting and not depend on the lay user to perform complex calculations to facilitate optimization.

Should the user require the capacity of optimizing for economic purposes, the blackbox solution necessitates real-time monitoring of tariff information from the smart grid as in the case where Mary chooses to disconnect from the utility if the rates become too high and use stored energy if she anticipates sunshine the next day. With the advent of time-varying pricing, flattening the demand curve is a paramount consideration. Should additional hardware be intro-

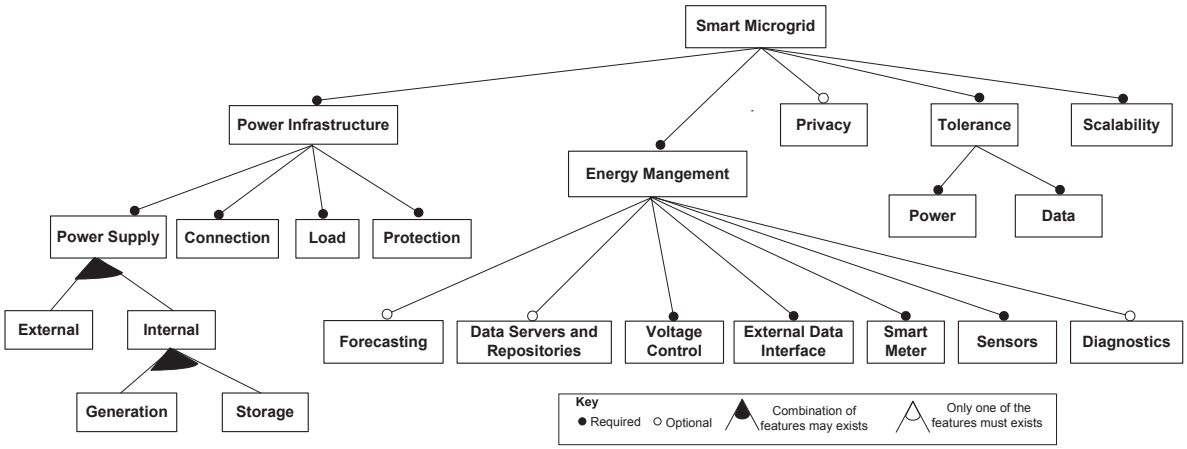

Fig. 1. Feature diagram for the microgrid.

duced within the microgrid, the black box should absorb and compensate. Lastly, thresholds, which if exceeded could result in equipment damage or raise safety concerns, will need to be identified and anticipated during operation. The consolidation of these considerations become the basis of our feature model addressed next.

B. Domain Analysis

A crucial aspect within the development of any DSML is a detailed and methodological introspection of the application domain to ascertain the predominant features and concepts [13]. Feature analysis is at times an ad-hoc learning process requiring constant and consistent refinement as domain objects are identified, abstracted and structured [13]. Following the Feature Oriented Domain Analysis methodology (FODA) [14], introspection begins by defining the scope of our domain.

The developmental methodologies engaged within the research of the microgrid required a familiarity with the domain terminology, to communicate effectively with domain experts for the purposes of verifying the abstraction of the essence of the domain. The primary artifact of analyzing the microgrid is the feature diagram [15], as seen in Figure 1, which shows the composite and atomic features of the microgrid.

Figure 1 shows the feature diagram for the mictrogrid. The feature diagram shows that a microgrid must have a power infrastructure, an energy management component, provide tolerance and be scalable. From our analysis privacy is currently an optional feature. Using the key for the symbols, shown to the lower right of the diagram, the remainder of the diagram can be interpreted. Note that power supply may have an external power supply, internal power supply, or both.

IV. The Microgrid Modeling Language

The development of the graphical DSML, MGridML was accomplished utilizing Microsoft DSL tools, a part of the the Visual Studio SDK [16]. The DSML is defined by its metamodel which comprises of the abstract syntax and static semantics. Figure 2 shows the partial abstract syntax for MGridML. A model of the microgrid is referred to as an

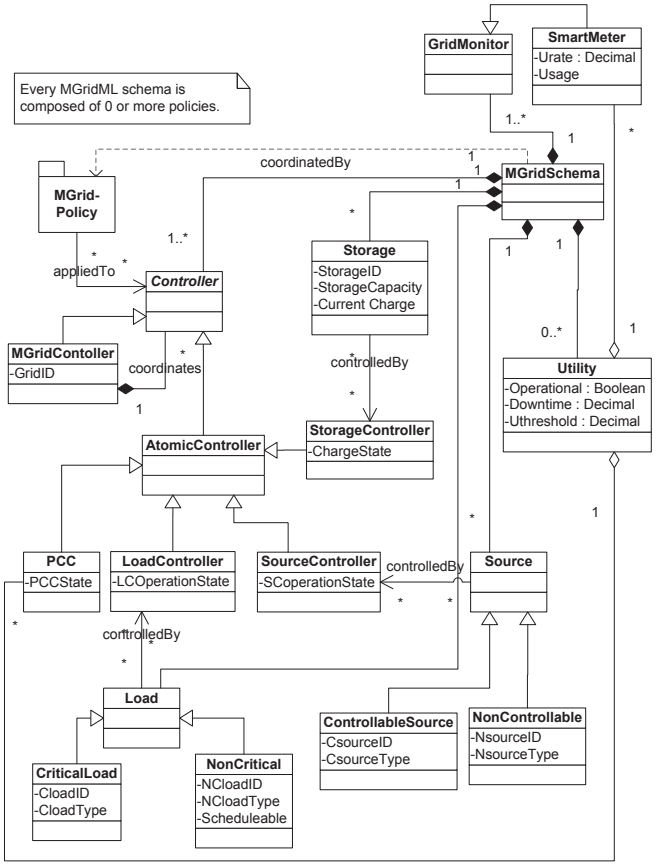

Fig. 2. Partial abstract syntax for MGridML.

MGrid schema. The MGrid schema is composed of one or more grid monitors, one or more controllers, one or more storage units, one or more loads, one or more sources and zero or more utilities. The schema may also contain zero or more MGrid policies not describe in this paper. We use the polices to constrain the behavior of the system based on the environment or end-user preferences.

The CERTS microgrid concept provides the basis for the

architecture and acceptable behavior of elements within our models. Key to the structure of the modeling language is its mapping to unique critical functions. Figure 3 shows an MGrid schema using a concrete syntax produced using the matamodel in Figure 2. Due to space limitations we do not define the concrete syntax for MGrdiML. The computer shape in the middle of the model represents the MGrid controller that coordinates the activities of loads (lower left of the figure), the sources (right of the figure) and the PCC shown as the smart meter. Policies are attached to the various entities in the model. For example one policy that is defined for safety is that a storage source cannot be charging and discharging at the same time. This policy is shown in the lower right corner of the model. Note that the model shown in Figure 3 would be created by an expert, such as a technician.

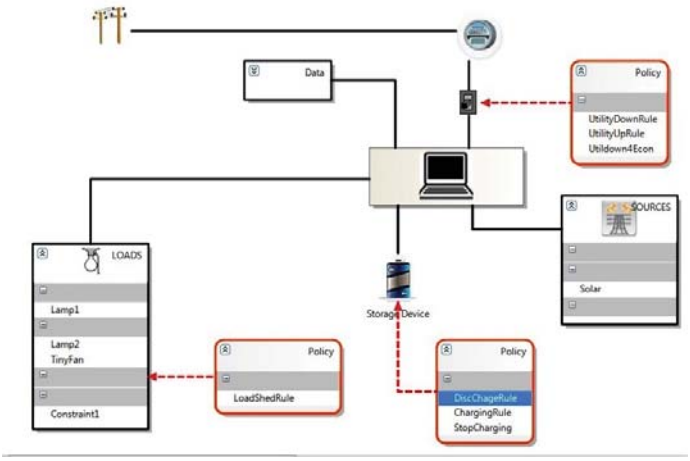

Fig. 3. MGrid schema for the scenario.

V. The Virtual Machine

In this section we describe the MGridVM which follows a similar structure to the Communication Virtual Machine (CVM) developed by Deng et al. [17]. The MGridVM uses a four layered architecture similar to CVM.

Figure 4 shows the structure of the MGridVM. The key on the right side of the figure uses a color code to identify with components belong to which layer. The layers of the MGridVM are described as follows.

Microgrid Management Interface (MMI) - Gives the user the ability to conceive, describe and obtain the feasibility of desired behaviors and contingencies of the underlying physical components of the microgrid through MicroGridML, the DSML described earlier. Facilitation is at an abstract level to be intuitive yet expressive enough to describe most of the configurations and functionality of the microgrid. The output to the underlying layer is a feasible schema or instantiation of the grid model with artifacts which describe possible transformations. The user may chose to to run a simulation based on the current hardware configuration over a specified period of time. In this case the hardware negotiation layer is disconnected and a mockup based on repository data is used as

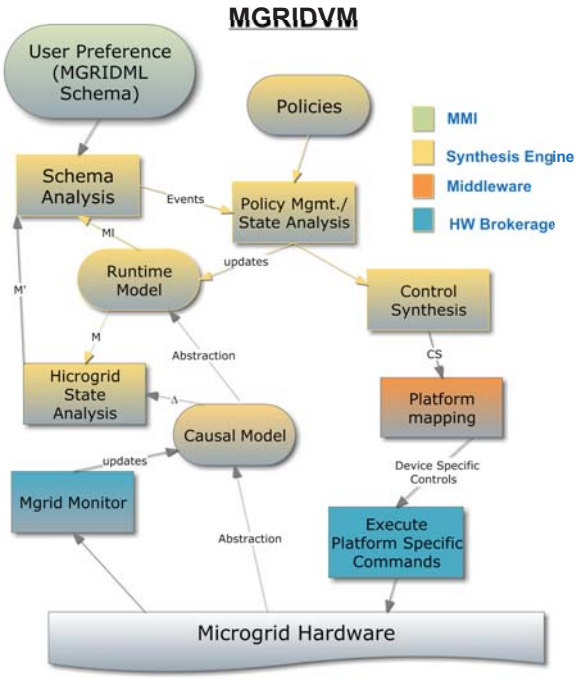

Fig. 4. The MGrid Virtual Machine

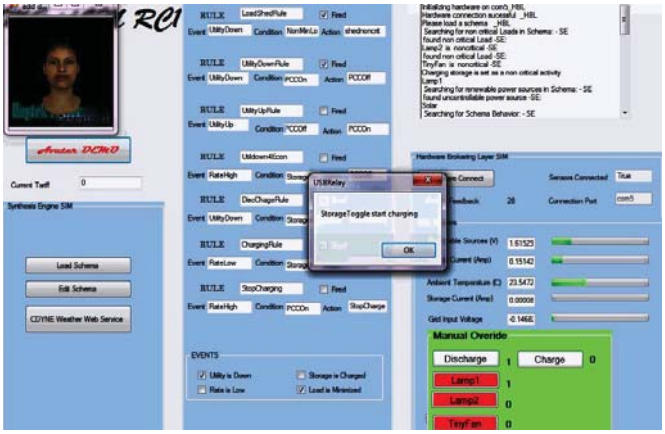

Fig. 5. MGridVM Management Interface.

data-source. Figure 5 shows the user interface for our current prototype for the MMI.

Synthesis Engine (SE) - Transforms the behaviors and contingencies in the declarative MicroGridML into an executable MicroGrid Control Script (MGCS). The actions and commands inherent within the MGCS, serve as directives to manage the physical grid components. This layer contains a runtime model which reflects the current state of the microgrid. Changes to the runtime model are either user initiated, whereby the user sends a new model to be implemented, or by changes in the microgrid hardware states. A schema analyzer transforms the difference between the new model and the executing model into system events. We defined our policies in terms of a targeted triple of Events, Conditions and Actions; system events determine which policies become active, but only after policy manager scrutiny. The final component of

this layer is a state analyzer which updates the runtime model to be consistent with the state of the hardware.

Grid Control Middleware - Transforms the platform independent control script into hardware specific commands. It is at this layer whereby the virtual machine may amalgamate diverse devices with distinct commands.

Hardware Brokerage - This layer is primarily responsible for executing device specific commands upon the physical hardware below and monitoring the status of its devices.

VI. Validation

To validate the efficacy and feasibility of our approach, we developed a microgrid testbed (see Figure 7). The testbed was based on the running scenario outline earlier in Section III-A, but the abstraction took into consideration the critical features of a microgrid. The testbed operates on approximately 5V DC, eliminating the need for DC/AC PWM inversion for the PV minisource. The MGridVM serially communicates with the testbed via two USB interfaces. The first, a sensory interface, monitors voltage and current levels at specific points in the testbed. The second, a relay bank, actuates component switching. Storage is in the form of one Lithium Ion battery producing at 4.75V and the LV grid source is represented by a 5.0V AC/DC adapter rated at 100mA. Figure 6 shows a schematic drawing of the testbed used to validate the feasibility of our approach.

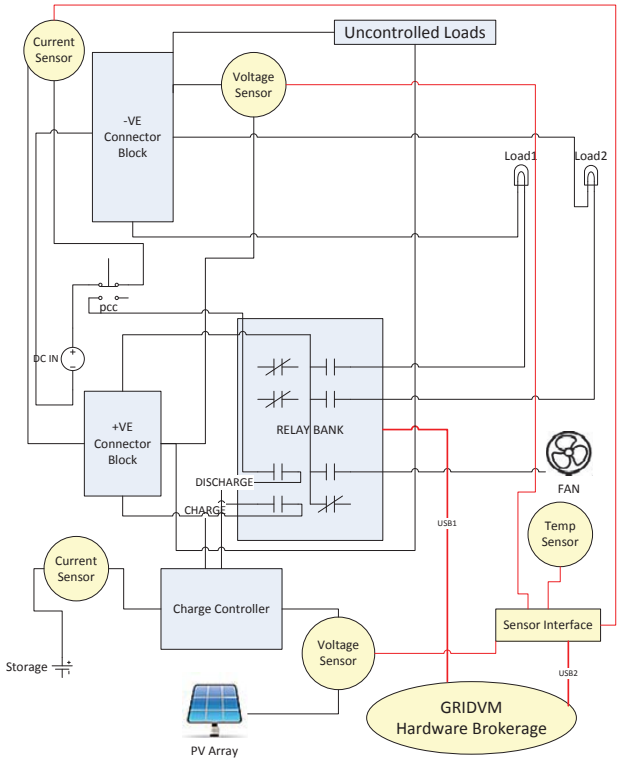

Fig. 6. Schematic of the testbed.

Voltage and current levels within the testbed are continuously monitored by sensors according to a defined data acquisition rate and sent to the sensory interface. The hardware brokerage layer of the MGridVM receives these monitored updates and analyzes the values to determine changes in component states. Values that fall outside the scope of the defined threshold levels indicate an important state change and an appropriate event will be generated. For example, should the grid source voltage level drop to 2.0V, the brokerage layer would receive the new voltage value, compare the value to the predefined threshold of 4.0V and generate a *UtilityDown* event. Based on the policies in effect that are driven by the *UtilityDown* event, the appropriate control script would be generated. Assuming there exists a policy P_n such that:

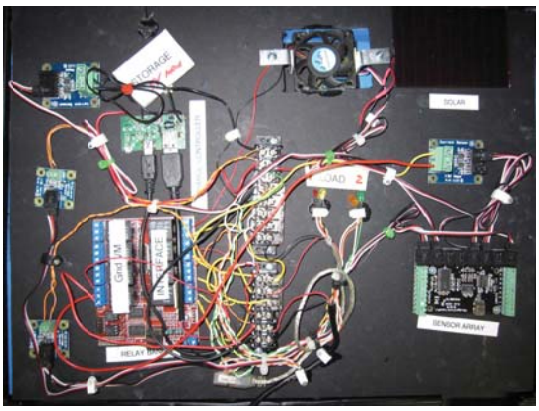

Fig. 7. Hardware implementation for the testbed.

$$P_n = \langle event \rangle\ UtilityDown$$
$$\langle condition \rangle\ StoreLevel > StoreThreshold$$
$$\langle action \rangle\ DischargeBattery()$$

In our scenario P_n would cause a control script to be generated for the storage to be discharged into the mircogrid, assuming the current condition of the storage level exceeds that of the storage threshold level. The round trip is completed when the control script is sent down to the hardware brokerage level to be executed via the USB connection to the relay bank on the testbed itself.

VII. Related Work

There has been significant effort in the research community to address energy management. In general, the challenge of operating a microgrid lies in the fact that at all times the balance between generation and demand has to be maintained. Much of the work in the area of microgrids tend to focus on the electrical aspects such as efficient designs and hierarchical integration [18], [19], [20] of generation and load into existing electric power distribution infrastructure. This work compliments much of the aforementioned research by providing orthogonally, a simplified software engineering approach to support the management of the microgrid through models.

Other researchers have also investigated software approaches to support energy management. Zaidi et al. [21] proposes an approach for self-configuring microgrids that focuses on the demand side management. Individual load are

assigned to intelligent control nodes containing switching and power measuring features that are remotely accessible through wireless radios. Control algorithms are used to identify the type of loads by looking at their power consumption profiles, which are measured by the control nodes and communicated to the micgrogrid controller. Similar to Zaidi's work, our approach leverages intelligent controller to support demand side energy management. Unlike Zaidi's work, where loads are assigned predefined priorities and load isolation decisions are based on the predefined priorities, our work provides a user-centric focus to energy management. End users define load priorities and preferences as user defined policies which influences the weighting of the load isolation algorithms.

Livengood et al. [22], proposes a software energy management systems, an energy box, capable of optimizing residential energy consumption through a suite of stochastic dynamic programming algorithms centered around demand pricing. Livengood et al.'s approach however introduces some complexity for the creation and modification of the management algorithms. Our approach differs in the use of a DSL and an intuitive modeling environment that supports the manipulation of management rules. MgridML captures domain expertise within the language enabling the end user to make fine grained adjustments to the microgrid activities, while still being sheltered from its complexity.

The DSL approach is utilized in Habitation [23], a domain specific language for home automation system design. Similar to our work, a model-driven paradigm is employed, providing a higher level of abstraction to the user of the tool. the Habitation language however, targets the representation and manipulation of loads. MGridML is designed to address the complete energy system with algorithms concerned with the balancing of energy between loads and sources. Additionally, Habitation uses a code generation methodology while MGridVM uses a runtime model interpretation technique to support dynamic reconfiguration of the microgrid.

VIII. Concluding Remarks

In this paper we presented a model-driven technique to address the need for robust, user-driven software overlay for energy management. This approach provides for energy management of the microgrid and is furthermore an enabling technology for automated demand response. Our user-driven approach to energy management considers the role of the microgrid user as critical to overall consumption reduction. Future directions of this research will be geared towards load and source forecasting and extending the virtual machine to facilitate mobility. We will further fine tune our human computer interface according to design dimensions with Embodied Conversational Agent feedback.

***Abstract*—Various methods have been developed for improving the quality of a software product, especially for high-assurance and mission-critical software systems. One commonly used approach is software quality modeling, in which software practitioners utilize software metrics and defect data collected during the software development process to build defect prediction models that will help to find poor-quality program modules. Those modules predicted to be fault-prone will receive more inspection and testing, thereby improving their quality. Efficacy of defect prediction models is influenced by relevance between software metrics and fault data. Usually not all software metrics in data repositories contribute equally to the occurrence of faults. Choosing the most important metrics (features) prior to the model training process is needed to improve the effectiveness of defect predictors. In this paper, we study 18 filter-based feature selection techniques and evaluate their effectiveness through a case study performed on 16 different software data sets. Among the 18 techniques, six of them are standard filter-based methods, while 11 of them are threshold-based feature selection (TBFS) techniques proposed by our research team recently. The last one is based on signal to noise ratio (S2N), which is a widely used concept in electrical and communication engineering, but which is rarely used in feature selection. The experimental results demonstrate that the TBFS techniques perform similarly to the standard techniques and the S2N technique shows significantly better performance than the other 17 approaches.**

***Index Terms*—threshold-based feature selection, filter-based feature ranking techniques, software defect prediction, software metrics, software quality, signal to noise ratio.**

I. Introduction

One effective method for improving the quality and reliability of a high-assurance software project/product is to detect and correct software defects (bugs) early enough during the software development process and prior to system deployment and operation, since for such high-assurance systems certain defects or failures can have disastrous consequences. Various techniques and approaches have been created for this purpose. Among them, software quality modeling is an effective and attractive approach. In software quality assurance, practitioners often use software metrics (attributes or features) gathered during the software development process and various data mining techniques to build classification models for predicting whether a given program module (instance or example) is in the fault-prone (*fp*) or not fault-prone (*nfp*) class [1]. Such a strategy allows practitioners to intelligently allocate project resources and focus more on the potentially problematic modules.

However, in the practice of software quality estimation, we find that not all collected software metrics are useful or make equally important contributions to classification results. Simply training a defect prediction model using the available set of software metrics without regard to the quality of the underlying software measurement data is not recommended. Selecting a subset of features that are most relevant to the class attribute is necessary and may result in better predictions.

In this paper, we investigate 18 filter-based feature ranking techniques to select subsets of features (metrics or predictors). Among the 18 techniques, six of them are commonly used, namely, chi-square (CS), information gain (IG), gain ratio (GR), symmetrical uncertainty (SU), and ReliefF (two types, RF and RFW) [2]. Eleven of them are threshold-based feature selection techniques (TBFS) proposed by our research team; a preliminary investigation of one of these 11 TBFS techniques has been reported in our recent work [3]. The remaining technique is based on signal to noise ratio (S2N), which is a widely used concept in electrical and communication engineering, but which has only been used in data mining research very recently.

Our proposed threshold-based feature selection (TBFS) techniques substantially extend the FAST algorithm proposed by Chen and Wasikowski [4]. FAST is based on the area under a ROC (Receiver Operating Characteristic) curve generated by moving the decision boundary of a single feature classifier with thresholds placed using an even-bin distribution. This means that they calculated a ROC curve by discretizing the distribution, while our technique is much more general than their work. Our technique does not require discretization, making it more precise and avoiding the determination of how wide the bins should be. Further, there are 11 different versions of TBFS which are based on 11 different classifier performance metrics for feature ranking. Another nice property of our technique is that it can be extended to incorporate additional metrics.

In order to evaluate the effectiveness of the 18 filter-based feature selection methods, we perform a case study on 16 software data sets. The case study data consists of software measurement and defect data from three real-world software projects, including four data sets from a very large high-assurance telecommunications software system (LLTS) [5], three data sets from NASA software project KC1 [6], and nine data sets from the Eclipse project [7].

Following feature selection, defect prediction models are constructed using the Naïve Bayes classifier with the training data consisting of the software metrics selected by the 18 different approaches. The empirical results demonstrate that our proposed TBFS techniques have similar performance to the six commonly used feature selection approaches. In addition, the S2N technique shows significantly better performance than the other 17 techniques (6 standard methods + 11 TBFS methods). Moreover, some techniques exhibit more stable performance than other techniques with respect to different data sets. One thing we would like to emphasize is that from a software engineering point of view, a practitioner appreciates working with a smaller set of metrics for defect prediction than analyzing a large number of metrics.

The remainder of the paper is organized as follows: Section II summarizes some key related work. Section III describes the 18 filter-based feature ranking techniques and other methodologies used in this study. Section IV presents an empirical case study, including

software measurement data, results and analysis. Section V draws the conclusion of the paper and provides some directions for future work.

II. Related Work

One of the challenging problems in the data mining process is high dimensionality of data, which not only requires extensive computation during the learning process but also may deteriorate learning results. Feature selection (or attribute selection) is an effective method for handling high dimensional data. In the selection process, the most important and relevant features will be selected to build classifiers. Feature selection techniques are broadly categorized into two groups: *wrapper*-based and *filter*-based. The wrapper-based approach involves training a learner during the feature selection process, while a filter-based approach uses the intrinsic characteristics of the data for feature selection and does not rely on training a learner. The primary advantage of the filter-based approach over the wrapper-based approach lies in its faster computation.

Hall and Holmes [8] investigated six attribute selection techniques that produce ranked lists of attributes and applied them to several data sets from the UCI machine learning repository. Ilczuk et al. [9] investigated the importance of feature selection in judging the qualification of patients for cardiac pacemaker implantation. Forman [10] studied a few number of filter-based feature ranking techniques in the context of text mining.

Although feature selection has been widely applied in various data mining problems, its application in software quality and reliability engineering has been rather limited. Rodríguez et al. [11] applied feature selection to five software engineering data sets using three filter-based models and two wrapper-based models. The authors stated that the reduced data sets maintained the prediction capability of the original data sets while using fewer attributes. Chen et al. [12] have studied feature selection using wrappers in the context of software cost/effort estimation. In their study, serval COCOMO-I and COCOMO-II data sets were used. They concluded that the reduced data set could improve the estimation and recommended feature selection in cost modeling, particularly when dealing with very small data sets. Pizzi et al. [13] described a stochastic metric selection method to identify the software metric subset that is most effective at predicting software module complexity. This classification method was empirically evaluated and validated against three benchmark approaches. The main advantage of this research, claimed by the authors, is that a project manager or software architect could utilize the predictions to identify highly complex modules for review and possible revision. In a recent study [14], we investigated feature selection techniques using the filter-based method for software defect prediction. It was concluded that the performances of the classification models either improved or were not affected when only 15% of the original features were used.

III. Methodology

A. Standard Filter-Based Feature Ranking Techniques

The procedure of feature ranking is to score each feature according to a particular method, allowing the selection of the best features. The six commonly used filter-based feature ranking techniques examined in this work include [2]: chi-square (CS), information gain (IG), gain ratio (GR), two types of ReliefF (RF and RFW), and symmetrical uncertainty (SU).

The chi-square (χ^2) statistic is used to evaluate the distribution of the class as it relates to the values of the target feature. The values of the features must be discretized into a number of intervals before performing the test. The χ^2 statistic is defined as follows:

$$\chi^2 = \sum_{i=1}^{I} \sum_{j=1}^{n_c} \frac{(O_{i,j} - E_{i,j})^2}{E_{i,j}}$$

where I is the number of different values (or intervals) of the feature, n_c is the number of classes (n_c=2 for a binary classification problem), $O_{i,j}$ and $E_{i,j}$ are the observed number and the expected number of instances corresponding to value (or interval) i and class j. The larger the χ^2 statistic, the more likely it is that the distribution of values and classes are dependent; that is, the feature is relevant to the class.

Information gain, gain ratio, and symmetrical uncertainty are measures commonly used in the field of information theory [2]. Information gain (IG) is the information provided about the target class attribute Y, given the value of another attribute X. IG measures the decrease of the weighted average impurity of the partitions compared to the impurity of the complete set of data. IG tends to prefer attributes with a larger number of possible values. If one attribute has a larger number of values, it will appear to gain more information than those with fewer values, even if it is actually no more informative. One strategy to solve this problem is to use the gain ratio (GR), which penalizes multiple-valued attributes. Symmetrical uncertainty (SU) is another way to overcome the problem of IG's bias toward attributes with more values, doing so by dividing by the sum of the entropies of X and Y.

Relief is an instance-based feature ranking technique introduced by Kira and Rendell [15]. It measures the importance of features by considering how much their values change when comparing a randomly chosen instance with its nearest hit (an instance from the same class) and its nearest miss (one from a different class). ReliefF is an extension of the Relief algorithm that can handle noise and multiclass data sets, and is implemented in the WEKA tool [2]. When the `WeightByDistance` (weight nearest neighbors by their distance) parameter is set as default (false), the algorithm is referred to as RF; when the parameter is set to 'true', the algorithm is referred to as RFW.

Algorithm 1: Threshold-Based Feature Selection

input :
1. Data set D with features $F^j, j = 1, \ldots, m$;
2. Each instance $\mathbf{x} \in D$ is assigned to one of two classes $c(\mathbf{x}) \in \{P, N\}$ where $P = fp$ and $N = nfp$;
3. The value of attribute F^j for instance $\mathbf{x}$ is denoted $F^j(\mathbf{x})$;
4. Metric $\omega \in$ {FM, OR, PO, PR, GI, MI, KS, DEV, GM, AUC, PRC}.

output: Ranking $\mathbb{R} = \{r^1, \ldots, r^m\}$ where r^j represents the rank for attribute F^j, i.e., the r^j-th most significant attribute as determined by metric ω.

for $F^j, j = 1, \ldots, m$ **do**
- Normalize $F^j \mapsto \widehat{F}^j = \frac{F^j - \min(F^j)}{\max(F^j) - \min(F^j)}$;
- Calculate metric ω using attribute $\widehat{F}^j$ and class attribute $\{c(\mathbf{x}) | \mathbf{x} \in D\}$, $\omega(\widehat{F}^j)$; (The detailed formula of each metric ω is provided in Sections III-B1 through III-B11.)

Create attribute ranking $\mathbb{R}$ using $\omega(\widehat{F}^j)$ $\forall j$

B. Threshold-Based Feature Selection

The threshold-based feature selection (TBFS) technique was proposed by our research team and implemented within WEKA [2]. The procedure is shown in Algorithm 1. Each independent attribute works individually with the class attribute, and that two-attribute data set is evaluated using different performance metrics. More specifically,

the TBFS procedure includes two steps: (1) normalizing the attribute values so that they fall between 0 and 1; and (2) treating those values as the posterior probabilities from which to calculate performance metrics. Note that no classifiers were built during the feature selection process.

Analogous to the procedure for calculating rates in a classification setting with a posterior probability, the true positive (TPR), true negative (TNR), false positive (FPR), and false negative (FNR) rates can be calculated at each threshold $t \in [0,1]$ relative to the normalized attribute $\widehat{F}^j$. Precision $PRE(t)$ is defined as the number of positive examples with $\widehat{F}^j > t$ divided by the total number of examples with $\widehat{F}^j > t$. The feature rankers we propose utilize these five rates as described below. The value is computed in both directions: first treating instances above the threshold (t) as positive and below as negative, then treating instances above the threshold as negative and below as positive. The better result is used. Each of the 11 metrics are calculated for each attribute individually, and attributes with higher values for FM, GM, PR, PO, AUC, PRC, MI, KS and OR and lower values for GI and DEV are determined to better predict the class attribute. In this manner, the attributes can be ranked from most to least predictive based on each of the 11 metrics.

1) F-Measure: The F-measure (FM) is derived from *recall* (or true positive rate) and *precision*.

$$\text{FM} = \max_{t\in[0,1]} \frac{2 \times TPR(t) \times PRE(t)}{TPR(t) + PRE(t)}.$$

Recall and precision are calculated at each point along the normalized attribute range of 0 to 1. The maximum F-measure obtained by each attribute represents how strongly that particular attribute relates to the class, according to the F-measure.

2) Odds Ratio: The odds ratio (OR) is defined as:

$$\begin{aligned}\text{OR} &= \max_{t\in[0,1]} \frac{TPR(t)(1-FPR(t))}{(1-TPR(t))FPR(t)} \\ &= \max_{t\in[0,1]} \left(\frac{TPR(t)}{FPR(t)}\right)\left(\frac{TNR(t)}{FNR(t)}\right)\end{aligned}$$

OR is the maximum value of the ratio of the product of correct to incorrect predictions.

3) Power: Power (PO) is defined as:

$$\begin{aligned}\text{PO} &= \max_{t\in[0,1]} \left((1-FPR(t))^k - (1-TPR(t))^k\right) \\ &= \max_{t\in[0,1]} \left((TNR(t))^k - (FNR(t))^k\right)\end{aligned}$$

for some integer $k \geq 1$. Note that if $k = 1$, Power is equivalent to KS (described in Section III-B7). In this work, we use $k = 5$ as in Forman [10].

4) Probability Ratio: The probability ratio (PR) is defined as:

$$\text{PR} = \max_{t\in[0,1]} \frac{TPR(t)}{FPR(t)}$$

5) Gini Index: The Gini index (GI) was first introduced by Brieman et al. [16] within the CART algorithm. For a given threshold t, let $S_t = \{\mathbf{x} \mid \widehat{F}^j(\mathbf{x}) > t\}$ and $\bar{S}_t = \{\mathbf{x} \mid \widehat{F}^j(\mathbf{x}) \leq t\}$. The Gini index is calculated as:

$$\begin{aligned}\text{GI} &= \min_{t\in[0,1]} \left[1 - \left(P^2(TP(t) \mid S_t) + P^2(FP(t) \mid S_t)\right)\right] \\ &\quad + \left[1 - \left(P^2(TN(t) \mid \bar{S}_t) + P^2(FN(t) \mid \bar{S}_t)\right)\right] \\ &= \min_{t\in[0,1]} \left[2PRE(t)(1-PRE(t)) + 2NPV(t)(1-NPV(t))\right]\end{aligned}$$

where $TP(t)$ is the number of true positives given threshold t (and similarly for $TN(t)$, $FP(t)$ and $FN(t)$). NPV or *negative predictive value* represents the percentage of examples predicted to be negative that are actually negative and is very similar to the precision — in fact, it is often thought of as the precision of instances predicted to be in the negative class. The Gini index for the attribute is then the minimum Gini index at all decision thresholds $t \in [0,1]$.

6) Mutual Information: Let $c(\mathbf{x}) \in \{P, N\}$ denote the actual class of instance $\mathbf{x}$, and let $\hat{c}^t(\mathbf{x})$ denote the predicted class based on the value of the attribute F^j and a given threshold t. The mutual information (MI) computes the criterion with respect to the number of times a feature value and a class co-occur, the feature value occurs without the class, and the class occurs without the feature value. The MI metric is defined as:

$$\text{MI} = \max_{t\in[0,1]} \sum_{\hat{c}^t\in\{P,N\}} \sum_{c\in\{P,N\}} p(\hat{c}^t, c) \log \frac{p(\hat{c}^t, c)}{p(\hat{c}^t)p(c)}$$

where

$$\begin{aligned}&p(\hat{c}^t = \alpha, c = \beta) = \frac{\mid \{\mathbf{x} \mid (\hat{c}^t(\mathbf{x}) = \alpha) \cap (c(\mathbf{x}) = \beta)\} \mid}{\mid P \mid + \mid N \mid}, \\ &p(\hat{c}^t = \alpha) = \frac{\mid \{\mathbf{x} \mid \hat{c}^t(\mathbf{x}) = \alpha\} \mid}{\mid P \mid + \mid N \mid}, \\ &p(c = \alpha) = \frac{\mid \{\mathbf{x} \mid c(\mathbf{x}) = \alpha\} \mid}{\mid P \mid + \mid N \mid}, \\ &\alpha, \beta \in \{P, N\}.\end{aligned}$$

7) Kolmogorov-Smirnov Statistic: The Kolmogorov-Smirnov Statistic (KS) measures the maximum difference between the cumulative distribution functions of examples in each class based on the normalized attribute $\widehat{F}^j$. The distribution function $F_c(t)$ for a class c is estimated by the proportion of examples $\mathbf{x}$ from class c with $\widehat{F}^j(\mathbf{x}) \leq t$, $t \in [0,1]$. In a two class setting with $c \in \{N, P\}$, KS is computed as

$$\text{KS} = \max_{t\in[0,1]} |F_P(t) - F_N(t)|.$$

The larger the KS value, the better the attribute is able to separate the two classes, and hence the more significant the attribute is. The range of KS is between 0 and 1.

8) Deviance: The deviance (DEV) is the minimum residual sum of squares based on a threshold t. It measures the sum of the squared errors from the mean class given a partitioning of the space based on the threshold t. As it represents to total error found in the partitioning, lower values are preferred.

9) Geometric Mean: The geometric mean (GM) is the square root of the product of the true positive rate and true negative rate. GM ranges from 0 to 1, and an attribute that is perfectly correlated to the class provides a value of 1. GM is a useful performance measure since it is inclined to maximize the true positive rate and the true negative rate while keeping them relatively balanced. GM is calculated at each value of the normalized attribute range, and the maximum value of GM is used as a measure of attribute strength.

10) Area Under the ROC Curve: Receiver Operating Characteristic, or ROC, curves graph true positive rate on the y-axis versus the false positive rate on the x-axis. The resulting curve illustrates the trade-off between true positive rate and false positive rate. In this study, ROC curves are generated by varying the decision threshold t used to transform the normalized attribute values into a predicted class. In other words, the true positive and false positive rates are calculated as the threshold for the normalized attribute varies from 0 to 1. The area under the ROC curve (AUC) is used to provide a

single numerical metric for comparing the predictive power of each attribute. This definition is different than the one used by Chen and Wasikowski [4], which consider only a small subset of the possible threshold values when calculating the true positive and false positive rates.

11) Area Under the Precision-Recall Curve: The area under the precision-recall curve (PRC) is a single-value measure that originated from the area of information retrieval. A precision-recall curve is generated by varying the decision threshold t from 0 to 1 and plotting the recall (y-axis) and precision (x-axis) at each point in a similar manner to the ROC curve. The area under the PRC ranges from 0 to 1, and an attribute with more predictive power results in an area under the PRC closer to 1.

C. Signal to Noise Ratio Technique

Signal to noise ratio (S2N) [17] is a simple univariate ranking technique which defines how well a feature discriminates two classes in a two class problem. S2N, for a given feature, separates the means of the two classes relative to the sum of their standard deviation. The equation to calculate S2N is

$$\text{S2N} = \frac{(\mu_P - \mu_N)}{\sigma_P + \sigma_N}$$

where μ_P and μ_N are the mean values of a particular attribute for the samples from class P and class N, and σ_P and σ_N are the corresponding standard deviations.

D. Classification Algorithm

The software defect prediction models are built using the naïve Bayes (NB) [2] algorithm. This learner was selected for two key reasons: (1) it does not have a built-in feature selection capability, and (2) it is commonly used in both the software engineering and data mining domains. Prior research has shown that naïve Bayes classifiers often perform well, even on real-world data where the variables are related [18]. The WEKA data mining tool [2] is used to implement the classifier and the default parameter settings are adopted.

E. Performance Evaluation

The Area Under the ROC (Receiver Operating Characteristic) curve, abbreviated as AUC, is used for evaluating the defect prediction models in this study. The AUC metric is illustrated earlier in the paper. It is worthwhile to mention that AUC is commonly used to evaluate software defect prediction models [1]. An ROC curve illustrates the classifier's performance across all decision thresholds, i.e., a value between 0 and 1 that theoretically separates the *fp* and *nfp* modules. The AUC values range from 0 to 1, where a perfect classifier provides an AUC value of 1 [2].

IV. Case Study

A. Software Measurement Data

Experiments conducted in this study used software metrics and defect data collected from three real-world software projects, including a very large high-assurance telecommunications software system (denoted as LLTS) [5], NASA software project KC1 [6], and the Eclipse project [7].

LLTS consists of 42 software metrics, including 24 product metrics, 14 process metrics, and four execution metrics. The dependent variable is the class of the program module. A module with one or more faults is considered *fp*, and *nfp* otherwise. The LLTS software system consists of four successive releases labeled SP1, SP2, SP3, and SP4, where each release is characterized by the same number and type of software metrics, but has a different number of instances (program modules). The SP1, SP2, SP3, and SP4 data sets consist of 3649, 3981, 3541, and 3978 program modules, respectively.

TABLE I
Software Data Set Characteristics

	Data	#Attri.	#Inst.	#fp	%fp	#nfp	%nfp
LLTS	SP1	42	3649	229	6%	3420	94%
	SP2	42	3981	189	5%	3792	95%
	SP3	42	3541	47	1%	3494	99%
	SP4	42	3978	92	2%	3886	98%
NASA	KC1-5	62	145	36	25%	109	75%
	KC1-10	62	145	21	14%	124	86%
	KC1-20	62	145	10	7%	135	93%
Eclipse	E2.0-10	208	377	23	6%	354	94%
	E2.0-5	208	377	52	14%	325	86%
	E2.0-3	208	377	101	27%	276	73%
	E2.1-5	208	434	34	8%	400	92%
	E2.1-4	208	434	50	12%	384	88%
	E2.1-2	208	434	125	29%	309	71%
	E3.0-10	208	661	41	6%	620	94%
	E3.0-5	208	661	98	15%	563	85%
	E3.0-3	208	661	157	24%	504	76%

The original NASA project KC1 [6] includes 145 instances, each containing 94 independent attributes. After removing 32 Halstead derived measures, we have 62 attributes left. We used three different thresholds to define defective instances, thereby obtaining three versions of the preprocessed KC1 data set. The thresholds are 20, 10, and 5, indicating instances with number of defects greater or equal to 20, 10, or 5 belong to the *fp* class, or the *nfp* class otherwise.

From the PROMISE data repository [7], we obtained the Eclipse defect counts and complexity metrics data set. The original data for the Eclipse packages consists of three releases denoted 2.0, 2.1, and 3.0, respectively. We chose three post-release defects thresholds (*thd*) to determine the defective instances for each release. Similar to the NASA KC1 data sets, a program module with thd or more post-release defects is labeled *fp*, while those with fewer than thd defects are labeled *nfp*. In our study, we use *thd* ϵ {10, 5, 3} for release 2.0 and 3.0, while we use *thd* ϵ {5, 4, 2} for release 2.1. All nine derived data sets contain 208 independent attributes. Releases 2.0, 2.1, and 3.0 contain 377, 434, and 661 instances, respectively. The sixteen data sets used in this work reflect software projects of different sizes with different proportions of *fp* and *nfp* modules. Table I lists the characteristics of the sixteen data sets utilized in this work.

B. Experiments

Before using a filter-based feature ranking technique, the practitioner must choose how many features to select. To our knowledge, no guidance is provided in related literature on the appropriate number of features to select. A recent study [19] recommended using $\lceil \log_2 n \rceil$ features (n is the total number of the independent attributes) to build Random Forests learners for binary classification for imbalanced data sets. Moreover, a preliminary investigation showed that $\lceil \log_2 n \rceil$ is also appropriate for various learners. Consequently, we still choose $\lceil \log_2 n \rceil$ attributes that have the highest scores. That is, for the four LLTS data sets, $\lceil \log_2 n \rceil = 6$, where $n = 42$; for the three NASA KC1 data sets $\lceil \log_2 n \rceil = 6$, where $n = 62$; and for the nine Eclipse data sets, $\lceil \log_2 n \rceil = 8$, where $n = 208$.

1) Results of the Feature Selection Techniques: Following the feature selection algorithms, the NB classification models are constructed with data sets containing only the selected attributes. The defect prediction models are evaluated with respect to the AUC performance metric.

The classifier performance results are presented in Table II. In our experiments, ten runs of five-fold cross-validation were performed for model training. The values presented in the tables represent the average AUC for every classification model constructed over the ten runs of five-fold cross-validation. All the results of 18 feature selection techniques and over 16 different software data sets are reported. The best feature selection technique in terms of classification performance (AUC) for each data set (column) is highlighted in **bold**. We also summarize the average performance (last column of the table) for each feature selection technique across the 16 data sets. The results demonstrate that S2N outperformed the other feature selection techniques for 10 out of 16 data sets and also on average. For the other six data sets the best feature selection techniques are scattered at GR(1), RF(2), RFW(2) and AUC(1), where the value in parenthesis represents the number of best cases.

We also performed a one-way ANalysis Of VAriance (ANOVA) F-test on the classification performance for each technique across all the data sets to examine the significance level of the performance differences. The underlying assumptions of ANOVA were tested and validated prior to statistical analysis. The main factor of our ANOVA experiment is the 18 feature ranking techniques. The null hypothesis for the ANOVA test is that all the group population means are the same, while the alternate hypothesis is that at least one pair of means is different. Table III shows the ANOVA results. The p-value is less than the typical cutoff of 0.05, implying that for the main factor, the alternate hypothesis is accepted, namely, at least two group means are significantly different from each other. We continued our statistical validation by performing a multiple comparison test on the main factor with Tukey's Honestly Significant Difference (HSD) criterion. Note that for both ANOVA and multiple comparison tests, the significance level was set to 0.05.

The multiple comparison results, as shown in Figure 1, display a graph with each group mean represented by a symbol ($\circ$) and the 95% confidence interval as a line around the symbol. Two means

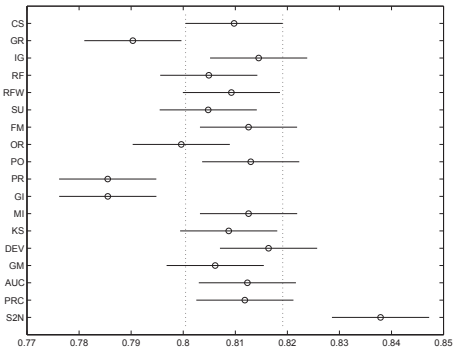

Fig. 1. Multiple Comparison

are significantly different if their intervals are disjoint, and are not significantly different if their intervals overlap. Based on the multiple comparison results, we can conclude the following points:

- For the six standard filter-based feature selection techniques, GR performed worst, IG performed best and the other four methods sit in between.
- For the 11 proposed threshold-based feature selection techniques, PR and GI performed poorly, DEV, PO, FM, MI, AUC, and PRC performed relatively better than other techniques, and OR, KS, and GM performed moderately.
- Overall, the proposed threshold-based feature selection techniques had fairly similar performance to the six standard filter-based feature selection methods. However, the S2N technique showed significantly better performance than the other 17 techniques.
- Moreover, some techniques demonstrated relatively stable performance with respect to different data sets such as MI, KS, S2N and SU, while other techniques, such as RF and RFW, showed more fluctuational performance with respect to different data sets.

2) Discussion on Selected Software Metrics: From a software engineering point of view, a discussion on which software metrics were selected is warranted. Due to paper size limitations, we only present the results on LLTS SP1 (see Table IV). Table IV presents the six selected software metrics for each of the top three feature selection techniques (S2N, PO and PRC). It is found that the selected

32*	STMCTL	# of control statements.
36*	VARSPNSM	Total span of variables.
37	VARSPNMX	Maximum span of variables.
39	VARUSD2	# of second and following uses of variables. VARUSD2=VARUSD-VARUSDUQ where VARUSD is the total # of variable uses.
42	TANCPU	Execution time (microseconds) of an average transaction on a tandem system.

* the metrics selected by two of the top three methods (S2N, PO and PRC)

attributes were spread over 15 different software metrics, and there were very few overlaps of the selected metrics between the top three methods, only three metrics {11, 32, 36} selected twice. Table V lists more detailed information of the 15 metrics.

Our recent work [20] has shown that classification models built on smaller subsets of attributes via the six commonly used filter-based feature selection techniques had similar or better performances than those built with a complete set of attributes. Thus, we did not present the results for full data sets in this paper.

V. CONCLUSION

In the software quality modeling process, one problem often encountered by software practitioners is the presence of excessive metrics in a training data set. In this study, we presented 18 filter-based feature ranking techniques to choose the most important software metrics. Among the 18 techniques, six are standard filter-based techniques, while 11 are the threshold-based techniques we proposed, and the remaining one is the signal to noise ratio (S2N) technique rarely used in feature selection. We used the naïve Bayes classifier to build classification models with data sets containing only the selected attributes. The experiments were performed on 16 different data sets obtained from three types of software projects. The key conclusions include: (1) our proposed threshold-based feature selection techniques performed similarly to the standard feature selection techniques; (2) the S2N technique showed significantly better performance than the other 17 techniques; and (3) some techniques (such as MI, KS, S2N, and SU) demonstrated more stable performance than other techniques (such as RF and RFW) with respect to different data sets. Future work will include more case studies with software measurement data sets of other software systems. In addition, evaluation of the classification models using different learners such as multilayer perceptron, support vector machine, and *k*-nearest-neighbors will be examined.

***Abstract*—Software maintenance includes activities related to keeping already developed software up to the needs and wishes of its users. In order to accomplish that there is a need to understand how this software works. This task can be simplified when the software is built using simple, easy to use and maintain components.**

In order to learn more about software artifacts programmers estimate their quality. They inspect the code, and based on their experience they offer their judgment and provide a score in a specific scale. An important aspect of that process is to understand how programmers perform such evolution. What software measures are subconsciously used during the evaluation? What kinds of measures are used to evaluate different software quality attributes?

In order to answer some of those questions we present a procedure suitable for estimating importance of software metrics and their subconscious utilization by programmers. The proposed approach is based on feature selection techniques.

Keywords: software maintenance, usability, and complexity; feature selection techniques; software evaluation process; software metric-based representation of programmers, tag-clouds

I. INTRODUCTION

Among all phases of a software life cycle the maintenance phase seems the most often forgotten. Yet at the same time it determines a long-term success of a software system. The activities related to maintenance depend on the level of understanding of software artifacts that constitute the software. This, on the other hand, depends on quality of artifacts – how they are design and implemented.

Quality of software artifacts is the subject to many research activities. Many aspects of that quality – especially reliability and defectiveness – are topics of numerous publications [1-4]. An important facet of defining and identifying software quality is related to a process of human evaluation of software objects. This process raises a number of questions: What does it mean for a programmer that a piece of code is of good quality, i.e., that it is usable, simple and easy to understand, or maintainable? Is a programmer consistent with his/her evaluations across multiple artifacts? Can we see some patterns among programmers – do they recognize the same software measures as important?

In order to identify important metrics for a programmer during an evaluation process, we propose a simple feature selection-based approach. The approach is suitable for finding important software measures that "describe" and "represent" an individual preforming a software object evaluation process. The proposed process uses a number of feature selection techniques, i.e., techniques that identify the most suitable software data features for representing software artifacts. The obtained results are combined together in order to find a single view characterizing a programmer performing evaluation. We also use tag-clouds [6] for visualization purposes.

We illustrate application of the proposed approach on a software engineering data. The data represents 366 software object described with 64 software metrics. Three programmers examined each object, and evaluated it from the point of view of complexity, usability and maintainability.

II. FEATURE SELECTION METHODS

Feature selection also known as attribute selection is an important pre-processing step in most data mining and machine learning problems. Apart from improving the quality of the machine learning data set, the main goal of a feature selection process is to look for a subset of features that is equivalent to the set of all features for a specific task [7].

There are two categories of feature selection methods: *wrappers* and *filters*. Wrappers are algorithms that use feedback from a learning algorithm in order to determine which feature(s) are needed in order to build a classification model. Filters are algorithms in which a feature subset is selected without any involvement of a learning algorithm (classifier). An additional categorization leads to feature selection techniques and feature ranking techniques. Feature selection methods select subsets of attributes that have good predictive power when used together. Feature ranking techniques ranks the attributes according to their individual predictive power [7].

A. Software for feature selection

There are several data analysis software systems already equipped with feature selection algorithms, such as MATLAB, SciLab, NumPy, and the R language. Apart from these, there are software systems that have been customized specifically for feature-selection tasks: Weka, RapirMiner, and Orange, to name just a few [8].

In Weka [9], feature selection can be performed in three different ways: 1) using selection methods directly; 2) using a meta classifier; or 3) using a filter. In the paper, the attribute selection has been done using two types of techniques: *SubSet evaluators*, and *Attribute (Ranking) evaluators*.

B. SubSet Evaluators

In the type of *SubSet Evalutors* we have applied three different methods.

ConsistencySubsetEval: The value of a subset of attributes is assessed by the level of consistency in the class values when the training instances are projected onto the subset of attributes. The common practice is to use it in conjunction with a Random or Exhaustive search which looks for the smallest subset with consistency equal to that of the full set of attributes [10].

CfsSubsetEval: A subset of features is evaluated by taking into consideration the individual predictive capability of each feature along with the degree of redundancy between them. Subsets of features which are highly correlated with the class while having low inter-correlation are preferred.

FilteredSubsetEval: A method for running a random subset evaluator on data that has been passed through an arbitrary filter. The structure of the filter is entirely based on the training data.

Those methods are combined with different serach techniques. A list of all applied combinations is included in Table I.

TABLE I. SUBSET EVALUATORS

Subset Evaluator:	Search Method:
ConsistencySubsetEval	BestFirst
CfsSubsetEval	GenericSearch
ConsistencySubsetEval	GenericSearch
FilteredSubsetEval	GreedyStepwise
ConsistencySubsetEval	LinearForwardSelection
CfsSubsetEval	RankSearch
CfsSubsetEval	ScatterSearchV1
CfsSubsetEval	SubsetSizeForwardSelection

C. Attribute Evaluators (Ranking Methods)

Weka provides a number of Attribute Evaluators. Among them we have used the following ones.

FilteredAttributeEval: Similar to FilteredSubsetEval.

GainRatioAttributeEval: Assesses the value of an attribute by measuring the gain ratio with respect to the class.

ChiSquaredAttributeEval: Assesses the importance of an attribute by calculating the value of the chi-squared statistic with respect to the class.

InfoGainAttributeEval: Assesses the importance of an attribute by measuring the information gain with respect to the class.

OneRAttributeEval: Assesses the value of an attribute by using the OneR classifier.

ReliefFAttributeEval: Assesses the value of an attribute by recurrently sampling an instance, and taking into consideration the value of the given attribute for the nearest instance of the same and different class.

SVMAttributeEval: An SVM Classifier is used to assessed the value of an attribute. Attributes are ranked by the square of the weight assigned by the SVM. For multiclass problems, attribute selection is performed by ranking attributes for each class independently using a one-vs-all method, and then processing the top of each pile to determine a final ranking.

SymmetricalUncertAttributeEval: Assesses the value of an attribute by measuring the symmetrical uncertainty with respect to the class.

All of these methods are run with Ranker as a selection method.

III. MULTI-METHOD ALGORITHMS

The process of identifying the most important criteria used subconsciously by programmers evaluating quality of the software artifacts is replaced by selection of the most important features of data generated via the human evaluation process. The process embraces number of selection techniques (Section III) and a simple procedure of fusing the results obtained from the selection processes.

A. Fusing Results of SubSet Evaluators

Every time we run a *SubSet Evaluator* we obtain a subset of features that according to the method we ran is the most discriminative. This means that using multiple selection methods we obtain multiple subsets of "super" features.

There are a number of ways in which we could combine these subsets – where the simplest ones are to do a union, or perform an intersection. However, we would like to make the merge in more conscious manner, and take advantage of utilization of multiple selection methods. A very simple algorithm applied for selecting the most significant features based on multiple different *SubSet Evalators* is presented in Figure 1.

```
// initialization
create counter for each feature
initialize counters to 0

// feature evaluation
for each subset of features
  for each feature from the subset
      increase the counter of that feature by 1
  rof
rof
sort features based on the value of their counters

// selection process
calculate a threshold value
      = 0.75*no_SubSet_methods
select features with values above the threshold
normalization of counters of the selected features
```

Figure 1. **Algorithm SF_SubSetE**:
Selection of Features from SubSet Evaluators

The algorithm SF_SubSetE is applied after all eight *SubSet Evaluators* (Table I) are run on the data. The result of that is a

single subset of best features. The example of its utilization is shown in Section VI.

B. Fusing Results of Attribute Evaluators

As for the *SubSet Evaluators,* a similar algorithm has been constructed for identification of the best features obtained from *Attribute Evaluators*, Figure 2. Its application to the software data is also presented in Section VI.

```
// initialization
create counter for each feature
initialize counters to 0

// feature evaluation
for each ranking
  for each feature from the ranking
      increment the counter of that feature by a number
      representing the position of the feature in
      the ranking
  rof
rof
sort features based on the value of their counters

// selection process
calculate a threshold value
      = 0.25*no_Rank_methods*no_features
select features with values below the threshold
normalization of counters of the selected features
```

Figure 2. **Algorithm SF_AttrE**:
Selection of Features from Attribute Evaluators

IV. Data Description

An experiment has been performed to generate data required for illustration of the proposed approach to support quality analysis. In the experiment, objects of the system EvIdent [5] have been independently analyzed and ranked by three programmers based on three quality attributes: complexity, maintainability and usability. Independently, quantitative software measures of these objects have been compiled.

A. Exeprimantal Setup

EvIdent is a user-friendly, algorithm-rich, graphical environment for the detection, investigation, and visualization of novelty/change in a set of images as they evolve in time or frequency. It is written in Java and C++ and is based upon VIStA, an application-programming interface (API) developed at the National Research Council, Figure 3.

The VIStA API is written in Java and offers a generalized data model, an extensible algorithm framework, and a suite of graphical user interface constructs. Using the Java Native Interface, VIStA allows seamless integration of native C++ algorithms. Figure 3 shows the class model and relationships between the three main Java packages used in VIStA.

B. Data Set

All Java-based EvIdent/VIStA objects have been used in this study (C++-based objects have been excluded). For each of the 366 software objects, three programmers, called '#1', '#2' and '#3', were asked to independently rank objects' maintainability, complexity and usability in the scale from 1 to 5 (where 1 means VERY POOR, 2 means POOR, 3 means OKAY, 4 means GOOD, and 5 means VERY GOOD). The programmers determined maintainability, complexity and usability of objects based on their own judgment and experience.

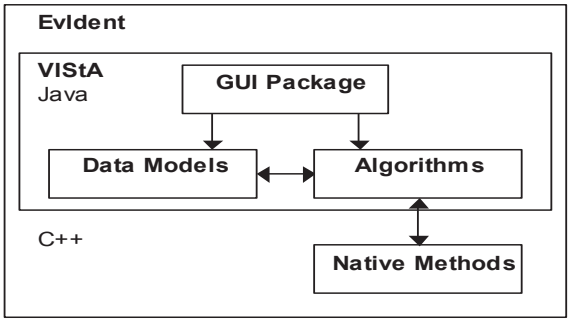

Figure 3. EvIdent software model with VIStA

At the same time, a set of 64 software metrics was calculated for each object. As the result, the collected data set consists of 366 data points represented by a set of 64 software metrics and three value assigned to each point by three programmers. A list of the extracted metrics can be found in Appendix.

V. Software Data Analysis

The available software data (Section IV) is processed using described feature selection methods (Section III). The whole procedure for identifying the best features is as follow:

StepA: the *SubSet Evaluators* are applied to the data; the results are processed using the algorithm SF_SubSetE

StepB: the *Attribute Evaluators* are applied to the data, and the algorithm SF_AttrE is used to identify the most significant features

StepC: the *correlation* between each pair: feature-quality attribute is calculated; a simple threshold (value of 0.7 is used here) is applied to select sets of most related features

StepD: the obtained three sets of features are fused using an arithmetic average of their scores; the features in the **upper quartile** (the one with the score above 0.75) are selected

The procedure is repeated for each programmer and each quality attribute. In total there are nine sets of best features selected for each combination of programmer-quality attribute. The following subsections illustrate details of the procedure for the **programmer_#1** and the quality attribute **complexity**.

A. SubSet Evalutor Results

In the first step – **StepA** – *SubSet Evaluators* are applied to the software data. The algorithm for fusing the results presented in Section IV has been applied next. The overall results are presented in Table II. As it can be seen in the table, the application of the **StepA** leads to the sequence of nine software metrics. We can say that these metrics represent the

programmer_#1 during evaluation of complexity of software objects. In other words, we can assume that these metrics are "important" indicators of complexity for the **programmer_#1**.

TABLE II. FEATURES OBTAINED USING SUBSET EVALUATORS FOR: PROGRAMMER_#1 – COMPLEXITY

LOC
WDC
CYCO
HLUR
MIC
TOK
MNL1
HLDF
HLVL

B. Attribute Evaluator Results

The *Attribute Evaluators* and the algorithm SF_AttrE have been also used to process the software data, **StepB**. The results are shown in Table III.

TABLE III. FEATURES OBTAINED USING ATTRIBUTE EVALUATORS FOR: PROGRAMMER_#1 – COMPLEXITY

HLPL
HLUR
HLOR
HLEF
HLON
WDC
HLDF
HLVL
HLVC
TOK
HLUN
DEC

These eleven metrics also represent the **programmer_#1** as the evaluator of **complexity** of software objects.

C. Correlation Results

The third set of processing methods is a simple calculation of correlations, **StepC**. It is performed for each pair software – complexity. The results are in Table IV.

TABLE IV. FEATURES OBTAINED USING CORRELATION FOR: PROGRAMMER_#1 – COMPLEXITY

HLUR
HLDF
HLVC
HLUN
CBO
FNOT
WMC1
CYCO

The set of metrics obtained using correlations is the third representation of the **programmer_#1**'s view at the **complexity** of objects.

D. Fusion of Results

The results obtained using **StepA**, **StepB** and **StepC** are fused together in order to achieve a single representation of the **programmer_#1**. As it has been indicated earlier, an arithmetic average has been used to combine scores of the metrics, and then all metrics with the combined score below 0.75 are rejected. The obtained set of the metrics characterizes the **programmer_#1**, Table V.

TABLE V. FEATURES REPRESENTING PROGRAMMER_#1 – COMPLEXITY

HLUR
LOC
WDC
HLDF
CYCO
HLVL
TOK
HLOR

The above described process has been applied to all available data, i.e., other quality attributes and other programmers. The final result – the metrics representing programmers as th evaluators of different quality attributes are included in Table VI.

TABLE VI. COMPLEXITY, MAINTAINABILITY AND USABILITY OBTAINED USING A FUSION OF SUBSET AND ATTRIBUTE EVALUATORS AND CORRELATION FDSFDS

programmer_#1	**programmer_#2**	**programmer_#3**

VI. ANALYSIS OF RESULTS

A. Single Quality Attribute Across Multiple Programmers

At first, we look at "the description" of all three programmers when they evaluated objects from the point of view of different quality attributes. Figure 4 shows sets of mutually overlapping features that represent the programmers when they evaluate complexity of objects. We could say that each of them "uses" Halstead program volume (HLVL). There are also features that are "shared" between pairs of

programmers. A single-metric-overlap exists between the **programmer_#1** and the **programmer_#2**, while a large overlap is between the **programmer_#1** and the **programmer_#3**. There is no overlapping between **programmer_#2** and **_#3**.

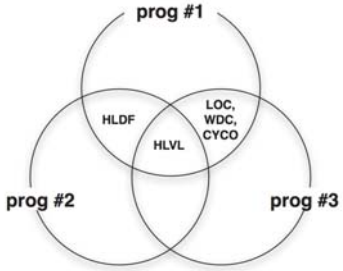

Figure 4. Complexity

The diagram in Figure 4 gives an interesting insight into a practice of describing, characterizing and evaluating programmers. We could hypothesize that **programmer_#1** and **_#3** could think in a similar way when they estimate complexity. Another interesting conclusion is that lines of code (LOC) and number of decisions (WDC) and pathways (CYCO) are important factors influencing estimation of complexity.

Similar diagrams are presented for the other two quality attributes: maintainability (Figure 5), and usability (Figure 6).

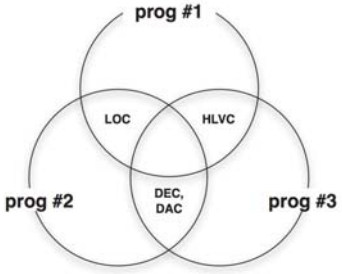

Figure 5. Maintainability

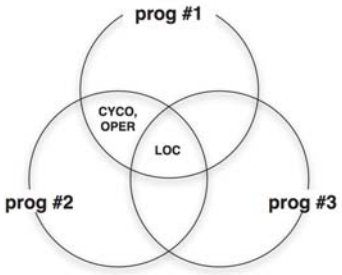

Figure 6. Usability

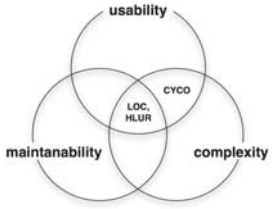
It seems that for maintainability, Figure 5, the programmers share at least one "common" metric describing maintainability. We see that lines of code (LOC), sum of operators and operands (HLVC), and number of decision keywords (DEC) and number of reference types (DAC) influence programmers' evaluation processes.

For the case of usability, all programmers where recognizing lines of code (LOC) as an important judging criteria. Additionally, for both **programmers_#1** and **_#2** number of loops (CYCO) and number of operations (OPER) are deciding factors about usability of objects.

B. Single Individual Across Multiple Quality Attribues

Let us take a look how each programmer has evaluated software objects when he/she was asked to appraise complexity, usability, and maintainability of objects.

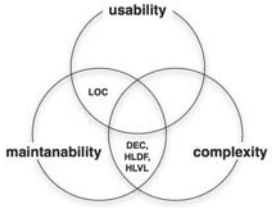
The **programmer_#1** consistently "use" two factors for all three evaluations, Figure 7 (a). These two factors are lines of code (LOC) and number of unique operators (HLUR). A number of pathways (CYCO) is an important factor in estimating usability and complexity. There is no common metric describing evaluation of usability and maintainability. Figure 7 (b) represents a tab-cloud [6] that characterizes the programmer. The tag-cloud has been created based on metrics obtained during StepA, StepB and StepC of the data analysis process (Section VI). The size of the fonts indicates importance of shown matrics. Once again we see HLUR, LOC, CYCO, HLVC as important "labels" describing the programmer.



(a) (b)

Figure 7. Programmer_#1: overlapping metrics (a), and tag-cloud (b)

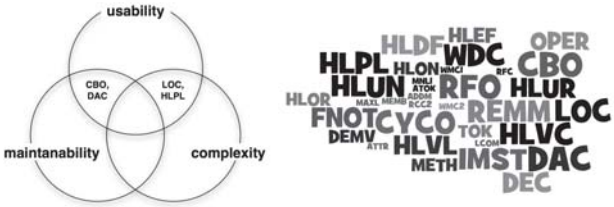
The **programmer_#2** is "shown" in Figure 8. Once again we see lines of code (LOC) as an important factor together with number of decision keywords (DEC), Halstead difficulty (HLDF), and program volume (HLVL). It seems that the **programmer_#2** thinks differently when evaluating usability and complexity/maintainability. The tag-cloud, Figure 8 (b), confirms importance of LOC, HLVC, HLUN, and CBO.



(a) (b)

Figure 8. Programmer_#2: overlapping metrics (a), and tag-cloud (b)

The factors influencing evolution of objects preformed by the **programmer_#3** are shown in Figure 9. It seems that once again some of the metrics we have already seen in the case of the other two programmers are also important for the **programmer_#3**: lines of codes (LOC) and Halstead program length (HLPL) for usability and complexity; number of reference types (DAC) and coupling (CBO) for usability and maintainability. The tag-cloud "adds" HLUN, WDC, RFO, CYCO and REMM.



(a) (b)

Figure 9. Programmer_#3: overlapping metrics (a), and tag-cloud (b)

VII. CONCLUSIONS

The importance of quality of software attributes is unquestionable. It is essential to understand what programmers mean when they say that an object is of high quality, and to know what aspects of software component influence their behavior. The approach we proposed uses multiple feature selection techniques for identifying a small set of software metrics describing a human evaluator. Some metrics representing programmers and relationships among them have been determined. To verify these findings we need to confront the obtained results with the programmers.

APPENDIX

The attributes of the data used in this paper are briefly described in the Table III.

TYPE	Type: GUI (=1), Data Model (2), Algorithm (3), Other (4)
METH	Number of methods
LOC	Number of lines of code
ALOC	Mean LOC per method
MLOC	Median LOC per method
RCC1	Ratio of comment lines of code to total lines of code including whitespaces and comments
RCC2	True comment ratio
TOK	Number of tokens
ATOK	Mean TOK per method
MTOK	Median TOK per method
DEC	Number of decisions: for, while, if, switch, etc.
ADEC	Mean DEC per method
MDEC	Median DEC per method
WDC	Weighted number of decision based on nesting level
AWDC	Mean WDC per method
MWDC	Median WDC per method
INCL	Number of inner classes
DINH	Depth of inheritance
CHLD	Number of children
SIBL	Number of siblings
FACE	Number of implemented interfaces
RCR	Code reuse: ratio of overloaded inherited methods to methods that are not overloaded
CBO	Coupling between objects
LCOM	Lack of cohesion of methods
RFO	Response for an object (response set contains the methods that can be executed in response to a message bing received by the object
RFC	Response for class
MNL1	Maximum method name length
MNL2	Minimum method name length
MNL3	Mean method name length
MNL4	Median method name length
ATCO	Attribute complexity
CYCO	Cyclomatic complexity
DAC	Data abstraction coupling
FNOT	Fan out
HLDF	Halstead difficulty
HLEF	Halstead effort
HLPL	Halstead program length
HLVC	Halstead program vocabulary
HLVL	Halstead program volume
HLON	Halstead number of operands
HLOR	Halstead number of operators
HLUN	Halstead number of unique operands
HLUR	Halstead number of unique operators
MIC	Method invocation coupling
MAXL	Maximum number of levels
MAXP	Maximum number of parameters
MAXO	Maximum size operations
ATTR	Number of attributes
ADDM	Number of added methods
CLAS	Number of classes
CHCL	Number of child classes
CONS	Number of constructors
IMST	Number of import statements
MEMB	Number of members
OPER	Number of operations
OVRM	Number of overridden methods
REMM	Number of remote methods
PKGM	% of package members
PRVM	% of private members
PROM	% of protected members
PUBM	% of public members
DEMV	Violations of Demeters Law
WMC1	Weighted methods per class (each method weighted by is CYCO)
WMC2	Weighted methods per class (inherited methods excluded)

A Dual Clustering Approach to the Extract Class Refactoring

Keith Cassell, Peter Andreae, Lindsay Groves
School of Engineering and Computer Science
Victoria University of Wellington
Wellington, New Zealand
{*kcassell, pondy, lindsay*}*@ecs.vuw.ac.nz*

***Abstract*—Large classes typically have many internal interactions between their members, making them difficult to understand and expensive to maintain. When large classes are split into smaller, more cohesive classes, maintainability costs can be reduced; however, the very complexity that makes the classes costly to maintain also makes them difficult to split. Our ExtC tool uses clustering techniques to help solve this problem. By clustering based on the structural characteristics of the class, followed by additional clustering based on semantics, ExtC divides the members of large classes into groups. These groups provide the basis for refactoring the large classes into smaller, more cohesive ones.**

***Keywords*-Refactoring; betweenness; clustering; cohesion; extract class; graph theory; maintainability; object-oriented.**

I. Introduction

Code maintenance is expensive. We propose a solution to a common maintenance problem in object-oriented systems – the presence of large, complex classes, sometimes known as *god classes* [1].

In his book on refactoring [2], Fowler identifies a large class as being a "bad smell" that may be a symptom of an underlying software problem, and he recommends the *Extract Class* refactoring as a potential remedy for the problem. One of the challenges in performing this refactoring is determining how to split a large class, i.e. how to group the original class's attributes and methods into revised classes.

Our novel contribution is the sequential use of two complementary clustering techniques to determine how to revise Java classes. We first use a divisive structural clustering technique to separate a class's members into groups based on statically determined dependencies between the members. This typically breaks a large class into multiple groups, some of which may consist of only one or two members. Then we use an agglomerative "semantic"[1] clustering technique to combine the smaller groups with the larger ones. In many cases, these groups can be used to form the basis of two nontrivial classes, both of which are more cohesive than the original.

[1]Some "semantic" techniques, including the vector space model we use, are based on statistics. However, when given sufficient data, some statistical techniques approximate the results given by knowledge-based semantic techniques. We use "semantic" in this paper for convenience and to be consistent with other researchers [3], [4], [5].

II. Refactoring Approach

To help show how the structure of a class relates to its amenability to Extract Class, consider the portion of the intraclass dependency graph shown in Figure 1[2]. Intraclass dependency graphs are concise representations of single classes built from a static analysis of source code. The nodes of a graph represent a class's members – circles for methods and stars for attributes, and each edge represents a method calling a method or a method accessing an attribute.

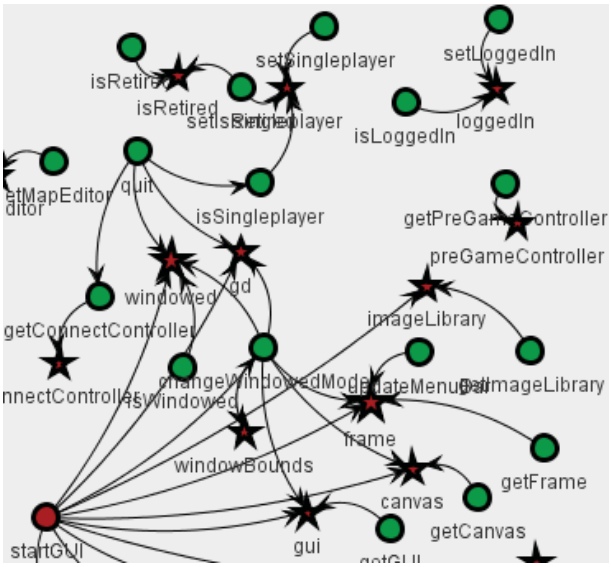

Figure 1. FreeColClient Dependency Graph

The disconnected nature of the example graph shows that this class has several loosely related responsibilities. For example, the members represented by the three nodes in the upper right (`loggedIn`, `isLoggedIn`, and `setLoggedIn`) are not accessed by any other code in the class.

A. Goals

When refactoring to improve maintainability, it is useful to keep as much of the existing structure of the code as possible, while addressing the potential maintainability problems

[2]generated from code at https://svn.freecol.org/svnroot/freecol/freecol/trunk:/src/net/sf/freecol/client/FreeColClient.java

of large classes. Extract Class breaks a class into two classes. We refer to the class that gets refactored as the *original class*, the post-refactoring class that is most like the original class as the *modified class*, and the other post-refactoring class as the *extracted class*. Following refactoring, we want the modified and extracted classes to be smaller and more cohesive than the original class, and the modified class should implement the same interfaces as the original class.

In addition, we want to avoid situations where we replace one maintenance problem with another. For example, in breaking up a large class, we do not want to create trivial classes that do too little (the *lazy class* smell [2]). For example, although it would be cohesive, we would not create a new class from `loggedIn`, `isLoggedIn`, and `setLoggedIn`, because such a class would do too little.

B. Design

Unsupervised clustering techniques group together entities that are highly related, so clustering algorithms should be useful for identifying cohesive new classes, given information about existing classes [6]. Our initial approach to extracting classes [7] used a structural divisive clustering algorithm. By using an algorithm that creates clusters by splitting an intraclass dependency graph, we can be conservative and group members together while keeping existing inter-member relationships intact.

However, while inspecting the dependency graphs of hundreds of large classes, we observed that a significant percentage of the graphs were composed of disconnected subgraphs, and many of these subgraphs consisted of three or fewer members. Our divisive clustering technique does not assist in determining how those isolated members should be assigned to classes, so our initial implementation kept the members represented by the small subgraphs with the original class.

While we still feel that the intraclass structural information should be the primary guide for refactoring, there is additional information available that we had not used. Semantic information embedded in identifier names and comments has been used to measure cohesion [4], to identify topics in source code [5], [8], and to help refactor [3], [4]. We decided to use semantic information as a secondary information source for clustering. Because semantic clustering techniques partially rely on meaningful terms being embedded in the identifiers, we feel they are less reliable than structural information.

Our current dual clustering approach consists of divisive clustering based on structural information, followed by agglomerative clustering based on semantic information. Divisive clustering splits the members of the class into at least two groups, and the agglomerative clustering connects the small groups of members with the larger groups. The two resultant groups serve as inputs for the Extract Class refactoring.

1) Divisive clustering based on structure: We use a structural divisive clustering algorithm known as betweenness clustering [9] for our initial step of breaking apart a large class. Betweenness clustering is a general graph-based technique that has been applied to many domains, including software refactoring [7]. For refactoring large classes, the graph represents the class, the nodes represent the class's members, and the edges represent a dependency between the members, e.g. a method calling a method or a method accessing an attribute. The betweenness value of an edge is the number of shortest paths between pairs of nodes that pass through it. The high betweenness edges tend to be within the centrally located "thin areas" of a graph.

Betweenness clustering operates by iteratively removing the edge with the maximum betweenness value. After each edge removal, the algorithm recalculates the betweenness values of the edges prior to the next edge removal. The successive removal of edges will disconnect the connected portions of the graph and form new clusters.

We run betweenness clustering on undirected versions of intraclass dependency graphs and stop the clustering once the first new cluster is formed. The disconnected subgraphs represent the members of the class that have high interconnectivity (cohesion) amongst themselves relative to members outside the cluster. The two largest clusters serve as seeds for agglomerative clustering.

2) Agglomerative clustering based on semantics: Agglomerative clustering is an iterative process of combining clusters of one or more entities – it starts with seed clusters and adds closely related clusters to them until some stopping criterion is reached. For the purpose of restructuring classes, the entities to be clustered are attributes and methods. The determination of the clusters to combine is done using a *similarity function* or *distance function* that calculates how similar (or distant) two entities are based on the characteristics (or *feature set*) of the entities. Because a similarity function can be considered a kind of distance function (two similar things are less distant conceptually), we generally use the term "distance function" in this paper.

Several researchers [3], [10], [11] have used structural information to create a feature set for use in agglomeratively clustering class members. Because we already make use of structural information in betweenness clustering, we use semantic information instead.

Consider the `retire` method in Figure 2. The only class member it references directly is the `client` attribute; however, there is a wealth of other information available. Some of this is structural information pertaining to other classes, for instance, it calls the `Message` class's `createNewRootElement` method. There is also semantic information encoded in variable names, e.g. `reply` and in string constants, e.g. "highScore".

We use document clustering techniques and treat the class's methods and attributes as "documents". The docu-

```
public boolean retire() {
 Element retireElement =
  Message.createNewRootElement("retire");
 Element reply=client.ask(retireElement);
 boolean result = reply != null
  && "true".equals(
      reply.getAttribute("highScore"));
  return result;
}
```

Figure 2. FreeColClient's retire method

ments' contents are the words present in the identifiers and constants (but not words within comments). Code adapted from TopicXP [8] extracts this information. The words stored include the stemmed form of the full identifier, e.g. `createnewrootel`, and the stemmed form of its components, e.g. `creat` and `root`. Certain common words are filtered out, including Java reserved words like `new` or `boolean`. Words are stored together with their number of occurrences in the document.

We use UCLA's S-Space package [12] to create a *vector space model* of these documents. In a vector space model, documents are represented as vectors, where each element in the vector corresponds to a unique word in the corpus (the collection of documents). We can then compute the distance between two documents (class members) based on the cosine similarity [13] of their vectors.

III. Extract Class Experiments

A. Experimental Design

To test the hypothesis that dual clustering provides an effective way of determining how to split large Java classes, we ran experiments consisting of the following steps:

1) Software metrics identify large noncohesive classes from within open-source software projects.
2) Clustering algorithms form two clusters from each class's members.
3) Using the two clusters as input, an automated Extract Class refactoring separates each of the original classes into two classes.
4) Software metrics quantify the changes caused by the refactoring.

Most of the analysis and clustering in these experiments is done using a series of plug-ins for the Eclipse platform [14]. We use the open-source Metrics2 [15] Eclipse plug-in to collect metric data. Our open-source ExtC (*Ext*ract *C*lass) Eclipse plug-in [16] provides capabilities for identifying god classes using metrics, visualizing those classes, and proposing class splits based on clustering.

1) Identifying large, noncohesive classes: Our god class query checks the following conditions:

1) number of instance methods (NOM) > 20
2) weighted method count (WMC) [17] ≥ 47.0
3) tight class cohesion (TCC) [18] < 0.34
4) depth in the inheritance hierarchy = 1.0

The first three conditions specify the class's size, cohesion, and complexity. The fourth simplifies the analysis by eliminating the effects of inherited members. We use Metrics2 to collect the measurements and store them in a database.

We ran this query on data gathered from four mature open-source projects – FreeCol[3] 0.94, Heritrix[4] 1.8.0, Jena[5] 2.5.5, and Weka[6] 3.6.3, covering a variety of domains. Thirty classes matched the query.

2) Clustering the members: Semantic clustering requires a document corpus from which similarity can be determined. We use code adapted from TopicXP [8] to extract semantic information from the source code and to create documents from the classes' members. We store a corpus of documents for each project. Then, we use UCLA's S-Space package [12] to build vector space models for each of these corpora, which are saved and used later in the clustering step.

ExtC provides a batch mode of operation to cluster the members of the classes that match the god class query. The results determine whether the classes are good candidates for an Extract Class refactoring. If the clustering steps produce two clusters of seven or more members, we refactor. We use a cluster size of seven as a threshold to avoid producing new classes that do too little (lazy classes). (Seven is approximately the average number of methods per class [1].) The dual clustering step does not take long – on average less than seven seconds per class when run on a low end PC.

3) Refactoring the large classes: We use an automated Extract Class refactoring to reduce the variability of how the classes are refactored. This helps reduce the risk of the refactoring and makes evaluation and comparison of the refactoring results more consistent.

Because Eclipse does not have an Extract Class capability capable of moving methods into a new class, we use IntelliJ IDEA's [19] Extract Class refactoring to split off a new class. We manually input the results of the clustering into the IDEA GUI. IDEA does the code manipulation necessary to form the new class and to modify other classes that might be affected by the refactoring.

4) Measuring the modified software: We use Metrics2 to collect measurements on the modified software. The data collected includes the number of instance methods, weighted method count, and tight class cohesion.

B. Data Collected

We collected connectivity data on the intraclass dependency graphs of the matching classes after removing some "special" methods (e.g. constructors and *toString*) that might

[3] http://www.freecol.org/
[4] http://crawler.archive.org/
[5] http://jena.sourceforge.net/
[6] http://www.cs.waikato.ac.nz/ml/weka/

link together functionally unrelated members. The following observations are particularly interesting:

1) Not one of the 30 classes had a completely connected dependency graph.
2) Multiple large groups are relatively rare. Only 20% of the classes had more than one large group, and none had more than two large groups.
3) Multiple small groups are extremely common, with 50% of the classes having seven or more.

These observations lend support to our belief that divisive clustering techniques alone do not adequately address the allocation of all of the class members to revised classes.

Based on the results of the clustering, seven of the 30 classes did not warrant refactoring, because they did not produce two clusters with at least seven members each. Four of those classes did not even produce two clusters of at least four members.

Table I summarizes the results for the 22 classes[7] where a class of seven or more members could be extracted based on the clustering results. The letter in parentheses after each class name indicates the project from which the class came. Following a column that indicates the change in cohesion values (ΔTCC), there are three groupings of columns. The *Original Class* columns contain the measurements for the class before refactoring, while the *Modified Class* columns contain the measurements for that class after a class was extracted from it. The *Extracted Class* columns contain the measurements for the class that was extracted from the original. The following measurements are shown:

- *#A* - number of attributes.
- *#M* - number of instance (non-static) methods.
- *TCC* - Tight Class Cohesion ranges from 0 (least cohesive) to 1 (most cohesive).
- *WMC* - Weighted Methods per Class ranges from 0 (least complexity) upwards.

The classes are sorted according to the change in TCC values between the original class and the modified class.

There is a peculiarity in the table. In the first row, the extracted class for `Rule` has no instance attributes or methods and has a TCC of 0. This class is entirely composed of static methods. Because TCC is calculated based on the connections between methods and attributes (of which there are none), the TCC score is 0, even though the methods of the class call each other.

C. Analysis of Results

In general, there were slight improvements in both cohesion (TCC) and complexity (WMC). 55% of the 22 classes showed cohesion increasing or staying the same for both the modified and extracted classes, and an additional 41% showed cohesion increasing for either the modified or the extracted class.

The modified classes that had a poor ΔTCC generally had an associated extracted class with a high TCC score. All told, 45% of the 22 extracted classes had a TCC of at least 0.5, indicating that these classes are relatively cohesive. Two of these classes had the maximal score of 1.0.

It is not surprising that most improvements in TCC are small. TCC measures the proportion of connected methods to the maximum possible number of connected methods. The large classes that were selected by our god class query had low TCC scores largely because they had many disconnected members, as indicated by the large number of disconnected subgraphs in the dependency graphs. Splitting such a class can eliminate some of the disconnectedness; however, many of the small, structurally disconnected portions of the original class become small, structurally disconnected portions of either the modified class or the extracted class.

One class, Weka's `Node`, showed decreased cohesion for both the modified and extracted classes. It is interesting to see why. `Node`'s intraclass dependency graph contains 11 disconnected subgraphs, most of which consist of a single field and its accessors. Only one of the subgraphs has seven members or more, and this larger subgraph is relatively cohesive. However, due to how our algorithm works, the large group gets broken apart to form seeds and the smaller groups agglomerate with them. This contrasts with the more typical case of `FreeColClient` (Figure 1), where the initial seeds were not derived from the same cohesive group.

One result that may be surprising is that the modified class often has about the same number of methods as the original. One might expect that the count would have decreased by the number of methods that had migrated to the extracted class. This "surprise" is due to the conservative nature of IDEA's Extract Class refactoring, which maintains the public interface of the class by using delegation. The logic of the original method is moved to the extracted class, while the class from which it was extracted has a proxy method that calls the moved method. This conservative approach is necessary to avoid potentially breaking an external client's code. If it is known that there are no external clients, then the delegation could be removed in many cases, because the calling code of the internal clients could be adjusted at the time of the refactoring.

As expected, almost all classes showed a decrease in complexity as measured by WMC. Because WMC is not a normalized metric, removing methods from a class generally decreases the class's WMC score.

IV. Comparison with Related Work

A variety of techniques have been proposed for making large classes more maintainable. In this section, we discuss those that concentrate on refactoring large classes using

[7]IDEA's Extract Class failed to operate on one of the classes to be refactored.

Table I
REFACTORING RESULTS

clustering, rather than on those that do more extensive reorganizations of class hierarchies [20].

Other researchers have used agglomerative clustering to determine how to refactor. Serban and Czibula's CASYR algorithm [11] creates feature sets for classes, methods and attributes based on structural information about methods calling other methods or methods accessing attributes. For example, a method's feature set will include the names of the method itself and the attributes accessed by it, and an attribute's feature set will include the names of the attribute itself and the methods accessing it. Serban and Czibula use a *Jaccard similarity* function to determine the similarity between feature sets, where the similarity score is equal to the number of common features divided by the total number of features for the entities being compared. The JDeodorant Eclipse plug-in uses a similar agglomerative technique to extract classes [10] but uses a slightly different feature set.

We contend that betweenness clustering using an intra-class dependency graph has advantages over agglomerative clustering using local structural information. Betweenness clustering's primary advantage is that it uses extended structural information in addition to local information – the overall relationship of a member to other members is embedded in the intraclass dependency graph on which the betweenness algorithm works, and this information is used when determining clusters. Furthermore, due to how it operates, betweenness clustering retains most existing intraclass member relationships. The edges removed from the graph to form a cut set are relationships that will be re-established between the members of the evolved classes.

Researchers based predominately at the University of Salerno [3], [4] are the only ones that we know of who use both structural and semantic information to cluster members and extract classes; however, their approach is significantly different from ours. Their most recent approach [3] combines structural and semantic information to calculate pairwise similarities between all of a class's members. Their similarity function has three weighted terms. Two pertain to structural characteristics of the code, while the third uses latent semantic indexing to compute the semantic similarity between members.

Using these similarity measures, they create a graph whose nodes are the class's members and whose weighted edges contain the similarity scores between the connected nodes, so initially, the graph is fully connected. Then, all edges with a weight below a certain threshold are removed, which disconnects the graph. In their second step, they combine the small groups with the larger ones using the same similarity function discussed above.

We believe that betweenness clustering on the actual intraclass dependency graph is superior to their first step of creating a disconnected graph whose nodes are linked by similarity scores. Because their graph is built using similarity scores, it does not necessarily retain existing call relationships between members within the class. Betweenness does retain most of the existing intraclass relationships, so using

it as the basis for new class formation should generally entail less change, and therefore, less risk.

V. Conclusions

In this paper, we advocate using clustering techniques to determine how to refactor large classes. Our approach to identifying extract class opportunities goes beyond previous attempts by using two distinct clustering phases. The first uses structural information to split the members of a large class into groups. The second uses semantic information to combine the smaller groups with the larger ones.

To test the hypothesis that our clustering techniques offer useful advice for splitting classes, we ran the algorithm against 30 open source classes and collected metric data both on the original classes and on the refactored classes. Based on this data, it appears that our clustering techniques can effectively identify how to split some large classes, but not others. For 40% of the 30 classes, we were able to create two more cohesive classes from the original class.

There is much potential future work. There are many uncertainties about how best to apply clustering techniques to software, including a need for additional study of semantic clustering. While semantics have an intuitive appeal, it is not clear how they can best be applied to software engineering in general, and refactoring in particular. Besides the techniques themselves, there are also questions about the "data" on which they should operate, for example, whether both code and comments should be considered as input.

While there is still much work to do, we feel that clustering techniques already provide benefit for a number of software engineering tasks. In particular, this paper has demonstrated how complementary clustering techniques can be used to refactor large classes to make them measurably more more cohesive and less complex.

***Abstract*—The objective of feature selection is to identify irrelevant and redundant features, which can then be discarded from the analysis. Reducing the number of metrics (features) in a data set can lead to faster software quality model training and improved classifier performance. In this study we focus on feature ranking using linear Support Vector Machines (SVM) which is implemented in WEKA. The contribution of this study is to provide an extensive empirical evaluation of SVM rankers built from imbalanced data. Should the features be removed at each iteration? What should the recommended value be for the tolerance parameter? We address these and other related issues in this work.**

I. Introduction

Software quality models are trained using software measurement data (metrics) and various data mining techniques to get useful information that can be used to find higher quality software production. The characteristics of software metrics (a.k.a. features or attributes) influence the performance and effectiveness of the quality model. Previous studies [1], [2], [3] have shown that the performance of software quality models are improved when irrelevant and redundant features are removed before modeling. In this study, we investigated feature selection by the means of a feature ranking method using linear support vector machines (SVM ranker). This SVM ranker has been implemented in WEKA [4]. WEKA is an open source data mining and machine learning package implemented in JAVA at the University of Waikato. Many researchers and practitioners in the data mining and machine learning community commonly use WEKA, but past work has provided no empirically proven recommendation on the appropriate default values for the parameters $percentToEliminatePerIteration$ (percentage of attributes to be removed at each iteration) and $toleranceParameter$ (for checking the stopping criterion) for the SVM ranker. The parameter values are critical to the performance and running time of the ranker (see Section III). In fact, a bad selection of parameter values can entirely prevent experiment completion. We contend that default values built into WEKA for SVM ranker are not reasonable for experimentation. This work, as far as we know, is the first to conduct comprehensive experimentation with the SVM ranker in WEKA and recommend empirically proven default values for the $percentToEliminatePerIteration$ and $toleranceParameter$ parameters.

Since the introduction of SVM ranker [5], there has been little empirical work on the topic. As far as we know, there is no related work that empirically recommends default settings for the $percentToEliminatePerIteration$ and $toleranceParameter$ parameters for the SVM ranker in the WEKA tool. Therefore, we present, in this work, a comprehensive empirical evaluation of learning from imbalanced data by varying the $percentToEliminatePerIteration$ and $toleranceParameter$ parameters.

In this study, we built classification models using naïve Bayes (NB), multilayer perceptron (MLP), k-nearest neighbors (KNN), support vector machines (SVM), and logistic regression (LR) on the smaller subsets of selected attributes. Each classification model is assessed with the Area Under the ROC (Receiver Operating Characteristic) curve (AUC). The empirical validation of the different models was implemented through a case study of three consecutive releases of a very large telecommunications software system (denoted as LLTS), nine data sets from the Eclipse software project, and three data sets from NASA software project KC1. Our experimentation is done in WEKA using the 15 different data sets with varying degrees of class imbalance. In the experiments, ten runs of five-fold cross-validation were performed. Statistical analysis using Analysis of Variance (ANOVA) models is used to determine reasonable default values for the $percentToEliminatePerIteration$ and $toleranceParameter$ parameters. By varying the parameters $percentToEliminatePerIteration$ and $toleranceParameter$, this work is the first to compare the SVM ranker on imbalanced data and recommend a default setting for each of the parameters.

Experimental results demonstrate the default setting in WEKA for $toleranceParameter$ (1.0E-10) is not appropriate value, but 1.0E-03 is reasonable. This work further shows that SVM ranker with no backward elimination performs similar to or better than the ranker with full backward elimination. Thorough experimentation makes our work extremely comprehensive and dramatically augments the reliability of our conclusions.

The remainder of the paper is organized as follows. Section II presents the feature selection techniques. Section III describes the data sets, experimental design, and a discussion of the results. Section IV presents background on feature selection and the SVM ranker in different domains. Finally, we conclude the paper in Section V and provide suggestions for future work.

II. Feature Selection

Feature selection has been applied in many data mining and machine learning applications [6]. The main goal of feature selection is to select a subset of features that minimizes the prediction errors of classifiers. It is broadly classified as feature ranking and feature subset selection, where feature ranking sorts the attributes according to their individual predictive power, and feature subset selection finds subsets of attributes that collectively have good predictive power. In this study, we investigated a feature ranking method, called SVM ranker.

The Support Vector Machine (SVM) classifier is one of most commonly used classifiers. It builds a linear discrimination function using a small number of critical boundary instances (called support vectors) from each class while ensuring a maximum possible separation [7].

SVM has been extended to form an embedded method of feature selection. A linear classifier is trained and features are ranked based on the weight (calculated from the support vectors) of each feature. The larger the weight, the more important role the feature plays in the decision function. This ranking procedure can be applied recursively. Guyon et al. [5] introduced recursive feature elimination for support vector machines, SVM-RFE. SVM-RFE uses a backward elimination procedure recursively. At each iteration one or more features with the lowest score (weight) are eliminated. The process is repeated until a predefined number of features remains.

SVM ranker has been implemented in WEKA, called *SVMAttributeEval*. By default, WEKA uses $percentToEliminatePerIteration = 0$ and $attsToEliminatePerIteration = 1$ (one feature is removed at each iteration) and $toleranceParameter = 1.0E\text{-}10$. The tolerance parameter defines the stopping criterion for SVM model optimization. The lower the tolerance parameter, the higher the computational complexity. In our experimentation we first change the tolerance parameter to 1.0E-03 to reduce computational cost. Along with the default value of $percentToEliminatePerIteration$ and $attsToEliminatePerIteration$, this variation is called SVM ranker with full backward elimination. Our experiments also set $percentToEliminatePerIteration$ to 100 (regardless of value of $attsToEliminatePerIteration$), indicating no backward elimination, and consider different values for $toleranceParameter$, specifically 1.0E-03, 1.0E-05, 1.0E-07, and 1.0E-10. In total, five SVM rankers are evaluated in this study (tolerance of 1.0E-03 with full backward elimination, and tolerance of 1.0E-03, 1.0E-05, 1.0E-07, and 1.0E-10 with no backward elimination). Our experiments demonstrated that 1.0E-10 is not an appropriate value, and in particular 1.0E-03 is more reasonable. We also showed that SVM ranker with no backward elimination performed similar to or better than the ranker with full backward elimination, while the computational cost of no backward elimination is much lower than full backward elimination.

SVM ranker has been used as feature selection method in several domains. However, for imbalanced data in the software engineering domain, a comprehensive evaluation of the ranker, with varying values for $percentToEliminatePerIteration$ and $toleranceParameter$, has not been performed. Researchers and practitioners who use WEKA have no guidance on these settings and too often rely on the default values in the WEKA tool. Our work shows that the default value for $toleranceParameter$ is not appropriate for experimentation with imbalanced data. To our knowledge, there has been no previous study to empirically recommend $percentToEliminatePerIteration$ and $toleranceParameter$ values for SVM ranker in the WEKA tool.

III. Experiments

A. Experimental Data Sets

Experiments conducted in this study used software metrics and fault data collected from real-world software projects, including a very large telecommunications software system (denoted as LLTS) [1], the Eclipse project [8], and NASA software project KC1 [9].

The software measurement data set of LLTS contains data from four consecutive releases, which are labeled as SP1, SP2, SP3, and SP4. We only provide results for SP2, SP3, and SP4 since we couldn't get results for SP1 when tolerance parameter was set to 1.0E-10 for no backward elimination due to computational complexity. The software measurement data sets consist of 42 software metrics, including 24 product metrics, 14 process metrics, and four execution metrics [1]. The dependent variable is the class of the program module: fault-prone (*fp*) or not fault-prone (*nfp*). A program module with one or more faults is considered *fp*, and *nfp* otherwise.

TABLE I
Software Data Sets Characteristics

	Data	#Metrics	#Modules	%fp	%nfp
LLTS	SP2	42	3981	4.75%	95.25%
	SP3	42	3541	1.33%	98.67%
	SP4	42	3978	2.31%	97.69%
Eclipse	Eclipse2.0-10	208	377	6.1%	93.9%
	Eclipse2.0-5	208	377	13.79%	86.21%
	Eclipse2.0-3	208	377	26.79%	73.21%
	Eclipse2.1-5	208	434	7.83%	92.17%
	Eclipse2.1-4	208	434	11.52%	88.48%
	Eclipse2.1-2	208	434	28.8%	71.2%
	Eclipse3.0-10	208	661	6.2%	93.8%
	Eclipse3.0-5	208	661	14.83%	85.17%
	Eclipse3.0-3	208	661	23.75%	76.25%
NASA	KC1-20	62	145	6.90%	93.10%
	KC1-10	62	145	14.48%	85.52%
	KC1-5	62	145	24.83%	75.17%

From the PROMISE data repository [8], we also obtained the Eclipse defect counts and complexity metrics data set. In particular, we use the metrics and defects data at the software package level. The original data for the Eclipse packages consists of three releases denoted 2.0, 2.1, and 3.0 respectively. We transform the original data by: (1) removing all nonnumeric attributes, including the package names, and (2) converting the post-release defects attribute to a binary class attribute: fault-prone (*fp*) and not fault-prone (*nfp*). Membership in each class is determined by a post-release defects threshold *t*, which separates *fp* from *nfp* packages by classifying packages with *t* or more post-release defects as *fp* and the remaining as *nfp*. In our study, we use $t \in \{10, 5, 3\}$ for release 2.0 and 3.0, while we use $t \in \{5, 4, 2\}$ for release 2.1. These values are selected in order to have data sets with different levels of class imbalance. All nine derived data sets contain 208 independent attributes. Releases 2.0, 2.1, and 3.0 contain 377, 434, and 661 instances respectively.

The original NASA project, KC1 [9], includes 145 instances containing 94 independent attributes each. After removing 32 Halstead derived measures, we have 62 attributes left. We used three different thresholds to define defective instances, thereby obtaining three structures of the preprocessed KC1 data set. The thresholds are 20, 10, and 5, indicating that instances with numbers of defects greater than or equal to 20, 10, or 5 belong to the *fp* class. The three data sets are named KC1-20, KC1-10, and KC1-5.

The fifteen data sets used in the work reflect software projects of different sizes with different proportions of *fp* and *nfp* modules. Table I lists the characteristics of the 15 data sets utilized in this work.

B. Classification Algorithms

The software defect prediction models were built with five commonly used classification algorithms including naïve Bayes, multilayer perceptron, K-nearest neighbors, support vector machine, and logistic regression. The five learners were selected because of their common use in software engineering and other application domains. Unless stated otherwise, we use the default parameter settings for the different learners as specified in WEKA. Parameter settings are changed only when a significant improvement in performance is obtained.

1) Naïve Bayes (NB) [10] utilizes Bayes's rule of conditional probability and is termed 'naive' because it assumes conditional independence of the features.
2) Multilayer Perceptron (MLP) [11] is a neural network of simple neurons called perceptrons. Some related parameters of MLP were set as follows. The 'hiddenLayers' parameter was set to 3 to define a network with one hidden layer containing three nodes. The 'validationSetSize' parameter was set to 10 to cause the classifier to leave 10% of the training data aside to be used as a validation set to determine when to stop the iterative training process.
3) K-Nearest Neighbors (KNN) [12], also called instance-based learning, uses distance-based comparisons. The choice of distance metric is critical. KNN was built with changes to two parameters. The 'distanceWeighting' parameter was set to 'Weight by 1/distance' and the 'kNN' parameter was set to 5.
4) Support Vector Machine (SVM) [13], also called SMO in WEKA, had two changes to the default parameters: the complexity constant 'c' was set to 5.0 and 'build Logistic Models' was set to true. By default, a linear kernel was used.
5) Logistic Regression (LR) [14] is a statistical regression model for categorical prediction by fitting data to a logistic curve.

C. Performance Metric

The classification models are evaluated using the Area Under ROC (Receiver Operating Characteristic) Curve (AUC) performance metric. AUC has been widely used, providing a general idea of predictive potential of the classifier. The ROC curve is used to characterize the trade-off between true positive rate and false positive rate. An ROC curve illustrates the classifier's performance across all decision thresholds, i.e., a value between 0 and 1 that theoretically separates the *fp* and *nfp* modules. AUC is a single-value measurement that ranges from 0 to 1, where a perfect classifier provides an AUC value of 1. It has been shown that AUC has lower variance and is more reliable than other performance metrics (such as precision, recall, or F-measure) [15].

D. Results Analysis

Before using a feature ranking technique, the practitioner must choose how many features to select. These selected features will be used for modeling. In this study, we choose the top $\lceil \log_2 n \rceil$ features that have the highest scores, where n is the number of independent features for a given data set. The reasons why we select the top $\lceil \log_2 n \rceil$ features include (1) no general guidance has been found in related literature on the number of features that should be selected when using a feature ranking technique; (2) a software engineering expert with more than 20 years experience recommended selecting $\lceil \log_2 n \rceil$ number of metrics for software quality prediction; and (3) a recent study [16] showed that $\lceil \log_2 n \rceil$ is appropriate for various learners. Thus, for the three LLTS data sets, $\lceil \log_2 42 \rceil = 6$; for the nine Eclipse data sets, $\lceil \log_2 208 \rceil = 8$; and for the three NASA KC1 data sets $\lceil \log_2 62 \rceil = 6$.

Following the feature selection algorithm (SVM ranker in this study), the classification models are constructed with data sets containing only the selected features. The defect prediction models are evaluated with respect to the AUC performance metric. We used WEKA for the defect prediction model building and testing process. In the experiments, ten runs of five-fold cross-validation were performed. The ten results from the five folds were then combined to produce a single estimation. In total 18,750 models were evaluated during our experiments.

E. Experimental Results

The classification performance results are reported in Table II and III. Note that each value presented in the table is the average over the ten runs of five-fold cross-validation outcomes. Due to paper size limitations, we could not present each individual ranker's performance. We only present results of no backward elimination with tolerance parameters 1.0E-03 and 1.0E-10, and full backward elimination. All the results of three rankers over 15 different software data sets are reported. We also summarize the average performance (last row of table) for each feature selection technique across 15 data sets. The best model across all data sets is indicated in **boldfaced** print. The results demonstrate that, on average, SVM ranker with no backward elimination and tolerance parameter 1.0E-03 outperformed the other SVM rankers when four classifiers (NB, MLP, SVM, and LR) are applied to the selected subset of features. For the KNN learner, SVM ranker with full backward elimination performed best.

We also performed a two-way ANalysis Of VAriance (ANOVA) F test on the classification performance of learners and SVM rankers for the LLTS data sets and over all 15 data sets separately to statistically examine the various effects on performance of the classification models. Due to size limitation, we didn't present ANOVA results for the Eclipse and KC1 data sets. The underlying assumptions of ANOVA were tested and validated prior to statistical analysis. The two factors were designed as follows. Factor A represents five classifiers and Factor B represents five SVM rankers (no backward with four different tolerance parameters and full backward eliminations). The null hypothesis for the ANOVA test is that all the group population means are the same, while the alternate hypothesis is that at least one pair of means is different.

Table IV shows the ANOVA results. It includes two subtables, and each represents the result for each individual case (three data sets of LLTS and all 15 data sets). All the p-values for Factor A and the p-value for Factor B of the LLTS data sets are less than the typical cutoff value of 0.05, indicating that for the classification performance (in terms of AUC), the alternate hypothesis is accepted, namely, at least two group means are significantly different from each other for at least one pair of groups in the corresponding factors or terms. For Factor B of all 15 data sets, the p-value (0.9795) is much greater than the cutoff value of 0.05, which implies no significant difference exists between the five rankers across all 15 data sets. The p-values for the interaction terms A×B are greater than 0.05, indicating Factor A is the same at every level of B.

We further conducted multiple comparisons for the main factors and interaction term A×B with Tukeys Honestly Significant Difference (HSD) criterion. The multiple comparison results are shown in Figure 1 and 2, where each sub-figure displays graphs with each group mean represented by a symbol (○) and 95% confidence interval around the symbol. Two means are significantly different if their intervals are disjoint, and are not significantly different if their intervals overlap. Matlab was used to perform the ANOVA and multiple comparisons presented in this work. Based on the multiple comparison results, we can conclude the following points:

- For Factor A, LR performed best. This is true regardless of which data sets are used to build classification models. KNN, MLP, and NB produced moderate performance and SVM performed poorly.
- For Factor B, no backward elimination with tolerance parameter 1.0E-03 performed better than full backward elimination .

- For interaction A × B, 25 groups produced by five learners combined with 5 rankers are presented. It can be seen that Factor A was different at every level (groups) of Factor B. For example, LR performed better than other learners when no backward elimination with tolerance parameter 1.0E-03 ranker is used to select features.

F. Threats to Validity

A typical software development project is very human intensive, which can affect many aspects of the development process including software quality and defect occurrence. Consequently, software engineering research that utilizes controlled experiments for evaluating the usefulness of empirical models is not practical. Experimental research commonly includes a discussion of two different types of threats to validity.

In an empirical software engineering effort, threats to external validity are conditions that limit generalization of case study results. The analysis and conclusion presented in this article are based upon the metrics and defect data obtained from 15 data sets of three software projects. The benchmark WEKA data mining tool was used for feature selection (SVM ranker) and all learners, and all of the parameter settings have been included in this work to allow the experiments to be repeated. The parameters for the SVM rankers were chosen to ensure good performance in many different circumstances and to be reasonable for the imbalanced data sets. Experimentation with different settings for the $tolerance Parameter$ provides guidance to the research community as to the recommended value for that parameter. Our comparative analysis can easily be applied to another software system. Moreover, since all our final conclusions are based on ten runs of five-fold cross-validation and statistical tests for significance, our findings are grounded in using sound methods.

Threats to internal validity are unaccounted for influences on the experiments that may affect case study results. Poor fault proneness estimates can be caused by a wide variety of factors, including measurement errors while collecting and recording software metrics, modeling errors due to the unskilled use of software applications, errors in model-selection during the modeling process, and the presence of outliers and noise in the training data set. Measurement errors are inherent to the data collection effort. In our experiments we utilize 15 real-world imbalanced software data sets, which greatly enhances the reliability of our conclusions. Performing numerous repetitions of cross validation greatly reduces the likelihood of anomalous results due to selecting a lucky or unlucky partition of the data. Moreover, the experiments and statistical analysis were performed by only one skilled person in order to keep modeling errors to a minimum.

IV. Related Work

The main goal of feature selection is to select a subset of features that minimizes the prediction errors of classifiers. Feature selection has been applied in many data mining and machine learning applications. A good overview on feature selection was provided by Guyon and Elisseeff [17]. They outlined key approaches used for attribute selection, including feature construction, feature ranking, multivariate feature selection, efficient search methods, and feature validity assessment methods. Liu and Yu [18] provided a comprehensive survey of feature selection algorithms and presented an integrated approach to intelligent feature selection.

In this paper, we examine a feature ranking technique, called SVM ranker. Mladenic et al. [19] investigated three feature weighting methods and conclude that feature selection using weights from linear SVMs yields better classification performance than other feature weighting methods when combined with the three explored learning algorithms including NB, Perceptron, and SVM. Chang and Lin [20] showed that linear SVMs with simple feature rankings are effective on data sets in the Causality Challenge. The goal of Causality Challenge [21] is to investigate problems in which the training and testing sets might have different class distributions.

SVM ranker is used in the bioinformatics domain recently [22], [23]. Canual-Reich et al. [22] compared a feature perturbation method to SVM-RFE, 50% of features were removed at every iteration until 10% of total initial features remain. Results demonstrates that the perturbation method outperformed SVM-RFE for most sets of features. Abeel et al. [23] studied an ensemble feature selection method for biomarker identification. An ensemble of a single feature selection method (SVM-RFE, 20% features were removed at each iteration) was built. Experimental results show that the ensemble

feature selection method improves classification performances and biomarker stability.

We also noticed that although feature selection has been widely applied in many application domains for many years, its applications in the software quality and reliability engineering domain are limited. Chen et al. [24] have studied the applications of wrapper-based feature selection in the context of software cost/effort estimation. They conclude that the reduced data set improved the estimation. Rodriguez et al. [3] evaluated three filter- and three wrapper-based models for software metrics and defect data sets, with the conclusion that wrappers were better than filters but at a high computational cost.

V. Conclusion

This work presented a comprehensive experimental analysis of the performance of linear SVM for feature ranking (SVM ranker) with different $percentToEliminatePerIteration$ and $toleranceParameter$ parameters. Much of the related work on SVM ranker has not focused on selecting reasonable values for the two important parameters, $percentToEliminatePerIteration$ and $toleranceParameter$. In most previous studies, researchers and practitioners simply utilize a particular value for $percentToEliminatePerIteration$ and $toleranceParameter$ without much supporting evidence. Our analysis provides guidelines to researchers and practitioners in data mining and machine learning to select a value of 100 for $percentToEliminatePerIteration$ and 1.0E-03 for $toleranceParameter$ when selecting a subset of features.

In the experiments, we first set $percentToEliminatePerIteration$ to 100 (no backward elimination) and considered four different $toleranceParameter$ values (1.0E-03, 1.0E-05, 1.0E-07, and 1.0E-10). We then set $percentToEliminatePerIteration$ to 0 and using the default value of 1 for $attsToEliminatePerIteration$ (full backward elimination) and $toleranceParameter$ to 1.0E-03. In total, five SVM rankers are considered. Our experimentation on the SVM rankers is done in WEKA using 15 different data sets from three real-world software projects with varying degrees of class imbalance. Classification models were built using five commonly used learners: naïve Bayes (NB), multilayer perceptron (MLP), K-nearest neighbors (KNN), support vector machines (SVM), and logistic regression (LR) with the selected features. These models are used to identify faulty software modules. The conclusions of our experimentation show that the default settings in WEKA for $percentToEliminatePerIteration$ (0) and $toleranceParameter$ (1.0E-10) are not appropriate values, and in particular 100 for $percentToEliminatePerIteration$ and 1.0E-03 for $toleranceParameter$ are more reasonable. This work further shows the robustness of the LR learner when compared to four other learners. Thorough experimentation makes our work extremely comprehensive and dramatically augments the reliability of our conclusions.

Future work may include experiments using additional data sets from the software engineering domain as well as from other application domains. In addition, different data sampling techniques can be considered in the feature selection process of imbalanced data.

***Abstract*—Software quality and reliability can be improved using various techniques during the software development process. One effective method is to utilize software metrics and defect data collected during the software development life cycle and build defect predictors using data mining techniques to estimate the quality of target program modules. Such a strategy allows practitioners to intelligently allocate project resources and focus more on the potentially problematic modules. Effectiveness of a defect predictor is influenced, among other factors, by the quality of input data. Two problems which often arise in the software measurement and defect data are high dimensionality and class imbalance. This paper presents an approach for using feature selection and data sampling together to deal with the problems. Three scenarios are considered: 1) feature selection based on sampled data, and modeling based on original data; 2) feature selection based on sampled data, and modeling based on sampled data; and 3) feature selection based on original data, and modeling based on sampled data. Several software measurement data sets, obtained from the PROMISE repository, are used in the case study. The empirical results demonstrate that classification models built in scenario 1) result in significantly better performance than the models built in the other two scenarios.**

***Index Terms*—software quality classification, high dimensionality, class imbalance, feature selection, data sampling**

I. Introduction

The success or failure of a software project depends on the product's quality and reliability. Software practitioners collect software metrics and fault data during the software development process, and then analyze the data for defect prediction modeling. Typically, a software quality estimation model is trained using software metrics and defect data collected from prior development experiences of the organization, and then the trained model is applied to the project under development. This helps practitioners strategically allocate project resources, for example by assigning more inspection and testing to the potentially problematic modules.

The effectiveness of software quality estimation models is influenced, among other reasons, by two key quality of data factors: (1) the set of software metrics (predictors or independent attributes) used to build the models, and (2) the proportion of minority (i.e., fault-prone) instances in the software measurement data set. Related literature has shown that an overabundance of features (i.e., attributes) exists in various software project data repositories [1], [2]. In addition, studies also show that not all features make equally important contributions to the dependent variable. Selecting a subset of features that are most relevant to the class attribute is necessary and may result in better predictions [3]. In the context of the software quality classification problem (e.g., classifying program modules into fault-prone (*fp*) and not-fault-prone (*nfp*) groups), class imbalance (or skewed data) occurs frequently [4]. The class imbalance problem occurs when, for a given data set, instances (program modules) of one class are clearly outnumbered by the instances of the other class. For software measurement and defect data, the *fp* modules are often much fewer than the *nfp* modules. A classic learner trained on such an imbalanced data set is likely to have a large number of misclassifications of the minority class (e.g., *fp* modules) instances. This is an extremely severe problem in the software quality assurance domain, as the model would lead to missed opportunities to re-inspect and correct a poor quality module prior to system deployment. Data sampling is a proven method for alleviating the problems associated with class imbalance [4].

This study investigates a process that combines feature selection and data sampling to deal with the problems of high dimensionality and class imbalance that exist during software defect prediction. We used nine filter-based feature selection techniques, which come from three different families. Among the nine techniques, three of them are standard feature ranking methods, five of them are threshold-based feature selection techniques we recently proposed [5], and the last one is signal-to-noise, a rarely-used feature ranking method. We used only one data sampling technique, that is random undersampling.

The process of using feature selection and data sampling may lead to several different scenarios depending on whether feature selection takes place before or after data sampling and which data set, sampled or unsampled data, is used to build a classifier. Three scenarios are examined in this study:

- Scenario 0: data sampling takes place **before** feature selection is performed, and then a classifier is built using the features selected and **unsampled** (original) data.
- Scenario 1: data sampling takes place **before** feature selection is performed, and then a classifier is built using the features selected and **sampled** data.
- Scenario 2: data sampling takes place **after** feature selection is performed, and then a classifier is built using the features selected and **sampled** data.

Two more scenarios are also produced, where one technique (feature selection or data sampling) is used alone, However, we ignore these two options in this study, because all software data sets investigated exhibit both the class imbalance and high-dimensionality problems. To our knowledge, this paper is one of the very few studies which have considered both feature selection and data sampling together.

In order to compare the effectiveness of the three approaches (scenarios), we conducted a case study based on nine software measurement and defect data sets obtained from the PROMISE software project repository [6]. The key contributions of this paper are summarized as follows: (1) Using filter-based feature selection techniques combined with sampling to deal with the common problems of software data sets, i.e., high dimensionality and class imbalance. (2) Exploring three approaches (scenarios) when using feature selection and data sampling simultaneously. (3) Employing nine different feature ranking techniques from three different families to make the results easier to generalize.

The remainder of the paper is organized as follows. Section II describes related work. The nine filter-based feature selection techniques and the random undersampling method, as well as the

classifier and the associated performance metric used in this study are presented in Section III. A case study is described in Section IV. Finally, conclusions and future work are summarized in Section V.

II. Related Work

Feature selection, as an effective method for handling high-dimensional data, has been extensively studied for a long time in the data mining and machine learning community. Generally, feature selection is divided into two categories, *wrapper*-based feature selection and *filter*-based feature selection. For wrapper-based techniques, the same classifier or inductive algorithm is used to both select the relevant features and execute the mining process [7]. Therefore, for a given data set, a wrapper-based technique may produce different feature subsets when using different learners. The potential problems of a wrapper-based technique lie in its high computational cost and a risk of overfitting to the model. In contrast, a filter-based technique is learner-independent. Once the data set is given, the filter-based technique will produce a feature subset (or feature subsets) that is (or are) correlated to the dependent attributes irrespective of which learner will be used after. In this study, the nine feature selection techniques used belong to the filter-based category.

Numerous variations of feature selection have been employed in a range of fields [1], [8], [9], [10], [11]. Jong et al. [8] introduced methods for feature selection based on support vector machines (SVM). Ilczuk et al. [9] investigated the importance of attribute selection in judging the qualification of patients for cardiac pacemaker implantation. In the context of text mining, Forman [10] investigated multiple filter-based feature ranking techniques. Rodríguez et al. [1] applied feature subset selection with three filter-based models and two wrapper-based models to five software engineering data sets. Chen et al. [11] have studied feature selection using wrappers in the context of software cost/effort estimation.

Class imbalance, which appears in various domains [12], [13], is another significant problem in data mining. One effective method for alleviating the adverse effect of skewed class distribution is sampling, which will add or remove instances from a data set until it becomes more balanced with respect to its class distribution [14], [15]. In this study, we used random undersampling due to its simplicity and effectiveness [15]. We will leave other sampling techniques as our future work.

While considerable work has been done for feature selection and data sampling separately, limited research can be found on investigating them both together, particularly in the software engineering field. Chen et al. [11] have studied data row pruning (data sampling) and data column pruning (feature selection) in the context of software cost/effort estimation. However, the data sampling in their study was not specific for the class imbalance problem, and unlike this study, the classification models are meant for non-binary problems. Moreover, they focused only on the case in which data sampling is used prior to feature selection.

A recent work of our research team investigated both feature selection and data sampling in the domain of software quality engineering [16]. The paper presented four approaches (scenarios) which include the three scenarios studied in this paper and the scenario where feature selection is used alone. In that paper, six standard filter-based feature ranking techniques were adopted. The conclusion was that data sampling performed prior to feature selection resulted in significantly better performance than data sampling performed after feature selection. The present study is an extension of the earlier work, exploring new ground in three ways: (1) We used nine different feature selection techniques from three different families instead of only six commonly used (standard) filter-based feature ranking techniques, which makes our conclusion more generalized; (2) In addition to considering the different scenarios, this study also looked at the different feature ranking techniques and examined their impact on the classification performance; and (3) The conclusion of this study is different than the previous one, possibly as a result of the aforementioned changes. We try to keep all the experimental settings the same as we did before to ensure effectiveness of the comparisons between the two studies.

III. Methodology

A. Feature Selection Techniques

In this paper, we investigate nine filter-based feature ranking techniques from three different families, including three standard methods, five threshold-based feature selection techniques, and the signal-to-noise approach. Following is an overview of each ranker family.

1) Standard Filter-Based Feature Rankers: Feature ranking assigns a score to each feature according to a particular method (metric), allowing the selection of the best set of features. Due to the space limitation, we only present three filter-based feature ranking techniques [17]: chi-square (CS), information gain (IG), and ReliefF (RF). More details are shown as follows.

i. The chi-square (CS) statistic, denoted as χ^2, is used to examine the distribution of the class as it relates to the values of the target feature. The null hypothesis is that there is no correlation. Given the null hypothesis, the χ^2 statistic measures how far away the actual value is from the expected value:

$$\chi^2 = \sum_{i=1}^{r} \sum_{j=1}^{n_c} \frac{(O_{i,j} - E_{i,j})^2}{E_{i,j}}$$

where r is the number of different values of the feature, n_c is the number of classes ($n_c = 2$ in this work), and $O_{i,j}$ and $E_{i,j}$ are the observed and expected number of instances with value i which are in class j, respectively. The larger the χ^2 statistic, the more likely the feature is relevant to the class.

ii. Information gain (IG) is a measure based on the concept of entropy from information theory [17]. IG is the information provided about the target class attribute Y, given the value of another attribute X. IG measures the decrease of the weighted average impurity of the partitions compared to the impurity of the complete set of data. IG tends to prefer attributes with a larger number of possible values.

iii. Relief is an instance-based feature ranking technique introduced by Kira and Rendell [18]. ReliefF (RF) is an extension of the Relief algorithm that can handle noise and multiclass data sets, and is implemented in the WEKA tool [17].

2) Threshold-Based Feature Rankers: The family of threshold-based feature selection (TBFS) techniques was developed and implemented by our research group within WEKA. A full discussion of this approach (although limited to cover only the AUC performance metric) can be found in [5]. In TBFS, each independent attribute is paired individually with the class attribute, and that two-attribute data set is evaluated using a number of different performance metrics. This feature ranking framework includes normalizing the attribute values (so that they fall between 0 and 1) and treating those values as the posterior probabilities from which to calculate performance metrics. In fact, this allows the use of performance metrics to describe how well the feature correlated with the class. Note that no classifiers were

built during the feature selection process. Five performance metrics used in TBFS are listed below.

i. Mutual Information (MI). Let $c(\mathbf{x})$ denote the actual class of instance $\mathbf{x}$, and let $\hat{c}^t(\mathbf{x})$ denote the predicted class based on the value of the attribute F^j and a given threshold t. Then MI is defined as:

$$\text{MI} = \max_{t\in[0,1]} \sum_{\hat{c}^t\in\{P,N\}} \sum_{c\in\{P,N\}} p(\hat{c}^t, c) \log \frac{p(\hat{c}^t, c)}{p(\hat{c}^t)p(c)}$$

where

$$p(\hat{c}^t = \alpha, c = \beta) = \frac{\mid \{\mathbf{x} \mid (\hat{c}^t(\mathbf{x}) = \alpha) \cap (c(\mathbf{x}) = \beta)\} \mid}{\mid P \mid + \mid N \mid},$$
$$p(\hat{c}^t = \alpha) = \frac{\mid \{\mathbf{x} \mid \hat{c}^t(\mathbf{x}) = \alpha\} \mid}{\mid P \mid + \mid N \mid},$$
$$p(c = \alpha) = \frac{\mid \{\mathbf{x} \mid c(\mathbf{x}) = \alpha\} \mid}{\mid P \mid + \mid N \mid},$$
$$\alpha, \beta \in \{P, N\}.$$

ii. Kolmogorov-Smirnov (KS) statistic measures the maximum difference between the cumulative distribution functions of examples in each class based on the normalized attribute $\widehat{F}^j$.

$$F_P(t) = \frac{\mid \{\mathbf{x} \in D \mid (\hat{F}^j(\mathbf{x}) \leq t) \cap (c(\mathbf{x}) = P)\} \mid}{\mid \{\mathbf{x} \in D \mid c(\mathbf{x}) = P\} \mid},$$
$$F_N(t) = \frac{\mid \{\mathbf{x} \in D \mid (\hat{F}^j(\mathbf{x}) \leq t) \cap (c(\mathbf{x}) = N)\} \mid}{\mid \{\mathbf{x} \in D \mid c(\mathbf{x}) = N\} \mid}.$$

KS is computed as

$$\text{KS} = \max_{t\in[0,1]} |F_P(t) - F_N(t)|.$$

With respect to KS, an attribute provides the best performance at a specific t value when the distance between the two distribution functions is maximized. The larger the KS value, the better the attribute is able to separate the two classes. The range of KS is between 0 and 1.

iii. Deviance (DV). For a given threshold t, define $v(\mathbf{x}) = 1$ if example $\mathbf{x}$ belongs to the positive class, otherwise, $v(\mathbf{x}) = 0$. Then DV is defined as:

$$\text{DV} = \min_{t\in[0,1]} \left[\sum_{\mathbf{x}\in S_t} \left(v(\mathbf{x}) - v(S^t)\right)^2 + \sum_{\mathbf{x}\in \bar{S}_t} \left(v(\mathbf{x}) - v(\bar{S}^t)\right)^2 \right]$$

where $v(S^t) = |S_t|^{-1} \sum_{\mathbf{x}\in S_t} v(\mathbf{x})$. In other words, the equation measures the sum of the squared errors from the mean class given a partitioning of the space based on each possible threshold t. The minimum value is preferred.

iv. Area Under the ROC Curve (AUC). The receiver operating characteristic [19], or ROC, curve graphs true positive rate on the y-axis versus the false positive rate on the x-axis. ROC curves are generated by varying the decision threshold t (between 0 and 1) used to transform the normalized attribute values into a predicted class. AUC is used to provide a single numerical metric for comparing the predictive power of each attribute. The range of AUC is between 0 and 1, and larger value is preferred.

v. Area Under the Precision-Recall Curve (PRC) is a single-value measure that originated from the area of information retrieval. A precision-recall curve is generated by varying the decision threshold t from 0 to 1 and plotting the recall (y-axis) and precision (x-axis) at each point in a similar manner to the ROC curve. The area under the PRC ranges from 0 to 1, and an attribute with more predictive power results in an area under the PRC closer to 1.

3) Signal-to-Noise: Signal to noise (S2N) [20], in the context of the feature ranking problem in data mining, defines how well a feature discriminates two classes in a two class problem. The equation to calculate S2N is

$$\text{S2N} = \frac{(\mu_P - \mu_N)}{\sigma_P + \sigma_N}$$

where μ_P and μ_N are mean values of a particular attribute for the samples from class P and class N, and σ_P and σ_N are standard deviations of this attribute from the sample set for class P and class N. Because of its discriminating power among the classes, S2N is highly efficient to properly order the features in terms of their relation to the output class. But this technique has not been used as often for feature selection.

B. Data Sampling Techniques

A number of data sampling techniques have been studied in the literature, including both majority undersampling and minority oversampling techniques [14], [15]. We consider random undersampling (RUS) as the data sampling technique in this study. Random undersampling is a simple, yet effective, data sampling technique that achieves more balance in a given data set by randomly removing instances from the majority (*nfp*) class. The post-sampling class distribution is a parameter for any data sampling technique. In our study, the post-sampling distribution of the *nfp* and *fp* instances is 65% and 35% respectively. Other settings such as 50:50 were also considered, but those results are not presented due to similarity of conclusions.

C. Classification Performance Metric

The effectiveness of each approach is assessed by evaluating the classification performance of the models subsequently trained and tested with that particular approach. In our experiments, we use AUC as the classification performance metric. Our selection of AUC is based on one of its characteristics, namely its invariance to a priori class probability distributions. AUC does not emphasize one class over the other as may be the case in some other performance metrics, thus it is not biased against the positive (*fp*) class. Given the imbalanced nature of our data sets (see in later section), AUC is an appropriate measure for comparing the classification performance of the learners. In fact, AUC serves as an aid to both feature ranking and final classification evaluation in this study.

D. Classifier

In this study, the software quality prediction models are built with support vector machine (SVM) [21]. This learner was selected because of its common use in the software engineering domain and data mining, and also because it does not have a built-in feature selection capability. SVM, also called SMO in WEKA, had two changes to the default parameters: the `complexity constant c` was set to '5.0' and `build Logistic Models` was set to 'true'. By default, a linear kernel was used.

IV. A Case Study

A. Data Sets

In our experiments, we use publicly available data, namely the Eclipse defect counts and complexity metrics data set obtained from the PROMISE data repository [6]. In particular, we use the metrics and defects data at the software packages level. The original data for the Eclipse packages consists of three releases denoted 2.0, 2.1,

TABLE I
DATA CHARACTERISTICS

Data#	Rel.	thd	#Attr.	#Inst.	#fp	%fp	#nfp	%nfp
1	2.0	10	209	377	23	6.1	354	93.9
2	2.0	5	209	377	52	13.8	325	86.2
3	2.0	3	209	377	101	26.8	276	73.2
4	2.1	5	209	434	34	7.8	400	92.2
5	2.1	4	209	434	50	11.5	384	88.5
6	2.1	2	209	434	125	28.8	309	71.2
7	3.0	10	209	661	41	6.2	620	93.8
8	3.0	5	209	661	98	14.8	563	85.2
9	3.0	3	209	661	157	23.8	504	76.2

and 3.0 respectively. Each release as reported by Zimmermann et al. [22] contains the following information: the name of the package for which the metrics are collected (name), the number of defects reported six months prior to release (pre-release defects), the number of defects reported six months after release (post-release defects), a set of complexity metrics computed for classes or methods and aggregated in terms of average, maximum, and total (complexity metrics), and the abstract syntax tree of the package consisting of the node size, type, and frequency (structure of abstract syntax tree(s)). For our study we transform the original data by: (1) removing all non-numeric attributes, including the package names, and (2) converting the post-release defects attribute to a binary class attribute with fault-prone (*fp*) being the minority class and not-fault-prone (*nfp*), the majority class. Membership in each class is determined by a post-release defects threshold thd, which separates *fp* from *nfp* packages by classifying packages with thd or more post-release defects as *fp* and the remaining as *nfp*. In our study, we use thd = {10, 5, 3} for releases 2.0 and 3.0 while we use thd = {5, 4, 2} for release 2.1. This results in three groups. Each group contains three data sets, one for each release. The reason why a different set of thresholds is chosen for release 2.1 is that we would like to keep similar class distributions for the data sets in the same group. All data sets contain 209 attributes (208 independent attributes and 1 dependent attribute). Table I shows the characteristics of the data sets after transformation for each group. These data sets exhibit different distribution of class skew (i.e., the percentage of *fp* examples).

B. Design

The primary objective of the experiments is to evaluate the effectiveness of feature selection techniques when combined with data sampling. Different scenarios may be produced depending on whether sampling is performed prior to or after feature selection and which data set, sampled or unsampled data, is used to build a classifier. The three different scenarios examined are described as follows:

- **Scenario 0**: Data sampling is performed **before** feature selection and the selected features are applied to the **unsampled** (original) data to form the training data set.
- **Scenario 1**: Data sampling is performed **before** feature selection and the selected features are applied to the **sampled** data to form the training data set.
- **Scenario 2**: Data sampling is performed **after** feature selection and the selected features are applied to the **sampled** data to form the training data set.

C. Results & Analysis

The experiments were performed on the three groups of Eclipse data sets. Nine feature ranking techniques from three different families were used to rank the attributes according to their respective scores. Then, we selected $\lceil \log_2 n \rceil$ attributes that had the highest scores, where n is the number of the independent attributes in the original data set. In this study, $n = 208$, so $\lceil \log_2 n \rceil = 8$. We choose $\lceil \log_2 n \rceil$ attributes because 1) related literature does not provide guidance on the appropriate number of features to select; and 2) one of our recent empirical studies [23] showed that it was appropriate to use $\lceil \log_2 n \rceil$ features when using WEKA to build random forests learners for binary classification in general and imbalanced data sets in particular. Although we used a different learner here, a preliminary study showed that $\lceil \log_2 n \rceil$ is still appropriate for various learners.

After feature selection and data sampling were implemented in the different scenarios, we built SVM models using the training data sets with the selected attributes, and we used AUC to evaluate the performance of the classifications. All results are reported in Table II. In the experiments, ten runs of five-fold cross-validation were performed. The values in the table represent the average AUC for the classification models constructed over the ten runs of five-fold cross-validation. For each data set, the average performance (Avg. column) for each feature selection method across three different scenarios, and the average performance (Avg. row) of each scenario over nine feature selection techniques are also presented. The best feature selection technique (based on their average performance) for each data set is highlighted with ***underline***, and the best scenario (based on their average performance) is highlighted with **bold**. The results demonstrate that the classification models have better performance when using AUC, PRC, IG and MI feature selection techniques and also that scenario 0 shows better performance than the other two scenarios.

We also conducted a two-way ANalysis Of VAriance (ANOVA) F test on the classification performance over the nine data sets to examine whether the performance difference (better/worse) is statistically significant or not. The two factors considered in the test are: Factor A, representing three scenarios, and Factor B, representing nine feature ranking techniques. The null hypothesis for the ANOVA test is that all the group population means are the same and the alternate hypothesis is that at least one pair of means is different. In addition, the interaction between Factor A and Factor B is also taken into account in the test. Table III shows the ANOVA results. The p-value is zero or close to zero for each main factor (Factor A and Factor B). This means that at least two scenarios performed significantly differently from each other and at least two feature selection techniques present significantly different performances. The p-value of the interaction term is greater than the typical cutoff 0.05, meaning that the interaction does not significantly affect classification performance. In other words, changing the value of Factor A will not significantly influence the value of Factor B, and vice versa.

We further carried out a multiple comparison test [24] on each main factor and their interaction with Tukey's honestly significant difference criterion. Figure 1, including three subfigures, shows the multiple comparisons for Factor A, Factor B, and interaction A×B, respectively. The figures display graphs with each group mean represented by a symbol (○) and 95% confidence interval as a line around the symbol. Two means are significantly different if their intervals are disjoint, and are not significantly different if their intervals overlap. Matlab was used to construct the ANOVA models and perform the multiple comparisons presented in this work, and the assumptions for constructing ANOVA models were validated. From these figures, we can see the following points:

- Of the three scenarios, Scenario 0 performs significantly better than the other two scenarios, followed by Scenario 2, then Scenario 1.
- Among the nine feature selection methods, AUC performs

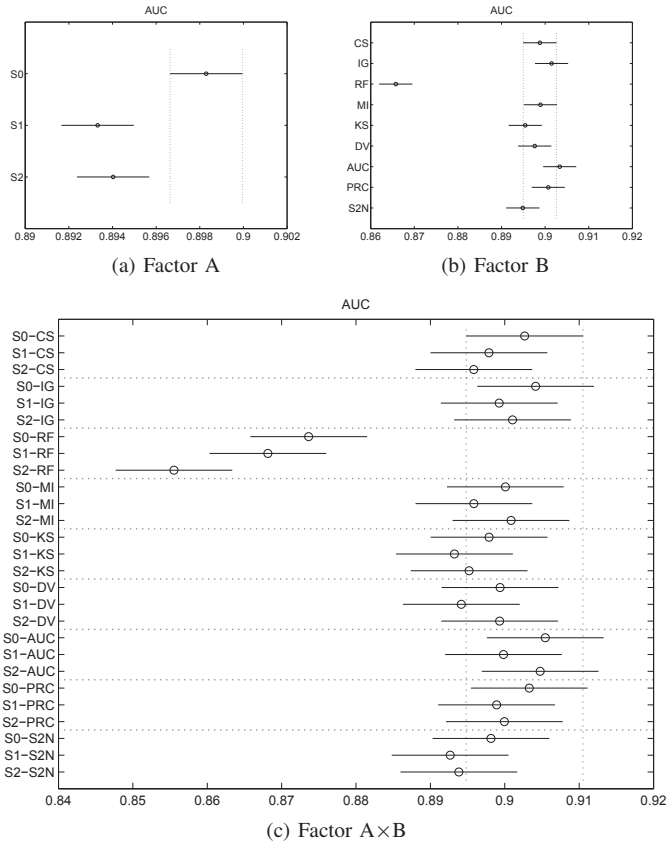
B	0.2794	8	0.0349	43.05	0.0000
A×B	0.0152	16	0.0009	1.17	0.2864
Error	1.9491	2403	0.0008		
Total	2.2553	2429			

best, followed by IG, PRC, MI, CS, and DV, then KS and S2N. RF performs significantly worse than others. The nine techniques ordered in terms of their performance from best to worst are: AUC^A, IG^{AB}, PRC^{AB}, MI^{AB}, CS^{AB}, DV^{AB}, KS^B, S2N^B, RF^C. The methods labeled with the same superscript are from the same performance group, in which no statistically significant difference is found between the methods, while the methods labeled with different superscripts come from different performance groups, in which statistically significant differences are found between the methods.

- There are 27 groups for interaction A×B; these are formed by each of nine feature selection techniques being combined with three scenarios. The group means demonstrate that the classification performance is not heavily influenced by these interactions. Among 27 groups, S0-AUC (classification models built in Scenario 0 and using the AUC feature selection technique) demonstrates better average performance than the other groups over the nine data sets. RF-based groups perform worst.

In addition to the primary experiment discussed above, we also compared defect prediction models built on smaller subsets of attributes to those built with a complete set of attributes (no feature selection or sampling used at all). Table IV shows the classification



(a) Factor A (b) Factor B

(c) Factor A×B

Fig. 1. Multiple Comparisons

TABLE IV
CLASSIFICATION PERFORMANCE OF SVM ON FULL DATA SETS

Data#	AUC	Data#	AUC	Data#	AUC
1	0.8064	4	0.7988	7	0.8030
2	0.8904	5	0.8039	8	0.8897
3	0.8235	6	0.8154	9	0.8673

performances of the SVM learner using the original data with 208 software metrics. Each value presented in the table is the average AUC over the ten runs of five-fold cross-validation outcomes. The results demonstrate that all three strategies (scenarios) perform better or significantly better than the case where no feature selection or sampling is used at all, except for the 9th data set when RF is used.

V. CONCLUSION

In the context of software defect prediction, two key problems often faced by software practitioners are the presence of excessive metrics in training data sets and a relatively small proportion of fault-prone modules to learn from.

In order to overcome the problems, we studied a process using feature selection and data sampling together to modify the training data to improve software defect prediction models. Three scenarios are investigated: (1) feature selection based on sampled data, and training data based on original data; (2) feature selection based on sampled data, and training data based on sampled data; and (3) feature selection based on original data, and training data based on sampled data. The main objective of this paper is to examine and compare all three scenarios and assess their effectiveness in the context of software quality prediction. We used nine different filter-based feature ranking techniques to select the software metrics and random undersampling to deal with class imbalance. The SVM classifier was employed to build classification models. The experiments were performed on nine software measurement data sets obtained from the PROMISE repository. The results show that sampling performed prior to feature selection and training data based on original data resulted in significantly better performance than the other two approaches (scenarios). In addition, among the nine filter-based feature ranking techniques, AUC performed better than other methods. Moreover, all three strategies performed significantly better than the case where no feature selection or sampling is used. The above result is of particular importance to a software quality analyst, since a useful model can be built using only selected software metrics. This provides a less cumbersome and more insightful model for analyzing the software quality trends of the target project, as compared to analyzing the model with respect to a large set of metrics.

Future work will include experiments using data sets from different software projects. Various sampling techniques, learners, and performance metrics will also be examined in future work.

BUGMINER: Software Reliability Analysis Via Data Mining of Bug Reports

Abstract

Software bugs reported by human users and automatic error reporting software are often stored in some bug tracking tools (e.g., Bugzilla and Debbugs). These accumulated bug reports may contain valuable information that could be used to improve the quality of the bug reporting, reduce the quality assurance effort and cost, analyze software reliability, and predict future bug report trend. In this paper, we present BUGMINER*, a tool that is able to derive useful information from historic bug report database using data mining, use these information to do completion check and redundancy check on a new or given bug report, and to estimate the bug report trend using statistical analysis. Our empirical studies of the tool using several real-world bug report repositories show that it is effective, easy to implement, and has relatively high accuracy despite low quality data.*

1 Introduction

Finding and fixing the faults in a software is an indispensable while time-consuming quality assurance task in software development. Our definition of *fault* is a programming error that leads to an erroneous result in some programs during execution. A *software bug* is the common term used to describe a fault, error, flaw, mistake, or failure in a program that produces an incorrect or unexpected result, or causes it to behave in unintended ways. When a software bug is identified, it is often reported and recorded into a bug report database using some bug tracking tools so that further analysis or fix can be performed, possibly by a developer or tester. For some real-world software, their bug report databases have accumulated a large amount of historic bug reports. For example, as of February 2011, Debbugs, *i.e.*, Debian bug tracking system, has accumulated 615,000 bug reports [4, 3].

These accumulated bug reports may contain valuable information that could be used to improve the quality of the bug reporting, reduce the cost of quality assurance, analyze software reliability, and predict future bug report trend. One of the challenges in bug reporting is that the bug reports are often incomplete (*e.g.*, missing data fields such as product version or operating system details). Another challenge is that there are often many duplicate bug reports for the same bug. Software developers or testers normally have to review these redundant bug reports manually, which is time-consuming and cost inefficient.

We developed a tool named BUGMINER that is able to derive useful information from historic bug reports using data mining techniques, including machine learning (*e.g.*, SVM [15, 5]) and natural language processing, and use these information to do completion check through classification and redundancy check through similarity ranking on a new or given bug report. BUGMINER can also perform bug report trend analysis using Weibull distribution [13]. We implemented the tool and experimented it using three real-world bug report repositories including Apache Tomcat [1], Eclipse [7], and Linux Kernel [11]. Our experiments demonstrate that it is effective, easy to implement, and has relatively high accuracy despite low quality data.

The rest of the paper is organized as follows. In the following section, we give background information on bug reporting. In Section 3, we present the details of our approach, followed by our empirical studies in Section 4. Lastly, we compare related work in Section 5, before we conclude in Section 6.

2 Background on Bug Reporting

Bug tracking tools are often developed as a database-driven web application. The web interface allows multiple geographically distributed users to enter the bug reports simultaneously. The backend database stores the records for the reported bugs. Table 1 lists some main attributes (*i.e.*, data fields or columns) of a typical bug report for Apache Tomcat using Bugzilla [1, 2]. These attributes are meta in-

formation of the bug report. The field bug_id is an unique identifier for a distinct bug instance. A bug report is often modified by subsequent reviewers or developers who are trying to verify or fix the bug. Table 2 lists the additional commentary entries related to the same bug listed in Table 1. Each new entry (*i.e.*, new long_desc record) records the author name, entry date and time, and the free text description. The entry date and time for the first and last long_desc record, along with the first author's name, are also stored in the main attributes list of the same bug (*i.e.*, creation_ts, delta_ts, and reporter). There is no predefined limit on how many additional commentary entries a bug report can hold. Bug report datasets will be further explained in Section 4.2.

Table 1. Main attributes of a bug report

Attribute Name	Sample Value	Attribute Name	Sample Value

3 Approach

3.1 Architecture

Figure 1 illustrates the architecture of BUGMINER. There are two types of bug reporters: human users such as software developers, testers, and end users; automatic error reporting processes that run as a service on users' computers. The bug reporters generate new bug reports and enter the related information via the bug tracking tool's interface. The bug tracking tool then store the new bug report into the bug report database.

BUGMINER consists of three data mining and statistical processing engines: automatic completion check engine; automatic redundancy check engine; and bug report trend analysis engine. These three engines process the historic data stored in the bug report database and the new bug report coming in. The results from these engines are then directed to the bug tracking tool so that these results can be reviewed and stored. In the following subsections, we will describe each engine in detail.

3.2 Attributes and Feature Selection

BUGMINER analyzes bug report data based on two sets of attributes: 1) static meta information, and 2) bag-of-words (*i.e.*, a collection of distinct free text words) attributes. For each bug report in Bugzilla, users need to fill in a predefined set of bug information, as shown in Table 1. This set of attributes has two characteristics: 1) static: the list of fields is fixed for all types of software products, and those fields are available for all bug reports; 2) meta information: they describe the general information about the bug report but doesn't go to the details of the problem. Bug report analysis based solely on the static and meta information is very limited. In BUGMINER, we further include the free text data of a bug report in our analysis.

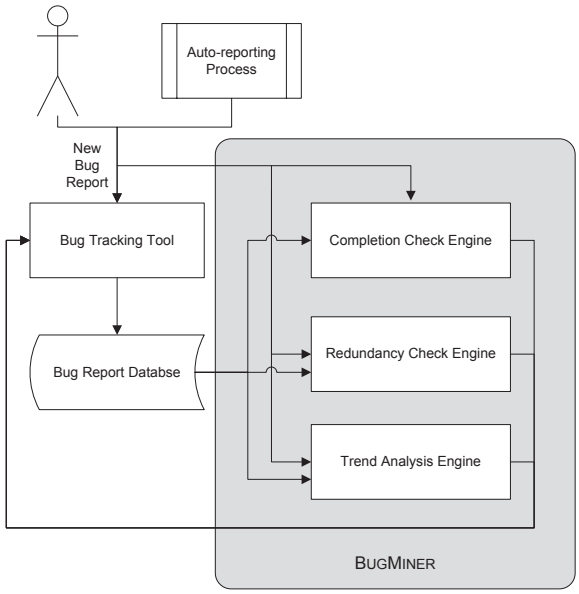

Figure 1. BUGMINER **architecture**

The free text data usually describes a bug scenario in natural language followed by some sample code. We represent the textual data as a bag-of-words. Each data instance is a high dimensional vector with words being attributes. The values of the attributes are Term Frequency-Inverse Document Frequency (TF-IDF) weight [12], which gives a higher weight on words that are frequent in certain data records but not too common across all records. Stemming, a process of reducing inflected (or sometimes derived) words to their stem or root form, is not necessary because the vocabulary usually doesn't have a variety of morphed forms, and imperfect stemming may bring in additional noisy content unnecessarily. Our feature selection also bases on inverse document frequency (IDF) and global term frequency. Words with a low IDF (*e.g.*, stopwords such as 'the' and 'a') are removed because they are too common and lack discriminative power. Words with a very low global term frequency are also removed because they are rare and their inclusion leads to a high dimensionality, which may cause "curse of dimensionality" problem in machine learning.

3.3 Automatic Completion Check Engine

When a bug report is filed, the bug information submitted are sometimes incomplete (*e.g.*, missing data fields). BUGMINER's automatic completion check engine derives these missing data fields through mining historic data and classification using the partially filled information. It reduces manual effort, keeps the bug report complete, and helps developers and testers to analyze the bug report more precisely.

3.3.1 Classification Using Support Vector Machine

Missing field autocompletion can be solved as a supervised learning problem. By training a classification model on existing data, we can predict the missing values. In BUGMINER, we use Support Vector Machines (SVM) as the classifier. SVM is a popular machine learning method because of its high performance. It formulates the classification modeling process as a quadratic minimization problem, and finds hyperplanes in a high dimensional space that separate data instances of different categories, while maximizing the margins between categories.

We first use a set of historic bug reports (*e.g.*, each one with n attributes) as training data to build a linear SVM model. For a new or given bug report with one missing data field a (*i.e.*, $n-1$ attributes filled and 1 attribute missing), we use the trained SVM model as a classifier and the filled $n-1$ attributes to predict the value of the missing a field for this bug report. In the case of multiple data fields are missing for a report (*e.g.*, $n-m$ attributes filled and m attributes missing), we use the SVM model and the $n-m$ filled attributes to predict the missing fields one by one.

3.4 Automatic Redundancy Check Engine

A common way of searching a bug report database to find out whether a new or given bug report already exists or not is to use keyword search, which normally uses keyword in combination with some wildcat characters such as '%' and '?' to construct database query string that can be executed on the database table. This kind of search based on keyword matching is often imprecise and may generate a large amount of useless or irrelevant results. The similarity ranking used by BUGMINER's automatic redundancy check engine is able to tell whether the new bug report is a duplicate or not more precisely. Furthermore, the similarity ranking can find out the most similar prior bug reports and sort them for the user.

3.4.1 Similarity Ranking Using Cosine Similarity

We represent bug report dataset in a vector space model (*i.e.*, term vector model), an algebraic model for representing text documents as vectors of identifiers, such as index terms [14]. Each bug report is a vector that consists of a list of feature values. As described in Section 3.2, BUGMINER uses two sets of features: 1) static meta information; 2) bag-of-words attributes with TF-IDF values.

We measure the similarity between two bug reports based on Cosine similarity, *i.e.*, the Cosine of the angle between the two vectors that represent these two bug reports, as shown in the following formula:

$$Distance_{COS}(a,b) = \frac{\sum_i a_i \times b_i}{\sqrt{\sum_i a_i^2} \times \sqrt{\sum_i b_i^2}},$$

where a and b represent two vectors. Its result equals 1 when the angle between two vectors is 0 (*i.e.*, two vectors are pointing in the same direction), and its result is less than 1 otherwise.

For a new or given bug report, we compute the Cosine similarity value (*i.e.*, csv) between this new bug report's vector and all the prior bug reports' vectors, and then rank the csv values in an descending order. The historic bug report with the highest csv value (*i.e.*, the closest one to 1) is the most similar prior record.

3.4.2 Similarity Ranking Using KL Divergence

In addition to Cosine similarity, we rank all prior bug reports based on their relevance to the new bug report using probability distribution. Kullback-Leibler (*i.e.*, KL) divergence [6, 12] is an effective relevance metric that assumes each data instance in a high dimensional feature space is characterized by a probability distribution. KL divergence measures the dissimilarity between two probability distributions, as shown in the following formular:

$$D_{KL}(a||b) = \sum_{t \in V} P(t|M_a) log \frac{P(t|M_a)}{P(t|M_b)},$$

where M_a and M_b represent the probability distributions for vector a and b respectively. V is the vocabulary of all terms and t is a term in V. KL divergence measures how bad the probability distribution M_a is at modeling M_b. Previous work [19] presents results suggesting that model comparison approach outperforms both query-likelihood and document-likelihood approaches. However, this metric is asymmetric, *i.e.*, $D_{KL}(a||b) \neq D_{KL}(b||a)$. In order to use it as a distance metric, we adopt a symmetrized KL divergence method for similarity ranking, which is defined as:

$$Distance_{KL}(a,b) = \frac{1}{2} D_{KL}(a||b) + \frac{1}{2} D_{KL}(b||a).$$

The result is symmetric and nonnegative. It equals 0 when two distributions are identical. It is bigger than 0 otherwise, and the larger the value the greater their dissimilarity.

For a new or given bug report, we compute the symmetrized KL divergence value (*i.e.*, kld) between this new bug report's vector and all the prior bug reports' vectors,

and then rank the kld values in an ascending order. The historic bug report with the lowest kld value (*i.e.*, the closest one to 0) is the most similar prior record.

3.4.3 Is the New Bug Report a Duplicate? What are the Similar Bugs Reported before?

We categorize a new or given bug report into one of the three categories according to the ranked csv and kdl values, along with the value ranges they fall into:

- If a prior report exists with $csv \geq c\_r_2$ and $kld \leq k\_r_1$, it is highly likely to be a duplicate (or repeat) of a prior report.
- If a prior report exists with $c\_r_1 < csv < c\_r_2$ or $k\_r_1 < kld < k\_r_2$, it has similar prior report.
- If all prior reports have $csv \leq c\_r_1$ and $kld \geq k\_r_2$, it does not have any similar prior report.

The value range parameters (*i.e.*, c_r_1, c_r_2, k_r_1, and k_r_2) can be determined based on heuristics obtained from experiments.

3.5 Bug Report Trend Analysis Engine

After major software releases, the number of software bugs tend to increase initially. As these bugs are fixed, the number of bugs gradually decreases, which resembles the "bathtub curve" in reliability engineering. The increase and descrease of the number of bugs normally lead to the similar trend of the number of bug reports. Weibull distribution can be used to model this kind of pattern and provide the basis for trend analysis.

3.5.1 Report Incidence Distribution

For the Weibull distribution, the incidence (*e.g.*, failure or bug report) density function $f(t)$ and cumulative incidence distribution function $F(t)$ are

$$f(t;\lambda,k) = \frac{k}{\lambda}(\frac{t}{\lambda})^{k-1}e^{-(t/\lambda)^k}, \quad t \geq 0,$$

$$F(t;\lambda,k) = 1 - e^{-(t/\lambda)^k}, \quad t \geq 0,$$

where $k > 0$ is the shape parameter and $\lambda > 0$ is the scale parameter of the distribution. The instantaneous incidence rate (or hazard function) when $t \geq 0$ can be derived as

$$h(t;\lambda,k) = \frac{f(t;\lambda,k)}{1 - F(t;\lambda,k)} = \frac{k}{\lambda}\left(\frac{t}{\lambda}\right)^{k-1}.$$

A value of $k < 1$ indicates that the incidence rate decreases over time. A value of $k = 1$ indicates that the incidence rate is constant (*i.e.*, k/λ) over time. In this case, the Weibull distribution becomes an exponential distribution. A value of $k > 1$ indicates that the incidence rate increases with time.

3.5.2 Estimation of Coming Bug Report

We first use historic data to fit the Weibull function and derive the λ and k parameters. Then for any given time t, which is the number of weeks (or other chosen time units such as days or hours) after the starting date, the number of bug reports that may happen during that week can be estimated using the Weibull's density function $f(t)$. The result is an estimate of how many bug reports may happen during the t-th week after the starting event, *e.g.*, a new software release. Similarily, the instantaneous incidence rate can be estimated using the hazard function $h(t)$. These estimates give software developers or testers a baseline for designing the software testing and maintenance plan.

4 Empirical Studies

4.1 Implementation

We implemented BUGMINER in Java using some existing machine learning and statistical analysis tools, including Weka [17] and MATLAB [9].

4.2 Bug Report Datasets and Data Processing

We experiment BUGMINER on the bug report repositories of three real-world software (Apache Tomcat [1], Eclipse [7], and Linux Kernel [11]). Table 3 lists some statistics of these bug report repositories. For example, the Apache Tomcat dataset contains two product versions—Tomcat 3 and Tomcat 7. The OS is the operating system the software runs on. The components are the functional components of the software.

Table 3. Software and bug report datasets

Software Name	# bug reports	# product	# OS	# components
Apache Tomcat	1525	2	16	16
Eclipse	1674	2	17	13
Linux Kernel	1692	16	1	106

We first apply pattern matching to extract static meta information, as listed in Table 1. Then we process free text descriptions using tokenization and bag-of-words feature selection as described in section 3.2. The dimensionalities of the term feature space range from 4000 to 13,000 depending on the dataset. After the attribute data sources are combined, the final vector space to represent bug report instances includes static meta information and bag-of-words features.

4.3 Results and Analysis

Our experimental results show that BUGMINER is effective in automatic completion check, automatic redundancy check, and bug report trend analysis. The following subsections present the detailed results and analysis.

4.3.1 Classification for Missing Field Autocompletion

For missing field autocompletion, we train classification model on 80% of the data and do blind-test on the remaining 20% of the data. For example, for Apache Tomcat, we use 1220 (or 80%) bug reports as training data and use 305 (or 20%) bug reports as the testing data. Table 4 lists the classification results for the Tomcat version. The accuracy of the classfication on testing instances is 99.02%. This means the product version in this case can be determined by the automatic completion check engine highly accurately.

Table 4. Classification results of products

TP Rate	FP Rate	Precision	Recall	F-Measure	ROC Area	Class
0.991	0.014	0.996	0.991	0.993	0.989	tomcat 3
0.986	0.009	0.973	0.986	0.98	0.989	tomcat 7
0.99	0.012	0.99	0.99	0.99	0.989	Weighted Avg.

Table 5 lists the classification results for the operating system version for Tomcat. The accuracy of the classification on testing instances is 68.52%.

Table 5. Classification results of OS versions

TP Rate	FP Rate	Precision	Recall	F-Measure	ROC Area	Class
0.888	0.449	0.758	0.888	0.818	0.719	all
0.356	0.081	0.432	0.356	0.39	0.637	linux
0.087	0.018	0.286	0.087	0.133	0.535	other
0.176	0.014	0.429	0.176	0.25	0.581	solaris
0.786	0.047	0.629	0.786	0.698	0.869	windows xp
0.685	0.294	0.632	0.685	0.647	0.696	Weighted Avg.

Table 6 lists the classification results for the software component related to the bug report. The accuracy of the classfication on testing instances is 53.11%. The results show that it is relatively difficult to accurately determine the problematic component based on the bug reports in this case.

Table 6. Classification results of components

TP Rate	FP Rate	Precision	Recall	F-Measure	ROC Area	Class
0.5	0.007	0.714	0.5	0.588	0.747	auth
0.868	0.067	0.73	0.868	0.793	0.9	catalina
0.2	0.039	0.313	0.2	0.244	0.58	config
0.368	0.037	0.583	0.368	0.452	0.665	connectors
0.5	0.003	0.5	0.5	0.5	0.748	encoding
0.622	0.041	0.676	0.622	0.648	0.79	jasper
0.667	0.003	0.667	0.667	0.667	0.832	manager
0.6	0.154	0.513	0.6	0.553	0.723	servlet
0.1	0.007	0.333	0.1	0.154	0.547	webapps
0.531	0.091	0.535	0.531	0.518	0.72	Weighted Avg.

We also did some experiments on the bug report datasets of Eclipse and Linux Kernel. Table 7 shows the summary of classification accuracy rates for the datasets tested. As the number of classes increases, the accuracy rate tends to decrease; nevertheless, the accuracy rates (*e.g.*, 53.11% for Tomcat's components) are relatively high if they are compared to the chance baseline (*i.e.*, probability is $1/n$ if there are n possible components).

4.3.2 Similarity Ranking

We first transform the historic training bug reports and the testing bug report to vectors using the vector space model.

Table 7. Summary of classification accuracy

Software Name	product	OS	components
Apache Tomcat	99.02%	68.52%	53.11%
Eclipse	97.90%	66.47%	67.37%
Linux Kernel	76.33%	N/A	58.88%

After the csv and kld value for each training bug report are calculated, all the training bug reports are then sorted in an descending order based on the csv value and in an ascending order based on the kld value. The bug reports at the top of the ranked lists are the most similar ones to the testing bug report.

Based on the heuristics from the experiments, we determine the value range parameters as $c\_r_1 = 0.2, c\_r_2 = 0.9, k\_r_1 = 2.0$, and $k\_r_2 = 10.0$ for Tomcat. Table 8 lists some sample results for a given bug report #393. From the results, the bug report #393 is highly likely to be a duplicate of some prior reports because there exists historic bug reports with $csv \geq 0.9$ and $kld \leq 2.0$ (*i.e.*, bug report #330 and #296). Furthermore, bug report #228 is likely to be a similar bug report of #393 because it has $0.7 < csv < 0.9$ or $2.0 < kld < 10.0$. To determine whether a new or given bug report is in fact a duplicate usually requires human judgement. Our manual verification shows that the similarity ranking results produced by BUGMINER are highly accurate despite the low quality data.

Table 8. Similarity ranking results

bug_id	csv	kld
330	0.928	1.940
296	0.917	0.816
228	0.717	9.868

4.3.3 Trend Analysis

We implement the bug report trend analysis based on the Weibull distribution. We first aggregate the historic data to compute a vector of the time (i-th week) and the number of bug reports whose first reporting date falls in the i-th week. Then a result vector returns the 95% confidence intervals for the estimates of the parameters of the Weibull distribution given the historic vector data. The two-element row vector estimates the Weibull parameter λ and k. The first row of the 2-by-2 matrix contains the lower bounds of the confidence intervals for the parameters, and the second row contains the upper bounds of the confidence intervals.

Table 9 shows the estimates of the Weibull parameters for Apache Tomcat 3. The value of k is less than 1, which indicates that the incidence rate decreases over time. The related curve fit is illustrated in Figure 2. The starting time, (*i.e.*, the 0 on the x-axis) is the week of August 25, 2000. The curve fit shows that the Weibull distribution closely resembles the actual bug report incidence distribution.

Table 9. Weibull parameter estimates

Software	λ	λ_{low}	λ_{high}	k	k_{low}	k_{high}
Tomcat 3	0.3885	0.2280	0.6621	0.2241	0.2041	0.2461

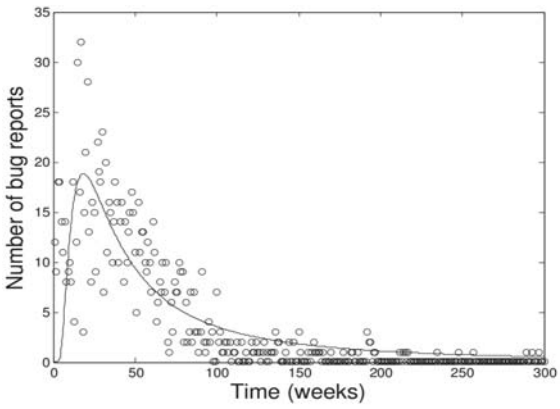

Figure 2. Weibull fit for Tomcat 3

5 Related Work

Some prior studies have been done on applying data mining on software engineering. [10] described the concept of software intelligence and the future of mining software engineering data. [18] presented a general overview of data mining for software engineering and described an example of duplicate bug detection using vector space-based similarity. [16] also described an approach to detect duplicate bug reports using both natural language and execution information. Our redundancy check engine uses both probability distribution-based KL divergence and vector space-based Cosine similarity ranking, instead of only vector space-based similarity. Furthermore, our approach provides a similarity ranking list that can be used for search, instead of only Yes and No on duplication check. [8] presented text mining of bug reports to identify security issues. Their work aims to identify security problems such as buffer overlow through mining the bug reports. Their purpose and techniques are different from our approach.

6 Conclusion

In this paper, we presented BUGMINER, a tool that is able to derive useful information from historic bug report database via data mining, use these information to do completion check and redundancy check on a new or given bug report, and to estimate the bug report trend using statistical analysis. We did empirical studies of the tool using several real-world bug report repositories. The experimental results show that BUGMINER is effective, easy to implement, and has relatively high accuracy despite low quality data. BUGMINER can be integrated into some existing bug tracking tools or software testing suites for more intelligent and cost-efficient software reliability analysis.

***Abstract*—Most applications need to invoke some Application Programming Interfaces (APIs), e.g. JDK (Java Development Kit) API. When invoking those APIs, applications must follow some API constraints. Violation of these constraints will lead to some severe program defects. To detect this kind of defects, lots of static and dynamic approaches are explored, using formally described API constraints. While most existing approaches explore API constraints on a single object, this paper focuses on API constraints on interacting objects (COIOs). We proposed a novel specification language LACOIO (Language for API Constraint on Interacting Objects) which can cover all state-of-the-art reported API COIOs. We implemented a LACOIO compiler which can automatically generate monitoring code for runtime verification from API constraints that are specified using LACOIO and implemented the runtime verification framework. We evaluated the proposed approach by comparing it with Tracematch – a popular constraint specification language.**

Keywords- Runtime verification; runtime monitoring; specification; program analysis.

I. INTRODUCTION

Most applications need to invoke some Application Programming Interfaces (APIs), e.g. JDK (Java Development Kit) API. When invoking APIs, applications must follow some API constraints. For example, one constraint related to JDK is: "*instance of java.io.InputStream must be closed explicitly*". Violation of these constraints will lead to some severe program defects. To detect this kind of defects, lots of static and dynamic approaches are explored [9, 12]. For both kinds of approaches, formally described constraints are widely used in the detecting process. Static analysis tools can read these formally described constraints and check the code automatically, while dynamic verification frameworks can use these constraints to generate monitors automatically to verify applications at runtime. Finite state automaton (FSA), temporal logic, and regular expression are typical formal methods used to describe API constraints [3, 5, 8].

While most existing approaches explore API constraints on a single object [7, 8, 11], some studies explore API constraints on multiple interacting objects (COIOs) [2, 10]. For example, one constraint related to JDK (we call it SafeIterator Constraint) is: "*an array list of java.util.ArrayList cannot be updated when it is being traversed by an iterator of java.util.Iterator"*. Fig. 1 shows the FSA-based expression for this constraint [3].

However, the event symbols in this FSA reveal only the event names without information about which objects these events belong to. Actually, this FSA makes some implicit assumptions: event CREATE_LIST occurs on a java.util.ArrayList object *al*; event CREATE_ITERATOR occurs on the java.util.Iterator object *i* which is created by *al*; all UPDATE events belong to the same object *al*; and all NEXT events belong to the same object *i*.

When an API constraint involves a group of objects like this, it is very difficult to distinguish which object an event is associated with. Some approaches [1, 5] add free variables to events (symbols in the FSA) to address this problem. These approaches use a variable binding strategy to associate objects with events. In Fig. 2, two free variables *al* and *i* are introduced as well as two operators "=" and ".". Edge "*al*= CREATE_LIST" indicates that the returned object of the operation which is matched to the event CREATE_LIST is bound to object *al*. Edge "*al*.UPDATE" matches the updating operations which happen on object *al*. Other edges can be explained similarly. Specification in Fig. 2 has two benefits. First, it points out which object an event is associated with; secondly, it points out how objects *al* and *i* are bound together, i.e., *i* is the Iterator object that is created by *al*.

However, for constraints on interacting objects whose number is not stable, it is still very difficult to describe them formally, even with existing free-variable-based approaches (See section II for details). Moreover, the approach of formal specification has great impact on the implementation of corresponding verification framework. In this paper, we proposed a novel specification language LACOIO (Language for API Constraint on Interacting Objects) to describe API constraints. The proposed language is powerful enough to describe state-of-the-art reported API COIOs easily and leads to efficient runtime verification.

The rest of the paper is organized as follow: In Section II we present a COIO example to introduce our motivation and give a brief introduction to COIO specification problem. In Section III we present the proposed specification language LACOIO. In Section IV we introduce the implementation of LACOIO compiler and the runtime verification framework. Section V is the evaluation of our work. Section VI is the introduction of related work. We conclude our paper in Section VII.

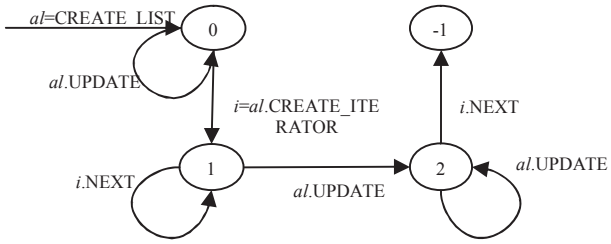

Figure 2. Extended FSA for constraint on ArrayList and Iterator

```
20 DB db = new DB();
21 Connection conn=db.dbConnect(
22              "jdbc:mysql://…", "root", "");
23 Statement stmt = conn.createStatement();
24 ResultSet rs1 = stmt.executeQuery(…);
25 ResultSet rs2 = stmt.executeQuery(…);
26 // rs1 is unavailable after rs2 is created.
27 while (rs1.next())// Constraint is violated!
28 {…}
```
Figure 3. Sample codes that violate SafeJDBC constraint.

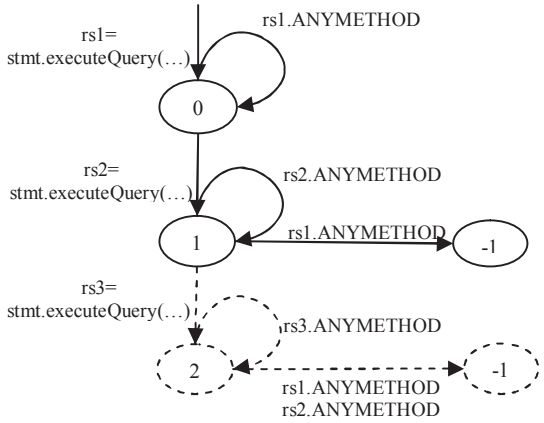

Figure 4. An example which tries to use FSA with free variables to specify SafeJDBC.

II. PROBLEM STATEMENT

To clarify the complexity of API COIO verification, we present another motivating example. The constraint is about JDBC (we call it SafeJDBC Constraint): "*if two java.sql.ResultSet objects (e.g. rs1 and rs2) are created by the same java.sql.Statement object (e.g. stmt) through Statement.executeQuery(...) method, the first ResultSet rs1 becomes unavailable after rs2 is created*" [4]. In other words, we cannot access *rs1* through any of its methods after *rs2* is created. Fig. 3 is a piece of sample code that violates SafeJDBC. SafeJDBC involves at least 3 objects, *stmt* of class Statement, the *rs1* and *rs2* of class ResultSet. Now we try to describe it by FSA which introduces free variables similarly as Fig. 2. In Fig. 4, the real line elements describe the violation pattern involving three objects: *stmt*, *rs1*, *rs2*. "-1" in the FSA stands for the state when a violation is detected. Usually, at runtime, such an FSA instance will be created to verify behavior of the three objects.

However, the problem is: what if a third instance of ResultSet *rs3* is created? Even if we can extend the FSA to describe the violation pattern when *rs3* is involved (see the dotted line elements in Fig. 4), what if more instances of ResultSet are created?

There are two facts that make it problematic to describe the constraint by FSA, even with introduction of free variables. (1) The verification must be carried out on instance-level (not the class-level). Although this type of constraint involves finite classes, the number of involved objects is undetermined. It is impossible to enumerate all runtime instances in an FSA. (2)The other characteristic of such kind of constraints is that, whether behavior of one object will lead to violation of the constraint depends on behavior of another object of the same class. This situation prevents us from describing the behavior of such two objects in two separate FSAs.

A. Problem-related Terminologies

Before introducing the details of COIO specification problem, we first explain some relevant terminologies.

Monitor. A monitor is an instance for a constraint. It inspects and verifies the behavior of a set of interacting objects. In Fig. 4 the monitor is an FSA instance which is created to verify the behavior of *stmt, rs1, rs2, rs3*.

Monitee. At runtime if an object is involved in the verification and will be monitored, we call it a *monitee*. In Figure 4, object *stmt, rs1, rs2, rs3* are monitees.

Monitee set. All monitees that are verified in one monitor constitute the monitee set of the monitor. In Fig. 4 the monitee set is {*stmt, rs1, rs2, rs3*}. The monitee set of a monitor can be divided into several subsets according to the monitees' types. The monitees of a certain class C constitute the monitee set of C. For example, there is a monitee set {*rs1, rs2, rs3*} of ResultSet.

Binding point. Assume C1, C2 are two classes, C1 has a method *m* whose signature involves C2, we call *m* a *binding point* for C1 and C2, e.g., method `ResultSet Statement.executeQuery(String str)` is a binding point for Statement and ResultSet.

Binding relationship. Assume *m* is a binding point for C1 and C2. At runtime when *o1* and *o2* are objects of C1 and C2 respectively and *m* is executed on *o1,* we call *o1* and *o2* are bound (by *m*) or *o2* is bound to *o1* (by *m*), written *o1 BP o2*. For example, when "`rs2 = stmt.executeQuery(…)`" is executed, *stmt* and *rs2* are bound by method "`ResultSet Statement.executeQuery(String str)`", written *stmt BP rs2*.

B. Problem of Specification

In this paper we restrict our focus on COIO whose monitee set is defined as $\{k\} \cup \{ i \mid k\ BP\ i \}$, where *k* is an instance of a

class C. *k* is called the **core object** in the monitor while C is called the **core class** of the COIO. We reviewed state-of-the-art literatures and found even with this restriction the proposed approach can cover all state-of-the-art API constraints.

From the definitions of monitee set of COIO monitor, we know that there is always one core object in the monitee set of each COIO monitor and all the other objects are involved by binding relationship. This indicates a one-to-many mapping between the object of core class and objects of other involved classes in COIO. Constraint SafeJDBC is such a COIO: *stmt* is the core object in its monitee set and all the ResultSet typed objects that are created by *stmt* are involved in the same monitor by binding point "`ResultSet Statement.executeQuery (String str)`". Fig. 5 illustrates the monitee set, its monitees, and related objects.

The key challenge for traditional FSA monitor is that its monitee set must be a fixed set. That means, for FSA, we must present each possible object of the monitee set in FSA description, which is impossible in the aforementioned case before runtime because the number of objects in the monitee set is undetermined. For example, in Fig. 4, we must include all the objects *stmt, rs1, rs2, rs3* to describe the constraint. It is likely that more ResultSet objects are created in the near future. So the FSA-based approach can't describe such undetermined cases.

III. Language for API Constraint on Interacting Objects

LACOIO can describe complex COIOs in a succinct way and make specifications easy to understand. Complete grammar and more examples can be found in [13]. In this section, we explain the LACOIO specification with the example of SafeJDBC constraint (see Fig. 6).

A. Monitor:

A monitor is defined with the key word **monitor**. At runtime a monitor instance represents an instance of COIO verification case.

B. Monitee set management and binding:

The monitee set is defined with key word **monitee**, contains the objects that are involved in a monitor instance. The monitor usually contains two kinds of monitee sets: monitee set for core class which contains only one core object and monitee sets for other classes. In our specification, we do not distinguish these two kinds of monitee sets. Monitee sets are maintained dynamically at runtime and do not need to be determined before runtime. In the example, two monitee sets @stmt and @rs are specified respectively for class Statement and ResultSet. At runtime each SafeJDBC monitor maintains such two sets. Since Statement is the core class for SafeJDBC, there is only one object of Statement in @stmt which is the core object. Whenever a ResultSet object is obtained by the binding point "`ResultSet Statement. executeQuery(…)`", the returned ResultSet object is bound to the core object and thus put into @rs.

C. User-defined variable :

We allow users to define their own variables with keyword **var** to store historical states that can be acquired in the future, e.g. a reference to certain monitee in the monitee set, a status tag, etc. In Fig. 6, "**`var`** `ResultSet $last`" defines a variable called $last of type ResultSet. It is used to store the reference to the most recently created ResultSet object.

D. Event

When a method is invoked on a monitee, it will be mapped to the corresponding event that is specified in the constraint according to particular mapping rules. It is similar with the process of mapping method calls to edges in an FSA. An event declaration consists of event type, event name, contract part, pre/post-condition, revise part, and action.

The contract part. The contract part specifies the rules that how method invocations should be mapped to events. For example, in Fig. 6, the contract part "`@stmt.executeQuery (String)`" of event `STQUERY` states that invocation to "`executeQuery(…)`" methods on the object which is in the *@stmt* set should be mapped to the `STQUERY` event.

Pre/Post-condition. Pre/Post-conditions are defined for every event in the constraint, which are identified by "`[ ]`" before/after a contract part. They are part of the mapping rules. Only when pre/post-conditions are both *true* can a method invocation be matched to an event successfully. They are boolean expressions on *$target*, *$args[n]*, *$return* and the user-defined variables. *$target, $args[n],* and *$return* are reserved keyword that are used to refer to the target object, the *n*th argument, and the return value of a method call, respectively. The pre/post-conditions are checked before/after the invocation of the method which is specified in an event declaration. When

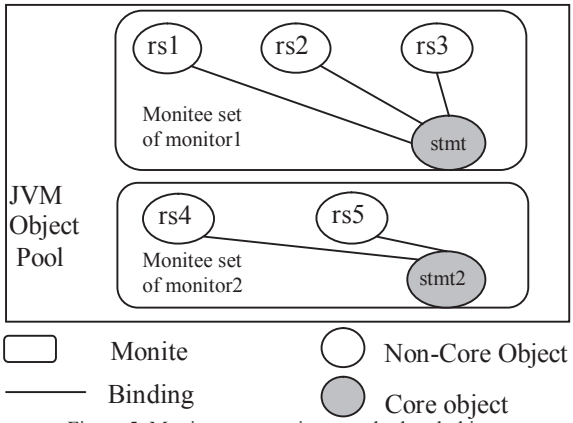

Figure 5. Monitee set, monitees, and related objects.

```
1 monitor SafeJDBC {
2 monitee @stmt< Statement>, @rs<ResultSet>;
3       var ResultSet $last = null;
4       init Connection.createStatement()
5               (@stmt.add($return))
6               { /* empty action */}
7       event STQUERY
8               @stmt.executeQuery(String)
9               (@rs.add($return))
10              { $last = $return;  }
11      validate RSNEXT
12              [$last!=$target]
13              @rs.next()
14              { System.out.println("Error");  }
15 }
```

Figure 6. Specification of constraint SafeJDBC

pre/post-conditions are both *true*, we say that an event match happens. For example, when "`next()`" is invocated on a ResultSet object *rs1*, the monitor will try to map the invocation to *RSNEXT* according to the contract part of event *RSNEXT*. The pre-condition "`$last!=$target`" of *RSNEXT* will be checked to determine whether the accessed ResultRet *rs1* is not the most recently created one. If the condition is satisfied, event `RSNEXT` will be matched.

Revise part. Revise part states how the monitee sets should be maintained when an event match happens. There are four types of operations for the monitee set: add, remove, assign and clear. For example, when `STQUERY` event match happens, the revise part "`@rs.add($return)`" states that the returned ResultSet object should be added into monitee set *@rs*.

Action. Action includes operations to the monitees, user-defined variables, *$target/$return/$args[n]*, and also some simple java statements. The action part is executed only when the event match happens. For example, when event `STQUERY` is matched, operation "`$last = @return`" will be executed.

There are two special types of events: `init` and `validate` event. An `init` event (denoted by keyword **init**) represents the start of the verification, and it is also the point of construction of the core object. When an `init` event match happens, a monitor is instantiated, thus there must be only one `init` event. In SafeJDBC specification, the contract part "`Connection.createStatement()`" of the `init` event states that invocations of "`createStatement()`" method on all Connection objects should be mapped to the `init` event. When a `validate` event (denoted by keyword **validate**) match happens, a violation is detected. In the action part of `validate` event, users can perform some actions to handle constraint violations. For example, in the SafeJDBC specification example, when "`next(…)`" is invoked on one of the ResultSet monitees and ResultSet object referred by *$target* does not equal *$last*, `validate` event `RSNEXT` is matched and constraint violation is reported.

IV. THE IMPLEMENTATION

The specification file will be compiled to monitoring codes. The compiler takes LACOIO specification as input and compiles it into two parts. (1) One is an AspectJ [6] file which acts as a middle representation file. In general, the responsibility of the AspectJ file is to declare probes that map method invocations to events and transfer messages at runtime. Pointcuts will be generated according to event contract declarations. The codes in an advice will be generated to transfer the method invocation messages to corresponding envoy. (2) The other part is classes that contain the actual verification logic codes which include classes of envoys and monitors. AspectJ file is subsequently weaved to the original byte code file of the target system and an instrumented class file is produced. The instrumented class and the verification logic classes will be deployed to JVM.

The structure of the runtime verification framework is shown in Fig. 7. JVM objects pool is presented in the left side in which there are objects of verification concern. The squares

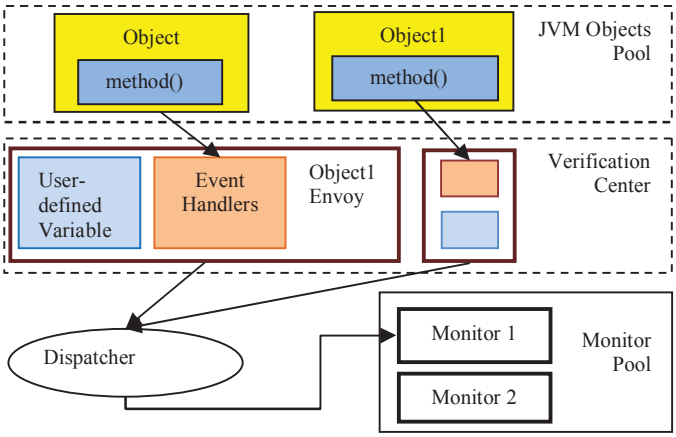

Figure 7. Runtime verification framework for COIO

in the objects represent methods that have been instrumented with probes. The probes send messages to the corresponding objects. The handler of the envoy will process the messages sent from the probes. And if necessary, the envoy will pass the message to the monitor for further processing.

V. EVALUATION

A. Expression Ability

We compare the ability of expression of LACOIO with that of Tracematch[1]. Tracematch is a prevalent language that can also describe some constraints on multiple interacting objects by introducing free variables. The basic logic that LACOIO and Ttracematch use is equivalent to FSA. They introduce different extended features which make them more powerful than FSA. Moreover, LACOIO makes the specification of constraints which involve multiple objects more succinct and understandable by allowing explicit monitee set declaration, flexible user-variable definition and pre/post-conditions.

We present another example SafeDropDownList to illustrate the advantages that LACOIO brings. SafeDropDownList is originally a constraint on the usage of DropDownList and ListItem in ASP.NET framework, which was first proposed in [2]. We simulate two similar interfaces of DropDownList and ListItem in Java (see Fig. 8). A DropDownList *list* may contain several ListItem *i1, i2*... The ListItem *i1, i2*… can be obtained by calling method "`findItemByName(String)`" on *list*. A ListItem is set to "selected" or "deselected" by calling the mehod "`setSelected(boolean isSlected)`" on it.

```
public interface DropDownList
{ ListItem findItemByName(String item_name);… }
public interface ListItem
{ void setSelected(boolean isSlected);… }
```

Figure 8. Stimulated DropDownList and ListItem in Java

```
5  DropDownList list = new DropDownList();
       ……
10 ListItem i1=list.findItemByName(ITEM_NAME_1);
11 ListItem i2=list.findItemByName(ITEM_NAME_2);
     ……
21 i1.setSelected(true);
22 //Forget to call: i1.setSelected(false);
23 i2.setSelected(true); //Constraint Violated!
```

Figure 9. Sample codes that violate SafeDropDownList.

```
1 monitor SafeDropDownList{
2 monitee @list<DropDownList>,@items<ListItem>;
3 var ListItem $selected = null;
4
5   init DropDownList.new()
6        (@list.add($return))
7        { /* empty action */}
8   event FIND_ITEM
9        @list.findItemByName(String)
10       (@items.add($return))
11       { /* empty action */}
12  event SELECT
13       [args[0]==true && $selected== null]
14       @items.setSelected(boolean)
15       {   $selected= @target;      }
16  validate SELECT_FALSE
17   [args[0]==true && $selected!= null]
18   @items.setSelected(boolean)
19   {System.out.println("Error Reported"); }
20  event DESELECT
21   [args[0]==false && $selected==$target]
22   @items.setSelected(boolean)
23   {  $selected = null;      }
24}
```

Figure 10. SafeDropDownList Specification in LACOIO

```
tracematch(DropDownList l, ListItem i1, ListItem i2) {
sym get1 after returning(i1) :
      call(* DropDownList.findItemByName(..)) && target(l);
sym get2 after returning(i2) :
      call(* DropDownList.findItemByName(..)) && target(l);
sym select after : target(i1) && private(boolean b) (
  call(void ListItem.setSelected(boolean) && args(b) && if(b)));
sym deselect after : target(i1) && private(boolean b) (
  call(void ListItem.setSelected(boolean) && args(b) && if(!b)));
sym select2 after : target(i1) && private(boolean b) (
  call(void ListItem.setSelected(boolean) && args(b) && if(b)));
distinct i1, i2;
  (get1 get2 (get1|get2)* select (get1|get2|select)* select2) |
  (get1 select (get1|select)* get2 (get1|get2|select)* select2)
  { error("Selecting " + i2 + " without deselecting " + i1);}
}
```

Figure 11. SafeDropDownList Specification in Tracematch

SafeDropDownList states that: "multiple ListItems in a DropDownList cannot be set to 'selected' at the same time". In other words, before trying to select a ListItem by calling `setSelected(true)` on it, one must first call `setSelected(false)` on the previously selected ListItem. Fig. 9 is a piece of sample code that violates this constraint.

Fig. 10 and 11 are constraint specifications written in LACOIO and Tracematch respectively. Both specifications define the same number of events (or symbols in Tracematch). But in Tracematch users are required to write a quite verbose regular expression. In LACOIO, we allow user to define a simple variable "*$selected*" to store the current selected ListItem. So with our approach we only need to check whether *$selected* is *null* when a second ListItem is about to be selected. However, with Tracematch, a pattern of events must be expressed in a temporal manner as regular expression, which is actually not necessary for verification. For example, the information of the temporal order of "select", "get1" and "get2" is not necessary for identifying a violation. All that is necessary to know is that the three events did happen before "selected2" happens.

Although LACOIO does not express the logic formula explicitly, by introducing user-defined variable properly it can express all the constraints that can be expressed by FSM and regular expression. Our motivation to hide the logic formula is that we find many state-of-the-art constraints are not pure temporal problem and can be expressed by our language more straightforwardly. (See [13] for more specification examples).

B. *Performance*

In this sub-section, we illustrate the performance improvement that our language design brings to the verification of some typical type of complex COIOs like SafeDropDownList (mentioned in section V.A) which involve interacting objects of the same class. To evidence this point, we verify a Java application which manipulates one DropDownList and multiple ListItems with respect to the SafeDropDownList constraint. The experiments are conducted on a PC equipped with Intel Pentium IV 3.0G Hz processor, a 2GB RAM, and a single 300GB 7200 RPM SATA disk. The operation system is Ubuntu 9.10. JDK version is 6.0.

Fig. 12 shows the execution time when Tracematch and our approach are applied. We run the application multiple times. X-axis shows the total number of ListItems that are created in a particular round of execution. Y-axis shows the time cost for the execution. As we expect, as the number of ListItems increases, the execution time increases for both Tracematch and our approach. But the increasing rate for Tracematch is approximately 7.4 times as that for our approach.

The main reason for this result is that, in LACOIO, monitee sets are declared explicitly and maintained at runtime. Since the DropDownList object is the core object of the monitor, the behavior of all ListItems that belong to the same DropDownList will be verified in one monitor instance. Compared to LACOIO monitor, the Tracematch monitor specified in Fig. 11 states the behavior pattern of three objects: DropDownList l, ListItem i1 and i2. In fact, the specification implies that information of each pair of ListItems which belongs to the same DropDownList are tracked and matched in one pattern. If there are three ListItem i1, i2, i3, the behavior of object pairs <i1,i2>,<i1,i3> and <i2,i3> will be verified by

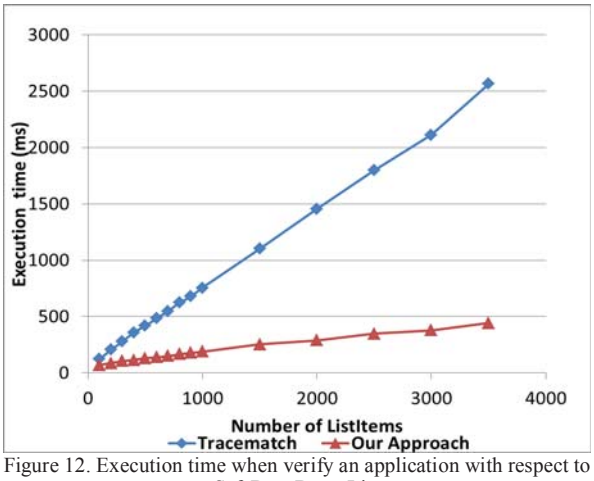

Figure 12. Execution time when verify an application with respect to SafeDropDownList

three automaton instances that are derived from the specified regular expression. But in LACOIO monitor, <i1, i2, i3> are verified in one monitor instance, which avoids unnecessary verification and decreases the complexity.

VI. RELATED WORK

Tracematch [1] is a seamless extension of AspectJ and is a new history-based language. The logic that it relies is regular expression. It introduces free variables in the matching patterns. At runtime, the monitored objects and other values can be bound to the declarative variables so that the event can be matched not only by event kind but also by the value that associated with the free variables. MOP [5] is a formal framework for software development and analysis, in which the developer specifies desired properties using definable specification formalisms, along with code to execute when properties are violated or validated. It supports several logic formalisms, including CFG, FSM, regular expression, etc. MOP allows specifications with parameters. The free variables in Tracematch and parameters in MOP allow user to specify some COIOs. However, since the free variables or parameters are limited to a fixed number, when they are applied to verify some complicated COIOs that involve multiple objects of the same class like SafeDropDownList, the specification will became verbose and hard to understand. LACOIO can lower the complexity of such specification and its monitor leads to a better performance for this type of COIOs.

Jaspan [2] proposed a lightweight specification system which can describe framework constraints that are temporal and involves multiple objects. Main differences between work in [2] and ours are: (1) the former is designed for static analysis. Some relations among objects are predicated so that they are not precise. The predicted relations are used for further analysis which makes the result unsound. LACOIO in this paper does not make any prediction. The verification is based on real runtime information of objects' behavior and its result is sound (but not complete). (2) LACOIO is more flexible as it introduces user-defined variable, actions, etc, while the language in [2] only allows very simple pre/post-conditions, which makes it not applicable to specify constraints like SafeIterator and SafeHashMap[13].

Yahav [4] proposed an approach to verify safety properties using separation and heterogeneous abstractions. They presented a language for specifying separation strategies for decomposing a single verification problem into a set of sub-problems and then utilized heterogeneous abstraction during the verification of the transformed verification problem. However, this is not a general approach to describe many state-of-the-art API constraints. Moreover, this approach is designed for static program analysis, which is not appropriate for runtime verification of COIO.

VII. CONCLUSION

This paper proposed a novel specification language LACOIO to describe complex constraints on multiple interacting objects. We presented the language design and the implementation of the language compiler and the runtime verification framework. We have demonstrated that with LACOIO, we can describe complex COIOs in an easy and succinct manner and our language design has led to improvement of performance.

Abstract

To alleviate the complexity and changeability of development of large scale embedded system, the Model Driven Development is accepted by various fields of industries and their standards. In this approach, design models with vast configuration data are translated into executives automatically. However it's difficult to detect incorrect values from the configuration information. In this paper, we introduce lightweight formal approach using SMT solver for the automation of configuration inspection activity, which is rather to be suited to industrial purpose.

Keywords : Embedded System, Automatic Configuration Inspection, Formal method, SMT

1 Introduction

Software developers in the project of large scale embedded system such as automotive, avionics, and mobile system are challenged to meet delivery dates in the face of complex system architectures and ever-evolving technological platforms. To overcome these challenges, MDD(Model Driven Development) is adopted by the automotive industrial standards, AUTOSAR[1]. For the aeronautic domain, the European project DIANA investigated the use of MDD in the context of Integrated Modular Avionics and the ARINC 653[2] standard. MDD facilitates on systematic use of models from a very early phase of the design process and through various model transformation steps automatically generates source code[3]. However, in those standards, the heavy use of configuration data expose developers to error-prone configuration file editing, so the validation for early error detection of configuration is needed.

System configuration is one of activities performed during the development of a system, which is to provide configuration information for all the software within the system. It's an important activity of the development of embedded software, because it gives the flexibility to the system development. The output of the activity is the system configuration description which is used to actually generate and build the executable image. Mainly configuration data are used to set to particular values for operating system, system timers, and so on.

Source code inspection is a commonly used technique for verification of software in industry. Recently from international standard like ISO 26262[4] and DO178-B[5] rigorous applying of verification activities is emphasized. However, the inspection is performed manually, which is time consumed and error-prone. Thus more rigorous and automatic inspection is required and formal methods are popular techniques in this sense. Although formal methods are becoming more widely used, formal proof has achieved less industrial acceptance, due to cost and limitations of tools and scalability problem. However, configuration inspection with lightweight formal method can be a practical approach for automation of verification and validation[6].

In this paper, we describe an automated approach to configuration inspection that utilizes lightweight formal method using SMT(Satisfiability Modulo Theory)[7] solver. In our approach configuration files are represented by configuration trees and these trees are translated into logical expressions in the form of SMT input language.

This work was supported by the GRRC(Gyeonggi Regional Research Center) program of Gyeonggi province and the WBS(10038486) program of the Ministry of Knowledge Economy, Korea.

Also the set of constraints of configuration data is translated into logical expression. The logical expressions are solved by SMT solver for detecting violation of constraints of the configuration.

Our major contributions in this paper include (1) the establishment of the approach to apply formal method to automation of configuration inspection, (2) the design of the translation algorithms from the configuration code to the logical expressions, (3) the implementation of a prototype software tool to support the activities, and (4) the presentation of a case study of inspecting DPS(Driver Positioning System) to evaluate the correctness of the approach and the tool.

The remainder of this paper is organized as follows. Section 2 presents the logical foundation as background. Section 3 describes the automation of configuration inspection. Section 4 reports applying the method to DPS system as a case study with prototype tool. Finally, we conclude the paper and point out future research in section 5.

2 Background

In the last two decades, the great progress has been made in the field of determining the satisfiability of first order logic formulas, because it focuses not general first order satisfiability, but rather satisfiability with respect to some background theory, which fixes the interpretations of certain predicate and function symbols. The research field of satisfiability of formulas based on those background theory is SMT[9].

In SMT formulas usually involve several theories at once, which include not only theories of real and integer arithmetic but also theories of array, list, tree, record and so on. This is particular useful to verify software system. Since recent SMT solvers such as Yices[10] are good at solving linear arithmetic problem, we translate the inspection problem into Yices input language and solve the linear arithmetic formulae to fine out any violation of the system configuration. In this paper, we use logical expressions constructed by the following abstract syntax:

$\phi ::= \neg\phi \mid \phi \wedge \phi \mid (\phi) \mid term = term \mid term > term$

$term ::= variable \mid constant \mid term + term$

This Arithmetic involves the addition and multiplication of the real numbers, so the domain of *variable* and *constant* is real number. If $P = \{p_1, \ldots, p_n\}$ denotes the set of logical expressions of the configuration data and each element in P forms (*variable* = *constant*), the logical formula of the whole configuration data is $\phi_P \equiv p_1 \wedge \ldots \wedge p_n$. If $C = \{c_1, \ldots, c_m\}$ denotes the set of logical expressions of configuration constraints, the logical formula representing the configuration constraints is $\phi_C \equiv c_1 \wedge \ldots \wedge c_m$. In order to check the correctness of configuration data, we can check $\models \phi_P \wedge \neg\phi_C$. If the result of the satisfiability check is unsatisfiable, then the configuration is correct, otherwise incorrect data exit in the configuration. And from the model of the formula $\phi_P \wedge \neg\phi_C$, we can obtain the values of violated variables in the configuration.

3 Automation of Configuration Inspection

In this section, we describe the automatic method of configuration inspection. Configuration files consist of the definition of data structure and the set of assignment of variables called configuration parameters. In order to be analyzed, the configuration files are represented by configuration tree which looks like parse tree and then the logical expressions is constructed from the configuration tree. With constraints between configuration parameters, the set of logical expressions is solved by SMT solver.

3.1 Construction of configuration tree

Configuration data consists of the part of definition of structure and the part of declaration of variables and their value assignments. For example, a structure type A and B is defined and its variables are declared with their values in the left hand side of figure 1. The right hand side of below figure shows the configuration tree corresponding to the configuration code.

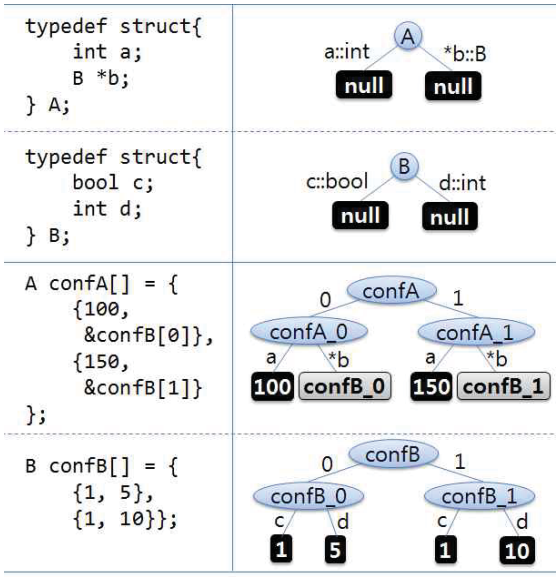

Figure 1. Configuration data and tree representation

In the figure 1, roots of trees are labeled by the name of defined structure type or the name of declared variable.

Each arc in the trees is labeled by the name of elements corresponding to a structure or an index number for array type. Non-terminal nodes are labeled by the composition of names of their parent and arc. Terminal nodes are labeled with values and the name of reference if the value of given variable is reference. For all variables declared in the given configuration files, if configuration trees are constructed completely, we can make a configuration tree as each arc forward a reference node links to the non-terminal node in other tree which has the same name with the reference node like figure 2.

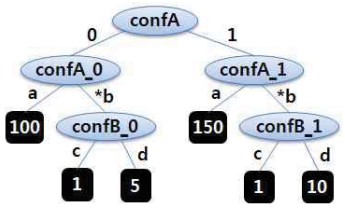

Figure 2. Example of configuration tree

After making the merged tree, logical expressions can be constructed. For example, the logical expression of configuration tree in the figure 2 is as follow:

$confA\_0\_a = 100 \wedge confA\_1\_a = 150 \wedge$
$confB\_0\_c = 1 \wedge confB\_0\_d = 5 \wedge$
$confB\_1\_c = 1 \wedge confB\_1\_d = 10$

In the above expression, a name of variables consists of the name of the parent node and the label of arc corresponding to each terminal node and equalities stand for the assignments of configuration code.

3.2 Formalization of configuration constraints

Configuration constraints are generally specified in standard documents as requirements and each constraint is the particular relation among deferent configuration parameters. It is presented by natural language such as "if $a > 100$ then c is true" and "If c is true then $d \times 20 > a$". This kind of statement can be naturally translated into the logical expression. However, the remarkable assumption is that there exists the mapping point as the same name between two variables in the expression of constraint and of configuration files. In order to translate the constraints into logical expressions, the names of variable within the logical expression of the constraint should be refined with respect to the configuration tree. To do this, we can assume the sub-tree whose root node has the highest arc among the set of arc labeled by names of the variable used in the expression of the constraint. For example, the logical expression $(a > 100) \Rightarrow c$, representing the constraint "if $a > 100$ then c is true", is refined to $(confA\_0\_a > 100) \Rightarrow (confB\_0\_c = 1)$ and $(confA\_1\_a > 100) \Rightarrow (confB\_1\_c = 1)$, which are caused by the array **confA** in the figure 2. If all refinements of expressions of constraint are completed, we can translate those expressions into Yices input language. From the second constraint "If c is true then $d \times 20 > a$", we can make below two logical expressions:

$(confB\_0\_c = 1) \Rightarrow (confB\_0\_d \times 20 > confA\_0\_a)$
$(confB\_1\_c = 1) \Rightarrow (confB\_1\_d \times 20 > confA\_1\_a)$

Notice that the above first formula is violated. So we can think that the configuration data is incorrect. However, with examining given constraints carefully, two example constraints are in the transitive relation. Through the connection of these two constraints, we can guess the fact "if $a > 100$ then $d \times 20 > a$". If it is right, the violation is meaningless. Because the value of a is not larger than 100, the relation between $d \times 20$ and a needs not be considered. That problem occurs frequently in the development of embedded system, because developers apt to declare some dummy variables in the configuration code carelessly. To mitigate safety critical problems, these constraints should be modified.

4 Applying Automatic Inspection to DPS

DPS(Driver Positioning System) is an embedded software for controlling the seat adjustment functionality of a car, which is developed by ETRI and consists of two ECU(Electronic Control Unit) for driver seat module and steering column module, respectively. This system is based on AUTOSAR (AUTomotive Open System ARchitecture) that is an open and standardized automotive software architecture, jointly developed by automobile manufacturers, suppliers and tool developers[11].

AUTOSAR CT(conformance test)s check whether a variant of a BSW module or cluster (the test object) implemented by one or another product supplier, complies with relevant AUTOSAR specifications. AUTOSAR CTs verify whether the object under test satisfies selected conditions imposed in the relevant specification documents[12]. AUTOSAR CT Specifications are a part of the formally released AUTOSAR document set, and have a strict relationship to the relevant AUTOSAR specification documents. AUTOSAR CT can be applied to test objects on several levels of integration of BSW modules. As the size of the test objects increases from modules to subsystems to complete system including the RTE. Currently, AUTOSAR CT focus on individual modules[13].

Each CTSpec of BSW modules includes testcases not only for the correct functionality of test objects in terms of

their public input/output behavior in typical, but also for the correct configuration. For the behavioral testing, concrete testcases and methods are proposed with TTCN-3 language. But for static testing, it gives natural-language testcases and just recommends inspection of source code without any methods. In this point of view, our method is one of practical methods to inspect the violation of configuration. The automatic configuration inspection to DPS was performed on the development machine. AUTOSAR BSW modules used in DPS are 29 modules, in which 19 modules are examined with 113 testcases for configuration inspection. Figure 3 shows the snapshot of inspection tool and presents the violation out of configuration within CanNM modules[14]. Fortunately detected configuration error is not real error to lead the system to bad situation, but caused by dummy data in the configuration. One of violated constraints is as follow:

If a Network Management PDU is received the CanNm Message Cycle Timer is reloaded with the node specific timing parameter CANNM_MSG_REDUCED_TIME. The node specific time CANNM_MSG_REDUCED_TIME should be greater than ½ CANNM_MSG_CYCLE_TIME and less than CANNM_MSG_CYCLE_TIME.

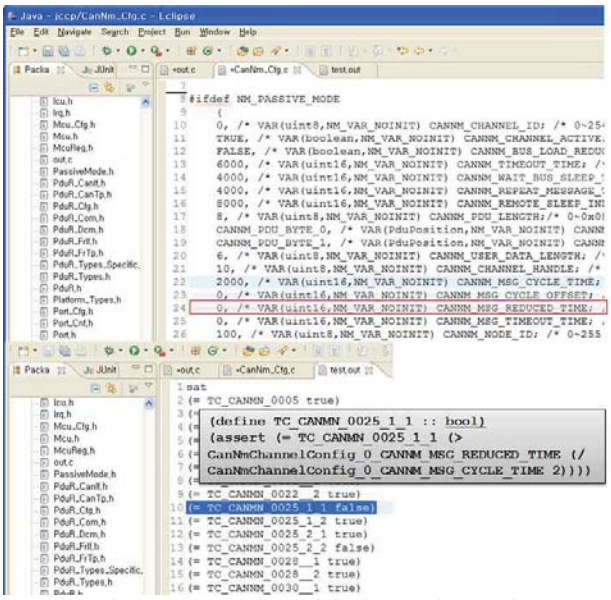

Figure 3. Snapshot of the inspection tool

5 Conclusions and Future researches

To overcome the problem of development of large scale embedded system, the Model Driven Development is accepted and vast configuration data are used, which gives flexibility to the development. To do automatic configuration inspection, we introduce lightweight formal approach using SMT solver. We proposed the translation algorithm and developed prototype tool as eclipse plug-in.

In the case AUTOSAR CT, among 6000, 4500 testcases are included in static testing, some part of them are about configuration inspection[15]. It is very hard to inspect configuration files by testers who are not involved in development process, because the files are generated by IDE tool and written with various macros. Therefore this automation of inspection is very useful for developers and testers. Formalization of requirements is helpful to establish correctness of requirements and check the inconsistence among requirements. In this paper, although our approach is applied to automotive system, we have plans to apply this method to check configuration constraints in ARINC 653 standard in the near future. Another future research is how to systematically translate requirements in a specification document to logical expressions. We expect that the requirement patterns can be applied.

Formalizing Reusable Aspect-Oriented Concurrency Control

Neelam Soundarajan, Derek Bronish, Raffi Khatchadourian
Computer Science and Engineering

{neelam,bronish,khatchad}@cse.ohio-state.edu

Abstract

Java and its library provide powerful concurrency control mechanisms. However, their use can lead to similar synchronization code being scattered *across multiple classes, synchronization and functional code being* tangled *together, and similar code being duplicated in many applications. Aspect-oriented (AO) programming makes it possible to address these problems. The precise behavior of systems built using AO techniques can, however, be difficult to understand. We propose a specification approach to precisely express key concurrency and synchronization properties of such systems. We illustrate the approach with a simple example.*

1 Introduction

Java provides a number of concurrency control mechanisms that allow a designer to specify that particular methods of a class are *synchronized*. When a *thread* invokes such a method on an object, it is suspended until it acquires the *lock* associated with the object, then proceeds to execute the method, releasing the lock when the method finishes. A finer-grained version allows an individual statement (or block) of a method to synchronize on the *this* object or, possibly, a different object. However, use of these mechanisms can reduce the degree of concurrency considerably. To alleviate this, the Java library provides the `Lock` interface implemented by classes such as `ReentrantLock`. By using *lock* objects appropriately, one can regain concurrency. But, at the same time, their use introduces some problems. First, if concurrency was not foreseen or its degree not anticipated when a class was designed, the approach requires invasive changes to the class. Second, synchronization and functional code of a class are often *tangled* together. Third, similar synchronization code may be *scattered* across multiple classes since similar synchronization concerns may arise in each one.

Aspect-oriented (AO) techniques help address such problems. The synchronization code can be contained in an *aspect*, separating it from the functional code. Moreover, by defining the *pointcuts* in the aspect suitably, the aspect's *advice* can apply to methods of multiple classes, thereby meeting the synchronization needs of each class. Synchronization code that is common to different applications can be defined in *abstract* aspects with *subaspects* for each application specializing it for that application, thereby eliminating code duplication.

The precise behavior of systems built in this manner can, however, be difficult to understand and formal specifications can help. We develop an approach that allows us specify, in the form of *contracts*, important behaviors, especially concurrency behaviors, of abstract aspects; and, in the form of *subcontracts*, specify how subaspects specialize the contracts to achieve behavior specific to the given system. We illustrate the approach by applying it to a simple example based on one in [7].

In Section 2, we consider related work. In Section 3, we sketch the model underlying our specifications. In Section 4, we present our specification approach via a simple case-study. Section 5 concludes the paper.

2 Background

Several approaches have been developed for reasoning about sequential AO systems. Dantas and Walker [3] consider *harmless* advice that does not modify the behavior of *base-code*, i.e., the underlying program. In [6], we consider how to provide information to arrive at the "richer" behavior caused by the advice without reanalyzing base-code. Katz and Katz [5] consider similar *rely-guarantee* specs. Aldrich [1], and Griswold *et al.* [4] propose ways to minimize the effects of aspects on base-code. Zhao and Rinard [12] consider abstract aspects but the the types of abstractness they allow are limited. Xu *et al.* [10] review approaches to reasoning about concurrency. Long & Long [8] present a formal specification of Java concurrency. Yang & Poppleton [11] present a model checker for concurrent Java.

3 Model Of Multi-threaded Computation

Fig. 1 outlines, in RESOLVE [9] style, the main components of a model of multi-threaded computation in a language with reference semantics as in Java. A *shared heap state*, lines 1–3, represents the *objects* in the sys-

tem. A *thread*, lines 7–8, consists of its id, a boolean indicating if it is active, and its control-flow-state which, lines 4–6, represents the sequence of method calls made in the thread that have not yet completed. A *synchronized lock*, lines 9–11, consists of the id of the associated object, whether it is currenly locked and, if so, the id of the holding object, and two sets of threads waiting to execute, respectively, synchronized and unsynchronized methods on the object. The other type of lock (not for a specific object), lines 12–13, consists of a boolean indicating whether it is locked, if so the id of the object holding it, and the set of ids of the objects waiting for it. A *lock*, lines 14–15, is one of these two types; note that this model is inadequate for dealing with *read-write* locks which we do not consider. A *system*, lines 16–17, consists of a heap, its current threads, and its locks.

```
1 math type Heap_State is
2  partial function from ObjectId
3         to ObjectValue
4 math type Control_Flow_State is
5  sequence of tuple of
6   (m: method sig, obj: ObjectId)
7 math type Thread is tuple of
8   (id, active, cfs)
9 math type Synch_Lock is tuple of
10   (object, locked, holder,
11    waitersForSynch, waitersForUnsynch)
12 math type Other_Lock is tuple of
13   (locked, holder, waiters)
14 math type Lock is
15   Synch_Lock or Other_Lock
16 math type Threaded_System is tuple of
17   (heap, threads, locks)
18 constraint: l: Synch_Lock
19  l.locked ⇒ [l.holder.active
20  ∧ head(l.holder.cfs).obj=lId
21  ∧ head(l.holder.cfs).m is synchronized
22  ∧ ∀ t ∈ waitersForSynch:
23    not t.active ∧ head(t.cfs).obj=lId
24    ∧ head(t.cfs).m is synchronized]
```

Figure 1. Model of threaded system

The model must satisfy certain constraints, one of which, lines 18–27, is that if a `synch_Lock` is locked, the thread holding it must be `active`, must, as indicated by its `cfs`, be currently executing a synchronized method on the corresponding object, and threads whose id's are in `waitersForSynch` must be inactive and waiting to execute a method on the object.

4 Case Study

Due to lack of space, we present our specification approach via a simple case-study, in Fig. 2, based on the `Shape` example of [7]. Instances of the class represent shapes with `x`–, `y`–coordinates, and `height` and `width` which may be accessed using `get` methods; `move` methods allow us to move the shape; `magnify()` and `shrink()` to expand and contract it.

```
1 class Shape
2 {protected int x = 0, y = 0,
3   height = 5, width = 10;
4  public int getX() { return x; }
5  //getY(), getHeight() etc. similar
6  public void moveNorth() { y++; }
7  //moveSouth(), moveEast(), etc. similar
8  public void magnify() {
9   height=height+5; width=width+10;}
10 public void shrink() {
11  height=height-5; if(height<=0)height=5;
12  width=width-10;if(width<=0)width=10;}}
13
14 protected final Lock locLock =
15  new ReentrantLock();// lock for location
16 protected final Lock dimLock =
17  new ReentrantLock();// and dimension
18 public int getX() { int tx;
19  locLock.lock(); tx = x;
20  locLock.unlock(); return tx; }
21 //getY() similar; getHeight(),getWidth()
22 // similar but using dimLock
23 public void magnify() {
24  dimLock.lock();...;dimLock.unlock();}
25 //move methods similar but using locLock
```

Figure 2. Shape class and Split locks

Suppose the application has many threads accessing a `shape`. Making each method *synchronized* would prevent interference between the threads but minimize concurrency. Instead, we use *two locks*, lines 14–17, one for location, the other for dimension. The methods, lines 18–25, which access/modify the location, respectively dimension, acquire the former, respectively the latter, perform their work, and release the lock.

4.1 Split Lock Aspect

In the AO approach in Fig. 3, `_lock1`, `_lock2` serve the same purpose as `locLock`, `dimLock`; `fstSetOps()`/`secondSetOps()` pointcuts correspond to calls that should use `_lock1`/`_lock2`. The advice, lines 7-10, is the synchronization code. Fig. 4 defines the subaspect for *Shape*, achieving the same level of concurrency as before but without scattering/tangling.

Suppose now `shrink()` was changed as follows: if the object was shrunk below a certain size, move it to a more visible place by changing `x` and `y`; and suppose we left the subaspect as in Fig. 4. This system may behave acceptably in all test cases. Indeed, the only time it

```
1 public abstract aspect SplitLockAspect
2  perthis(fstSetOps() || scndSetOps()){
3  protected abstract pointcut fstSetOps();
4  protected abstract pointcut scndSetOps();
5  private Lock _lock1 = new ReentractLock();
6  private Lock _lock2 = new ReentractLock();
7  before():fstSetOps(){ _lock1.lock();}
8  after() :fstSetOps(){ _lock1.unlock();}
9  before():scndSetOps(){ _lock2.lock();}
10 after() :scndSetOps(){ _lock2.unlock();}
```

Figure 3. SplitLock Aspect

would misbehave is if one thread invoked, say, `getX()` on a `shape` at the same time another was executing `shrink()` on it, *and* the size of the `shape` was below our minimum, *and* the timing of the two executions resulted in a strange value being returned for `x`.

```
1 aspect ShapeSplitLockAspect
2      extends SplitLockAspect {
3  pointcut fstSetOps() :
4     execution(Shape.getX())
5   ||execution(Shape.getY())
6   ||execution(Shape.moveNorth())||...
7  protected pointcut scndSetOps() :
8   execution(Shape.getHeight())||...
9   ||execution(Shape.shrink())||...
```

Figure 4. Subaspect for Shape System

4.2 Contracts and Subcontracts

Consider an abstract aspect *AB*. We specify *AB* in an *aspect contract*. For *abstract* portions of *AB*, we will use *abstraction concepts* in the contract. These will not be *defined* in the contract but will be *used* in it. The contract will also impose certain constraints that definitions, provided in subaspects, for the concepts must satisfy.

Part of the `SplitLockAspect` contract appears in Fig. 5. Line 5 requires that the definition, in a subaspect, of `firstSetOps()` must be such that all methods whose execution join points match it must be from a *single* class. This represents that the lock is not intended to prevent simultaneous execution of methods from different classes. The next clause, for `scndSetOps()`, is similar. The next clause, line 6, requires that these two classes be the same. The next clause requires a given method to be mapped to (at most) one of these pointcuts. The subaspect in Fig. 4 can be easily seen to meet these requirements.

The constraint in lines 10–11 requires that the (union of the) set of objects accessed by the methods mapped to `firstSetOps` be disjoint from the set accessed by methods mapped to `secondSetOps`. But the information needed to check this constraint is *not* part of the subaspect in Fig. 4. The *abstraction concept*,

```
1 abstraction concepts:
2 set AccessedObjects(set mthds)
3  //objects accessed by methods in mthds
4 constraints:
5 [(|fstSetOps.Class|=|scndSetOps.Class|=1)
6 ∧(fstSetOps.Class=scndSetOps.Class)
7 ∧(firstSetOps.Mthds∩scndSetOps.Mthds=∅)]
8 AccessedObjects(S1 ∪ S2) =
9  AccessedObjects(S1)∪AccessedObjects(S2)
10 [(AccessedObjects(fstSetOps.Mthds)∩
11   AccessedObjects(scndSetOps.Mthds) = ∅)]
12 results:
13 [(m1∈fstSetOps.Mthds)∧(m2∈scndSetOps.Mthds)]
14       ⇒ [ nosuspension(m1,m2)
15           ∧ nosuspension(m2,m1)]
16 [(m1∈fstSetOps.Mthds)∧(m4∈ fstSetOps.Mthds)]
17       ⇒ noconcurrency(m1,m4)
18 [(m3∈scndSetOps.Mthds)∧(m2∈scndSetOps.Mthds)]
19       ⇒ noconcurrency(m3,m2)
```

Figure 5. Contract for SplitLock Aspect

`AccessedObjects` (line 2) (and its definition in the subcontract), help address this. The contract does not define it but the name (and associated comment) is suggestive: the set of objects accessed by the methods in `mthds`. The constraint in lines 10–11 uses it to capture the key requirement that the intersection between the sets of objects accessed respectively by the methods mapped to the two pointcuts be empty. Lines 8–9 impose a simple constraint on the definition, in the subcontract, of `AccessedObjects`: that it be distributive.

Lines (11-16) specify the results of using the aspect: if two methods are mapped to the two pointcuts, their respective executions will not suspend each other; but if they are mapped to the same pointcut, there will be no concurrency between their executions.

The subcontract `ShapeSplitLockAspect` needs to only define `AccessedObjects`. Since it is required, by the aspect contract, to be distributive, we can define it by specifying its value for each method mapped to the two pointcuts. This is easily done for our example; thus, for `getX()`, the value will be the set {`x`}; for `magnify()`, it will be {`width, height`}; etc.

Next we have to check that the contract's constraints are satisfied. It is at *this* point that we can locate the bug considered earlier where `shrink()` may modify `x` and `y`. Given this code, `AccessedObjects(shrink)` should be {`x, y, height, width`}; hence, the constraint in lines (8-9) is violated; thus, for example, `x` is in both `AccessedObjects(shrink)` and `AccessedObjects(getX)` and these two methods are mapped to the two pointcuts and the contract is violated.

Next, the definitions in the subaspect and subcon-

tract can be plugged into the aspect contract, in particular, into the *results* clauses of the contract to arrive at the specialized versions of these clauses that apply to this particular system. In the current case this will allow us to conclude, for example, from lines (15–16) of the contract, that if a thread was currently executing `getHeight()` on a shape object and another invoked `magnify()` on the same object, the latter would be suspended until the former finishes. To build another application in which `SplitLockAspect` could be used, we would only have to define the corresponding subaspect and subcontract, defining respectively the pointcuts and `AccessedObjects`; next, verify that, with these definitions, the constraints in Fig. 5 are satisfied; and, finally, arrive at the behavior of the application by plugging in the definitions into the results in Fig. 5.

How do we define **nosuspension**() and **noconcurrency**()? These are primitives provided by the formalism and are defined in terms of the model of Section 3. Thus **noconcurrency**(M), where M is a set of methods, means if `t1` and `t2` are two threads in the `threads` component of a system and `m1, m2` are elements of M, `m1` is in `cfs`, the control-flow-state of `t1`, `m2` is in `cfs` of `t2`, and the corresponding `obj` components are equal to each other, then the `active` component of `t2` must be *false* if that of `t1` is *true*. The precise set of primitives and their definitions is part of our current work. One other point is worth noting. Standard approaches to formalizing aspects typically make use of *pre-* and *post*-conditions. Why doesn't our contract for `SplitLockAspect` involve these? The answer is that our focus is on *concurrency* issues. Thus, for example, the constraint expressed in lines (8–9) of Fig. 5 can be compared with the notion of *interference freedom* [10]. Our clause, by requiring that the intersection of the sets of objects accessed by the two groups of methods to be empty, ensures that no method in the first group will interfere with any method in the second group.

5 Discussion

Our goal was to show how common synchronization patterns may be implemented using abstract aspects that are then specialized, using subaspects, for individual systems; and develop an approach to specify essential properties of the aspects and subaspects. Although the question of and reasoning about AO programs has received much attention, the problem of abstract aspects, especially for concurrency behaviors, and their specializations has not, to our knowledge, been addressed.

Our contracts and subcontracts had to refer to more than just the class variables. Hence we defined a model that provided a view of the threads that exist at runtime. And in our specs, we referred to components of this model, allowing us to specify the concurrency behaviors of interest. Importantly, the use of *abstraction concepts*, in conjunction with the constraints imposed on them, allowed us to represent the *intent* of the abstract aspect.

In Section 4, we relied on intuitive reasoning to show that the subaspect and its subcontract satisfy the aspect contract's requirements. For more complex systems, tool support would be needed. Bodden and Havelund [2] describe an AO algorithm, *Racer*, that uses new *concurrency-related* pointcuts that may be used to identify concurrency bugs. It should be possible to use a *Racer*-like approach to build a tool that will spot violations of our contracts/subcontracts and we plan to pursue this in future work. Along a different line, our model may help identify additional AO primitives that will be of use in writing concurrent programs; for example, primitives that allow the programmer access to information about the threads in the system may be useful. These would be analogous to such primitives as *cflow* but tuned to the needs of concurrency behaviors.

PIPE+ - A Modeling Tool for High Level Petri Nets

Su Liu, Reng Zeng, Xudong He
School of Computing and Information Sciences
Florida International University
Miami, Florida 33199, USA
{sliu002, rzeng001, hex}@cs.fiu.edu

Abstract— Petri nets are a formal, graphical and executable modeling technique for the specification and analysis of concurrent systems and have been widely applied in computer science and many other engineering disciplines. Low level Petri nets are simple and useful for modeling control flows; however, they are not powerful to define data and system functionality. High level Petri nets were developed to support data and functionality definitions [1]. To support the practical applications of Petri nets formalism, tools for designing and executing Petri nets are necessary. Although there are many existing tools for supporting low level Petri nets [5], few tools are available for high level Petri nets. There is especially a lack of tools to support high level Petri net notation proposed in the international standard [1]. In this paper, we present a tool, called PIPE+*, to support a subset of high level Petri nets proposed in [1]. PIPE+ is built upon an existing low level Petri net tool PIPE (Platform Independent Petri Net Editor) [2]. This paper describes the functionality of PIPE+ as well as illustrates the process of extending PIPE, which provides helpful insights for others to create Petri net tools suit their own needs. Furthermore, PIPE+ is an open source tool and thus is available for various enhancements from worldwide research community.

Keywords: Petri Net; Modeling Tools

I. INTRODUCTION

Petri nets have been used to describe a wide range of systems since their invention in 1962 [3]. They are a graphical and formal method for describing and studying concurrent and distributed systems [4]. Low level Petri nets are suitable to model control flows and are applicable to work flow systems; however are not adequate to describe complex systems. High level Petri nets (HLPNs) were developed to support the definition of data and functional processing [1]. To support the practical applications of Petri net formalism, tools for creating and executing Petri nets are needed. In [5], a Petri net tool database listed the tools developed in the past several decades. Unfortunately, many of the tools described in the database as well as in literature are no longer maintained or available and few of them support HLPNs, especially the HLPN definitions and notations proposed in the 2001 international standard [1]. Table 1 lists representative tools supporting some forms of HLPNs.

The HLPNs proposed in the international standards draws concepts from predicate transition nets, colored Petri nets, and algebraic Petri nets; and provides abstract and general definitions and notions. It is desirable to create a tool for editing and simulating the HLPNs; unfortunately no such tool exists yet. A realistic attempt is to develop a tool to support a restricted and concrete realization of HLPNs. The most critical components of the HLPN definitions are the net annotations with regard to transitions, which are algebraic terms of Boolean type. In [15], we viewed first order logic formulas as the algebraic terms associated with transitions and thus adopted the predicate transition net view as a concrete realization of HLPNs.

Table I A List of High Level Petri net Tools

Name	High level Net Type	Graphical Editor	Simulator
AlPiNA	Algebraic Petri Nets	Yes	No
CoopnBuilder	CO-OPN language	Yes	No
CPN Tools	Colored Petri Nets	Yes	Yes
HISIm	Hybrid Petri Nets	Yes	Yes
Renew	Object Oriented Petri nets	Yes	Yes
PIPE+	High level Petri nets	Yes	Yes

It requires tremendous effort to build a HLPN tool from scratch and is especially difficult to assure the quality of the initial design. It is desirable to leverage successful results and extend mature and existing tools. It is of tremendous value to build upon open source tools so that the resulting new tool can be shared and improved by the worldwide research community. PIPE+* is a tool to support HLPN where transition conditions are defined in terms of first order logic formulas [14]. PIPE+ extends a well developed open source low level Petri net tool called PIPE (Platform Independent Petri net Editor) [6]. Furthermore PIPE+ retains the original low level Petri net editing and executing features, which allows user to choose appropriate net levels to model target systems.

In this paper, we first briefly review the background of basic and HLPN concepts. We introduce the chosen low level Petri net tool PIPE that PIPE+ built on, and then present implementation details of the extension according to

* PIPE+ can be downloaded at http://www.cis.fiu.edu/pub/PIPEplus/

the HLPN concepts. We discuss limitations and applications of the tool, and our contributions and perspectives.

II. PETRI NETS AND HIGH LEVEL PETRI NETS

The Petri net structure consists of a finite set of places (drawn as circles), a finite set of transitions (drawn as bars), a finite set of directed arcs (drawn as arrows), and a set of tokens (drawn as dots) to define an initial marking. The arcs connect from a place to a transition or vice versa, never between places or between transitions. The places from which an arc runs to a transition are called the input places of the transition; the places to which arcs run from a transition are called the output places of the transition. The places can contain multiple tokens and thus are of multi set type (or bag). A distribution of tokens over the places of a net is called a marking. A transition may fire whenever there are enough tokens in all input places.

According to the international standard [1], a HLPN graph comprises: a net graph, place types, place marking, arc annotations, transition condition and declarations. The net graph is the net structure; place types are non-empty sets, restrict the data structure of tokens in the place; place markings are collection of elements (data items) associated with places, called tokens; arc annotations are inscribed with expressions which may comprise constants variables (e.g., x, y) and function images (e.g., f(x)); transition conditions are Boolean expressions inscribed in; declarations comprising definitions of place types, typing of variables and function definitions. For net execution, the most important is transition enabling. Enabling a transition involves the marking of its input places. When an enabled transition occurs, the enabling tokens from input place's are subtracted and the resulting tokens of the transition Boolean expression are added to the output places.

III. AN OVERVIEW OF PIPE

PIPE [2] is a Platform Independent Petri net Editor to edit, animate and analyze low level Petri nets, which has clear design and incorporates the latest XML Petri net standards of storing format, the Petri Net Markup Language (PNML). It is implemented in Java and can be logically divided into three major components [6], shown in Figure 1: the graphical user interface (GUI), a layer managing the interactions between the GUI and the modules (DataLayer), and analysis modules.

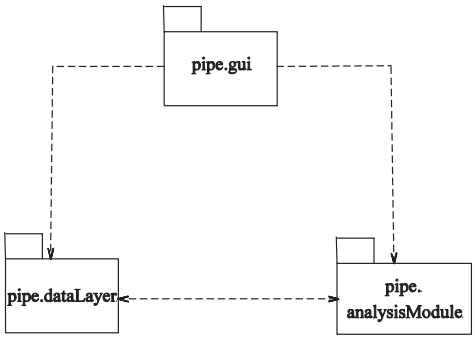

Figure 1 Package Diagram for PIPE

A. Graphical User Interface

PIPE's graphical user interface is developed using Java Swing API as it provides full GUI functionalities and mimics the platform it runs on. Besides, as PIPE is a cross platform application this was deemed useful for providing a native look and feel. The GUI component includes GUIFrame, GUIView and classes such as action, handler and widgets supporting Swing APIs. From a user perspective, there are two major parts: Editor and Simulator.

- ***Editor***: Users are able to edit a low level Petri net by clicking and drawing Petri net graphical elements through the menu bar, toolbar. On the toolbar, it lists all the Petri net element thumbnails, such as place, transition and arc, which can be selected and added to the white canvas (tabbed pane) of the editor. Besides, these added elements' annotations and attributes can be defined by selecting one of the elements and pop up an editing dialog box.
- ***Simulator***: There is a switcher button between editor mode and simulation mode. Using the simulator, a user is able to fire a random transition or fire a number of transitions randomly selected among enabled ones. The simulation process includes subtracting tokens from input places and adding them to output places while firing a transition. Besides, the animation history is displayed on the left bottom of the interface frame by listing transition's label orderly.

B. Internal Architecture of PIPE—The DataLayer

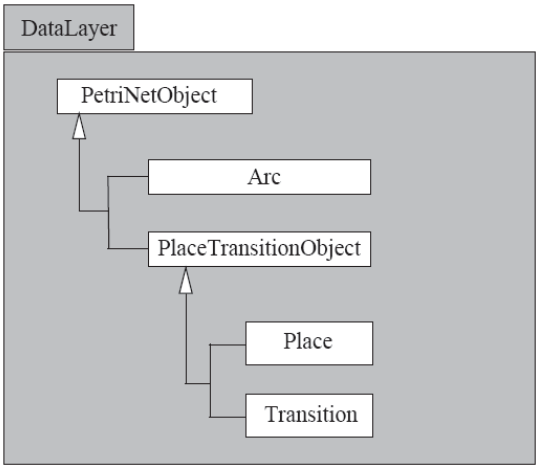

Figure 2 The Hierarchy of PetriNetOjbect Classes

The core component of PIPE is the data layer, which maintains states and contains all the classes used to represent a Petri net. Figure 2 shows the hierarchy of important Petri net object classes [6], including Arc, Place and Transition classes inherited from PetriNetObject because they have common variables and methods, such as id, name, location, etc.

In the data layer component, each Petri net is encapsulated by an instance of the DataLayer class, which contains all the Petri net objects stored in a list enabling the

easy addition of new objects. It contains not only methods to access all its internal objects and to return its internal lists, but also methods to calculate the current markup, initial markup, forwards incidence matrix, backwards incidence matrix, combined incidence matrix and enabled transitions.

Besides data layer, PIPE has analysis module to do analysis and conclusions on the properties of Petri net model, such as boundedness, liveness, reachable markings and so on.

C. *Saving and Loading*

PIPE is capable of saving and loading nets and writing the Petri net data layer into a Petri net Markup Language (PNML). An Extensible Stylesheet Language Transformation (XSLT) is used to transform it between PNML and XML files.

IV. PIPE+

A. *Overview of the Extension*

Similar to PIPE, PIPE+ is also an editor and a simulator. The editor is to model a system visually through a graphical interface. The goal is to utilize all the benefits that a HLPN provided with convenience. The details are presented below according to the HLPN concept's six elements in reference [1]. The simulator is no longer a simple black dot token animation game but to manage the movement of meaningful data. We developed a mandatory compiler with an interpreter to process token data inside transition conditions, which are defined using restricted first-order logic. Besides, a simulation algorithm is applied to ensure its fairness and improve its performance.

B. *A Net Graph*

Since the graphical elements of a HLPN are the same as low level ones, PIPE's graphical editor is retained.

C. *Place Type and Place Marking*

The main difference between high level and low level Petri nets is that tokens are no longer black dots, but complex structured data. Place types are non-empty sets that restrict the data structure of tokens in the places. The data structure is an array of basic types, such as integer and string, and defined by user. For example, assuming a log in user account as a token has two elements, username and password, which are represented by two basic data types, string and integer. In a HLPN's place, a place data type is inscribed to restrict the data structure of tokens. In another way, the data type of tokens can be added into the place has been already defined beforehand.

To implement the concept that tokens with data structure, a data storage system is needed. Based on PIPE, the data layer package is modified by adding three classes: DataType, Token, abToken (Figure 3).

- DataType: The main data structure in class DataType is a list storing basic types' name, which is used to show what data structure the token or place holds. The data structure consists of an array of basic types, such as string, integer, etc. For our tool, basic types are limited to strings and integers for the simplicity but are adequate for most of applications. For the convenience of extension on basic types, we introduce a new structure BasicType to data layer. The structure BasicType (see Figure 4) includes a flag data field "Kind" to indicate which type it is (in PIPE+, 0 represents integer, 1 represents string). Space is allocated to both integer and string since it is undecided before the "Kind" is defined. Further extension on basic types needs to enhance the class BasicType by allocating extra space and redefine "Kind".

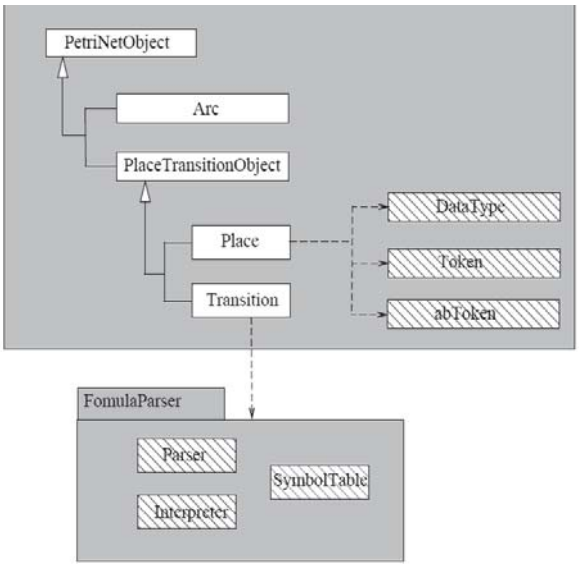

Figure 3 Extensions on DataLayer for PIPE+

- Token: Class Token is added to the data layer to maintain data value. The important field is a list storing instances of value with type of the BasicType, see Figure 4. Token is a basic data storage element in the places and its value is calculated by the transitions. The simulation process is fetching data value from the token's BasicType and fill the calculated result value to another token's BasicType.
- Abstract Token: Since first-order logic covers quantification, the whole collection of tokens in a place need to be checked by transition condition expressions. For example, if an expression includes "$\exists x \in X$", all the tokens in "X" needs to be checked to see whether a "x" exists, so the whole collection of tokens is fetched while checking enabledness of a transition. The tokens in this type of place are defined as a power set. A new class abToken (abstract token) is added into the data layer to store the power set. It has a field storing a list of regular tokens with the same data type, so it also has a data type to restrict the tokens data structure. We flatten the nested power sets by duplicating some fields.

For example, in a library system, one user may borrow a list of books, so that the database (power set) in library system is {username, password, books_borrowed{book1, book2,...} } is converted into {username, password, book1}, {username, password, book2}. This design sacrifices the space for the convenience of implementation, which can be further improved.

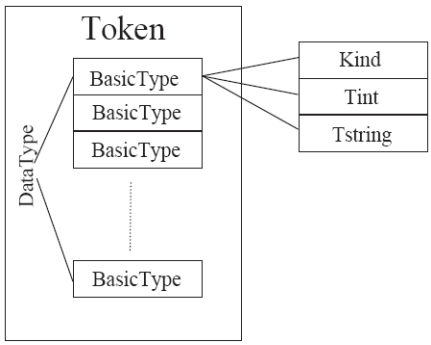

Figure 4 Structure of Class Token

As a result, the places in PIPE+ stores a list of regular tokens or an abstract token that contains a collection of regular tokens. Whether the connected transition can fetch a regular token or an abstract token depends on the place is a power set or not. The user can add, edit and delete tokens from places to create a net marking.

In PIPE+, a place stores tokens by List container, the place's capacity is built as unbounded (remember it has nothing to do with the number of different tokens that may appear in a particular place). However, in the discussion of [7], bounded and unbounded places have the same expressive power. A bounded place is preferable for the reason of visualization and redundancy.

In PIPE+, copies of token are allowed to store in the same place. Since whether the place needs to remove its copies of token depends on what the model it is, this can be further improved by supporting an option of copy remove.

D. Transition Conditions and Arc Annotations

Transition conditions are guards controlling the flowing of the tokens. PIPE+ use first-order logic to define transition condition formulas, which, syntactically, consists of variables and logic operators. Variables in the formula are predicates that can be instantiated by value from input tokens. Combined with logic operators the formula can be calculated. Semantically, as transition is a guard to control token flows, it has to check the value of tokens from input places and formulate new tokens conform to the output place type, the formula consists of two parts: pre-condition and post-condition. However, in PIPE+, the user is not supposed to separate the two conditions explicitly, because the interpreter can differentiate them by the type of variables.

In PIPE+, arc annotations are variables to assist transition expression calculation by mapping token values to expression's predicate variables. Arc variables are restricted to be appeared in the connected transition expression's variables for the mapping. Since a transition is connected by input and output arcs and arcs are connected to places, the predicate variables in the transition expressions are classed into input variables and output variables. For example, in Figure 5, a and b are input variables while c is output variable.

In a transition calculation process shown in Figure 5: In step (1), each token in the connected place is firstly bounded to the connected arc variable; as a pair, {variable, token}, they are fetched into a symbol table of the transition (note the pair with output variable's token value is temporarily empty and to be filled by the result of the expression calculation). In step (2), the input variables in the transition expression can locate token value through the pair's arc variables by looking up symbol table. In step (3), after transition expression calculation, the output variables are assigned with result value and the symbol table's output variable pairs are filled by the value. In step (4), the output pairs' token are added to the connected output places according to the arc's variables. For example, as c is on the output arc, c's token in symbol table [bob] is added to the output place.

Unless the transition formula cannot be satisfied by the value of the tokens fetched into symbol table, the tokens from input places (both regular token and abstract token) are consumed. However, a power set place with an abstract token usually has a backward arrow that makes it an output place as well, so the abstract token is returned to the place according to the post condition of the transition formula. In the case when the formula is unsatisfied, the currently fetched tokens in the symbol table are not consumed, so they are returned to the input places.

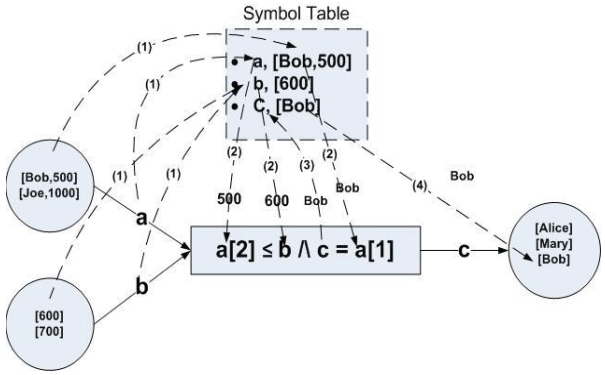

Figure 5 An Enabled Transition Formula Calculation Process

- *Restricted First Order Logic Transition Formula Expression*: In PIPE+, it is called restricted because the grammar we built for the tool has limitations. Since each predicate variable has to be instantiated, the user cannot use free variable that does not appear in the arc annotation, otherwise the calculation result is undetermined. Also, it does not support predefined function, like f(n), since the meaning of the function has to be declared beforehand, which is equivalent to define its

operations in a single logical sentence by using the connecting operator " ∧ ", which simplifies the implementation of expression interpreter. However, the restricted version of first order logic is still very powerful, because it does support complex expressions, such as:

$$(a = b) \wedge \exists c \in C((c[1] > a[2]) \wedge (C' = C - \{b\} \cup \{[a[1], c[2]]\})). \quad (1)$$

In (1), lower case letters represent regular tokens, upper case represent power set; *C*' by convention represents output variables and also is a power set (upper letters); it further indicates the clause is a post-condition because output variables at the left side of the equation means assignment; $c[n]$ means the n^{th} element value in *c*'s data structure.

- *Parser and Interpreter*: Because logical formulas need to be parsed and interpreted, we build a compiler with a parser and an interpreter for the restricted first order logic formula. The parser includes a scanner, which is built by a lex file and generated by jflex 1.4.3 [16]. A BNF grammar is built in cup file and generated by leveraging the tool jcup v11 [17]. Since the transition formula does not explicitly separate pre and post conditions, but only pre-conditions need to be calculated when checking whether the transition is enabled to fire or not, the interpreter has to differentiate pre and post conditions. A trick is found that in the post-condition, it usually starts with an output variable equals a subformula, for example, in (1),$(C' = C - \{b\} \cup \{[a[1], c[2]\})$ is a post-condition because $C'$is output variable. Therefore in the interpreter, when checking a clause with an "=" operator, the left hand side of the "=" variable is checked. If it is input variable, this clause is a pre-condition and the "=" is interpreted as a logic operator equal, which results in a Boolean true or false; on the other hand, if it is an output variable, the clause becomes a post-condition and the operator now is an assignment clause that assign the result value of right hand side formula to the left hand side output variable.
- Symbol Table: In PIPE+ each transition maintains a temporary symbol table to facilitate the interpreter. It does not use one big table for all the transitions, because it may cause name conflict and is hard to manage. The symbol table contains a list of elements that are structured by a pair of key and object. The pair of key and object is obtained from the transition's connected arc annotation and place. The reason we maintain the pair of key and object instead of key and token is because besides regular token type, the key may pair with a power set (abstract token type). Moreover, the symbol table is initiated each time before a logical formula is checked and cleared after the firing process.
- Declarations: In the standard[1], it comprising definitions of place types, typing of variables and function definitions. In PIPE+, the declarations are already in the modeling process by defining place data types, transition condition formulas and arc annotations.

E. Extensions On GUI

The GUI package in PIPE mainly consists of a GUIFrame, a GUIView, and some supporting classes. The GUIFrame is PIPE's graphical frame includes a menu, a toolbar and a statusbar. The GUIView is the panel to draw Petri net graphical elements. Since requirements and concepts for HLPNs are token storage and flow, our modification to PIPE's GUI is focused on Petri net elements places, transitions and arcs. The common procedure to extend PIPE's GUI is adding new selections on graphical elements' property setting menu for new features. In PIPE+, after modifying the gui.handler package for each Petri net element class, the new selections are shown in a popup menu by right clicking a Petri net element. The places now have the choices of defining data type and editing tokens; the transitions can contain logical formulas; the arcs can be labeled by variable key. These new features are triggered by additional selections on GUI and used through customized panels or dialogs.

F. Simulator

The simulator not only needs to execute the net model visually, but also has to ensure correctness, fairness and good performance. In PIPE+, the HLPN simulator designs as follows:

1) Graphical Simulation: Since in a low level Petri net, tokens are just black dots flowing from one place to another and the animation is visible to the user. In contrast, tokens in HLPNs are complex structured data, and especially when the number of tokens is large, which are inappropriate to be displayed upon graphical net; otherwise the graphical annotations are unreadable. Since the execution procedure is invisible to a user, the result can only be checked by looking into the contents of Places. In PIPE+, to view the tokens in the Places, user can open the Place edit panel and the value of tokens are displayed under the text area of Token List. Besides, the firing history is retained from PIPE by listing the fired transition name orderly and updated instantly after a transition fires, thus the user clearly knows a transition is fired.

2) Transition Occurrence Scheduling Algorithm: A scheduler is needed to coordinate the simulator's token flow strategy efficiently. Since the performance of the simulator mostly affected by the times of transition condition calculation, PIPE+ chooses the scheduling algorithm from [9] to minimize the recalculation of transition condition checking. The idea is to keep track of disabled transitions discovered during the search of enabled transitions, and use the locality principle, that is an occurring transition only affects the marking on immediate neighboring places, and hence the enabling of a limited set of neighbor transitions. For the implementation, we

maintain an unknown list and a disabled list. All transitions initialized as unknowns will be randomly picked and checked for enabling status. If the status is disabled, the transition will be moved to disabled list. Upon occurrence of a transition, we update the status of neighboring transitions to the unknown list if they are in the disabled list. The neighboring transitions can be found through occurred transitions' output places. Therefore, the disabled transition avoid recalculation if the tokens of its input places are not changed.

3) Enabling a Single Transition: In the HLPN concpets, tokens are meaningful data, when a selected transition start to check its expression, the expression's variables are to be instantiated. Since a transition may connect to a number of input places, where each place contains a list of tokens, to see whether the transition is enabled or disabled, it has to check all the possible combinations of instantiation tokens from its input places. For example, if there are three input places and each place has 3 tokens, the number of their combinations is $3 \times 3 \times 3 = 27$. If one of the three input places is a power set, no matter how many regular tokens inside the abstract token, it only counts as one abstract token. So the combinations reduces to $3 \times 3 \times 1 = 9$ combinations.

4) An Summarization of the Complete Internal Simulation Process:

a) All transitions in the net graph are initially stored in an unknown list; a disabled list is initialized to be empty;

b) A transition is randomly selected from the unknown list, and is checked for enabledness;

c) During the checking process of the selected transition, all the connected arcs and places of the transition are found;

d) Combinations of tokens from the transition's input places are orderly choosen to fill in its symbol table. Since symbols in symbol table are pairs of [key, object]. The keys are from arcs label; the objects are regular tokens. If the input place is a power set, the whole abstract token is sent as an object, otherwise only its first token is sent and the remaining tokens are still in place. For the symbol's key from output arcs, the object is empty because it is to be filled during transition firing action (after interpreting the post condition of transition formula);

e) The formula expression in the transition is checked utilizing a parser. A Boolean value is returned: if it is true, the transition is enabled and is fired immediately; if it is false, the transition is not enabled with the current input tokens, the tokens in symbol table will go back to the input places; if all the combination of input tokens cannot enable the transition, the transition is moved into a disabled list Both checking and firing a transition formula needs to parse and interpret the formula; however, the checking process only affects a formula's pre-condition while the firing process only affects a formula's post-condition.

f) After firing the transition, the tokens in the symbol table are sent to the output places according to the variables of arcs annotation and added to the tail of output places' token list. Since it changes the place marking of the output places, according to the scheduler algorithm's locality principle, if the dependent transitions are in the disabled list, it can now be moved back to the unknown list. Then go back to step b).

g) In step b, when unknown list is empty, the simulation process ended.

V. SOME ISSUES OF PIPE+

A. Limitations of PIPE+

1) Limited Basic Types: As we mentioned above, currently, the place data type of PIPE+ only supports two basic types, string and integer. Since PIPE+ using a structure to define basic types, the structure can be extended to accommodate more types.

2) Flat Tokens: For the convinience of implementation, the place data type of PIPE+ does not support nested powerset, such as {Bob, {book1, book2}}, but instead, it stores two flat tokens {Bob, book1}, {Bob, book2}.

3) Restricted First-order Logic for Transition Formula: A new grammar is built for the convenience of interpretation and to avoid ambiguity.

4) No True Concurrency: PIPE+ only supports interleaving semantics. Besides, it does not support timed Petri nets.

5) Randomly Fire Transition: The selection of the next transition to fire is performed randomly rather than choosen by the user.

6) Analysis Module: Lack of an integrated tool to analyze the properties of a net model;

7) Bugs and Errors: Since this is the first version of PIPE+ and our main purpose is to introduce the new tool, bugs are unavoidable.

B. Testing PIPE+

The most important part of testing is the transition condition formula. As the new parser and the interpreter were built for the restricted first-order logic formula, its correctness has to be assured. Our test cases are designed mainly on complex formulas including quantifier, relation expressions, arithmetic expressions and set expressions.

C. Compared to CPN Tools

CPN Tools [18] is a widely used industrial strength tool for constructing and analyzing colored Petri nets [19]. The main difference between CPN Tools and PIPE+ is the underlying specifying languages. Colored Petri nets utilize a functional programming language standard ML [12] while PIPE+ utilizes first-order logic formula. Since first order logic is well known, it is easier to use PIPE+. However CPN Tools provide more functionality, especially with regard to analysis.

D. Using PIPE+

PIPE+ has been applied to a Mondex[8] smart card system, which is an electronic purse payment system based on smart card technology. The model for a concrete transaction between two purses has eight operations (including abort) and four statuses, and we translated into PIPE+ model with ten transitions and four places. Figure 6 is a screenshot of Mondex in PIPE+, in which the simulation of a transition firing sequence is shown at the left bottom of the interface's frame. After no more transition is available to fire, the result of the simulation is a final marking that can be read by opening the places, msg_out and ConPurse, to view contents which are tokens' data.

VI. CONCLUSIONS

In this paper, we present a tool PIPE+ supporting high level Petri nets editing and simulation. We believe PIPE+ can be a valuable tool for concurrent and distributed system modeling and simulation. PIPE+ is built upon an open source tool PIPE for low level Petri nets. We illustrated the process of extending PIPE, and discussed our design strategies, which provide helpful insights for others to create Petri net tools suit their own needs. Furthermore, PIPE+ is an open source tool and thus is available for sharing and continuous enhancements from worldwide research community.

***Abstract*—Radio Frequency Identification (RFID) provides fast collection of large volume of data and can be used to identify physical objects with unique IDs. In order to provide semantically meaningful data to different applications, RFID data need to be processed to discover user-defined complex events. We propose a Petri net-based method for the detection of complex events in RFID. A model named ED-net is introduced to specify semantics of complex events, which is also taken as the basis for the implementation of an event detector. Formal model ED-net is an extension of ordinary Petri net, providing user-defined types, functions and expressions, which are suitable for the precise description of attributes and constraints of RFID complex events, with non-temporal, temporal and parameterized constraints. Through modeling all the events to be detected in one ED-net model, we avoid multiple detections of common sub-events of different complex events. Through the experimental evaluation, we verify the efficiency of our detection method. Keywords- RFID; Petri Net; Event Detecting

I. INTRODUCTION

Radio Frequency Identification (RFID) technology uses radio-frequency waves to automatically identify objects, which makes it possible to create a physically linked world where every object is automatically numbered, identified, cataloged, and tracked in real time. An RFID system generally consists of four parts: RFID tags, readers, middleware and application software. An RFID tag is uniquely identified by a worldwide unique ID, stored in its memory and defined by the electronic product code (EPC) standard [1]. Readers are capable of reading the information stored in RFID tags. RFID middleware systems are typically deployed between the readers and the applications in order to correct captured readings and provide clean and meaningful data to applications.

The RFID middleware plays the primary role in RFID data management. However, the characteristics of RFID data pose many challenges in the research of RFID middleware and complex event processing [2]. Firstly, the data generated from an RFID application are simple, and each RFID observation is of some form (epc, reader, timestamp); secondly, RFID data are temporal, dynamic and in large volume. They are generated dynamically and automatically, and must be processed in real time; thirdly, RFID data are inaccurate and have implicit semantics. Erroneous readings, such as missed or duplicate readings, have to be semantically processed. The information carried by RFID data also need to be analyzed to support advanced applications. Such information is often related to business knowledge and specific applications. Traditional event systems do not well support temporal characteristics of RFID events. Therefore, some novel and effective methods are needed for complex event processing in RFID technology.

The concept of complex event originated from active database. Lots of work has been done on complex event detection, both in active database and RFID applications. The work of [6] introduced a general purpose event monitoring system Cayuga, in which queries over event systems are expressed by Cayuga Event Language and implemented by Cayuga automaton. Petri nets are used for the modeling and detection of composite events for active object-oriented database system SAMOS [10]. The Snoop system [7] and EVE system [8] use graph-based approaches, and the work of [9] proposed EPS, in which a subscription tree used to process events.

Researchers also investigated specification languages and detecting methods for RFID complex events. The work of [11] proposed an event-oriented approach to process RIFD data by defining various constructors, including non-temporal and temporal constructors, to express the relationship among complex events. A tree-based algorithm [13] was advanced to improve existing algorithm RCEDA in [11], decreasing the time complexity of RFID complex event detection. SASE[12] executes complex event queries over real-time streams of RFID data, and a complex event language was proposed, supporting negation operating in sequences, parameterized predicates and sliding windows. But some operator-nested complex events were not referred in this language. Zhu [14] aimed at proposing a formal descriptive language $QDDC_{att}$ for complex events, supporting quantitative complex events.

Most of existing researches lack formal semantics to descript complex events, which may bring ambiguity and confusion in expressing and understanding complex events in RFID. Attributes (start time and end time) of a complex event are not defined strictly. Another problem is that existing detection methods are mainly developed for a single complex event, instead of a set of complex events. While in an RFID application, we often have more than one complex event to be detected, and these events share common sub-events. For

complex events $E_1 = (E_a;E_b) \wedge E_c$ and $E_2 = E_a \vee (E_d;E_e)$, they both contain a sub-event E_a. The detection of event E_a will be processed twice when the detections for E_1 and E_2 are carried on separately. This is time-wasting and should be avoided in real-time detection for complex events in RFID.

In this paper, we propose a Petri net-based method named ED-net for the description of complex events in RFID, which is convenient for describing temporal and parameterized constraints with locality property, token-flow mechanism and combinability. Moreover, ED-net has formal semantics which can guide us to design better software.

II. THE MODEL OF RFID EVENTS

An RFID event can be either a primitive event or a complex event. A primitive event is an RFID observation, which occurs at a point of time when an RFID tag is read by an RFID reader. A complex event is an RFID observation sequence, consisting of a set of primitive events and having special semantics. The time of a complex event could be considered as the point of time it is detected, or the entire time interval. The first case is often used in active database, while it will cause logical problems [3]. Therefore, we define the time of a complex event to be a time interval. In RFID event detection, both the temporal distance between two events and the interval of a single event are critical [5].

We introduce several signs and functions which will be used later. An event type is represented by E, and an event instance is represented by e; *t_begin(e)* returns the start time of an event instance *e; t_end(e)* returns the end time of an event instance e; *interval(e)* calculates the interval of an event instance e, and $interval(e) = t\_end(e) - t\_begin(e)$; $dist(e_1,e_2)$ calculates the distance between two event instances e_1 and e_2, and $dist(e_1,e_2) = t\_end(e_2) - t\_ end\ (e_1)$.The above functions are available for all the RFID events. Besides of these functions, users could define specific functions to distinguish primitive events. For example, *group(reader)* is used to represent to which group the reader of a primitive event belongs. Readers in the same group often have the same function; *type(epc)* is used to get the type of an object with tag *epc*.

Temporal constraints need to be taken into account when describing RFID events. The work of [11] discussed series temporal complex event constructors. Constructors for complex events in [11] are classifies into two categories: non-temporal complex event constructors and temporal complex event constructors. Non-temporal complex event constructors include OR($\vee$), AND($\wedge$), and NOT ($\neg$).$E_1 \vee E_2$ occurs when either E_1 or E_2 occurs. $E_1 \wedge E_2$ occurs when both E_1 and E_2 occur. $\neg E$ is usually combined with a temporal constraint, and it occurs when no instance of E occurs during a specific time interval.

Temporal complex event constructors specify temporal constraints of complex events, including the occurrence order of sub-events, distance constraint and interval constraint. These constructors can be nested in arbitrary order to describe various complex events. However, parameters are not included to express constraints on complex events. For example, operator *SEQ+* only requires one or more occurrences of an event, but the exact number of the occurrences is not specified. This might cause inaccurate description of complex events. Suppose we have a sequence of event instances: (e^1,e^3,e^5,e^6), where the superscript represents occurrence time of event e. According to the semantics of *SEQ+* operator, we can tell that complex event *SEQ+(E)* occurs more than once, (e^1,e^3), (e^3,e^5), (e^1,e^3,e^5), (e^1,e^3,e^5,e^6) could all be seen as the corresponding sets of events for complex event *SEQ+(E)*. Therefore, it is inconvenient to describe complex events with exact aggregation number, such as complex event E occurs when event E_1 has occurred ten times. In the following section, we will show how to model parameterized constraints with ED-net.

III. THE MODEL OF ED-NET

A. The static structure of ED-Net

Definition (ED-net) An ED-net (Event Detection Net) is a tuple $N = (\Sigma, P, T, A, C, G, B, E)$, and Σ is a finite set of non-empty types, called color sets; P is a finite set of non-empty places; T is a finite set of non-empty transitions; A is an arc set, $A \subseteq P \times T \cup T \times P$; C is a color function, $C : P \rightarrow \Sigma$; G is a guard function, $G : T \rightarrow \{Expr\}$, where $Expr$ is a boolean expression; B is a body function, $B : T \rightarrow \{Stat\}$, where Stat is a group of assignment operations; E is an arc function, $E : A \rightarrow \{AExp\}$, where $AExp$ is an expression whose value is a multi-set. The form of $AExp$ could be: $AExp := m'c|n'v|m'c + AExp|n'v + AExp$, where m and n are positive integers, c is a constant value of a specific color, and v is a variable. When m or n equals one, we just omit it in the expression. The sign '+' means addition of two multi-sets, as introduced in [15].

Fig. 1 shows an ED-net model and its instance. The model describes a complex event of the conjunction of two primitive events, with the constraint that readers of the two primitive events are in the same group.

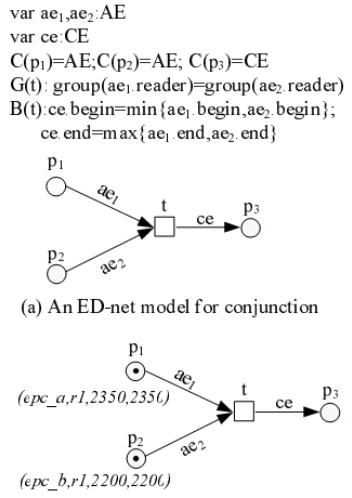

Figure 1. An example of ED-net model.

B. Dynamic behavior of ED-net

The state of an ED-net is represented by a marking that records the number and color of tokens in each place. A

marking is defined as a function $M : P \rightarrow \{C(p)_{MS} | p \in P\}$, where $C(p)_{MS}$ is the multi-set over the color set of place p. Take the instance of ED-net in Fig. 1 for example, its current state can be represented as a marking M: M = (1`(*epc_a*, *r*1, 2350, 2350), 1`(*epc_b*, *r*1, 2200, 2200), ∅). $M(p_1)$= {(*epc_a*, *r*1, 2350, 2350)}, $M(p_2)$= {(*epc_b*, *r*1, 2200, 2200)} and $M(p_3)$=∅ as place p_3 has no token.

The procedure of taking a step in an ED-net is as follows: First, check if a transition could be fired under current marking according to the firing rules introduced later. More than one transition may be enabled in one step, we randomly choose one to occur. Second, do the assignment operations according to the body of the transition, calculating the start and end time of the complex event. For example, for transition *t* in Fig. 1, value (*2200, 2350*) will be assigned to variable *ce*. Third, remove tokens from the input places of transition *t* and add tokens to the output places of transition *t*. The number and color of tokens to be consumed and produced are determined by corresponding arc expressions. According to the arc expression in Fig.1, tokens (*epc_a*, r_1, *2350*, *2350*) and (*epc_b*, r_1, *2200*, *2200*) are removed from p_1 and p_2 respectively and token (*2200*, *2350*) is added to p_3. Thus, the new marking of the ED-net is (∅, ∅, *1`(2200, 2350)*).

Firing conditions for a transition in P/T net [16] are also available in ED-net, which means that for a transition to be fired, there must be enough tokens in all of its input places. Besides of this, guard expression of the transition in an ED-net must be satisfied. We summarize the process of deciding whether a transition *t* could occur under marking *M* as follows: Firstly, check if all the input places of transition *t* are marked under marking *M*. We can see that p_1 and p_2 are both marked in Fig. 1; Secondly, If step 1 is satisfied, find a binding for variables appearing on all the input arcs of transition *t*. In Fig. 1, transition *t* has two input arcs p_1t and p_2t, and two variables ae_1 and ae_2 appear in the arc expressions. Under current marking, they could only be bound with (*epc_a*, r_1, *2350*, *2350*) and (*epc_b*, r_1, *2200*, *2200*) respectively. Multiple binding results could be found when tokens in input places are more than needed; Thirdly, Evaluate guard expression of transition *t* under a binding established in step 2. Only when the result is true, can transition *t* be fired. Otherwise, go to step 2 and choose another binding for corresponding variables. In case the guard expression cannot be satisfied under all the possible bindings, transition *t* cannot be fired.

C. ED-net models for complex events

Non-temporal complex events include conjunction complex event, disjunction complex event and negative complex event. The ED-net model for a conjunction complex event of two primitive events has been shown in Fig. 1. A negative event should be associated with a time-constrained event; otherwise it is meaningless to discuss the occurrence of an event during an endless interval. We will introduce the modeling of negative event in the model for an interval-constrained complex event (*WITHIN*).

A model for the disjunction of two primitive events is shown in Fig. 2. For convenience, we mark the name of the event under its corresponding place in the graphical representation of the model. Once one of places p_1 and p_2 is marked, which means that one sub-event is detected, transition t_1 or t_2 will be fired, and place p_3 will be marked with a token of color *CE* whose value is obtained from the corresponding primitive event. The model is also available for the disjunction of complex events; we only need to change colors of places p_1, p_2 and variables ae_1, ae_2 to be *CE*.

Temporal complex events refer to events with time-constraint, including the occurrence order of sub-events, distance of two events and the interval of an event. The work in [11] has listed a group of temporal complex event constructors covering most of the detecting situations. However, parameterized constraints are not included in the description of complex events. For example, constructors *SEQ+* and *TSEQ+* both express the periodic occurrence of one or more occurrences of an event, but neither specifies the exact number of occurrences. The imprecise description may cause unexpected results. Also, parameters are necessary and important in the specification of a complex event.

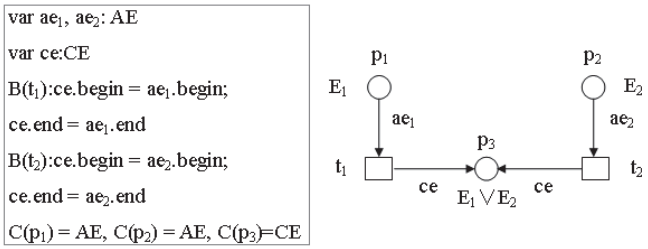

Figure 2. ED-net model for disjunction

Sequential constructor specifies that the occurrence of one event is after another. The semantics of "after" varies according to different understandings. When a user say event E_2 occurs after event E_1, all of these situations could be distinguished by the guard expression defined in the ED-net model. An ED-net Model for a sequence complex event E_1;E_2, and the semantics of "after" corresponds to the third situation, as the guard expression of transition t is $ce_1.end < ce_2.begin$.

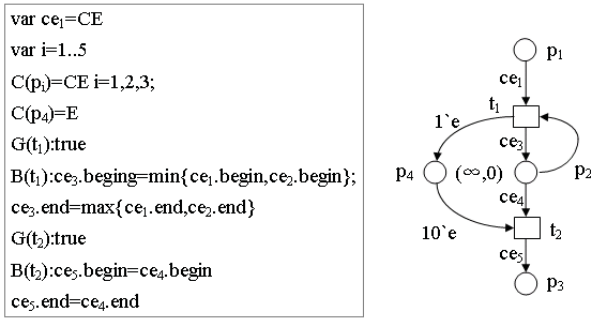

Figure 3. ED-net model for aggregation

The modeling of distance-constrained sequential complex event TSEQ(E_1; E_2,t_1,t_2) is similar to the model of sequential complex event, by changing the guard expression of transition *t* to be $(ce_1.end < ce_2.begin) \wedge (ce_2.end - ce_1.end > t_1) \wedge (ce_2.end - ce_1.end < t_2)$, which indicates that the distance of E_1 and E_2 is bounded by t_1 and t_2.

Fig. 3 shows an ED-net model for an aggregation complex event E, which occurs when its sub-event E_1 has occurred ten times. Places p_1 and p_3 corresponds to events E and E_1 respectively. As soon as E_1 occurs, place p_1 is marked. Then transition t_1 can be fired and a token e is produced in place p_4. The number of tokens in p_4 indicates the occurrence frequency of event E_1. When the number reaches 10, transition t_2 can be fired and ten tokens in p_4 are consumed according to the arc expression 10`e on arc p_4t_2.

We define the interval of an aggregation complex event to be from the earliest start time to the latest end time of all the sub-events. Instead of collecting all the sub-events and finding out the smallest and greatest values, we update the interval of complex event E each time a sub-event arrives, and when all the sub-events are detected, the latest value is the interval for E. In Fig. 3, transition t_1 updates the interval of complex event E according to the time of past occurrences of E_1 (from place p_2) and the time of E_1's new arrival(from place p_1). On the first arrival of E_1, transition t_1 will consume a token of (∞, 0) from place p_2, which is assigned on creation of the model. After the firing of t_1, token in p_2 will be updated to be (*ce1.begin, ce1.end*), which is exactly the time of the first occurrence of E_1:

$ce_3.begin = min\{ce_1.begin, ce_2.begin\} = min\{ce_1.begin, \infty\} = ce_1.begin$

$ce_3.end = max\ \{ce_1.end, ce_2.end\} = max\{ce_1.end, 0\} = ce_1.end$

After ten arrivals of E_1, transition t_2 occurs and place p_3 has a token whose color indicates the time of complex event E.

IV. Detecting Complex Events with ED-net models

In this section, we will introduce how to detect complex events based on ED-net. It is assumed that the RFID data have been filtered before the detection process and the inputs of the event detector is clean. The filtering step could eliminate redundant data [17] [18]. The detection process takes filtered RFID data as input, and sends signals to applications when an event is detected. As introduced in previous section, each event corresponds to a place in an ED-net, which is marked with a token when the event occurs. The ED-net model behaves dynamically by taking steps, and once an event place is marked after one step, associated actions defined in an application will be taken, such as sending an alarm or updating database.

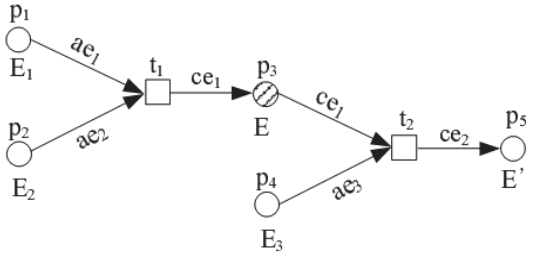

Figure 4. ED-net model for E and E′

The detection process could be divided into two parts: constructing an ED-net model for all the events to be detected and detecting complex events based on the ED-net model which takes RFID data as inputs. To improve the efficiency of the detection method, we combine ED-net models for different complex events and a step-by-step detection mode is applied. Details of the two parts are given below.

A. Constructing ED-net models

In the work of [11] detection is carried on separately. The graph-based computation model merges common sub-graphs, thereby avoiding multiple detections for sub-events. However, common sub-events in different complex events are not combined together. Therefore, they will be detected multi-times in separate detection processes. Instead of modeling all complex events separately, we combine the ED-net models for all the events to be detected in one ED-net model. Note that the final ED-net model may be composed of several independent parts which share no common sub-events.

Algorithm 1: Constructing ED-Net model

```
Input: complex events set S_E
Output: ED-Net model N
  foreach complex event e in S_E do
    if e has not been modeled in N then
       Get e's sub-events set C_E;
       foreach sub-event c_e in C_E do
       if c_e has been modeled in N then
    Add a place p' as a copy of place p;
       else
         Build c_e's ED-net model;
         Extend N with c_e's model;
       end
      end
      Build the ED-net model for event e
(taking its sub-events as inputs);
      Extend N;
    end
  end
return S_N
```

Main steps of constructing an ED-net model for a set of complex events are given in Algorithm 1. A complex event is often composed of several sub-events, which may also contain sub-events. The constructing of the complex event takes the places of its sub-events as inputs. Suppose we have complex events E=($E_1 \wedge E_2$) and E'=($E \wedge E_3$), assuming E_1, E_2 and E_3 are all primitive events. Fig. 4 shows the sketch of ED-net model for E and E'. The caption under place is the name of its corresponding event. The shadowed place p_3 corresponds to event E, and it is also a part of ED-net model for E'.

Different events often share common sub-events. Therefore, an event may be used in more than one detection model. In this case, we duplicate the place for the common sub-event. Event E participates in both complex events E_1 and E_2. Once an event E is detected in place p_1, the information will be duplicated to places p_2 and p_3, which will be used in the modeling of E_1 and E_2 respectively. In this way, event E only needs to be detected once, instead of twice in the separate detection for E_1 and E_2.

B. Detecting complex events with ED-net model

Detection for complex events behaves as Algorithm 2 lists. The detector works as long as RFID data are received. The marking of the ED-net model is a global variable, and whenever a primitive event is detected, the marking is updated. To state clearly, we use notations $\bullet t$ and $t\bullet$ to represent sets of input and output places of transition t respectively.

Algorithm 2: Detect complex events based on ED-net

```
Input: ED-net model N = (Σ,P,T,A,C,G,B,E)
M:Current marking of N;Enabled transition
set Te = ∅;
Repeat
  foreach t in T are marked do
    repeat
      Find b for variables related to t
    until G(t) is true under binding b;
          Add transition t to Te;
  foreach t in Te do
    Fire t;
    Evaluate output arc expressions of t
      foreach place p in •t do
         M'(p)= M(p) - E(pt);
      end
      foreach place p in t• do
         M'(p)= M(p) + E(tp);
         if p is a complex event
            Send M to applications;
         end
    foreach place p in P - (•t ∪ t•) do
       M'(p)= M(p);
    end
    Change current marking M to M';
    Remove transition t from Te;
  end
until no RFID data are received;
```

V. CONCLUSION

We have proposed a method for the detection of complex events in RFID, based on a formal model named ED-net. ED-net offers unified ways for describing both temporal and parameterized constraints of events and defining rules for calculating attributes of complex events. Color sets and functions are used to specify attributes and constraints of events. Constraints of a complex event are expressed by the structure of corresponding ED-net model and guard expressions associated with transitions. Attributes of a complex event can be obtained from those of its sub-events, and the calculation rule is specified in the bodies of transitions. Our detection method describes all complex events to be detected in one model; common sub-events are detected only once, instead of multiple times in independent detecting processes for these complex events, thereby improving efficiency of our methods.

We implement the prototype of ED-net with Java language in RFID test environment and compare it with traditional non ED-net algorithm such as RCEDA[11]. We produce the RFID complex events with 3 sub-events combined about 1000 per seconds, and the average latency of detecting complex events has been efficiently reduced in our experiments. In our experiment, the average CPU occupation time maintained an acceptable level with the average latency down in detecting.

Our future work is to promote our detection method in an RFID event detector and apply it in specific applications.

Abstract

This paper gives a novel method of investigating flow-sensitive pointer analysis for multithreaded program based on petri net. The method mainly borrows causal dataflow analysis idea from Azadeh Farzan. Petri net is used to describe control flow structure of multithreaded program. And pointer points-to information is propagated along causal dependencies of events in the partial order execution of petri net. The problem of pointer analysis is reduced to the coverability problem on the petri net.

***Keywords*—pointer analysis; multithreaded program; flow-sensitive; petri net**

I. Introduction

With development of multi-core technique and extensive use of program language supporting threads, multithreaded programs are becoming more and more common. However, many mature and traditional program analysis techniques mainly aim at sequential programs. Because of non-determination of multithreaded program semantics, analysis process of multithreaded program is more difficult, compared to that of sequential program. Interactions among multiple threads make it difficult to extend traditional program analysis techniques that are developed for sequential programs to multithreaded programs[5]. Research on analysis of multithreaded program is still immature.

Pointer analysis[4] is a fundamental static program analysis technique. With many years' research, there exist many publications about pointer analysis of sequential programs[1, 3]. Pointer analysis of multithreaded programs makes slow progress, compared to that of sequential programs. But there were still some work on multithreaded pointer analysis[5]. As far as flow-sensitive pointer analysis for multithreaded program is concerned, the main difficulty is the potential interferences among concurrent threads. Two threads interfere when a thread assigns to the shared pointer variable that another thread accesses(i.e., dereference, read or assign). Therefore, the key problem for designing flow-sensitive multithreaded pointer analysis algorithms is how to characterize inter-thread interference. This paper presents a novel method of investigating flow-sensitive pointer analysis for multithreaded program based on petri net. The method borrows causal dataflow analysis idea from[2]. It captures control flow structure using 1-safe petri net and explores partially ordered execution of petri net. The points-to information of pointer is propagated along causal dependency of events. Pointer analysis problem of multithreaded program is converted to the marking coverability problem of petri net.

The rest of paper is organized as follows. Section II introduces some preliminaries containing 1-safe Petri net and Mazurkiewicz trace. Section III presents multithreaded pointer analysis based on petri net. Section IV shows a case study and Section V gives some related work analysis. Section VI concludes.

II. Preliminaries

A petri net is a triple N=(P,T,F), where every element in set P is called a place, tokens in every place represents resources that each place owns, each element in set T is called a transition, set P and T satisfying $P \cap T = \emptyset$, and the binary relation F is called flow relation of net N, satisfying $F \subseteq (P \times T) \cup (T \times P)$. Net N is called 1-safe petri net if each place contains at most one token at any time. A trace alphabet is a pair (Σ,I) where Σ is a finite set

of events, every element representing action and relation $I \subseteq \Sigma \times \Sigma$ is called the independence relation, it being irreflexive and symmetric. $D = (\Sigma \times \Sigma) - I$ is called the dependence relation. A Mazurkiewicz trace is a behavior that describes a partially-ordered execution of events in Σ.

III. Multithreaded Pointer Analysis Based on Petri Net

This section mainly contains three parts. In the first place, the definition of multithreaded language PML(Pointer-included simple Multithreaded Language) is introduced. In the second place, the construction of petri net model of PML program is illustrated. In the last place, multithreaded pointer analysis based on petri net is proposed. For an arbitrary given PML multithreaded program P, the aim of pointer analysis is to determine the points-to set of pointer variable at some program point. The outline of the method of investigating flow-sensitive pointer analysis for multithreaded program based on petri net is as follows. Firstly, program P is transformed to P_transformed, which is semantically equivalent to program P. Secondly, petri net representation N of program P_transformed is constructed according to petri net representation of basic statement. Thirdly, CCD framework instance for multithreaded pointer analysis based on petri net is given. Fourthly, MOT(Meet Over All Traces solution) solution to reaching definition analysis of pointer variable is reduced to a coverability problem on the petri net which is solved by PEP(Programming Environment based on Petri Nets) tool based on partially ordered unfolding techniques.

A. Multithreaded language definition

The analyzed multithreaded program in this paper is based on simple multithreaded language PML(Pointer-included simple Multithreaded Language). The syntax of PML is shown in figure 1. Pointer_first_level in figure 1 is a set of pointer variable whoes type is declared as int *. And Pointer_two_level is a set of pointer variable whoes type is declared as int **.

B. Petri net model of PML program

For a given PML program P, this paper utilizes petri net to represent program control flow structure. In order to construct petri net model for PML program, there are two steps: (a)source code transformation of multithreaded program P keeping semantically equivalent, let transformed program be P_transformed; (b)model control flow structure of P_transformed using petri net.

P::=defn; threadlist
threadlist::=null | stmt || threadlist
defn::=int X | lock | int *p | int ** s |defn; defn
stmt::=stmt;stmt | X=e | *p=e| e=*p | p=&X| p=q | s=&p | p=*t | *s=q
|while(b){stmt} | if(b) then {stmt} else {stmt}
|acquire(l) | release(l) | skip
e::= i| Y| e+e| e-e| e*e| e/e
b::=true| false| e op e| b∨b | ¬b
$i \in Integer; X, Y \in Var; p, q \in Pointer\_first\_level;$
$s, t \in Pointer\_two\_level; l \in Lock; op \in \{<, \leq, >, \geq, =, ! =\}$

Fig. 1. Syntax of PML

1) Semantically equivalent source code transformation: For multithreaded program P, firstly, find all assignments statements in relation to dereference to two-level pointer variable, such as p=*t or *t=q statements. Secondly, do with the foregoing statements as follows: (using p=*t as an example to illustrate)

- scan source code of program P, for two-level pointer variable t, find all assignment statements where t is assigned. In the simple multithreaded language PML, pointer variable is one-level or two-level variable and PML currently doesn't consider type cast. So the value of two-level pointer variable is only changed by assignment statements such as $s = \&t$, or s=t. When the found assignments in the thread containing statement p=*t, the last assignment statement to t is selected. Otherwise, all assignment statements in other threads or some relevant assignment statements according to synchronization structure of multithreaded program are selected.
- convert statement p=*t to statement section(*) according to all selected assignment statements (t=&w, t=&v,$\cdots$,t=&q; let the number be N), as illustrated in figure 2. For statement *t=q, there exists corresponding statement section(**) similar to(*).
- replace all assignment statements in relation to dereference to two-level pointer variable t with statement section(*) or (**) firstly, then delete all assignment statements referring to variable t. The remainder is program P_transformed, which is semantically equivalent to program P. The pointer variables in program P_transformed are all single-level pointers. The assignment statements of pointer variable only contain following type: p=&X and p=q.

2) Petri net representation of program control structure: This paper models control flow structure of P_transformed using petri net. The transition corresponds to program statement, and the place is used to represent intra-thread control flow relation, inter-thread dependency relation and synchronization relation. Petri net representations of basic statements are illustrated in Figure 3.

```
{    int index =random(0,N-1);      //generate a number from 0 to N-1 randomly
     if (index= =0) then { t=&w;   p=w; }
        else if(index = = 1) then { t=&v;   p=v;}                    (*)
          else ……
        else if (index = = N-1) then { t=&q ; p=q; }
}
```

C. Multithreaded pointer analysis based on petri net

The method of investigating flow-sensitive pointer analysis for multithreaded program based on petri net in this paper mainly borrows causal dataflow analysis idea from [2]. PML Program P is transformed to P_transformed, which is semantically equivalent to program P. Thus pointer analysis of program P is equivalent to that of program P_transformed. P_transformed doesn't contain procedure call. The statements that could change pointer variable points-to information can only be basic statements such as p=q and p=&X. Under this circumstance, pointer analysis for program P_transformed, that is, determining points-to set of pointer variable p at program point n, is equivalent to determining which assignment statements referring to variable p in program P_transformed could reach program point n, namely reaching definition analysis of variable p. Then reaching definition analysis of pointer variable p is solved using a concrete framework instance based on CCD(Concurrent Causal Dataflow analysis) framework proposed in [2].

1) CCD framework instance for multithreaded pointer analysis based on petri net: The CCD framework instance used for multithreaded pointer analysis is a quintuple$(N, \mathcal{S}, \mathcal{F}, \mathcal{D}, \mathcal{D}^*)$, including petri net model of P_transformed N=(P,T,F), property space $\mathcal{S} = (\mathcal{P}(\mathcal{D}), \subseteq, \cup, \emptyset)$, finite pointer points-to set $\mathcal{D}$, powerset$\mathcal{P}(\mathcal{D})$, $\emptyset$ representing initial pointer points-to set, $\cup$ determining how we will combine points-to information along program control structure reaching the same control point in a program. For program P_transformed, let pointers=$\{$p | there exists assignment statement to pointer variable p in P_transformed$\}$. Scanning program P_transformed and finding all pointer assignment statements similar to $p = \&X$, for example $p = \&X, q = \&Y, p = \&A, s = \&C$, and denoting p-to=$\{X, A, \cdots\}$, q-to=$\{Y, \cdots\}$, s-to=$\{C, \cdots\}, \cdots$. Finally merging foregoing (*)-to set as set pointers-to. Thus, $\mathcal{D}$=pointers $\times$ pointers-to = $\{$(p,X) | $p \in$ pointers $\wedge$ $X \in$ pointers-to$\}$. For any transition t, set $\mathcal{D}_t$ and $\mathcal{D}_t^*$ are defined. $\mathcal{D}_t^*$ represents points-to information relative to transition t, and $\mathcal{D}_t$ expresses points-to information that may modify when it executes. $\mathcal{D}_t$ and $\mathcal{D}_t^*$ satisfy condition $\mathcal{D}_t \subseteq \mathcal{D}_t^* \subseteq \mathcal{D}$. And $\mathcal{D} = \{\mathcal{D}_t \mid t \in T\}$ and $\mathcal{D}^* = \{\mathcal{D}_t^* \mid t \in T\}$. For each transition t of petri net, function f_t is defined in order to represent how points-to information of pointer variable changes when t is executed.

2) MOT solution to multithreaded pointer analysis based on petri net: It can be verified that CCD framework instance for multithreaded pointer analysis based on petri net proposed in this paper is a distributive instance. The multithreaded pointer analysis problem can be solved by utilizing algorithm proposed in [2].

IV. Case Study

This section gives a simple PML program to illustrate the method of multithreaded program pointer analysis proposed in this paper.

- There are three threads in the example program, as given in figure 4. Some statements in three threads are synchronized by lock variable. The dealt problem is to determining the points-to information of pointer variable p in statement t14 and statement t32.

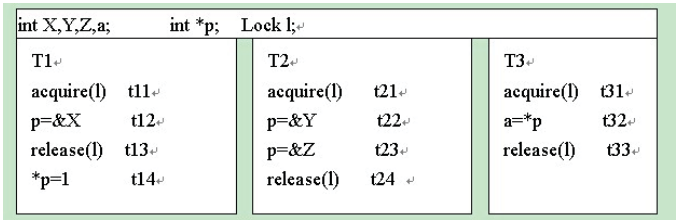

Fig. 4. A simple PML multithreaded program

- Petri net structure of program(Figure 5)
- Solution to MOT
  Points-to information of pointer variable at program point n is points-to information that holds before the execution of corresponding transition t of program's

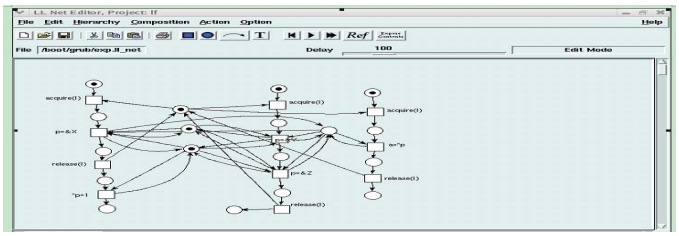

Fig. 5. Petri net structure of program

petri net. And the problem of computing MOT(t) solution is reduced to the problem of marking reachability on petri net.

From the experiment, we can acquire the conclusion that points-to information of pointer p holding before the execution of t14(*p=1) is d_1, d_2, d_3(let $d_1 = (p, x), d_2 = (p, y), d_3 = (p, z)$.), and that of pointer p holding before the execution of t32(a=*p) is d_1, d_3. Some related result are shown as figures 6,7.

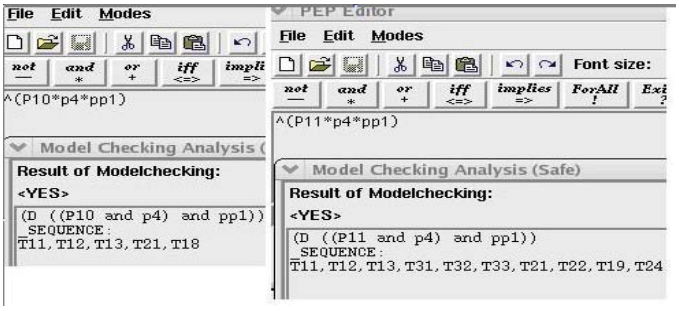

Fig. 6. Some related result

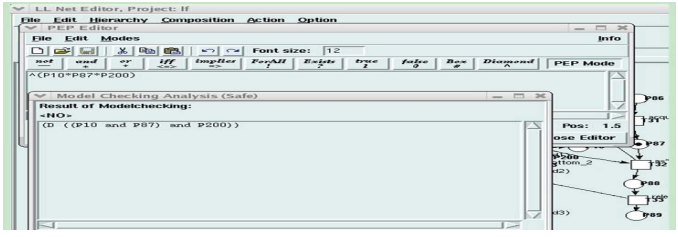

Fig. 7. Some related result

V. Related Work Analysis

Pointer analysis of multithreaded programs makes slow progress, compared to that of sequential programs. There were relatively little work on multithreaded pointer analysis. The first flow-sensitive pointer analysis algorithm for multithreaded program is proposed in[5]. It uses a parallel flow graph to represent multithreaded program. And no edges between concurrent threads are supposed. Similar to traditional sequential program flow-sensitive pointer analysis, dataflow equation systems for four basic pointer assignments and concurrent structure are established and are solved by fixed-point iteration algorithm. It handles many constructors and has many advantages, but it only analyzes programs with structured concurrent constructs such as **fork-join**, and it ignores synchronization constructs such as **lock**. Flow-sensitive pointer analysis for multithreaded program introduced in this paper is based on petri net.Petri net commendably represents synchronization constructs and unstructured multithreaded program. And petri net based pointer analysis provides a novel perspective to consider pointer analysis for multithreaded program. Multithreaded pointer analysis can be reduced to coverability problem on the petri net which is solved by PEP tool based on partially ordered unfolding techniques.

VI. Conclusion

This paper proposes a novel method of investigating flow-sensitive pointer analysis for multithreaded program based on petri net. The method has been applied to several simple designed programs and the experiment results show its effectiveness. It is motivated by causal dataflow analysis idea from[2]. It models multithreaded pointer program using 1-safe petri net, introduces CCD instance for multithreaded pointer analysis based on petri net, and solves the instance using petri net reachability analysis.

Facilitate IT-Providing SMEs in Software Development: a Semantic Helper for Filtering and Searching Knowledge

Riccardo Martoglia
DII – Department of Information Engineering
University of Modena and Reggio Emilia
Modena, Italy
riccardo.martoglia@unimo.it

Abstract— **Software development is still considered a bottleneck in the advance of the Information Society. The recently started FACIT-SME European FP-7 project targets to facilitate the use and sharing of Software Engineering methods and best practices among software developing SMEs. On top of an Open Reference Model (ORM) serving as an underlying knowledge backbone, specific filtering/search mechanisms will support the identification of adequate processes and practices for specific enterprise needs. In this paper, we focus on the proposal of knowledge-based text analysis and retrieval techniques which will form a key component of the advanced filtering mechanisms of the project. The proposed solution is designed to be more powerful and flexible than standard syntactic search techniques, but also to be easily applicable for any SME. The experimental evaluation on the preliminary implementation shows promising results.**

Keywords-software engineering; information retrieval; text analysis; semantic knowledge; semantic similarity.

I. INTRODUCTION AND MOTIVATION

Over the last years, Software Engineering (SE) research has provided more and more advanced and promising techniques for facilitating software development. In particular, the integration between Software and Knowledge Engineering has recently become very important, and several techniques possibly enabling better domain knowledge sharing and assisting developers in specific tasks such as component reuse [1] or software process assessment [2, 3], have been proposed to the research community [4].

Nonetheless, back to the "real" software development world, recent studies have shown that a large number of fundamental challenges still need to be faced. In Europe, software development is becoming a bottleneck in the development of the Information Society [5], while, on a global scale, the quality and productivity of work has not been able to keep up with the society software needs [6]. These issues are especially critical in the case of SMEs in the software development market: indeed, even if innovative SE methodologies are constantly devised and presented, many enterprises are usually not able to take full advantage from them since they generally lack the resources and knowledge needed for the internal deployment of the required methods and tools. Indeed, being software an often underpaid product, SMEs need to allocate mostly all of their available resources on its production rather than, for instance, on new technology training.

This is the challenging scenario of the recently started European FP7 3 years project "Facilitate IT-providing SMEs by Operation-related Models and Methods (FACIT-SME)". The main project goal is to facilitate IT SMEs in using SE methods for design and development, systematizing their application integrated with the business processes. Another fundamental goal is to provide efficient and affordable certification of these processes according to internationally accepted standards, and to securely share best practices, tools and experiences with development partners and customers. In order to achieve these goals, the project will develop a novel Open Reference Model (ORM) [7] for ICT SMEs serving as an underlying knowledge backbone and, on top of that, a customizable Open Source Enactment System (OSES) [8] will provide IT support for the project-specific application of the ORM. More specifically, the ORM will store existing reference knowledge for software-developing SMEs, including different engineering methods, tools, quality model requirements and enterprise model fragments of IT SMEs, in a computer-processable form. On top of the ORM repository, specific search mechanisms, which will be a key part of the OSES, will support the identification of adequate processes and data structures for a specific enterprise. Different application scenarios, identified with the support of the participating SMEs and enumerating the possible use cases of the FACIT-SME solution, will be dealt with. The most notable ones include supporting the organizations in their need to find a new methodology ("From Scratch" scenario) or to modify an existing one in order to better manage its software development projects ("From Methodology" scenario). In all cases, through a filtering phase, which takes as input company and project information and, for the second scenario, existing methodology descriptions, the organization will receive a set of suggestions in the form of the most relevant / useful elements and models in the ORM. Subsequent phases will also include helping the organization to easily check quality constraints and refining the models and results in order to adapt it to its needs. Besides five R&D partners providing the required competences, the project consortium also includes five SMEs operating in the ICT domain which will evaluate the results in daily-life application.

In this paper, we focus on the foundations we are laying for the filtering/searching mechanisms, carefully considering the actual user-targets these techniques will be aimed at. More specifically, we will primarily take advantage of textual

information, a vital knowledge source not only in the ORM defined in the project but also in the documentation already available in each enterprise. In this respect, we propose an innovative approach based on text analysis and semantic retrieval techniques leading to the following achievements:

- it is powerful enough to provide enhanced searching effectiveness over standard syntactic techniques;
- it is general and flexible as a basis of many functionalities offered by the OSES (i.e. for filtering software methodologies for software process assessment and improvement, quality requirements for helping in certification process, best practices for faciliting knowledge sharing, and so on);
- it is devised for IT SMEs, providing them with easy-to-apply methods that do not require big investments or knowledge prerequisites, allowing them to query for the information they need in the way they are used to;
- it exploits the large amounts of textual knowledge (i.e. methodology descriptions, and so on) already available in each enterprise, without requiring complex conversions toward complex structured formats which would be time and cost consuming.

Such approach forms the foundations of a **Semantic Helper** component which will be overviewed in Section II, while the analysis and semantic search techniques themselves will be deepened in Sections III and IV, respectively. Section V shows the promising results of a preliminary experimental evaluation, while Section VI concludes the also by briefly analyzing related works.

II. SEMANTIC HELPER OVERVIEW

The Semantic Helper will support other components of the FACIT-SME solution in filtering/searching/analyzing relevant information available in the ORM, including:

a) **assisted filtering / selection** of ORM elements given specific enterprise objectives (e.g. in "From Scratch" scenario to give pointers to useful information for certification status);
b) **assisted suggestion proposal** for a given enterprise methodology (e.g. in Scenario "From methodology" to help identifying relevant information or gaps between the given methodology and the ORM methodologies);
c) **automatic matching** between ORM documents (such as quality requirements and SE methodologies).

In order to facilitate such processes, a representation of the key parts of the ORM in a semantic and machine-processable way is needed. Given the predominant importance of textual information in the ORM, first of all we provide the Semantic Helper with appropriate **text analysis** techniques (see Section III), which are designed to automatically extract a shared "terminology" from the given set of **documents**. The extracted terminology is enriched with statistical and semantic information (i.e. links to thesauri and domain vocabularies, definitions, synonyms), in order to obtain a computer-processable semantic glossary Note that the analysis can be applied not only to documents coming from the ORM (e.g. about different quality requirements or software methodologies), but also to any "external" document or query submitted by an enterprise. In any case, once documents are reduced to a set of terms with associated information, appropriate **semantic similarity** techniques (detailed in Section IV) are exploited to easily identify relevant documents w.r.t. to a given query document, and to produce a list of suggestions ranked on the similarity (relevance) score.

III. TEXT ANALYSIS TECHNIQUES

A. Text Analysis and Keyword Extraction

The goal for text analysis and keyword extraction in the FACIT project is to design and develop an effective and easy-to-apply technique for automatically extracting terms (and their associated semantic information and statistics) from the submitted text documents. In particular, we wanted to devise a flexible technique to be exploited both for "off-line" analysis, thus working on the textual descriptions already available in the ORM, and for "on-line" querying operations, i.e. applied on the fly to the submitted query documents. Even if many packages are available for keyword extraction purposes, most of them do not allow sufficient configuration and extension options, making their integration with the future FACIT solution very complex. Therefore, we preferred to design a custom-made technique tailored to the FACIT environment. Here is a short summary of the steps performed, for each text document, in the text analysis phase:

1. **Tokenization**: the text is "tokenized" (words are identified, punctuation is removed);
2. **Stemming**: the tokens are "normalized" and "stemmed", i.e. terms are reduced to their base form (managing plurals, inflections, ...) (as we will see this will be very useful to enhance the effectiveness of the similarity computation phase);
3. **POS (Part of Speech) Tagging**: the tokens are "tagged" with Part of Speech tags (i.e. nouns, verbs, ...);
4. **Composite terms identification**: possible composite terms (such as "product action plan" or "product requirement") are identified by means of a simple state machine and of POS tags information;
5. **Filtering and enrichment:** by exploiting external knowledge sources, the most relevant terms are selected and they are associated to additional information (such as definitions, synonyms, …). More specifically we make use of the IEEE Software and Systems Engineering Vocabulary [1], a knowledge source covering specialist terms in the project area, and the WordNet[2] English thesaurus, possibly complementing the specialist source with general knowledge about English concepts;
6. **Term statistics and weights computation**: weights are computed for each of the terms, reflecting their

Figure 1. An excerpt of the FACIT-SME semantic glossary (global view)

importance and meaningfulness in the text. As we will see, this information is fundamental in computing accurate text similarities (more on this in the following sections).

By applying batch text analysis to the documents currently available in the ORM, we achieved a first significant result in the FACIT-SME project, i.e. the automatic generation of a **semantic glossary**, representing a first step toward the sharing of the most important concepts available in the model and the automatic computation of text similarities. Thanks to the automatic text analysis procedure, this first draft can be easily updated/enriched in case of new content added to the ORM, while more fine-grained user interventions for adding/modifying/eliminating information are also possible. The following section describes the semantic glossary structure more in detail.

B. FACIT-SME Semantic Glossary

The Semantic Glossary consists of a **global view** (all terms in all documents, together with their statistics) and a **per-document view** (terms occurrences in each of the documents with their statistics). The **glossary global view** is an alphabetical sort of all the extracted terms, in a tabular form. Figure 1 shows an excerpt of the glossary global view. The format is:

TERM - the extracted term;
WN – whether the term is present in WordNet thesaurus;
IEEE – whether the term is present in the IEEE vocabulary;
SYNS – possible synonyms for the term (as extracted from the IEEE vocabulary and/or WordNet);
DEFS – possible definitions for the term (as extracted from the IEEE vocabulary and/or WordNet);
IDF – the inverse document frequency of the term in the collection;
DOC_LIST – a list of the documents IDs in which the term occurs.

The **glossary per-document view** is a list of all the term occurrences in the documents, sorted on the document ID, together with their statistics. Figure 2 shows an exercpt of the glossary per-document view. For each term (in each document) the report contains:

DOC – the document ID in which the term occurs;
TERM - the extracted term;
TF - the frequency of this term in the document, normalized by total number of terms in document;
WEIGHT - the TF*IDF weight of the term.

DOC	TERM	TF	WEIGHT(TF*IDF)
QM0001	iso	1	6,8024
QM0002	management	0,3333	0,6931
QM0002	quality	0,3333	1,0303

Figure 2. An excerpt of the FACIT-SME semantic glossary (per-doc view)

The glossary includes both synonyms/definitions and weight information, allowing, as we will see, the similarity functions of the Semantic Helper to draw useful knowledge from both the semantic and the classic text retrieval worlds. As to the semantic information, note that even if all the similarity techniques described in the next section are designed to work (and, as proved in Section V, provide encouraging results) without further intervention, the list of synonyms and definitions retrieved from the external knowledge sources could easily be refined manually by experts or automatically by means of techniques such as sense disambiguation [9, 10]. In addition, as in classic Information Retrieval, the importance (**weight**) of each keyword in each document is estimated. Beside term frequency (**TF**), we compute the inverse document frequency (**IDF**)[3] [11], which provides an estimate of the meaningfulness of each term. The weight is then computed as TF*IDF. In this way, very common terms which are present in a large number of documents have a lower weight and will give a lower contribution to the final similarity, since they are probably less meaningful.

IV. SEMANTIC SIMILARITY TECHNIQUES

As anticipated in the past sections, the need of effectively and efficiently computing similarities between documents is crucial to the project. To this end, we want to define a document similarity formula $DSim(D^x,D^y)$ which, given a source document D^x and a target document D^y, quantifies the similarity of the source document with respect to the target document. Being documents represented by sets of terms, semantic similarity computation becomes a matter of computing similarities between sets of terms. Therefore, document similarity will, in turn, use a combination of the scores provided by a term similarity formula *TSim* between the document terms. The computation of *DSim* between a given D^x and all the possible submitted D^y induces a **ranking** of the available documents with respect to the source one, thus predicting which documents are relevant and which are not with respect to D^x. For instance, by computing the document

[3] IDF is obtained by dividing the total number of documents by the number of documents containing the term and then by computing the logarithm of that ratio

similarities between a given quality requirement description and all the available software methodology descriptions of the ORM, the induced ranking will suggest all the software methodologies that could be relevant/related to the given quality requirement.

We provide different options with respect to the similarity formulas, so to be able to experimentally assess the ones most suited to the project. Equation (1) shows the standard document similarity formula between a given source document D^x and a target document D^y: the similarity is given by the sum of all term similarities between each term in D^x and the term (defined in (2)) in D^y maximizing the term similarity with the term in D^x:

$$DSim(D^x, D^y) = \sum_{t_i^x \in D^x} TSim\left(t_i^x, t_{j(i)}^y\right) \quad (1)$$

$$t_{j(i)}^y = \ argmax_{t_j^y \in D^y} \left(TSim\left(t_i^x, t_j^y\right)\right) \quad (2)$$

Note that (1) is not meant to be symmetric, instead it is conceived so to facilitate the ranking of the documents D^y with respect to document D^x. In case symmetry is needed, the summation in (1) can by extended to the terms of both documents. As to term similarity, the most basic option, only considering equal terms, is shown in (3), where the similarity *TSim* between two terms t_i and t_j is basically a Boolean formula valued 1 if the two terms are equal, 0 otherwise.

$$TSim(t_i, t_j) = \begin{cases} 1 & t_i = t_j \\ 0 & otherwise \end{cases} \quad (3)$$

Equation (4) proposes an extended (and possibly more effective) document similarity option, taking into account the weights as extracted by the text analysis process:

$$DSim(D^x, D^y) = \sum_{t_i^x \in D^x} TSim\left(t_i^x, t_{j(i)}^y\right) \cdot w_i^x \cdot w_{j(i)}^y \quad (4)$$

where $w_i^x = tf_i^x \cdot idf_i$; $w_{j(i)}^y = tf_{j(i)}^y \cdot idf_{j(i)}$. In this case, each term contributes to the final similarity with a different weight *w*, i.e. more frequent and more significant terms contribute more to the similarity between the two documents.

Let us now consider more advanced options for term similarity. Equation (5), besides equal terms, also takes **synonyms** and **semantically related terms** into account:

$$TSim(t_i, t_j) = \begin{cases} 1 & t_i = t_j \ \ or \ \ t_i \ SYN \ t_j \\ r & t_i \ REL \ \ t_j \\ 0 & otherwise \end{cases} \quad (5)$$

More specifically, the case of maximum similarity (value 1) is extended to the case where the two terms are synonyms (*SYN* relation). Moreover, the formula provides a further case where the two terms are not equal or synonyms, nonetheless they are in some way strongly related from a semantic point of view: such terms will contribute with a similarity of *r*, where $0<r<1$.

While the synonym information straightly comes from the text analysis phase, we consider two different ways of exploiting the extracted information and the external knowledge sources to determine wheter two given terms are semantically related. Equation (7) shows a possible way of computing the similarity by exploiting the glosses (definitions) of the terms:

$$t_i \text{ REL } t_j \iff \text{GSim}\left(\text{gl}(t_i), \text{gl}(t_j)\right) \geq \text{Th} \quad (7)$$

$$\text{GSim}\left(\text{gl}(t_i), \text{gl}(t_j)\right) = \sum \left|\text{ovl}\left(\text{gl}(t_i), \text{gl}(t_j)\right)\right|^2 \quad (8)$$

In this case, two terms are semantically related (*REL* relation) if the gloss similarity *GSim* between their glosses exceeds a given threshold *Th*. The Literature presents many possible ways of computing similarities between glosses. We found the extended gloss overlap measure [12] shown in (8) to be particularly effective in our context, especially with the IEEE vocabulary glosses. It quantifies the similarity between the two glosses by finding overlaps in them (the similarity is the sum of the squares of the overlap lengths). Other gloss similarity measures could also be exploited and investigated in the future, such as the gloss vector one described in [13].

Another possible way of computing semantic relatedness is to exploit the relations between terms coming from the WordNet thesaurus. Indeed, we adopt one of the most widely used methods in knowledge management, relying on the hypernymy relations of the thesaurus:

$$t_i \text{ REL } t_j \iff \text{HSim}\left(t_i, t_j\right) \geq \text{Th} \quad (9)$$

$$\text{HSim}\left(t_i, t_j\right) = \begin{cases} -\ln \frac{\text{len}(t_i, t_j)}{2H}, & \exists \ \text{lca}(t_i, t_j) \\ 0, & \text{otherwise} \end{cases} \quad (10)$$

In this case, two terms are semantically related if their hypernym similarity *HSim* exceeds a given threshold *Th*. In particular, the *HSim* shown in (10) derives from the works [9, 14] and computes a score which is inverserly proportional to the length of the shortest path connecting the (senses of the) two terms. H is a constant, which for WordNet is defined as 16. On the other hand, the similarity is 0 if the two terms are not connected in the WordNet hypernymy structures.

Note that the different document similarity and term similarity formulas presented in this section can be selected in a fully orthogonal way, so to be able to adapt in a flexible way to the specific settings and needs of the project.

V. Experimental Evaluation

In this section we present the results of the preliminary effectiveness evaluation we performed on the proposed techniques in the context of the project. We formed a collection of 1500 documents (i.e. textual descriptions) about quality requirements which will be part of the final ORM and derive from existing quality models such as CMMI [15] and ISO 9000 [16]. Then, we created different queries with reference to this collection; each query is either composed by a short text containing candidate keywords, so to simulate possible querying situations following the "From Scratch" scenario of the project (queries Q1-Q6, selected as the most representative ones), or by a whole new document ideally representing the description of an existing enterprise requirement or methodology, similarly to the "From

Query	Results			No sem syn/rel (baselines)			No kw sel (baselines)		
	Prec	Rec	F	Prec	Rec	F	Prec	Rec	F
Q1	1,000	1,000	1,000	1,000	1,000	1,000	0,011	0,420	0,022
Q2	1,000	1,000	1,000	1,000	1,000	1,000	0,005	0,330	0,010
Q3	1,000	1,000	1,000	1,000	0,969	0,984	0,946	0,240	0,383

Q5	0,878	1,000	0,935	1,000	0,077	0,143	0,986	0,235	0,380
Q6	0,923	0,949	0,936	1,000	0,333	0,500	0,967	0,369	0,534

Figure 3. Effectiveness analysis in terms of precision, recall and F-measure (standard results on the left, two baselines on the right)

Methodology" scenario (queries QT1-QT4). Each query will be submitted to the current implementation of the semantic helper (text analysis and similarity computation), so to generate a set of possible "suggestions", i.e. pointers to the relevant documents in the collection. In order to evaluate the effectiveness of our approach, for each query the output of the helper will be compared to a "gold standard", i.e. the relevant answers which were manually selected from the collection by experts in the field.

The first analysis we conducted was to assess the quality of the retrieved results in terms of precision and recall, which are typical evaluation metrics in the information retrieval field[4]. Figure 3 shows the results for Q1-Q6 (left part of figure). The shown results are those obtained with the gloss similarity as the similarity relatedness function (later we will discuss the WordNet hypernym-based one). Besides precision and recall, we also report, as a summarizing figure, their weighted harmonic mean (F-measure). Further, in order to emphasize the contribution of the different applied techniques to the achieved results, in the right part of figure we also present the results concerning two baselines, i.e. a standard retrieval method ignoring semantic synonyms and related terms information and another method not exploiting the text analysis phase (including stemming and composite terms identification). Let us now analyze the results in detail.

As we can see from Figure 3, the precision and recall levels achieved by the described techniques are very satisfying for all queries (equal or higher to 0.84 and 0.94, respectively). The processing of all queries greatly benefits from the text analysis phase: as the results of the second baseline show, without it recall levels significantly drop to 0.2-0.4 (for instance, different inflections of the same word are not correctly identified). Text analysis can also greatly benefit precision as, for instance, in Q1 and Q2: since they contain, among others, such composite expressions as "interface requirement" (Q1) or "configuration management system" (Q2), not correctly identifying them leads to a very large number of irrelevant retrieved documents (in the second baseline precision drops to less than 0.01, compared to 1 for the standard results). Differently from Q1 and Q2, queries Q3-Q6 also require synonyms and related terms management in order to provide satisfying answers: for instance, one of the key terms in Q3 is "supplier", a concept which is expressed as "vendor" in some of the documents (recall goes from 1 to 0.96 of the first baseline), while Q4 contains "purpose" which is

[4] Precision is defined as the fraction of retrieved documents which are known to be relevant, recall is the fraction of known relevant objects which were actually retrieved.

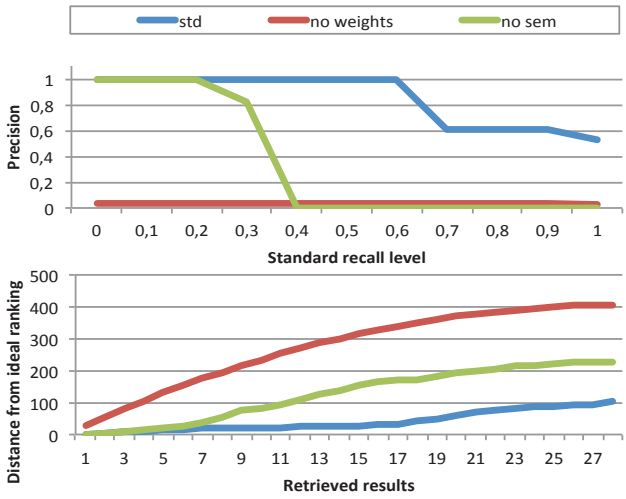

Figure 4. In-depth effectiveness analysis for query QT1: precision at standard recall levels (top) and distance from optimal ranking (bottom)

mostly expressed as "objective" in the collection (recall drops from 1 to less than 0.08). The same holds for the "related terms": by applying the gloss similarity semantic relatedness formulas exploiting the IEEE definitions, we achieve near-perfect recall levels (as opposed to the less than optimal ones of the first baseline) while also maintaining high precision levels. For example, most documents containing "review" are also relevant to Q5, which contains "audit", the ones containing "document" are also relevant to Q6 asking for "documentation", and so on. The WordNet based similarity proved equally useful as the gloss based one (for instance it correctly identifies the relatedness between "attribute" and "property", "procedure" and "process", and others), however we found that in some cases it may lead to several false positives, mainly due to the non-specialized nature of the employed thesaurus. For this reason, we decided to focus on the IEEE gloss similarity in these preliminary tests and to analyze the impact of the WordNet similarity more in detail in future tests.

We will now deepen the effectiveness analysis by considering queries QT1-QT4, in the form of actual text documents for which to find related documents in the collection. In this case, the queries are substantially more complex than Q1-Q6 and can possibly produce a very large number of results: for this reason, it is essential to evaluate not only which answers are returned but also their score and the induced ranking, so to assess whether the best suggestions are returned in the top positions and, thus, whether the proposed weighting scheme is effective. Figure 4 (top) shows, for QT1, the precision values obtained at different recall levels, i.e. when a given percentage of relevant documents have been found. The "standard" technique, which uses all the weights and semantic synonymy/relatedness information, is compared to non-weighted and non-semantic baselines. Notice that the standard technique achieves very high precision levels even at high recall levels: for instance, at recall level 0.6, the precision is still 1, while the baselines' precision levels have already dropped lower than 0.03. This confirms that our techniques are able to identify the most significant terms in the queries, without being misled by non-relevant ones. Figure 4 (bottom)

confirms the goodness of the retrieved results: for each alternative, the curve represents the normalized Spearman footrule distance [17] between the retrieved and the ideal ranking, i.e. the normalized sum of the absolute values of the difference between the ranks. Due to lack of space we do not show this detailed analysis for QT2-QT4, however we found that the good performance of QT1 is fully representative of all the queries. In particular, for QT1-QT4 the most relevant results are always among the first to be retrieved, and the precision at recall level 1 is always higher than 0.5 (orders of magnitude better than our baselines).

VI. Concluding Remarks

Several literature papers have highlighted possible benefits of combined knowledge engineering and software engineering approaches for specific SE tasks [2, 3, 4]. For instance, while standard reuse repositories are limited to plain syntactical search and generally suffer from low precision and recall [4], knowledge-based approaches such as [1] enhance the effectiveness of the component reuse task by proposing the usage of formal descriptions of components (in OWL) to be queried by specific graph query languages such as SPARQL. Other notable proposals have been presented, for instance, for facilitating software process assessment through formal descriptions of specific process improvement approaches such as CMMI [2, 3]. As already noted in [4], however, the discussion on integrating SE and KE approaches has been, in many cases, very academic, focusing on aspects like meta-modeling and neglecting applicability and usability.

The filtering/search approach we presented in this paper is designed to be effective and very easily applicable. In the FACIT-SME scenario, software-developing SMEs will be able to exploit all the advanced functionalities offered by these semantic foundations for a large number of tasks, such as software process and improvement and certification. Moreover, the approach does not have any prerequisite, such as the knowledge of complex formal representation/querying standards or the need of converting/updating the documentation already available in the enterprise. To this end, our proposal leverages on the strengths of both classic information retrieval (incorporating weight information [11]) and of knowledge-based techniques. In particular, semantic similarity techniques which already proved their effectiveness in a number of non-SE scenarios, from information disambiguation [9] to the querying of heterogeneous information in digital libraries and PDMSs [18], are adapted and extended in this new framework.

FACIT-SME has just started and the presented approach is the first step toward the project goals. Future work will include further analysis and refinements of the similarity techniques (especially for the WordNet-based ones), user feedback on the retrieved suggestions, Multilanguage information management and querying support, and the exploitation of other non-textual knowledge which will eventually be available in the ORM repository. Finally, the project evaluation phase, which will start soon, will involve user IT companies in actual scenarios in order to obtain useful opinions and suggestions about the quality of the proposed techniques and their improvement.

Acknowledgment

The research leading to these results has received funding from the European Community's Seventh Framework Programme managed by REA Research Executive Agency (http://ec.europa.eu/research/rea) ([FP7/2007-2013] [FP7/2007 - 2011]) under grant agreement n° 243695.

Inconsistency-Induced Heuristics for Problem Solving

Du Zhang

Department of Computer Science

Abstract

Inconsistency is ubiquitous in the real world, in human behaviors, and in the computing systems we build. Inconsistency manifests itself in data, information, knowledge, meta-knowledge, and expertise. The focus of this paper is on how inconsistency at the level of information or knowledge can be utilized as important heuristics in problem solving process. Using as an example a recent high profile question-answering system, the IBM's Watson computer system, we see the importance of reasoning about inconsistency in both Watson's tremendous success and its embarrassing moment in the first ever human-versus-machine Jeopardy! TV quiz show. We then describe a general framework for capturing inconsistency-induced problem solving heuristics. The take-home message is that inconsistency is a terrible thing to waste, and we should capitalize on what inconsistency reveals and utilize it to help improve our problem solving process.

Keywords*: inconsistency, heuristics in problem solving, inconsistency based heuristics.*

1. Introduction

Inconsistency is ubiquitous in the real world, in human behaviors, and in the computing systems we build. Inconsistency manifests itself in a plethora of phenomena at different levels in the depth of knowledge, ranging from data, information, knowledge, meta-knowledge, to expertise. Data inconsistency arises when patterns in data do not conform to an established range, distribution or interpretation. The exponentially growing volumes of data stemming from almost all types of data being created in digital form, a proliferation of sensors and sensor networks, and other sources such as social networks, complex computer simulations, space explorations, and high-resolution imagery and video, have made data inconsistency an inevitability. Information inconsistency occurs when meanings of the same data values become conflicting or when the same attribute for an entity has different data values. Knowledge inconsistency happens when propositions of either declarative or procedural beliefs, in explicit or tacit form, yield antagonistic outcomes for the same circumstance. Inconsistency can also emerge from meta-knowledge or from expertise. How to manage and reason in the presence of inconsistency in computing systems is a very important issue in semantic computing, social computing, and many other data-rich or knowledge-rich computing paradigms.

The focus of this paper is on how inconsistency at the level of information or knowledge can be utilized as important heuristics in problem solving process. Heuristics are strategies that rely on readily accessible but loosely applicable information to control problem solving processes [11]. Heuristic methods, such as a rule of thumb, an educated guess, an intuitive judgment, domain knowledge guided search, or common sense, are often deployed for problem solving processes where there does not exist an algorithmic approach or the search is exhaustive.

When confronted with inconsistency, human beings attempt to reason from inconsistency to consistency [7, 9]. Parallel to the cognitive consistency theory of human problem solving, generating and utilizing inconsistency induced heuristics is also conducive in computing system based problem solving process.

The rest of the paper is organized as follows. Section 2 offers a brief review on some related work. Section 3 describes the importance of reasoning about inconsistency through a recent high profile question-answering system, the IBM's Watson computer system, that demonstrates both its tremendous success and some embarrassing moment in the first ever human-versus-machine Jeopardy! TV quiz show. This case epitomizes the usefulness of inconsistency induced heuristics. In Section 4, we propose a framework where inconsistency in information or knowledge can be translated into useful problem-solving heuristics. Section 5 concludes the paper with remarks on future work.

2. Related Work

In cognitive science, the theory of *cognitive dissonance* underpins human behaviors toward

inconsistency [3, 5]. Human cognitions fall into irrelevant, consonant or dissonant categories. When confronted with dissonant cognitions or inconsistent knowledge, human beings will be in a cognitive, emotional, psychological, or behavioral dissonant state. As a result, individuals will experience some unpleasant psychological tension which has motivational properties not unlike those of hunger or thirst, and they will be motivated to reduce dissonance through behavioral changes.

There are cognitive dissonance related heuristics that are used to condition human behavior in the face of inconsistency, for instance, changing attitudes, beliefs or actions, justifying, blaming, or denying [3].

A number of reasoning paradigms in AI, such as resolution refutation or default reasoning, are based on recognizing and utilizing inconsistency as important heuristics [2].

As the basis for effective and powerful heuristics, inconsistency has also been incorporated into computing system based problem solving processes [19, 20]. Here we use digital forensics as an example to see how ample the opportunities are in taking advantage of inconsistency for problem solving objective. In the field of digital image forensics, there are a number of effective inconsistency based heuristics in detecting forgeries. The first type of heuristics is based on lighting inconsistency [4, 8]. In digital images, lighting inconsistency refers to a circumstance where shapes, colors, locations or directions, or number of sources of reflected light on objects are inconsistency. For instance, when specular highlights (small white specks of reflected light in people's eyes) in an image result in inconsistent lighting directions, number of sources, or shapes, it is evidence of image altering [4, 8]. So any presence of lighting inconsistency can be used as an effective heuristic to identify image tampering. The second type of heuristics is based on the local noise level inconsistency [10]. Normally in an authentic digital image, the noise is uniformly distributed across the entire image. Tools used to alter images often inject locally randomized noise to the forged regions so as to conceal the evidence of tampering, thus creating inconsistencies in the levels of noise in the image. The work in [10] described an approach that detects tampering through recognizing noise level inconsistencies in an image. The approach is based on decomposing an image into segments of various noise levels. The third type of heuristics is based on the blocking artifact inconsistencies [15]. In JPEG images, due to the fact that digital camera manufacturer and image processing software often utilize different JPEG quantization tables to balance between compression ratio and image quality, different blocking artifacts will be injected into the images as a result. When a digitally forged image is created from several sources, the resulting image invariably contains different sorts of compression artifacts. In addition, many image manipulation operations such as image splicing, re-sampling, or skin optimization, will generate differential blocking artifacts. These blocking artifact inconsistencies can serve as very effective heuristics in detecting tampered images.

Many other areas of endeavors can also benefit from recognizing the clues inconsistency helps reveal, and devising and utilizing inconsistency induced heuristics in the problem solving processes [19, 20].

3. What Watson Has Demonstrated?

A recent success story on utilizing inconsistency as an effective tool in problem solving is the IBM's Watson computer system. Watson was developed with the goal to compete at the human champion level in real time on *Jeopardy!*, an American TV quiz show that had its original series premiere in March 30, 1964, and that started its current series premiere in September 10, 1984. Early in 2011, Watson competed in the show's first ever human-versus-machine, two-game combined-point matchup. Broadcasted in three *Jeopardy!* episodes during February 14-16, 2011, Watson was pitted against two top human players, Ken Jennings, the record holder for the longest championship streak at 74 games, and Brad Rutter, the biggest all-time money winner on *Jeopardy!*. Watson was triumphant over the human players and walked away with the first prize of $1 million.

IBM's Watson computer system is an open domain question-answering system that was developed with advanced natural language processing, information retrieval, knowledge representation and reasoning, and machine learning technologies [6, 13]. Watson has a massive parallel computing infrastructure: 90 IBM Power 750 servers with each server having four POWER 7 processors, each POWER 7 processor having 8-core with each core capable of running 4 threads, and 16 terabytes of RAM. Underpinning Watson's open-domain question-answering capability is IBM's *DeepQA* technology that allows for question analysis and decomposition, hypothesis generation and filtering, evidence retrieval and scoring, merging and ranking answers, and confidence estimation (see Figure 1) [6]. Watson has access to its local resources of 200 million pages of structured and unstructured content including dictionaries, encyclopedias, news articles, and other reference materials [13].

A number of components in Watson use inconsistency as heuristics for hypothesis and evidence scoring. For instance, temporal reasoning is deployed in Watson to "detect inconsistencies between dates in the clue and those associated with a candidate answer" [6]. Another scoring component, geospatial reasoning, is capable of detecting spatial inconsistencies stemming from conflicting spatial relations such as "directionality, borders, and containment between geoentities" [6]. When scores for individual pieces of evidence are combined to produce overall evidence profiles for candidate answers, inconsistencies will be examined from dimensions such as name consistency or theory consistency [6].

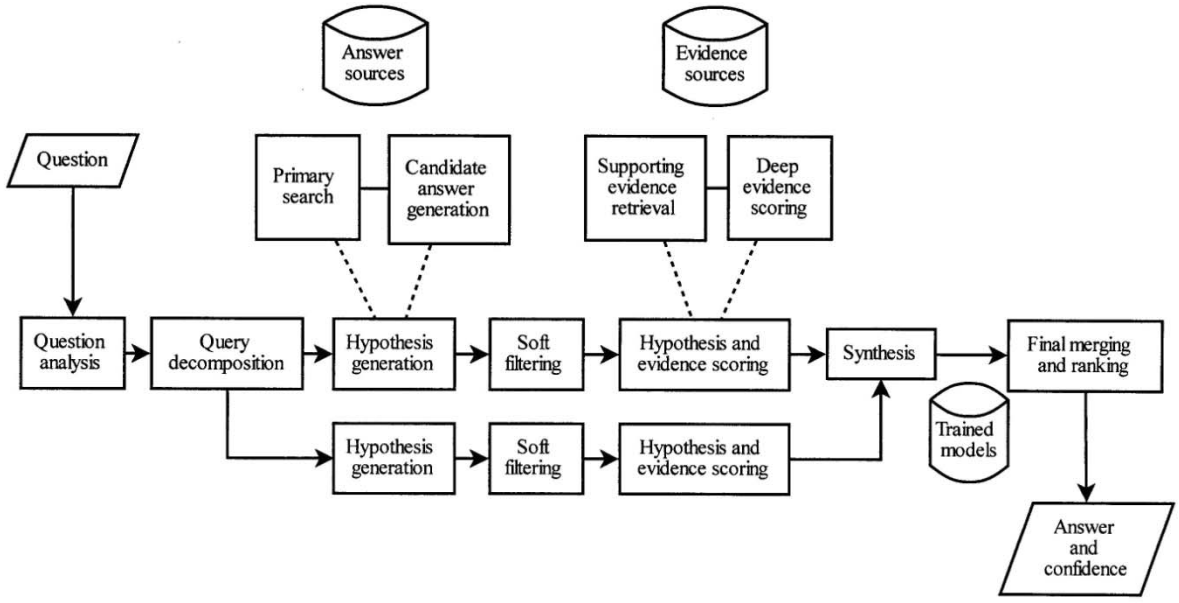

Figure 1. IBM DeepQA High-Level Architecture [6].

Despite the aforementioned inconsistency-based heuristics in place in its *DeepQA* engine, Watson flubbed during the Final *Jeopardy!* question at the end of the first match. The category for the Final *Jeopardy!* question was US Cities, and the answer was: "Its largest airport is named for a World War II hero; its second largest, for a World War II battle." Whereas both human players responded correctly with "What is Chicago?", Watson's response was a confused one: "What is Toronto?????".

The case of Watson's response of "Toronto" to the question category of "US Cities" constitutes what is referred to as anti-subsumption inconsistency in [16, 18]. Given a taxonomy of concepts, when there is no longer a subsumed relationship between a sub-concept (Toronto) and its super-concept (US Cities), this antagonistic circumstance is called anti-subsumption inconsistency. The manager of the Watson project at IBM Research, David Ferrucci, offered the following explanation on Watson's flub [14]:

> *First, the category names on Jeopardy! are tricky. The answers often do not exactly fit the category. Watson, in his training phase, learned that categories only weakly suggest the kind of answer that is expected, and, therefore, the machine downgrades their significance. The way the language was parsed provided an advantage for the humans and a disadvantage for Watson, as well. "What US city" wasn't in the question. If it had been, Watson would have given US cities much more weight as it searched for the answer. Adding to the confusion for Watson, there are cities named Toronto in the United States and the Toronto in Canada has an American League baseball team. It probably picked up those facts from the written material it has digested. Also, the machine didn't find much evidence to connect either city's airport to World War II. (Chicago was a very close second on Watson's list of possible answers.) So this is just one of those situations that's a snap for a reasonably knowledgeable human but a true brain teaser for the machine.*

What Watson has taught us is that there are still gaps in Watson's repertoire of hypothesis and evidence scoring components. The steps in soft filtering, deep evidence scoring, and final merging and ranking can be further strengthened by incorporating additional inconsistency based heuristics so as to avoid producing glaring conflicting answers.

4. Inconsistency-Induced Heuristics

Heuristics are criteria or approaches to be used to determine which course of action among several alternatives is the most promising one toward accomplishing some objective, and they are meant to strike a balance between keeping the criteria simple and keeping them discriminate fittingly between more promising and less promising choices [11]. Toward the aforementioned goals, inconsistency induced heuristics can be defined based on inconsistency categories, causes, morphology, and desired actions.

In this paper, we focus our attention on inconsistency at levels of information and knowledge in the depth of knowledge hierarchy of data, information, knowledge, meta-knowledge, and expertise. Table 1 summarizes the

causes of inconsistency and possible models of heuristics. Table 2 captures some of the most general categories and morphologies of inconsistency.

Table 1. Inconsistency Causes and Models.

Cause	*Ontology related reasons*
	Epistemic conflicts
	Conflicting defaults
	Lack of complete information
	Uncertainty
	Defeasible inheritance induced
	Assertion lifting
	Reliability of information sources
	Belief revision due to cognitive penetrability
	Deliberate act
	Concept forming process in description logic
Possible models of heuristics	*Closed-world reasoning*
	Mutually exclusive principle
	Locality of inconsistency principle
	Context principle
	Shortest path

Inconsistency can be caused by a whole host of circumstances. Ontologically, conflicting concept subsumptions, contradicting membership relations, or lack of constraints on ontology specifications can be causes for inconsistency. Epistemologically, different agents may hold beliefs that are inconsistent with each other. Conflicting defaults, lack of information, information source reliability can all contribute to inconsistency. In property inheritance, the case in which an inherited property can be overridden may result in inconsistency. When an agent's knowledge is compartmentalized, lifting assertions from one compartment to another can introduce inconsistency. Finally, inconsistency can also be the result of some deliberate act.

Heuristics in general can be derived or discovered under some simplified models [11]. The types of models that can be utilized in defining inconsistent phenomena induced heuristics include: closed world assumption to be used in calculating number of positive and negative pieces of evidence; mutually exclusive principle applied when sets of entities are mutually exclusive and jointly exhaustive; locality of inconsistency to be used to identify scopes or clusters of inconsistent phenomena [21]; context principle relying on analyzing the context for clues; and shortest path giving preference to shorter paths in inheritance networks [2].

When cast in the light of logical formalism, inconsistency can take on the following morphologies [16, 18]: (1) complementary: an atom and its negation; (2) mutually exclusive: mutually exclusive predicates that are syntactically different and semantically opposite of each other; (3) incompatible: an atom and the negation of its syntactically different but logically equivalent relation; (4) anti-subsumption: the antagonistic situation where a subtype is no longer subsumed by its supertype; (5) anti-supertype: the converse of the anti-subsumption where the negation of the supertype and one of its subtypes hold at the same time; (6) asymmetric: a symmetric relation and its negation both hold; (7) anti-inverse: a relation and the negation of its inverse relation exist; (8) mismatching: a concept and the negation of one of its conjunctive and substantiating sub-concepts hold; (9) disagreeing: propositions having reified but disagreeing quantities for the same attribute; (10) contradictory: relations containing attribute values that violate type restrictions or integrity constraints; (11) precedence: opposite precedence relationships being asserted for the same set of entities; and (12) inconsistent probability value type (*iProbVal*): if $\Delta \models L$, the probability value for L is outside the region specified by the extreme values of probabilities for Δ.

Table 2. Categories and Morphologies of Inconsistency.

Category	**Morphology**
Logical	*Complementary*
	Mutually exclusive
	Incompatible
	Anti-subsumption
	Anti-supertype
	Asymmetric
	Anti-inverse
	Mismatching
	Disagreeing
	Contradictory
	Precedence
	iProbVal
Temporal	*Partial temporal inconsistency*
	Complete temporal inconsistency
Spatial	*Topological inconsistency*
	Location/attribute inconsistency
	Structural/semantic constraint violations
Ontological	*Conflicting concept subsumptions*
	Contradicting membership relations
Argumentation	*Rebutting argument*
	Undercutting argument
	Counterargument
Contextual	*Inconsistent with context*
	Inconsistent to expectation

When the concept of time is incorporated, we have partial temporal inconsistency, and complete temporal inconsistency [17]. In the geospatial context, there are violations of geometrical properties and spatial relations (Topological inconsistency), spatial objects having conflicting geometric locations (location/attribute inconsistency), and structural/semantic constraint

violations [12]. In the ontological category, there are conflicting concept subsumptions and contradicting membership relations [20]. From the perspective of argumentation, inconsistency manifests itself in terms of rebutting argument which has a claim that is the negation of another argument's claim, undercutting argument which has a claim that contradicts some of the assumptions of another argument, and counterargument which is either rebutting or undercutting argument with regard to another argument [1]. Finally inconsistency can also arise from contextual related circumstances where responses to events are either inconsistent with the context or inconsistent with regard to expectation.

Before describing a general framework for inconsistency induced heuristics, we need to have some concepts in place. Let $\Im$ be a set containing (possible) conflicting circumstances or contradicting pieces of evidence and $\varphi(\Im)$ be a set of alternative outcomes or next steps in the presence of $\Im$. Let $\aleph$ denote elements in $\varphi(\Im)$:

$$\aleph = \{\delta_i \mid \delta_i \in \varphi(\Im)\}.$$

We use $\Re$ to represent a set of k attributes for the context of $\delta_i \in \aleph$:

$$\Re(\aleph) = \{\alpha_k(\delta_i) \mid \delta_i \in \aleph \wedge k \in [1,.., m]\}$$

Finally, ϖ is a set of weights for $\Re$:

$$\varpi(\Re) = \{\omega_k(\alpha_k(\delta_i)) \mid \delta_i \in \aleph \wedge \omega_k(\alpha_k(\delta_i)) \in [0, 1] \wedge \sum_{k=1}^{m} \omega_k(\alpha_k(\delta_i)) = 1\}$$

Now we are in a position to define a general framework for inconsistency induced heuristics.

Framework for Inconsistency Induced Heuristics

Input: $\Im$, $\aleph$, $\Re$, ϖ
Output: most desirable outcome: $\mathcal{M}$

- Identify category, morphology and cause of inconsistency[1]
- Select appropriate model of heuristics
- Calculate prognosis for each outcome
  Let ω_{ki} be the k^{th} weight for the i^{th} outcome;
  Let α_{ki} be the k^{th} attribute for the i^{th} outcome;
  for each $\delta_i \in \aleph$ do {
    $\text{prognosis}(\delta_i) = \sum_{k=1}^{m} \omega_{ki}\alpha_{ki}$
  }
- Determine the most desirable outcome
  $\mathcal{M} = \underset{i}{\text{argmax}}\{\text{prognosis}(\delta_i)\}$

return($\mathcal{M}$); □

Example. Let us use Watson's response to the airport clue as an example, and see how Watson could have avoided responding with an obvious wrong answer, had Watson been equipped with some scoring components based on inconsistency induced heuristics in its soft filtering, deep evidence scoring and/or final merging and ranking (Figure 1). To facilitate the discussion, assume the clue in the Final *Jeopardy!* question can be represented as follows where $\mathscr{C}$ is the domain of all north America cities and $\mathscr{A}$ is the domain of all airports in north America:

$$\exists x \in \mathscr{C}.\exists y \in \mathscr{A}.\exists z \in \mathscr{A}.\ [\text{city}(x) \wedge \text{us\_city}(x) \wedge \text{has\_largest\_airport}(x, y) \wedge \text{has\_2ndlargest\_airport}(x, z) \wedge \text{namedfor\_WWII\_hero}(y) \wedge \text{namedfor\_WWII\_battle}(z) \wedge \neq(y, z)].$$

Though no official analysis is available for Watson's performance in the televised *Jeopardy!* Show during February 14-16, 2011, from the initial explanation in [14], we can speculate that[2]

- Watson's hypothesis generation module produced several candidate answers including Toronto, Canada ("*the Toronto in Canada has an American League baseball team*"); Chicago ("*Chicago was a very close second on Watson's list of possible answers*"); and several US cities by the name Toronto ("*there are cities named Toronto in the United States*"). Let's assume that "Toronto, Iowa", "Toronto, Kansas", "Toronto, Ohio", and "Toronto, South Dakota" are the US cities Watson considered.
- At least three of the aforementioned cities survived the soft filtering, deep evidence scoring, and final merging and ranking stages to become candidates for the answer. These cities were in the following order of Watson's confidence: Toronto, Canada, Chicago, and a third city named Toronto in US.
- The other reasons given to explain Watson's behavior (weak connection between category and type of response desired, parsing of the language, and US Cities not appearing in the question) should not be as critical to the mistake as the lack of some inconsistency based sanity checking component to guarantee the consistency between the category and the candidate answers. When the system does not have adequate information or knowledge to respond to the question at hand, high precision becomes a more important issue.
- It seems that the "spatial containment" scoring component [6] failed in this case.
- Watson seemed to rely on other indirect evidence such as sport teams as part of evidence scoring (*Toronto in Canada has an American League baseball team*).

Using ap1, ap2, n1, n2, and bt to denote the following properties (attributes) for a city: has_largest_airport, has_2ndlargest_airport, namefor_WWII_hero, and namedfor_WWII_battle, and a major league baseball team, respectively, we have the following context for an

[1] Detecting and discerning category, morphology and cause of inconsistency are prerequisites to determining the type of heuristics to deploy. Space limit does not allow for elaboration in this paper.

[2] The quotes in italic were taken from David Ferrucci's explanations in [14] on why Watson responded with Toronto, Canada.

inconsistency induced heuristic (information in Table 3 was obtained via Google search: {Pearson, Downsview} for Toronto_Canada, {O'Hare, Midway} for Chicago, {Maquoketa, Clinton} for Toronto_IA, {Yates, Heir} for Toronto_KS, {Eddie Dew, Granatir} for Toronto_OH, and {Brookings, Clear Lake} for Toronto_SD).

Table 3. Possible Context for Sanity Checking.

city (candidate answer)	us_city	ap1	ap2	n1	n2	bt
Toronto_Canada	–	+	+	–	–	+
Chicago_IL	+	+	+	+	+	+
Toronto_IA	+	+	+	–	–	–
Toronto_KS	+	+	+	–	–	–
Toronto_OH	+	+	+	–	–	–
Toronto_SD	+	+	+	–	–	–

Since the set of incompatible evidence {city(Toronto_Canada), ¬us_city(Toronto_Canada)} would constitute an instance of anti-subsumption inconsistency [16, 18], hence we have $\Im$ = {city(Toronto_Canada), ¬us_city(Toronto_Canada)}. Given a possible set of weights for attributes in the context, ϖ ={0.5, 0.1, 0.1, 0.1, 0.1, 0.1} and let attribute values "+" and "–" be 1 and 0, respectively, then the contextual heuristic would return argmax{prognosis(δ_i)} = Chicago.

5. Conclusion

In this paper, we examined the general issue of inconsistency induced heuristics, and used the Watson question-answering system as a salient example to drive home the importance of taking full advantage of what inconsistency has to offer and capitalizing it to help improve problem solving processes. When utilizing inconsistency as effective heuristics, we need to understand various issues and dimensions antagonistic circumstances entail. As quoted in [7], Henri Poincare once said that contradiction is the prime stimulus for scientific research. Indeed, inconsistency is a terrible thing to waste.

Future work can be pursued in the following directions. Details of the proposed framework still need to be worked out. The specific patterns of heuristics under various models need to be fleshed out. How domain-specific information can be factored into the framework is another issue worth exploring.

Acknowledgement. We would like to express our sincere appreciations to the anonymous reviewers for their comments that help improve the content and the presentation of this paper.

***Abstract*—This paper aims at supporting the knowledge engineering process by proposing an approach to map CommonKADS knowledge models into specifications based on the Production Rule Representation (PRR) language. This approach starts by proposing a metamodel of CommonKADS knowledge models. We define the concept of inference group, required to perform the mapping transformations, and an algorithm that identifies inference groups automatically. We then proceed to the definition of transformation rules. The latter are applied to map CommonKADS knowledge models into a set of PRR production rulesets, combined with UML activity diagrams.**

Keywords – CommonKADS, Model Driven Approach, Production Rule Representation, metamodel, mapping

I. INTRODUCTION

It is well accepted that the cross-fertilization between software engineering and knowledge engineering can significantly improve the design of knowledge-based and expert systems. The aim of this paper is to present an approach enabling the mapping of CommonKADS knowledge models into specifications based on the Production Rule Representation language (PRR). The following aspects mainly motivate our work:

- The CommonKADS methodology is a widely used knowledge engineering method. Even if CommonKADS is more generally suited to systems where knowledge plays an important role, it does not necessarily lead to the development of expert systems. It focuses more on knowledge engineering issues. CommonKADS knowledge models are therefore specified at the analysis level. It can be considered as the Computational Independent Model (CIM) level of the Model Driven Approach (MDA [8]).
- On the other hand, PRR represents a relatively recent standardization effort conducted by OMG [10]. PRR is situated at the Platform Independent Model (PIM) level of MDA. We assume that the knowledge system will be implemented as production rules. PRR represents this knowledge in the design phase.
- There exists a possible convergence between CommonKADS knowledge models and PRR, since both are based on UML. However, the two are not completely related. Therefore, a mapping of CommonKADS knowledge models into PRR is an open research problem. We argue that such a mapping can be very useful.

To perform such a mapping, we propose an algorithm aiming at the definition of "inferences groups" as well as several transformation rules.

The rest of the paper is organized as follows. Section II is devoted to a presentation of related work. We describe in Section III the main concepts of the PRR metamodel. Our CommonKADS metamodel is presented in Section IV. The algorithm and the transformations used to map CommonKADS knowledge models into PRR are described in Section V. Finally, Section VI is devoted to the conclusion and future research.

II. RELATED WORK

CommonKADS [13] is a widely referenced methodology for designing knowledge-based systems [2,5,7,14,15]. As mentioned in the previous section, there exists a possible convergence between CommonKADS knowledge models and PRR, since both are based on UML. However, the two are not completely related. [1] offers an approach enabling a mapping between the knowledge model and JESS, based on a UML profile. However, the knowledge model presented in their approach is less detailed than the one presented in this paper. Moreover, this mapping is situated at the Platform Specific Model (PSM) level of MDA. Finally, let us mention that the description of the design level in CommonKADS [13] is relatively limited, especially compared to the richness of its analysis level as well as its knowledge model. The design level consists mainly in the "direct" mapping of concepts of the analysis level (including knowledge model concepts) as design classes. This approach does not help much the designer, hence the interest of a bridge with PRR in order to switch to the design level. [16] proposes to combine OWL, SWRL and JESS to build a knowledge level modeling. [17] describes and compares several rule languages with the objective of modeling

business processes. [4] is a recent and detailed state-of-the-art on rule-based systems.

III. MAIN CONCEPTS OF THE PRR METAMODEL

The Production Rule Representation language (PRR) [10] has been proposed by OMG for high-level (tool-independent) representation of rules. Fig. 1 is an excerpt of the metamodel of PRR, with the main concepts relevant in this research.

Production rules are the central concept of PRR. Production rules may reference and modify classes (possibly defined in a UML [11] class diagram). Rules are grouped into rulesets. A ruleset is a collection of rules with a particular mode of execution (operational mode). The mode of execution is either sequential or inferencing. In the *sequential* mode, rule execution order is determined by the sequence of rules in the ruleset. In the *inferencing* mode, the inference engine controls rule execution order. PRR currently supports forward chaining only, and suggests RETE [3] as a possible algorithm. A PRR rule may have a priority. Priorities are used for conflict resolution, i.e. to choose the rule to execute when there are several candidate rules.

A production rule is typically represented as *if [condition] then [action-list]*. An action may be the invocation of an operation associated with a class, the assignment of a value to an expression, or an action that updates the state of the rule engine (e.g. an action that asserts – creates – a new object).

Variables may be defined at the ruleset level or at the rule level. Rule variables are used for binding.

PRR rules can be represented formally, based on an extension of the Object Constraint Language (OCL) [9]. Imperative expressions are used to represent rules actions. Navigation call expressions are used to navigate within or between objects.

PRR is a powerful language for expressing rules, as illustrated in [12] in the domain of data warehousing and OLAP.

IV. MAIN CONCEPTS OF COMMONKADS KNOWLEDGE MODEL

CommonKADS knowledge models can be specified diagrammatically, and textually using the CommonKADS Modeling Language (CML). CML is a structured, semi-formal language. In [13], the syntax of CML is described, but the authors do not provide a metamodel of the CommonKADS knowledge model. Metamodels of the CommonKADS knowledge model have been proposed in the literature, but they are too succinct to be useful in our approach [1,6]. Our metamodel, defined as a UML class diagram, is presented in Fig. 2. It describes the main concepts of the CommonKADS knowledge model.

A knowledge model has three components: *domain knowledge*, *inference knowledge* and *task knowledge*. Domain knowledge represents the structure of the knowledge system, while inference knowledge and task knowledge represent its behavior. Another key difference is that inference and task knowledge are domain-independent, thus facilitating their reuse across several domains. For example, the assessment task may be used in several domains. The mapping of inference and task knowledge with domain knowledge is performed through the concept of knowledge role.

The structure of domain knowledge is described in a *domain schema*. This schema is represented as a UML class diagram. The main elements of a domain schema are concepts, relations and rule types. Concepts and relations correspond to the UML concepts of class (without operations) and association respectively. Rule types are specific to knowledge systems. They are prominently implication rule types, relating an antecedent concept to a consequent concept. The connection symbol specifies the semantics of the implication. The cardinalities of the antecedent (respectively the consequent) indicate the minimum and maximum number of expressions of the antecedent class (respectively the consequent class) in an instance of the rule type. Besides implication rule types, constraint rule types may be defined. Constraint rule types are internal to a concept. They can be considered as integrity constraints defined on this concept.

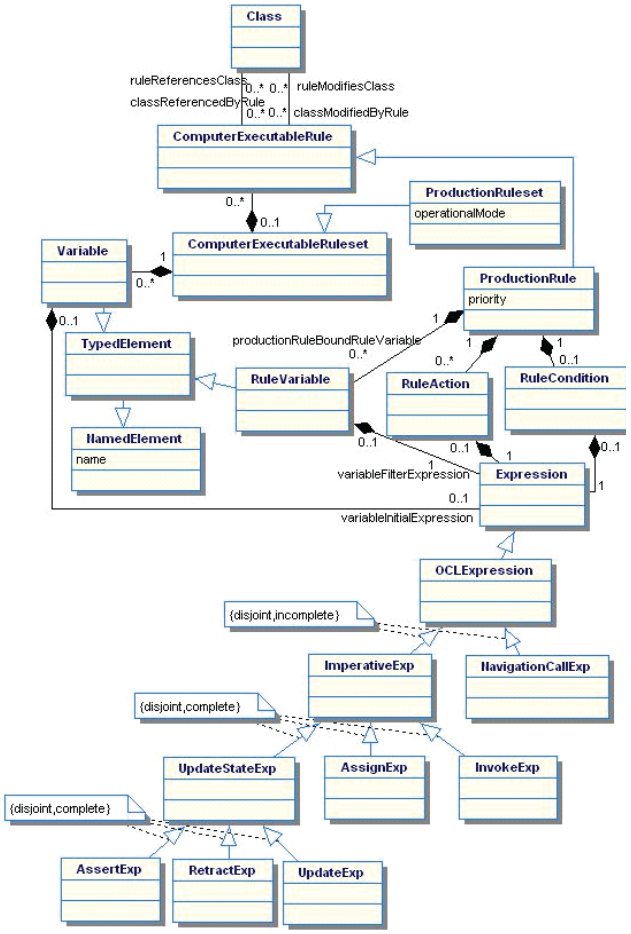

Figure 1. Main concepts of the PRR metamodel [10]

Knowledge bases are instances of domain schemas. They are primarily made of rule type instances.

The behavior of the knowledge system is represented with task knowledge and inference knowledge. Tasks, task methods, inferences and transfer functions are related through functional decomposition. A *task* may be performed through one (or possibly several alternative) *task method*(s) (OR-decomposition). A task method is then specified by its functions (inferences, transfer functions or tasks), related together by a control structure (AND-decomposition). The tasks of task methods are in turn OR-decomposed into task methods, etc… Inferences and transfer functions appear at the lowest decomposition level. An *inference* carries out a primitive reasoning step. Its internal structure may itself be complex but, in the knowledge model, it is represented as a black box. *Transfer functions* are used to communicate with the external world (information flows between the system and the user, at the initiative of the system or of the user). The transfer function "obtain", whereby the system asks the user to enter an information item, is frequently used. In this paper, we will focus on this transfer function.

Knowledge roles will be used to connect task and inference knowledge to domain knowledge. *Dynamic knowledge roles* are the inputs or outputs of functions. These roles will generally map to concepts in the domain schema. In the control structure of a task method, *intermediate knowledge roles* may be used (i.e. roles that are not input or output roles of the task specified by the task method). *Static knowledge roles* specify the collection of domain knowledge used inside an inference. A static knowledge role will generally map to an implication rule type in the domain schema.

Domain mappings perform the mapping of knowledge roles to the domain schema. In some cases, a role may map to a collection (a set or a list) of a concept.

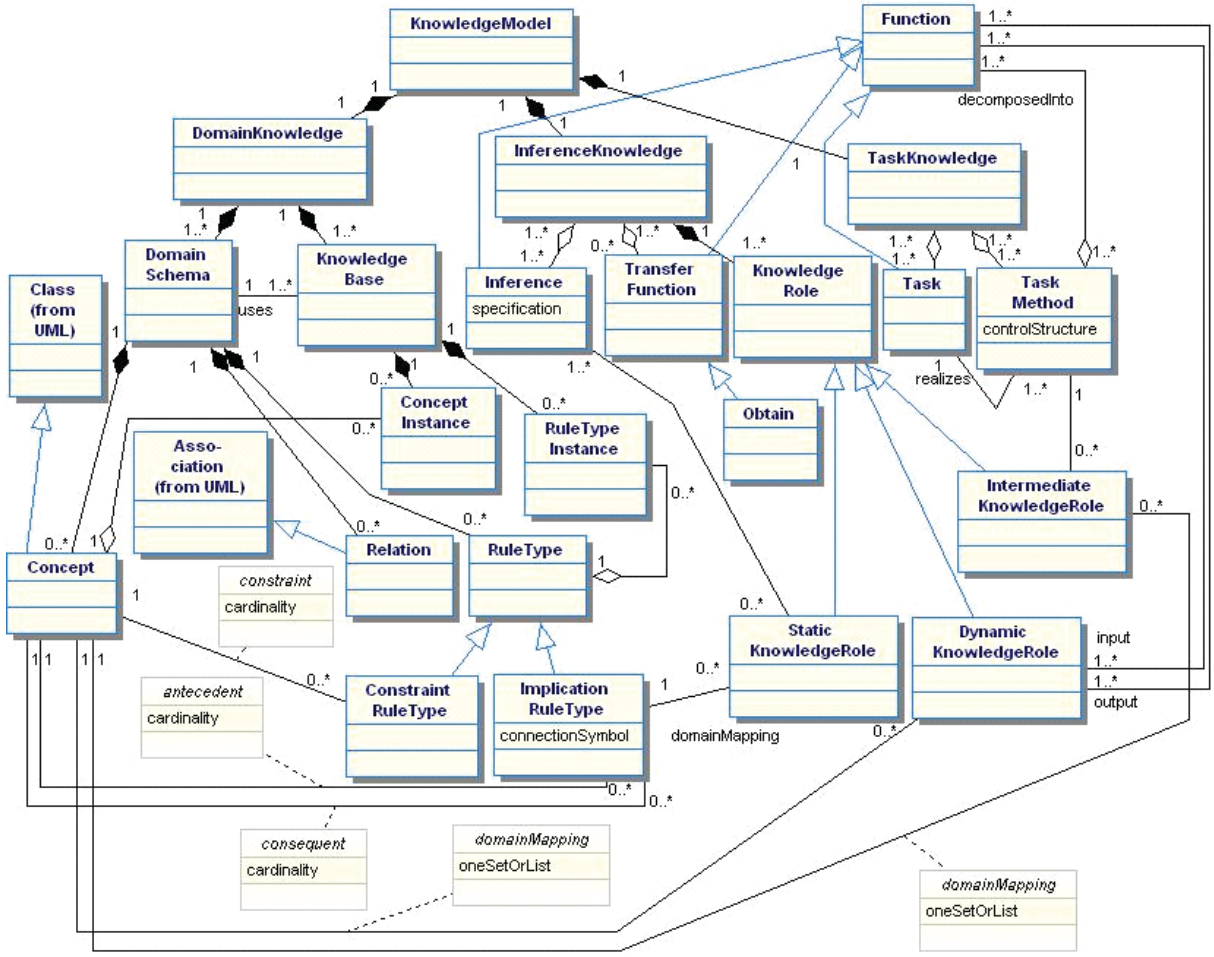

Figure 2. Metamodel of the CommonKADS knowledge model

V. MAPPING COMMONKADS KNOWLEDGE MODELS INTO PRR

A. Overview of our Approach

A specificity of our approach is to use PRR to represent knowledge in the design phase. Thus, our approach consists in mapping CommonKADS knowledge models into PRR. We assume that the knowledge system will be implemented as production rules in an expert system. In this context, the choice of PRR is appropriate.

Our approach is divided into two steps:

1. Before applying the mapping transformations, groups of inferences and transfer functions (more particularly, "obtain" transfer functions), are defined in the knowledge model. To this end, we propose an algorithm for defining such groups, called "inference groups". This algorithm operates on the control structure of task methods, represented as UML activity diagrams.
2. The transformations are then applied to map the knowledge model to the design level. The result is a set of PRR production rulesets, combined with UML activity diagrams.

B. Inference Groups

Before applying the mapping transformations, we need to group inferences and transfer functions (more specifically "obtain" transfer functions, on which we focus in this paper) into what we will call "inference groups". The rationale for this is to prepare for the mapping of inferences into PRR production rulesets. Inferences in CommonKADS are often more fine-grained than PRR can represent with a single production ruleset. It is therefore advisable, when possible, to group inferences and then map them into a single PRR production ruleset. This way, the sequencing of the inferences inside the group will be represented inside the PRR production ruleset, instead of having to represent this sequencing with a complementary formalism (in our case, UML activity diagrams). Furthermore, "obtain" transfer functions can in certain cases be mapped using variables in PRR production rulesets. However, to this end, they need to be grouped with an inference (or inferences) following them. The resulting inference group will be mapped into a single production ruleset in PRR. We present below the properties that must be satisfied by inference groups.

Property 1: An inference group is a group of two or more consecutive actions within the same control structure (i.e. inside the same "linear group of actions").

In our approach, we define a "linear group of actions" as one (or possibly more) action(s) not separated by a control structure. For example, actions separated by a decision node are in different control structures; actions in the "setup" part, the "test" part and the "body" part of an "until" loop each belong to different linear groups of actions. Our concept of "linear group of actions" is a specialization of the concept of ActivityGroup defined in UML [11]. Within a "linear group of actions", actions are linearly ordered. This follows from the fact that (1) these groups do not span across multiple control structures, and (2) we do not manage parallelism between actions (this could be the object of a future research).

We require actions of an inference group to be within the same control structure since the idea of defining an inference group is to map this group into a single PRR production ruleset, and control structures may not be used to combine the production rules within a production ruleset (as described in Section III, production rules in a production ruleset may only be executed sequentially or in forward-chaining mode).

Property 2: The actions of an inference group may only be inferences or "obtains". An inference group consists of one (or a series of) inference(s), possibly preceded by one (or several) obtains.

Inference groups may not contain tasks, because tasks are too high level to be mapped directly into PRR. In CommonKADS, a task needs to be further decomposed, as explained previously. In addition, inference groups do not integrate actions on roles (stereotyped actions <<WriteVariable>>, <<AddVariableValue>> and <<RemoveVariableValue>>), since these operations on variables (roles) are an important part of the global control structure of a task method, and therefore we avoid merging them with other actions into an inference group.

An inference group needs to contain at least one inference since a PRR production ruleset, into which the inference group will be mapped, is a collection of rules; and in CommonKADS, it is through inferences that rules are executed. The inference group may start with one (or several) obtain(s), which will be mapped using the concept of variable at the beginning of the PRR production ruleset.

Property 3: In an inference group, the outputs of "obtains" and of intermediary inferences are not used as inputs to actions or structured activity nodes outside the inference group.

When "obtains" and inferences will be merged into a single inference group, the output of the resulting inference group will be the output of the last inference of the inference group; the other outputs will no longer be represented explicitly, they will be internal to the inference group. Consequently, the outputs of an "obtain" or of an intermediary inference should not be needed outside the inference group.

C. The Inference-Group Building Algorithm

To identify inference groups within the activity diagram representing the control structure of a task method, the algorithm proceeds in two steps:

1. Grouping of actions into linear groups of actions.
2. Identification of inference groups within each of the linear groups of actions.

In step 1, the identification of linear groups of actions proceeds by identifying the first action of each group, and then recursively following the links (activity edges) to find the next action, until the last action of the group is met. Initially, all actions of the activity diagram are unmarked; actions are marked as they are incorporated into linear groups of actions.

An action is the first action of a linear group of actions if it is the target of an activity edge from a control node (e.g. a decision node), or if it is not the target (directly or through pins) of another action. Similarly, an action is the last action of a linear group of actions if it is the source of an activity edge to a control node (e.g. a merge node), or if it is not the source (directly or through pins) of another action. To find the following action of a given action, activity edges are followed. Since an action may have several indirect successors, we need to find the immediate successor. To this end, we use the constraint that the following action of an action may not be the target of another action that is not already present in the linear group of actions. Finally, in line with the definition of linear group of actions, we constrain an action and its immediate successor not to be separated by a control node (there should not exist a path of edges between an action and its next action such that this path contains a control node).

In step 2, inference groups are identified within each linear group of actions. This is done by traversing the actions of linear groups of actions in reverse order. Each time an inference is met, a candidate inference group is identified. The preceding inferences are recursively incorporated into the candidate inference group (as long as property 3 is satisfied); the preceding obtains are then recursively incorporated into the candidate inference group (as long as property 3 is satisfied). A candidate inference group is defined as an inference group if it contains at least two actions.

D. The transformations

Once the inference groups have been identified, the knowledge model is mapped to the design level, using the transformations described below. The result is a set of PRR production rulesets, combined with one UML activity diagram for each task method.

At the design level, we replace dynamic and intermediate roles by their domain mapping. This is at the expense of reusability, but reusability in CommonKADS is performed primarily at the analysis level through the reuse of template knowledge models. Furthermore, domain mapping makes activity diagrams more readable. We also simplify activity diagrams at the design level by keeping only the variables on which actions are performed (<<WriteVariable>>, <<AddVariableValue>> or <<RemoveVariableValue>>).

The transformations described below focus on the non-immediate mappings between the analysis level and the design level. (For example, implicitly, a concept, defined as a UML class in the domain schema, is mapped into a class at the design level; an action <<AddVariableValue>> in an analysis activity diagram is mapped into the same action in the design activity diagram, etc…)

Transformation T1: An inference or an inference group is mapped into an action, represented internally as a production ruleset.

Transformation T2: The input and output dynamic roles of an inference or an inference group are mapped into input and output parameters (pins) of the action resulting from transformation T1.

Transformation T3: The input dynamic roles of an inference or an inference group are mapped into parameters of the production ruleset resulting from transformation T1.

Transformation T4: For each static knowledge role of an inference or an inference group, the rule type instances of the implication rule type referenced by the static knowledge role are mapped into production rules in the production ruleset resulting from transformation T1.

Transformation T4.1: Each antecedent or consequent of the rule type (i.e. of the rule type of transformation T4), is mapped into at least one rule variable in each of the production rules.

Transformation T4.2: For each antecedent of the rule type, there are at least as many navigation call expressions in each of the production rules as indicated by the cardinality between the antecedent and the rule type. These navigation call expressions may be in the filter of the rule variable (or variables) representing the antecedent, or in the rule condition of the production rule.

Transformation T4.3: For each consequent of the rule type, there are at least as many rule actions in each of the production rules as indicated by the cardinality between the consequent and the rule type. These rule actions are of the assign type; they modify the class referenced by the consequent, or one of its subclasses.

Transformation T4.4: For each consequent of the rule type, an action of the assert type is created in each of the production rules to record the fact that the production rule has modified the consequent.

Transformation T5: For each input dynamic role of an inference, the class referenced by the role is used at least once in a rule variable filter expression in the production ruleset resulting from transformation T1.

Transformation T6: For each input dynamic role of an inference group, the class referenced by the role is used at least once (1) in a rule variable filter expression in the production ruleset resulting from transformation T1 or (2) in the initialization of a variable in the production ruleset resulting from transformation T1.

Transformation T7: Each "obtain" transfer function of an inference group is mapped into a variable in the production ruleset resulting from transformation T1.

Transformation T8: Each "obtain" transfer function outside an inference group is mapped into an action.

VI. CONCLUSION

In this paper, we have presented an approach for mapping CommonKADS knowledge models into specifications based on the PRR language. We have introduced the concept of "inference group", and defined an algorithm for automatically identifying inference groups, before proceeding to mapping transformations. In order to map knowledge models at the PIM level, we had to complete the concepts of PRR with UML activity diagrams.

Due to space limitations, it was not possible to illustrate our approach with an application. However, we have successfully applied the approach (including the mapping transformations) to a company buyout example, which is an example of assessment task.

Further research will concentrate on the following issues:

- Application of the mapping transformations to other scenarios (besides the company buyout example).
- Refinement of the transformations. In particular, in the current transformations, we do not take into account the distinction between sequential or inferencing operational modes, neither the concept of rule priority in the inferencing mode.
- Formal representation of the transformations with the QVT (Query/View/Transformation) language associated with MDA.
- Mapping of CommonKADS knowledge models into other languages than PRR at the PIM level (All CommonKADS knowledge is not necessarily meant to be represented as production rules).

***Abstract*—Noctua is a tool to assist the Knowledge Acquisition and Collaborative Knowledge Construction processes. Noctua contains a virtual catalyst designed to facilitate the task of eliciting and validating knowledge. The virtual catalyst queries collaborators, proposing new knowledge, seeking confirmation to the knowledge already elicited, and showing conflicting opinions. Noctua takes into account collaborators' profiles in order to ask them questions related to each one's field of knowledge or interest. In this paper we present Noctua and the first experimentation we did using the tool.**

Keywords - knowledge aquisition; virtual catalist; collaborative knowledge construction

I. INTRODUCTION

In this paper, we present a web tool called Noctua (http://projetos.dia.tecpar.br/noctua/), which can be used for Knowledge Acquisition (KA) and Collaborative Knowledge Construction (CKC). Noctua has a virtual catalyst that aim at overcoming some obstacles inherent to the KA process such as lack of expert's time availability and the difficulty in eliciting and representing knowledge. The catalyst also helps surpassing barriers innate to the CKC such as authorship registration and knowledge validation. The idea is to insert into the process a virtual member who plays the role of the catalyst, i.e. someone "whose talk, enthusiasm, or energy causes others to be more friendly, enthusiastic, or energetic" [3].

Noctua operates with conceptual knowledge, represented by Knowledge Pages [1] and procedural knowledge, represented by Production Rules [4].

The tool tracks users' actions and log their collaborations. Additionally, the tool registers users' opinions confirming or refuting something. This information is used by the virtual catalyst to choose which questions to ask and which ones not to ask to each user.

II. COLLABORATIVE KNOWLEDGE CONSTRUCTION

This section presents the fundamental concepts for the construction of the tool presented in section III.

A. The Knowledge and Knowledge Acquisition

For the purpose of this paper, knowledge may be considered as information combined with experience, context, interpretation and reflection, as defined in [5]. Milton presents in [1] a technical definition according to which "knowledge is the ability/skill/expertise to manipulate/transform/create data/information/ideas to perform skillfully/make decisions/solve problems".

Knowledge Acquisition (KA) may be defined as "the transfer and transformation of problem-solving expertise from some knowledge source to a computer program" [6]. It is both an art and a bottleneck in the construction of knowledge-based systems [4].

The construction of a glossary of terms used by experts should be one of the first steps in the design of knowledge-based systems. According to Rolston [4], knowing experts' vocabulary is a fundamental task in KA. Silva Junior et al. [7] state that "an adequate design of a cognitive system depends on the existence of a common vocabulary".

One of the most popular KA techniques is the interview, despite criticisms on its efficiency [8]. It may be structured or unstructured, depending on its level of formalism and specificity.

Creating scenarios is another KA technique, in which experts are stimulated to explain their knowledge. Milton [1] suggests the creation of scenarios that depict or envisage real situations. Scenarios with potentially inconsistent or missing information may stimulate experts to question them or to identify inconsistencies that were not recognized until then. This can be used by the knowledge engineer to make expert's knowledge explicit.

B. Collaborative Knowledge Construction

Ramalho and Tsunoda [9] state that the Information and Communication Technologies created new spaces and forms for the construction of knowledge. Systems for collaboration (or collaborative software) make use of the Internet to foster communication and information organization, providing tools that facilitate the coordination inside groups of collaborators.

However, according to some researchers, the collaboration via web has some disadvantages. Pettenati and Ranieri [10] suggest that distance collaboration has deep social problems related to trust and reputation of the participants. It requires the development of a group culture and faces difficulties related to knowledge representation and management. The difficulty of representing the group and the competence of each member as well as the lack of face-to-face contact may weaken the sense of belonging and quickly lower the motivation to cooperate.

According to Nabeth et al. [11], the participation in communities of CKC is not, in fact, spontaneous, but driven by factors such as direct awards, gains from enhanced reputation or personal influence power, personal satisfaction with perception of their effectiveness and reciprocity. Participation requires a climate of trust, a sense of community, and a perception of recognition. These authors suggest a maximum effort to make visible the actions of each collaborator and their perceived value in the development of the collaborative process. This is what they call Social Translucence.

C. Collaborative Tool for CKC

According to Ackerman et al. [12], a system for CKC must have 3 basic characteristics: a tool for recording interviews, a discussion forum and a local memory. Noy et al. [13] presented a users' reviews that compare the characteristics of several collaborative tools. They highlighted as desirable:

- An easy to use web interface;
- The capacity to show the reliability of each knowledge piece and each collaborator; and
- The capacity to allow disagreements and discussions about the knowledge under construction.

Lomas et al. [14] considered as important characteristics the possibility of synchronous and asynchronous collaboration as well as information about the authorship. Other important features cited by them are: adequate communication tools, easy-to-understand interface, image sharing, collaborative construction of documents and social interaction.

Noy and colleagues presented in [15], desirable characteristics of tools for collaborative development of ontologies. We think that these features would be also welcome at any CKC tool:

- The capacity of tracking the changes undergone by the knowledge during its construction and keeping all the related comments and discussions;
- The capacity to save old versions of knowledge, with the possibility of further changing it and to discard newer versions, as well as to compare two versions;
- Automatic identification of conflicting knowledge and mechanisms to resolve conflicts;
- Users with the power of mentoring, who have the final word on possible conflicts of knowledge.

D. Negotiation and Construction of Consensus

Collaborative construction of knowledge requires that all collaborators understand the shared knowledge representation and be able to express themselves by using it, to show their agreement or disagreement with other participants and to evolve, somehow, to a consensus or a final decision [2].

A collaborative tool must have rules about how knowledge might be proposed, changed or deleted. Dieng et al. [16] describe the CO4 protocol in which, when someone proposes a change in the knowledge, if there is no disagreement, the modification is performed. On the other hand, if there is any disagreement, the modification is not made. All participants are invited to comment and submit alternative proposals. The discussion ends when the rejected proposal is removed or when the disagreement is withdrawn.

According to Herrera and Fuller [17], negotiation is a key aspect in CKC because building consensus among the participants is a condition for the evolution of the knowledge within its life cycle. Those authors constructed a negotiation model that encompasses some predetermined actions such as: request for explanation, suggestions for modification, and adoption of a position by vote.

III. THE TOOL: NOCTUA

This section presents the general characteristics of our tool called Noctua, highlighting the main characteristics of the virtual catalyst.

A. The Noctua's Projects

Noctua allows every user to create KA/CKC projects. Every project starts out empty. This allows collaborators inside each project to work in their own area of knowledge and to express themselves in their own specific way, focus and desired depth.

B. Classification and Representation of Knowledge

Noctua allows the construction of two kinds of knowledge, according to a classification presented by Milton [1]:

- Conceptual Knowledge: tells what something is;
- Procedural Knowledge: tells how to do something.

Noctua represents Conceptual Knowledge using Knowledge Pages (KP), which describe the knowledge by means of natural language texts and pictures.

Procedural Knowledge is represented by Production Rules (PR) in the following format:

if <list of conditions> then <list of conclusions>

Both representations were chosen because of their similarity to natural language which allows people unfamiliar to computers easily express their knowledge, as well as understand the information expressed in those formats.

C. Features of the Collaboration Tool

To overcome the difficulties presented in section II (subsection C), the Noctua allows the owner of each project to classify users as owners, tutors, and collaborators, each one with different permissions within a project.

Every collaborator may question the validity of a rule or entry. Questioned knowledge becomes invalid and must be discussed by the collaborators. If consensus is not reached, the matter may be finally resolved by a tutor.

Noctua allows all knowledge to be tagged. Collaborative tagging forms a folksonomy that reflects the collaborators' knowledge about the domain and can be helpful in building richer domain models in a consensual way [18].

Social Translucence is guaranteed by several aspects in the tool, such as: the registration and the disclosure of the authorship, chat between collaborators, and the disclosure of events such as creation and deletion of knowledge pieces.

Silva Junior et al. [7] establish a set of basic functions desirable in a groupware to support collaborative ethnography. If those functions are adapted to KA or to CKC, it is possible to see that Noctua embodies all of them:

- Creating, updating and closing KA/CKC projects;
- Recording users' profiles (and actively using them);
- Assigning users to activities (projects and roles);
- Recording notes and historical data (forums and instant messages);
- Creating documents (KPs and PRs);
- Supporting discussion and negotiation (by questioning knowledge and also in forums and instant messages);
- Supporting the awareness of the level of participation and contribution (by showing authorship statistics of each one's participation);

D. The Virtual Catalyst

The catalyst stimulates knowledge creation by asking collaborators questions and requiring their opinions (as shown further in this paper). Acting as a newcomer among experts, sometimes the catalyst asks impertinent questions, but sometimes its questions requires experts to rethink their concepts, so they may not only make their knowledge explicit but also wider.

The catalyst presents a screen containing a presumed knowledge (rule or some information within an entry). This knowledge, however, can be an exact copy of what is in the database or be a knowledge piece amended by the removal or the insertion of information related to other knowledge piece. In fact, when applied to rules, this technique creates scenarios and it can be used as described on section II-A.

Some of the possible forms of stimulation based on information in KPs are:

- Could you write something about <concept X>?
- What the text below is related to?
- In the entry on <concept X> it is written: <phrase A>. Do you agree with that?
- Which of the following statements applies to <concept X>?
- Is there a feature common to <concept X> and <concept Y>?

Concerning the rules, the virtual catalyst may act in several ways:

- Take a rule as it is (but not mentioning this to the user);
- Take two rules, mix some of their conditions and conclusions into a new tentative rule;
- Take a rule and delete some of its conditions;
- Take a rule and insert a condition or a conclusion from other rule.

The basic instigating question in these cases is: "See the rule below. Do you confirm it?"

Alternatively, a tentative set of conditions may also be used to ask the collaborator to think forward, not only confirming or refuting what is written, but trying to find a new valid conclusion. The question, in this case, is:

- Is there a possible conclusion if these conditions are fulfilled? (Then what?)

Asking for a new conclusion can also be done by using an established conclusion as a condition in a possible new rule. This leads to the creation of new layers of rules, i.e., rules whose conditions are conclusions from other rules.

IV. EXPERIMENTING WITH THE TOOL

Noctua was experimented by a group of ten people (faculty members from the Pontifical Catholic University of Paraná (PUCPR) and the Federal University of Technology - Paraná (UTFPR), and engineers from the Paraná Institute of Technology (TECPAR), all of them experts in computer programming. The experiment started with a face-to-face meeting in which the tool was presented to the participants. They defined the subject of the experiment: food and wine pairing. The idea was to describe wines and dishes in the Hyper Glossary and create rules for combining them properly.

The results are shown in Table I. The quantity of spontaneous knowledge eliciting (Spo) is compared to the quantity of those elicited by means of questions made by the virtual catalyst (Noc):

TABLE I. NOCTUA EXPERIMENT RESULTS

	Quantity	Noctua %	Spontaneous %
Entries	12	17	83
Questions on entries	15	---	---
Opinions on entries	12	17	83
Rules	38	16	84
Questions on rules	96	---	---
Opinions on rules	48	29	71

It is possible to observe that the participants used the catalyst only a few times. They allowed Noctua to ask them 111 questions (an average of 11.1 questions per person) and yet about 1 in every 6 rules and entries was obtained after the

questions asked by the catalyst. This indicates that the catalyst is a potentially useful tool.

By analyzing the rules produced by the group, we observed that the process had a critical flaw: it was not carried out a preliminary step in which the input variables could be defined. Each participant created his own set of input variables instead of collaborating to create one only set. Some of them considered dishes as input variables and wines as conclusions, others made the opposite.

We also observed that 90% of the rules and 67% of the entries have one only author. This shows that each participant did not collaborate much to add information to what was started by another. They agreed, after the experiment, that this may have happened due to none of them being an expert in wines, so they did not feel comfortable to change each other's contributions.

A new experiment in which people will build knowledge about their own expertise is underway with a group of nursing students and teachers.

V. CONCLUSION

This paper presented a tool for knowledge acquisition and collaborative knowledge construction that uses KPs and PRs to represent knowledge. The tool uses the construction of glossaries, virtual interviews (by means of instant messages) and creation of scenarios as knowledge acquisition techniques. The proposed interface does not require users to have any computer programming skills. Terms inside an entry are automatically hyperlinked to other entries so the set of KPs constitutes a hyper-glossary. Logical interconnections between PRs are recognized and displayed as hyperlinks. The rule base and the hyper-glossary form an integrated knowledge base. Noctua also offers forums and instant messaging tools in order to help solving conflicts of opinion and to make collaboration more effective.

The very innovation, however, is the insertion of a virtual catalyst element in the KA/CKC process. Regarding the PRs, the catalyst proposes new rules and changes in the existing rules by means of exploring new combinations of already elicited rule parts. As for the KPs, the catalyst acts in many ways such as the request for images or definitions and the attempt to associate concepts using mutual references or common characteristics. In both cases (rules and entries), the catalyst also helps the knowledge validation by asking each collaborator his opinion about what was posted by other collaborators.

New experiments will be conducted only with groups of specialists focused on a specific aspect of their own area of expertise. Knowledge Acquisition process will include an initial step for the definition of input variables. Noctua will be helpful in this phase too, allowing collaborative construction and validation of these variables.

Future work will allow users to set entry classes, each one containing certain mandatory items. By doing so, the entries in the Hyper Glossary will be better characterized as Knowledge Pages. We also intend to make available other forms of knowledge representation such as graphs showing the interconnections between entries and rules as well as timelines to show how the knowledge evolved along the collaboration process. Additionally, Noctua will be integrated with an inference engine so the rules can be tested on-line.

***Abstract*—Ontology-based web service composition allows for integration of available web services in real-time to meet desired objectives. In order to evaluate the quality of composite web services at runtime, there is a pressing need to define a feasible real-time web service reliability model. In this paper, we present such a model. We first introduce a dynamic process model that supports the evaluation of web service reliability. Then we provide a hybrid reliability model for atomic web services by considering both software and hardware aspects of the services. In order to calculate efficiently the reliability of ontology-based dynamic composite web services, we present a recursive algorithm that evaluates the reliability of various service composition constructs in real-time. Finally, we use a case study to show how to compute and monitor the reliability of composite web services in real-time, and how our approach supports reliable ontology-based dynamic web service composition.**

Keywords-web service composition; ontology; reliability model; quality of service (QoS); dynamic process model; real-time.

I. INTRODUCTION

Web services are self-contained software components that can be published, discovered and invoked over the Internet. However, in many cases, a standalone web service is not sufficient to provide the needed functionality for certain user requirements [1]. This leads to the idea of composing different web services in order to meet such requirements. The process of web service composition can be either *static* or *dynamic*. In the former, the services are pre-determined during the design phase; while in the latter, only the service template can be initially defined, but the available web services associated with each constitutive component defined in the template must be determined at runtime. In order to discover, invoke, compose and monitor web services with a high degree of automation, we can use the semantic and ontological techniques [2]. In this paper, we adopt the semantic markup language for web services (OWL-S), which is an ontology language, to formally specify the semantics of web services. Such specification makes the definitions of web services machine-understandable. Decisions on adoption of a web service for service composition require matching not only the functional properties of the service, but also the nonfunctional properties such as service reliability. The functional and non-functional properties of a web service can be formally specified using an OWL-S profile. An OWL-S profile can be published and stored in an ontology-based UDDI (Universal Description, Discovery and Integration) such as an OWL-S/UDDI service registry so that when a service client searches it, services with matching profiles can be discovered and the corresponding grounding information can be retrieved. Since there may be more than one matched profiles published in an OWL-S/UDDI, a service client has to select one of them according to certain criteria such as the service reliability. This requires the calculation of service reliability in real-time. To achieve this, we first provide a hybrid reliability model for atomic web services, which considers both software and hardware aspects of the services. Then, to calculate the reliability of composite web services, we design an efficient recursive algorithm that evaluates various service composition constructs in real-time. By employing a real-time reliability model for service composition, our approach not only supports the selection of desirable web services for dynamic web service composition, but also provides an effective way to monitor the reliability of both atomic and composite web services in real-time.

Service reliability has been an important measure of the quality of web services for service composition. There are many different kinds of existing software reliability models for web services. Li *et al.* developed a user-oriented software reliability model for evaluating the reliability of web services [3]. Their approach can be used to evaluate the reliability of atomic web services based on an extended UDDI model, and to predict the overall reliability of a composite web service using a Business Process Execution Language (BPEL)-specified structure. Tsai *et al.* proposed a software reliability model that could dynamically evaluate the reliability of atomic and composite web services [4]. The model first calculates the reliability of atomic services by using group testing and majority voting, and then the overall reliability of a composite service by using an architecture-based model. The above approaches consider only the software aspect of web services and assume the reliabilities of the machines that host the web services are near perfection. Furthermore, they are typically based on BPEL-like architectures that require static binding of available web services with the service components defined in a process model at design time. Thus, they do not support dynamic web service composition. In contrast, our approach considers both software and hardware aspects of service reliability. Furthermore, since our approach supports ontology-based web service composition, it provides a feasible way for maintaining reliable composite web services at runtime.

There are also many previous efforts on ontology-based web service composition and formal modeling of dynamic service composition. Ma *et al.* introduced an ontology-based model for web service composition, called OMWSC [5]. They presented a goal-driven and ontology-based architecture that could support automatic composition of web services. Xiong *et al.* presented a service functional configuration net based on Petri nets for automatic service composition [6]. They described the configuration specification for component services through the structure of disassembly Petri nets, and obtained the optimal one using linear programming. Tan *et al.* introduced a formal method to derive possible web service composition candidates based on a service portfolio [7]. They first generated a service net (SN) containing all needed operations, and then used Petri net decomposition techniques to derive a subnet of SN that meets the business requirements. Although the above approaches support dynamic web service composition, most of them consider only the functional requirements for service composition, and none of them attempted to use service reliability as a major criterion for service selection. Different from the above approaches, we developed a real-time service reliability model for ontology-based web service composition. Thus, our approach supports dynamic composition of reliable web services at runtime.

II. ONTOLOGY-BASED WEB SERVICE COMPOSITION

A. Ontology-Based Web Service Composition

Specifying service related information semantically is the key to effective dynamic service discovery and service composition. Web service description language (WSDL) can be used to describe the syntax of a web service such as its input and output parameters, as well as related information such as the service provider and the service endpoint address; however, it does not support specifying the semantics of a web service. Therefore, WSDL has its limitations in supporting the dynamic service discovery, execution, composition and interoperation of web services. On the other hand, ontology-based techniques can not only be used to describe the syntax but also the semantics of web services. In ontology-based semantic modeling, the terms used in the concerned domain can be precisely defined, thus services can be matched based on their semantics rather than their syntax or keywords. In our approach, the process model is defined as a template, called a *Process Model Template* (PMT). In order to instantiate a PMT into an *Instantiated Process Model* (IPM), we need to search for available web services for its constitutive service components. For this purpose, each service component, which is also called a *simple component*, is associated with an OWL-S profile template. An OWL-S profile template is essentially an incomplete OWL-S profile with semantically defined input, output, preconditions and effects so that it can be matched with existing OWL-S profiles published in an OWL-S/UDDI. Based on the matched OWL-S profiles, a simple component can be bound to either an atomic or a composite web service. When a matched web service is a composite one, its process model must also be defined using a PMT, which can be instantiated further in the same manner. This procedure repeats until all matched web services become atomic. In this case, the process of instantiating the PMT is completed.

Since a profile template can be matched with more than one published OWL-S profiles, the most desirable one must be selected for execution. The criteria for service selection can be based on multiple features, such as provider, reliability, and price; however, for simplicity, in this paper, we only consider the reliability as the sole criterion for service selection. Since service reliability is a dynamic property, it requires the system be able to calculate it in real-time. This serves two purposes, namely the selection of web services for dynamic service composition and the real-time monitoring of web service reliabilities. With the monitoring function, a reliable service-oriented system can be maintained continuously – when the reliability of some web services drop to an unacceptable level, they can be replaced by other reliable ones at runtime.

B. Dynamic Process Model

A PMT is defined as a dynamic process model that consists of structural components, such as a *sequence* component and a *parallel* one. Each structural component contains simple components and possibly other structural ones. At runtime, a simple one can be bound to either an atomic web service or a composite one. The PMT is formally defined using Backus-Naur form (BNF) as in Fig. 1. As shown in the definition of PMT, the reliability requirements for a process model are described by using two parameters, namely `<desired reliability>` and `<marginal reliability>`. The former defines the desired reliability of an instantiated process model (i.e., a composite web service). A composite web service with at least the desired reliability is considered to be reliable. On the other hand, a composite web service with at least the `<marginal reliability>` but less than the `<desired reliability>` is considered as not reliable but is acceptable for a temporary usage. In this case, the application must try to search for more reliable ones in order to meet the reliability requirements of the composite web service. If it fails, a warning message must be sent to the user of the application. Furthermore, when the reliability of a composite web service becomes less than the marginal reliability, the composite web service becomes unacceptable and must stop its execution.

```
<PMT> ::= <pmt><desired reliability>
    <marginal reliability><process model></pmt>
<desired reliability> ::= <float>
<marginal reliability>::= <float>
<process model> ::= <process><start>
    <structural component><finish></process>
<structural component> ::= <sequence component>|
    <parallel component>|<loop component>|
    <choice component>
<sequence component> ::= <sequence><component>
    <component>{<component>}</sequence>
<parallel component> ::= <parallel>component>
    <component>{<component>}</parallel>
<loop component> ::= <loop><condition><component>
    </loop>
<condition> ::= <Boolean expression>
<choice component> ::= <choice><component>
    <component>{<component>}</choice>
<component> ::= <simple component>|
    <structural component>
<simple component> ::= <simple><component id>
    <owl-s profile template></simple>
<component id> ::= <string>
```

Figure 1. Definiton of PMT in BNF

A structural component can be one of the four major composition constructs, namely *sequence*, *parallel*, *loop*, and *choice* [4]. We now give a description of the major constructs defined in a PMT as follows.

Sequence In a sequence structural component, the constitutive components are executed in series. Fig. 2(a) shows an example with two simple components *A* and *B*, defined in a PMT. The directed arrow between *A* and *B* indicates the order of execution. When one of the constitutive components in a sequence construct is not functioning, the entire sequence structural component is not.

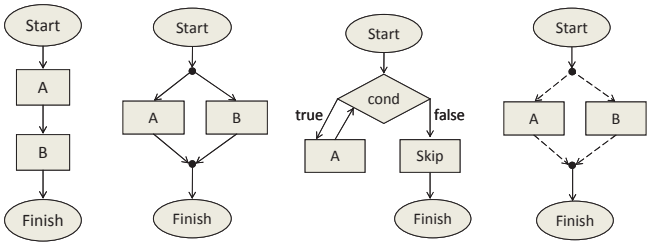

Figure 2. Examples: (a) sequence (b) parallel (c) loop (d) choice constructs

Parallel In a parallel structural component, two or more constitutive components can execute concurrently. The structural component terminates when all of its components have finished their execution. Fig. 2(b) shows a parallel structural component with two simple components *A* and *B*.

Loop A loop structural component refers to the repetitive execution of a simple or structural component. As shown in Fig. 2(c), when the condition *cond* is evaluated to be *true*, simple component *A* is executed repetitively. Only when it becomes *false*, the loop construct terminates. Note that the "skip" component is an empty component that is used to separate the loop construct from other components.

Choice In a choice structural component, only one of the constitutive components can be selected for execution. Fig. 2(d) shows an example of a simplified choice structural component with no guards (conditions). When guards are not defined, the component (*A* or *B*) to be selected for execution is determined manually by user inputs.

Fig. 3 shows an example of PMT with multiple structural components. The process model is defined as a parallel component with two sequence components defined as its constitutive ones, which can execute concurrently. The first sequence component consists of two components, namely simple component *A* and a choice structural component with two simple ones *B* and *C*. The second sequence component consists of two simple ones *D* and *E*.

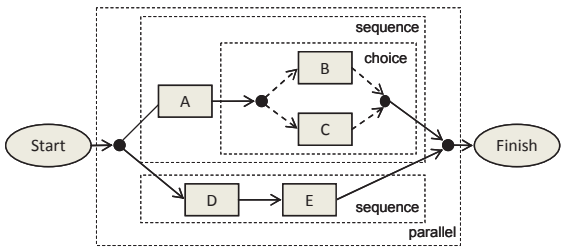

Figure 3. An example of PMT with mutiple structural components

C. Instantiation of PMT into IPM

When a PMT is instantiated into an IPM, each simple component defined in the PMT needs to be bound to either an atomic web service described by a WSDL file or a composite one specified by another PMT. Since such information must be recorded in the IPM when a matched web service is selected, we define an IPM as an extended version of a PMT with a set of placeholders for the mapping information that details how a simple component can be bound to a selected web service. At runtime, the placeholders are filled up with such detailed service information. The IPM can be formally defined using BNF as in Fig. 4.

```
<IPM> ::= <ipm><PMT><simple component mapping>
    {<simple component mapping>}</ipm>
<simple component mapping> ::= <simple mapping>
    <component id><placeholders for matched
    service></simple mapping>
<component id> ::= <string>
<placeholders for matched service> ::= <ph>
    <real-time reliability><service id>
    <service type>(<atomic service grounding
    info>|<composite service grounding info>)</ph>
<real-time reliability> ::= <float>
<service id> ::= <string>
<service type> ::= "atomic" | "composite"
<atomic service grounding info> ::= <wsdl file>
<composite service grounding info> ::= <ipm file>
```

Figure 4. Definition of IPM in BNF

As shown in the definition, the placeholders for a matched and selected web service are enclosed by the `<ph>…</ph>` tags. The item `<real-time reliability>` is the reliability of the web service that is bound to a simple component, which is calculated at runtime. The two parameters `<service id>` and `<service type>` are the identification and the type of the selected web service, respectively, where the service type can be either "atomic" or "composite." If the selected web service is an atomic one, the placeholder `<atomic service grounding info>` must be filled with the address of its WSDL file. On the other hand, if the selected one is a composite one, the placeholder `<composite service grounding info>` needs to be filled with the location of the IPM file that specifies the composite web service. The procedure for instantiating a PMT into a set of IPMs is defined in Algorithm 1. Note that it is defined recursively because a simple component can be mapped to a composite web service specified by another PMT file. In this case, that IPM file must also be instantiated by invoking the method *Instantiate-PMTintoIPM* recursively. As a result, the output of the algorithm is a set of IPM files organized in a tree-like structure. Furthermore, the instantiation process requires calculating web service reliabilities in real-time. This is because when more than one matched web services are discovered, their reliabilities need to be calculated in real-time, such that the most reliable one can be selected for execution. In order to calculate the reliability of a composite web service, an external method *CalculateReliability* (to be discussed in Section III-B) must be invoked. Note that calculating the reliability of a composite web service requires its IPM file as an input (line 17 of the algorithm), which has been generated after the recursive method call *InstantiatePMTintoIPM (ws.pmt)* in line 16.

Algorithm 1: Instantiate PMT into IPMs

Input: a *pmt* file to be converted
Output: a set of *ipm* files arranged in a tree structure.

```
1. InstantiatePMTintoIPM (File fname.pmt)
2.    copy fname.pmt to fname.ipm & create placeholders in fname.ipm
3.    create a PMT object pmt_obj from file fname.pmt
4.    foreach simple component sc in pmt_obj.process_model
5.       initialize sc.realtime_reliability to 0
6.       query OWL-S/UDDI using sc.profile_template
7.       foreach matched web service ws
8.          if (ws is atomic)
9.             extract reliability parameters from OWL-S profile
10.            calculate ws.reliability for atomic web service ws
11.            if (ws.reliability > sc.realtime_reliability)
12                sc.realtime_reliability = ws.reliability
13.               sc.service_id = ws.id
14.               sc.service_type = "atomic"
15.         else if (ws is composite)
16.            InstantiatePMTintoIPM (ws.pmt)   // create ws.ipm file
17.            ws.reliability = CalculateReliability (ws.ipm, true, null)
18.            if (ws.reliability > sc.realtime_reliability)
19.               sc.realtime_reliability = ws.reliability
20.               sc.service_id = ws.id
21.               sc.service_type = "composite"
22.      if (sc.service_type == "atomic")
23.         extract wsdl address from owl-s profile of sc.id
24.         set sc.service_type = "atomic"
25.         set sc.wsdl_file to the wsdl file of sc.service_id
26.      else
27.         set sc.service_type = "composite"
28.         set sc.ipm to the ipm file of sc.service_id
29.   save the service info of sc into its placeholders in file fname.ipm
```

III. Real-Time Service Reliability Evaluation

Service reliability represents an important attribute for the QoS of a web service deployed on a certain machine. In this paper, we take into account both hardware and software aspects of service reliability as both are needed to determine the reliability of a deployed atomic web service. Then based on the reliability of the participating atomic web services, we can calculate the reliability of a composite web service according to its dynamic process model.

A. A Hybrid Reliability Model for Atomic Web Services

Software reliability growth models (SRGM) are based on the assumption that the number of faults of a software system can be continuously reduced, which results in growth of its software reliability [8]. Although SRGM has been considered as one of the most successful techniques in software reliability engineering, it is most suitable for measuring and predicting the improvement of software reliability through the testing process [9]. In this paper, we assume that there are no features added and no faults removed once an atomic web service is deployed. In this case, the failure intensity of the software component (i.e., the atomic web service) will be constant. According to [10], the number of failures of the service in a given time follows a Poisson distribution. The corresponding formula to calculate software reliability can be defined as in (1).

$$R_{software}(\tau) = \exp(-\lambda\tau) \tag{1}$$

where λ is the constant failure intensity and τ is the execution time of the web service. When a web service is computation-intensive and executed continuously, τ can be further replaced by the elapsed time since the service is deployed.

On the other hand, hardware reliability can be represented by the two-parameter Weibull distribution [11]. The corresponding formula to calculate the reliability of a hardware component can be defined as in (2).

$$R_{hardware}(t) = \exp[-(\beta t)^{\alpha}] \tag{2}$$

where α is the shape parameter ($\alpha > 0$), and β is the scale parameter ($\beta > 0$). Note that the hardware reliability decreases with time. This is because after a certain age, the product enters its wear-out phase and the failure rate starts to increase.

Bowles tried to derive a combined hardware and software reliability model for networks [12]. According to [12], "The probability of successful operation of a device is the probability that the hardware does not fail and the probability that the software does not fail." Inspired by this idea, in this paper, we calculate web service reliability by considering both the reliability of the web service and the reliability of the machine where the web service is deployed. For simplicity, we assume that a web service is initially deployed on a new machine with the perfect reliability of 1. Thus, time t can be defined as $t = t_{current} - t_0$, where $t_{current}$ is the time when the reliability is calculated and t_0 is the time when the web service is deployed. Based on (1) and (2), the hybrid reliability model for atomic web service can be defined as in (3).

$$\begin{aligned} R_{service}(t) &= R_{software}(t) * R_{hardware}(t) \\ &= \exp(-\lambda t) * \exp[-(\beta t)^{\alpha}] \end{aligned} \tag{3}$$

where $R_{software}(t)$ is the reliability function of the atomic web service and $R_{hardware}(t)$ is the reliability function of the machine that hosts the atomic web service.

The needed parameters for calculating the reliability of a deployed atomic web service can be stored in an OWL-S profile as follows.

```
<profile: Reliability>
  <FailureIntensity datatype="float"> 0.0001
  </FailureIntensity>
  <Shape datatype="float">2</Shape>
  <Scale datatype="float">0.00002</Scale>
  <Date datatype="date">07/16/2010</Date>
  <Time datatype="time">14:30</Time>
</profile: Reliability>
```

Note that in the reliability portion of an OWL-S profile, we also include the parameters of the deployment date and time of the atomic web service because they are needed for calculating the web service reliability. Since the reliability of an atomic web service is time-dependent, the above parameters must be retrieved at runtime such that the reliability of the atomic web service can be calculated in real-time.

B. Reliability Model for Composite Web Services

The overall reliability of a composite web service depends on its structure, the degree of independence between service components and the availability of its constitutive web services. In order to calculate the reliability of a composite web service, we first need to consider the reliability of the major structural components defined in Section II-B. Based on

previous work [3, 4], we now define the reliability model for each structural component as follows.

Sequence The reliability of a composite web service composed of services in sequence can be calculated as in (4).

$$R_{sequence}(t) = \prod_{i=1}^{n} R_{service\_i}(t) \quad (4)$$

where the constitutive web services *service_i* ($1 \le i \le n$) are all independent of each other (i.e., the failure of one service does not lead to the failure of the others), and $R_{service\_i}(t)$ is the reliability function of each constitutive atomic or composite web service.

Parallel The reliability of a composite web service composed of services in parallel can be calculated as in (5).

$$R_{parallel}(t) = \prod_{i=1}^{n} R_{service\_i}(t) \quad (5)$$

where the constitutive web services *service_i* ($1 \le i \le n$) are all independent of each other. Note that the failure of any constitutive service results in the failure of the composite one because the successful termination of the latter requires the successful termination of all of its constitutive web services.

Loop The reliability of a composite web service composed of web services in a loop can be calculated as in (6).

$$R_{loop}(t) = \min_{0 \le i \le n}(R_{service\_loopbody}(t + i * \Delta t)) \quad (6)$$

where $R_{service\_loopbody}(t)$ is the reliability function of the loop body that can be an atomic web service or composite one; n is the number of iterations; and Δt is the execution time of each iteration. When $n*\Delta t$ is not a large value, the reliability of the loop structural component would be approximately the same as when it was executed the first time.

Algorithm 2: Calculate composite web service reliability

Input: an *ipm* file for a composite web service
Output: the real-time reliability of the composite web service

```
1.  CalculateReliability (File fname.ipm, Boolean initialization,
2.                        StructuralComponent structcom)
3.    initialize reliability to 1
4.    if (initialization == true)                    // step 1
5.      create an IPM object ipm_obj from file fname.ipm
6.      foreach simple component sc in ipm_obj
7.        if (sc.service_type == "atomic")
8.          calculate sc.realtime_reliability
9.        else sc.realtime_reliability =             // sc is "composite"
10.           CalculateReliability(sc.ipm, true, null)
11.   strc = ipm_obj.process_model                   // step 2
12.   if (strc is squenceComponent)
13.     foreach component com in strc
14.       if (com is simpleComponent)
15.         reliability *= com.realtime_reliability
16.       else reliability *= CalculateReliability(null, false, com)
17.   else if (strc is parallelComponent)
18.     foreach component com in strc
19.       if (com is simpleComponent)
20.         reliability *= com.realtime_reliability
21.       else reliability *= CalculateReliability(null, false, com)
22.   else if (…)       // other cases: redundant component,
23.   …                 // loop component, and choice component
24.   return reliability
```

Choice The reliability of a composite web service composed of web services in choice can be calculated as in (7).

$$R_{choice}(t) = \min_{1 \le i \le n}(R_{service\_i}(t)) \quad (7)$$

Since we consider the worst-case scenario, the reliability of a choice structural component equals the minimal reliability of the constitutive web services.

The algorithm for calculating the reliability of a composite web service is defined recursively as in Algorithm 2. Algorithm 2 involves two steps when calculating the reliability of a composite web service. In its first step, the reliabilities of all simple components are calculated. In a case when a simple component is bound to a composite web service, the method *CalculateReliability* must be invoked recursively with the parameter *initialization* being *true*. In the second step, the reliabilities of the structural components are calculated. Similarly, when a structural component contains another structural component as its constitutive component, the method *CalculateReliability* is also invoked recursively, but this time, the parameter *initialization* is set to *false* indicating that the algorithm is now processing its second step.

IV. CASE STUDY

To demonstrate the effectiveness of our approach, we utilize a case study of financial services, which involves investment in mutual funds and stocks. We define a process model for financial investment as a composite web service with a choice structure. As shown in Fig. 5, the choice is between buying mutual funds or stocks. The upper structural component represents mutual fund investment wherein the investor has a choice of investing in three types of mutual funds. They are *equity* that involves high risk, high gain funds, *debt* that represents low risk low gain funds, and *balanced fund* that gives almost steady gain with medium risk. In order to use the financial services, the investor needs to provide information about the type of fund, investment amount and personal information. For example, if the user wants to invest in equity funds, the *Equity* web service is selected and invoked, which provides a list of equity mutual funds along with their returns. Then the *SelectMutualFund* service is invoked to automatically choose the service with best returns for the user. Finally, the *BuyMutualFund* service will be invoked to buy the selected mutual funds. Similarly, the web services *Debt* and *Balanced* can be invoked to provide a list of debt funds and a list of balanced funds with returns, respectively. On the other hand, if buying stock is chosen, the process model has the *BuyStocks* service, where the input to this service is the stock to be bought, the number of stocks, and the rate at which the user wants to buy. When the specified stock is available at the preferred rate, the *BuyStocks* service is automatically invoked to buy the specified number of stocks.

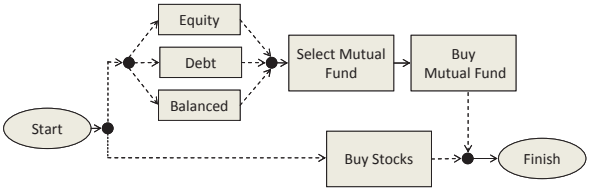

Figure 5. A process model for financial investment

In order to ensure the desired reliability of the financial services for investment, we develop a prototype service reliability monitoring tool. Fig. 6 shows the interface for monitoring the reliability of the financial investment service in real-time. Under the *ProcessModel* tab, it presents the predefined process model (as shown in Fig. 5) at the left hand side, and displays the real-time reliability of the composite web service at the right hand side. The interface also shows the status of the composite web service, which could be *normal*, *warning* or *unacceptable*. A *normal* status indicates that the reliability of the composite web service equals to or more than the desired reliability; a *warning* status indicates that the reliability is below the desired reliability but no lower than the marginal reliability. When the reliability falls below the marginal reliability, the status becomes *unacceptable*. Note that in this example, the *desired* and *marginal* reliabilities are set to 0.85 and 0.75, respectively. They can be easily re-configured by clicking on the *Configuration* tab. In addition, the interface also displays the current date and time as well as execution information of the composite web service. At the bottom part of the interface, all services bound to the simple components are listed. If the service is atomic (e.g., *EquityService*), the address of its WSDL and its real-time reliability are displayed (e.g., *http://192.168.1.112:8080/equity/EquityService?wsdl* and 0.92751); otherwise, if the service is composite (e.g., *BuyStocks1*), the address of the corresponding IPM file and its real-time reliability are displayed (e.g., *C://Files/BuyStocks1.owl* and 0.84917). The detailed information about a composite web service (e.g., *BuyStocks1*) can be retrieved by clicking on the *CompositeComponents* menu at the top of the interface. Note that when the real-time reliability of a composite service falls below the desired reliability, some of its constitutive web services with low reliabilities must be replaced by others in order to improve its QoS.

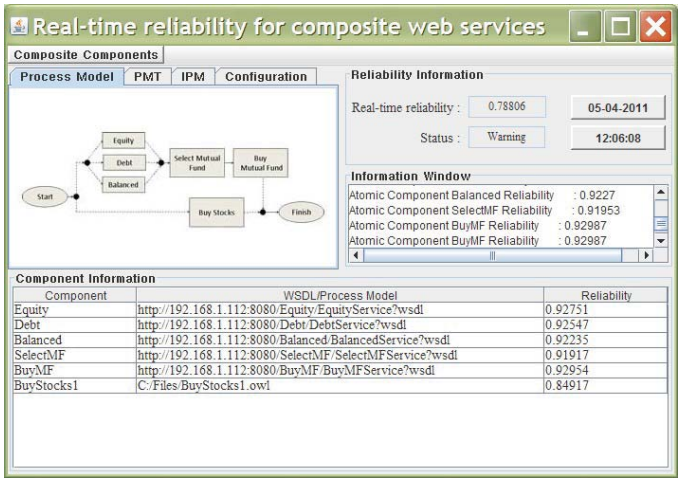

Figure 6. Interface for monitoring real-time web service reliability

V. Conclusions and Future Work

In this paper, we define a dynamic process model that consists of various constructs for web service composition. The dynamic process model is initially defined as a process model template, called PMT, where the constitutive components are not bound to any specific web services. At runtime, the PMT is instantiated into a set of instantiated process models or IPMs. During the instantiation process, web services that are matched with the simple components in a PMT are discovered and selected based on their real-time reliability values. In order to calculate the reliabilities of composite web services, we first present a hybrid reliability model for atomic web services. Then we define a real-time reliability model for a composite web service that aggregates the reliabilities of its constitutive components according to the definition of its dynamic process model. Our approach not only supports service selection for dynamic web service composition, but also supports maintaining a reliable composite web service at runtime by monitoring the service reliabilities in real-time. For future work, we will study existing software reliability models and propose the most suitable ones for atomic web services by considering additional factors such as software aging due to performance degradation or a sudden software crash. We will demonstrate how to automatically switch a web service to a reliable one when its reliability becomes unacceptable. By utilizing artificial intelligence techniques, we may further improve the service reliability model for automatic adjustment of its parameters at runtime. In addition, integrating the proposed reliability index into some existing approaches [5, 6] can also be considered as a worthy future direction.

Abstract—AI planning requires action models described by a formal action plan description language as input. However, building action models is a time-consuming task. Previously, some algorithms are based on the assumption that knowledge of states in the middle of observed plans could be complete and effects of actions could be deterministic. However, the assumption is not necessarily established in practice. In this paper, we assume knowledge of states in the middle of observed plans could be incomplete, and effects of actions are uncertain. We develop a novel algorithm to learn action models with conditional effects and probabilistic effects automatically, and evaluate the algorithm in two domains.

Keywords-Action model learning; Machine learning; Knowledge engineering; Automated planning

I. INTRODUCTION

Currently, automated planning is a hot research topic in artificial intelligence and increasingly applied in practice. The intelligent planning systems need to be provided with action models as input, however it's extremely difficult and time-consuming to build action models manually, even for those experts in relative fields. Therefore, it will save lots of manpower cost if action models can be obtained automatically from existing planning traces.

Recently, researchers have proposed some algorithms to learn action models, which assume that action models have determinate effect. However, effects are normally indeterminate in practice. For example, in slippery-gripper domain, whenever the gripper is dry or wet, there are two possible effects which are holding block or not holding block. In this action model, when gripper is dry, the possibility of holding block is 0.95, and that of not holding block is 0.05; when gripper is wet, the possibility of holding block and not holding block are both 0.5. In traditional planning research, we often assume that action models with conditional effects and probabilistic effects could be built manually by experience, but it's actually very difficult even for experts.

For solving this problem, we propose a new algorithm to learn action models with conditional effects and probabilistic effects automatically, which is called AMLCP (Action Model Learning with Conditional effects and Probabilistic Effects). The algorithm can be applied to learn action model with conditional effects and probabilistic effects from the given planning traces with incomplete state information. The obtained action model, which is shown to be approximate to the correct action model, can be provided to domain experts, and applied in the automated planning system for saving the manpower cost greatly.

In conclusion, compared to the previous action model learning algorithms, AMLCP made the following contributions: (1) obtained action models could have conditional effects and probabilistic effects. In practice, the effects of action are usually uncertain and conditional, with multiple possibilities. AMLCP can obtain action models with conditional effects and probabilistic effects; (2) state information of the planning traces could be incomplete. It is quite difficult to obtain complete state information in reality. AMLCP can be applied with incomplete state information.

The rest of the paper is organized as follows. In section 2, we introduce the related work. In section 3, we present the steps of the algorithm AMLCP in detail. In section 4, we construct experiments in three planning domains to estimate the error rates of learned action models by AMLCP. In section 5, we summarize the paper and discuss our future works.

II. RELATED WORK

Recently, researchers have proposed some algorithms to learn action models. According to whether state information is complete, these algorithms could be divided into two parts. Some algorithms are, to learn action models from plane traces with complete state information[1-8]. Gil et al. [1] build EXPO system, bootstraped by an incomplete STRIPS-like domain description with the rest being filled in through experience. Oates et al.[2] use a general

classification system to learn preconditions and effects of actions. Schmill et al.[3] learn action models by approximate computation in relative domains. Wang et al.[4] propose an approach to learn action model automatically by observing planning traces and refine the operators through practice in a learning-by-doing paradigm. Pasula et al. [5,6] present how to learn stochastic action models without conditional effects.

The other algorithms, are to learn action models with incomplete state information[7-13]. Yang et al. [7] build action model learning system-ARMS by using SAT, which can handle the case with incomplete state information, and acquire STRIPS action models. Amir et al. propose the algorithm SLAF[8-11] to learn action models with incomplete state information, which resembles version spaces and logical filtering and identifies all the models that are consistent sequence of executed actions. Lai et al. [12] construct AMLS system to learn action models from planning traces with incomplete state information, under the framework of genetic algorithm. For acquiring action models with better expression ability, Zhuo et al. [13] build a novel learning algorithm LAMP, which applies Markov logic networks to obtain action models with quantifiers and logical implications.

III. Action Model Learning with Conditional Effects and Probabilistic Effects

A. Definition of action model learning with conditional effects and probabilistic effects

A STRIPS-like planning problem with conditional effects and probabilistic effects can be defined as a four-tuple $<S,s_0,s_g,O>$, where S represents a set of states, and each state is a set of propositions. s_0 represents the initial state and s_g represents the goal state which is the final state following with a series of states transition, starting with initial state. O represents a set of action models with conditional effects and probabilistic effects, composed of a three-tuple $<a, PRE, CPEFF>$, in which a represents an action schema with action name and parameters, for example (*pickup ?b*); *PRE* represents preconditions. *CPEFF* represents conditional effects and probabilistic effects, formally expressed as $<(p_{i1},c_1,e_{i1})...(p_{ij},c_1,e_{ij})\ldots(p_{in},c_1,e_{in})>$, in which c_1 represents the i^{th} condition composed of literal and conditions c_1 $(1 \le i \le k)$ are mutually exclusive, the corresponding j^{th} effect is represented by e_{ij} with probability p_{ij}, which is the conjunction of literal. A possible action sequence is denoted as $<a_1,a_2,\ldots,a_n>$, transferring from initial state s_0 to goal state s_g. Furthermore, we call $(s_0,a_1,s_1,a_2,\ldots,s_n,a_n,s_g)$ as a planning trace, where the middle state s_i might be null, and a_i represents action schema.

Action model learning with conditional effects and probabilistic effects can be described as follows. Given planning traces set T, propositions set P as input, algorithm AMLCP outputs all the action models with conditional effects and probabilistic effects in A.

Table1 The Input Of Algorithm AMLCP

Preconditions	*(block ?b) (gripper ?g)*
Conditional effects and probabilistic effects	<(0.95 *(gripper-dry ?g)* (and *(holding-block ?b)*)), (0.05 *(gripper-dry ?g)* (and*(not(holding-block ?b))*))> <(0.5 (not *(gripper-dry ?g)*) (and *(holding-block ?b)*)), (0.5 (not *(gripper-dry ?g)*) (and*(not(holding-block ?b))*))>

Table 3 Framework Of Algorithm AMLCP

Input	1. A set of plan traces *T*; 2. A set of action schema *A*; 3. A set of predicates *P*.
Output	A set of action models with conditional effects and probabilistic effects.
Steps	1. Encode each plan trace as a set of propositions; 2. Generate candidate formulas, using *A* and *P*; 3. Apply MLNs to learn weights of all the candidate formulas; 4. Choose some of candidate formulas according to given threshold, and convert weighted candidate formulas to action models with conditional effects and probabilistic effects as output.

B. Framework of algorithm AMLCP

The motivation of our algorithm AMLCP is to transform action model learning problem into weights learning problem in MLNs, and obtain action models with conditional effects and probabilistic effects. The frameworks of algorithm AMLCP is shown in table 3.

C. Steps of algorithm AMLCP

In the following subsections, we will show a detailed description of each step of the algorithm AMLCP.

1) Step 1:encode plan traces

In the first step of algorithm AMLCP, we encode all the plan traces as a set of proposition databases *DBs* with plan traces *T* as input. Firstly, we use propositions to represent each state of plan traces.Secondly, we can consider an action as the transition of states, then action can be encoded as the conjunction of propositions.

2) Step 2: generate candidate formulas of each action

In STRIPS model, if a predicate is a negative effect of an action, then the predicate should be a precondition of the action; and a predicate can not be both positive effect and negative effect of an action. Considering the two characteristics, we describe an action model in two parts: preconditions and effects.

a) Preconditions

If predicate p is a precondition of action a, then p must be satisfied when the action a is executed, which can be described formally as:

$$\forall i,\bar{x},\bar{y},a(\bar{x},i)\rightarrow p(\bar{y},i), \quad (1)$$

where $\bar{x}$, $\bar{y}$ are parameters, and i is the state symbol.

b) Conditional effects.

If predicate p is a positive effect of action a with condition c, then p should be added to the next state after the action a when condition c is satisfied, which can be described formally as:

$$\forall i,\bar{x},\bar{y},a(\bar{x},i)\rightarrow p(\bar{y},i)\wedge p(\bar{y},i+1)\wedge c(\bar{z},i), \quad (2)$$

where $\bar{x}$, $\bar{y}$, $\bar{z}$ are parameters, and i is the state symbol. If predicate q is a negative effect of action a with condition c, then q is satisfied when a is executing and condition c is satisfied, but not satisfied after action a, which can be described formally as:

$$\forall i,\bar{x},\bar{y},a(\bar{x},i)\rightarrow q(\bar{y},i)\wedge\neg q(\bar{y},i+1)\wedge c(\bar{z},i) \quad (3)$$

Applying formulas (1)-(3), we can acquire candidate formulas of preconditions and conditional effects.

3) Step 3:Learn weights of candidate formulas

According to reference [16], Markov Logic Networks L consists of a set of pairs (F_i,ω_i), where F_i is a formula in first-order logic and ω_i is a real number. With a finite set of constants $C=\{c_1,c_2,\cdots,c_n\}$, it defines a Markov network $M_{L,C}$ as follows:

- $M_{L,C}$ contains one binary node for each possible grounding of each predicate appearing in L. The value of the node is 1, if the grounded predicate is true, and 0 otherwise.
- $M_{L,C}$ contains one feature for each possible grounding of each formula F_i in L. The value of this feature is 1 if the ground formula is true, and 0 otherwise. The weight of the feature is ω_i associated with F_i in L.

We apply Alchemy system[17] to learn weights of candidate formulas, by using weighted optimized pseudo log-likelihood. For each atomic formula, if it appears in *DBs*, then it corresponds to $x_i=1$, otherwise 0.

4) Step 4: Obtain action model with conditional effects and probabilistic effects

In the candidate formulas of preconditions, we choose those formulas with weights greater than some threshold as a set and convert it into the preconditions of action model. Similarly, we can choose some candidate formulas of conditional effects and calculate their corresponding probabilities. Finally, we can obtain action model with conditional effects and probabilistic effects.

Table 4 The Acquired Action Model

Action schema	pickup(?b ?g)
Preconditions:	*block(?b), gripper(?g)*
Probabilistic conditional effects:	*<(0.87 (gripper-dry ?g) (and (holding-block ?b))), (0.13 (gripper-dry ?g) (and(not(holding-block ?b))))> <(0.48 (not (gripper-dry ?g)) (and (holding-block ?b))), (0.52 (not (gripper-dry ?g)) (and(not(holding-block ?b))))>*

IV. EXPERIMENTS AND ANALYSIS

A. Datasets and evaluation criteria

To evaluate the algorithm ALMCP, we collected plan traces from planning domains slippery-gripper and sandcastle. The two domains have the characteristics we need to evaluate ALMCP algorithm, which means both of them have indeterministic effects. Using probabilistic planner Probabilistic-FF, we generated 20-100 planning traces from the two domains as training data.We consider the given action models as correct ones, and then use the correct action models to evaluate the error rates of learned action models.

B. Experimental results

Fig.1 and Fig.2 show performance of algorithm AMLCP with respect to the number of plan traces and thresholds used in selecting candidate formulas which are set to be 0.001,0.01,0.1,0.5, respectively.

From the results of the two experiments, the error rates are affected by the number of given plan traces. Generally, error rate decreases when the number of plan traces increase. When the number of plan traces is smaller, the error rate is higher. When the number of plan traces increases to some extent, the error rate decreases rapidly, but eventually it goes down slowly. It means that the difference between

learned action models and correct ones is obvious when information is limited, but the difference will decrease with enough information. It can be speculated that learned action models will be approximate to correct ones with enough number of plan traces.

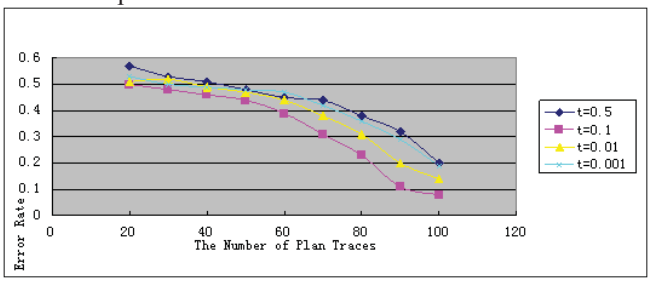

Fig.1 Error rates with respect to different number of plan traces, in slippery- gripper domain

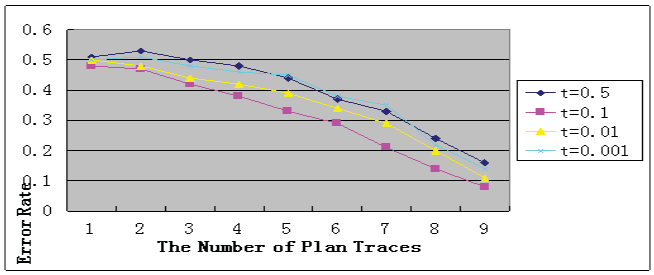

Fig.2 Error rates with respect to different number of plan traces, in soadcastle domain

V. CONCLUSION

In this paper, we proposed a novel algorithm AMLCP to learn action models with conditional effects and probabilistic effects from a set of observed plan traces where some intermediate states might be partially observable. Our AMLCP algorithm applies MLNs to learn action models automatically. The experimental results in two indeterminate planning domains show that AMLCP algorithm is quite effective. In the future, we could expand the algorithm to improve its expression ability and reduce error rates of learned action models.

***Abstract*—This paper proposes a method for fraud detection in automated selection exams, using knowledge engineering tools for identifying groups of answers with a strong indication of fraud, based on probabilistic evidence. Founded on an analysis of the wrong answers of the various candidates, the proposed method enables identification of suspicions, and evidence of fraud attempts through finding candidates with a significant number of identical wrong answers. This method of using knowledge engineering tools can be employed in various types of selection examinations, adapting to the characteristics and features of each one and contributing to the achievement of fair exams and free of fraud attempts.**

Keywords: knowledge engineering tools; fraud detection; selection exams; multiple-choice questions.

INTRODUCTION

The need for detection of various types of fraud in several fields of application has grown in recent years, possibly due to the great developments in information and communication technologies (ICT) that provide citizens with diverse resources and technological facilities for access to databases of public and private organizations.

The growing complexity of equipment and services provided by new technologies hinders the identification of possible failure points or some susceptible to fraud attempts. In several areas of activities, there is a lack of study and research that enables the creation of methods and techniques to prevent fraud and to reduce financial losses caused by this type of crime. Knowledge Engineering (KE) provides us with tools that can assist in detecting and preventing fraud, helping us to fight this type of crime.

The application of knowledge engineering tools in fraud detection is already common in many fields of study. It occurs mainly in the following areas: mobile communications (cellular), finance, electronic commerce, healthcare, credit cards and government organizations [1], [2]. A systematic review on the subject of this research has not identified a study published in the databases Scopus (www.scopus.com) or ISI Web of Knowledge (apps.isiknowledge.com) associating the keywords "detection," "fraud," "exam," and "examination." Based on the review conducted in the two largest databases, we can state that we did not find any study of application of KE tools to detect fraud in selection examinations. Therefore, we propose a new possibility for application of these tools.

Some related studies apply others' software techniques for fraud detection. In [3], artificial immune systems are used to identify fraud attempts in online credit cards operations. Data-mining techniques can also be applied for fraud detection in e-Commerce [4], mobile communication networks [5], and in conventional telephony [6]. Other studies specifically propose statistical methods for fraud detection in several areas [7], [8].

The model presented in this paper for the application of KE tools in fraud detection in admission exams is structured into eight sections: Section II makes a brief introduction to selection examinations processes, presenting their main characteristics. Section III presents the main types of fraud that can occur in a contest aimed at giving an overview of the method to be proposed in this paper. Section IV examines the various types of questions that can be adopted in an examination. Section V presents a statistical study of the probability analysis of identical wrong answers (IWA) to a specific type of question: multiple-choice. In Section VI, we present a proposed method for fraud detection in automated selection processes. Section VII presents and discusses the results, and finally in Section VIII, we give conclusions and suggestions for future work.

II - SELECTION EXAMS

A. Definition

A selection examination process can be defined as an activity consisting of several sub-processes or steps, with the aim of selecting candidates through the application of questionnaires, tests, and other selection tools to fill a limited number of vacancies.

B. Phases of a selection exam

The phases, steps or sub-processes of a selection examination are necessary to meet statutory deadlines for publication, call for entries, preparation of tests, allocation of material and human resources, realization of exams, test

This study was supported by CAPES, the Brazilian Government entity for the training of human resources.

reading, test processing, and disclosure of results for the subsequent filling of vacancies by admission or hiring. Figure 1 shows the complete cycle of the phases of a selection process.

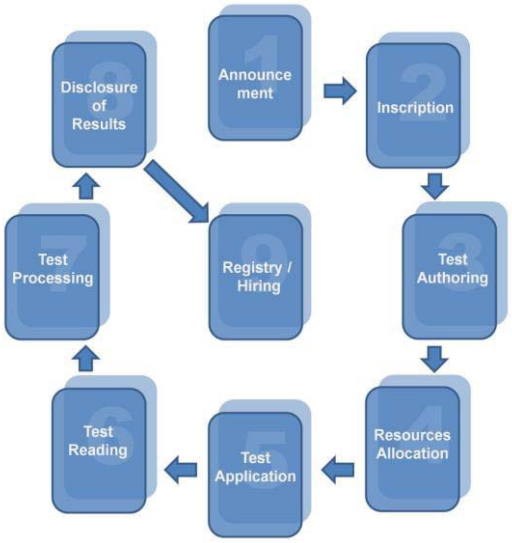

Figure 1. Phases of a selection exam.

The limitation of the vacancies is precisely the main motivation of the contest; if there were no limits to the vacancies or the number of qualified candidates for completion was not significant, selection would have been unnecessary.

The process initiates with the disclosure activities. The purpose of the announcement phase is to enroll the largest number of candidates, giving chances to all interested in attending the event. After complying with legal requirements for the announcement, the next phase opens up the inscription or registration for all applicants who may be qualified for the selection exam. Once the inscriptions are finished, in the next phase, we make the arrangements for the preparation of the tests that will be applied to candidates; this is done through enjoining experts or specialized companies for the authoring of tests and examinations. At the phase of resource allocation, the candidates are distributed by each exam place; all the materials and human resources are allocated for the next phase, such as rooms, equipment, proctors, and coordinators. In the test application stage, there are major activities related to the security aspects of a selection process, including review of all the candidates with metal detectors during their access to the exams places, planning and proctoring the application of the tests, and the electronic monitoring of all the examination locations.

Once the tests are completed, all material is collected in a safe place − usually the institution's information technology department − where the test reading phase is done with automatic readers, scanning responses of all candidates' tests for later assessment. In the test processing phase, all test answers are processed using the templates and automated processing systems for getting the results of the tests, creating the scores for the candidates, and generating their respective places (classifications). Finally, after verifying and auditing the whole process of assessment, final reports are issued for disclosure of the results toward the registry or hiring of selected candidates.

III. Fraud in Selection Exams

Currently, security is one of the most relevant points in managing selection processes, given the considerable number of technological tools that tempt people to perform activities of fraud, especially in contests where there is a great competition of candidates per position.

Security issues in exams can now be handled from the time of enrollment by consulting special database lists maintained by various Brazilian governmental institutions that contain the names of all candidates already identified in prosecution of fraud attempts, throughout the national territory. Despite having their entries approved, such candidates can be identified from the time of enrollment and allocated in special rooms to be monitored in their activities during application of the tests.

At the stage of resource allocation, some security measures can also be taken, trying to find candidates with relatives in the same contest and separating them in different rooms or places for application of the tests, avoiding their proximity.

However, it is at the phase of test application in which security issues should have greater weight because it is precisely at that point that the largest number of fraud attempts occurs. All measures already mentioned − such as the use of metal detectors and electronic monitoring of electronic transmissions − are key in this phase.

At the stage of test reading, it is also necessary to adopt preventive measures, with rigid control of access to the processing data center and precautions against possible reading processing errors.

Finally, in the phase of disclosure of results, safety measures must be adopted with respect to the risks of information leakage or premature disclosure of the results, avoiding harming the reliability of the whole process.

Our practical experience in conducting selection exams over two decades shows that occurrences of fraud attempts are fairly common on any type of competition or selection process.

The attempts of fraud range from traditional and frequent acts of trying to cheat or plagiarize during the test, copying the responses of a competitor in the same room, and even the most daring attempts, carried out by means of electronic transmission. All these attempts must be considered and scrutinized by the authorities responsible for conducting the selection process, and all the omissions in these security cases are inadmissible. Absolutely nothing can justify the absence of mechanisms for its prevention or precaution.

IV. Types of Questions

For a better understanding of the proposal for fraud detection presented in this article, it is necessary to describe the types of questions usually adopted in examination tests.

At first, the main types of questions used in tests can be grouped into three categories:

- Multiple-choice questions.
- True/false questions.
- Open questions.

Open questions significantly hinder the attempts of fraud since they require a response not coded and difficult to be transmitted − although not impossible. Open questions are the most difficult to process when adopted in contests with a large number of participants. Another disadvantage that this type of question presents is how to standardize criteria for evaluation, aiming to avoid disparities in the assessment by reducing the subjectivity and inconsistency among the different evaluators.

True/false questions inhibit the adoption of the fraud detection strategy proposed in this paper. With this type of test question, it becomes difficult to identify the "signature" or the statistical evidence of fraud, as will be shown below. For this type of question in particular, other strategies should be established for the automatic detection of fraud, taking advantage of their peculiarities.

Multiple-choice questions are still frequently adopted in selection processes for their tradition and simplicity [9]. One of their main advantages is the ease of representation on printed answer sheets that can be read by automatic readers. This procedure enables the processing of the large volumes of data collected in medium and large examinations.

The method for fraud detection proposed in this study assumes that the type of questions adopted in the contest is multiple-choice. This type of question presents an interesting feature that can be exploited for the automatic detection of fraud: We observe that when two or more candidates try to cheat on a test, the probability that their errors are equal is high; that is, the wrong answers are the same and the alternative letters answered incorrectly are also equal. Taking this observation as a basis, the method proposed in this paper makes a study of the statistical probability of simultaneous occurrence of errors on the same questions and the same alternatives to substantiate the mathematical evidence of a fraud attempt, further proposing KE tools to identify the occurrence of this problem, detecting and fighting some fraud activities in selection exams.

In the following section, we create a probability analysis of the simultaneity of the same wrong answers with the same wrong alternative letters in a test of multiple-choice questions using a total of 40 questions for a case study.

V. Probability Analysis

To illustrate the method proposed in this paper, we assume that the test being examined has 40 multiple-choice questions with 5 alternatives (ABCDE). A sample of the possible answers can be seen in Figure 2.

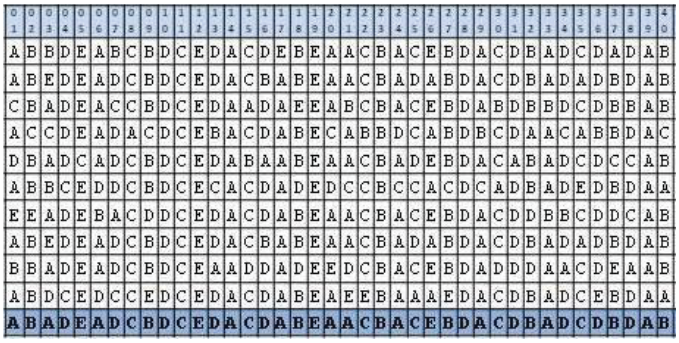

Figure 2. An example of answers of multiple-choice questions.

The first line of the figure shows the position of each of the 40 questions in the test paper. The bottom line, displayed with highlighted background, corresponds to the template of these multiple-choice questions. The 10 lines between are examples of candidates' responses.

To further facilitate visualization, we can eliminate all the correct answers of the candidates, since they are of no interest to our study. Figure 3 shows only the wrong answers, already highlighted.

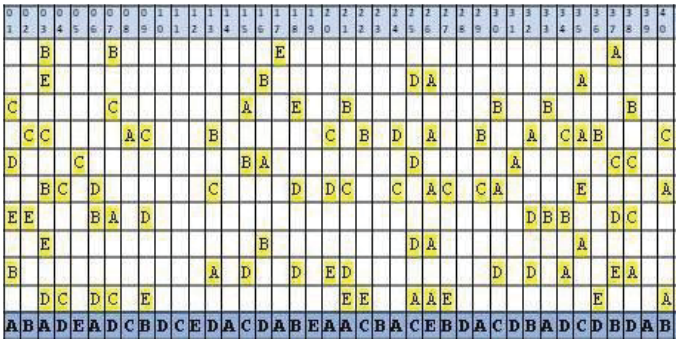

Figure 3. Only the wrong answers are displayed.

The research question for the analysis of probabilities is: What is the probability that two or more candidates err in a multiple-choice test with 40 questions (such as ABCDE) in the same question numbers and answering the same wrong alternative letters? Our hypothesis is that after a certain number of wrong answers exactly alike, the probability of occurrence is close to zero, providing formal evidence that there is a strong suspicion of a fraud attempt.

This probabilistic evidence substantiates the fraud detection method proposed in this study, applying KE tools for identifying high similarities in the wrong answers of the candidates in a selection exam that meets these characteristics and type of question.

C. *Calculating the probability*

For didactic purposes, it is necessary to define the concept of IWA. In this study, IWA are those special occurrences when two or more candidates miss the same questions, answering the same wrong alternative letters, resulting in a remarkable coincidence. One can intuitively predict that this coincidence has a significantly low probability of occurrence (i.e., it is almost impossible), and this fact sets up a strong indication of anomaly. We can interpret this occurrence as a "signature" of

the fraud attempt, a feature that makes it unique, singular, and − rightfully so − it should be investigated.

The probability of the simultaneous occurrence of IWA in an examination test can be expressed as follows:

Let:

a - the number of alternatives in each question and

k - the number of IWA,

then the probability (P) can be expressed as:

$$P = \left(\frac{1}{a^2} \right)^k$$

This equation represents a simplification of the problem and is based on the following assumptions:

- The questions are independent; that is, their responses do not interfere with the responses to other questions.
- The probability of each alternative (ABCDE) is equal.

Without this simplification, the solution would be far more complex, requiring a more detailed study of all proposed questions of a specific test to determine the probability of each question and each alternative individually. The proposed equation also implies that the probability of IWA does not depend on the size of the universe (i.e., number of candidates who have taken the test).

This equation demonstrates clearly that as the number of IWA increases, the value of its probability decreases significantly. We can perform the calculation in a small interval to analyze the behavior of the calculated probability. Table 1 shows the calculation of probabilities for the range of 1 to 10 IWA, considering a test with multiple-choice questions with five alternatives ("ABCDE," with $a = 5$).

TABLE I. PROBABILITIES OF IWA IN A MULTIPLE-CHOICE TEST WITH 5 ALTERNATIVES

IWA	P (%)
1	4.000000000000
2	0.160000000000
3	0.006400000000
4	0.000256000000
5	0.000010240000
6	0.000000409600
7	0.000000016384
8	0.000000000655
9	0.000000000026
10	0.000000000001

From Table 1, we conclude that, if the number of IWA is equal to or greater than 3, the probability is already minimal (0.0064%).

VI. PROPOSED METHOD

We have applied a SQL (Structured Query Language) script and relational databases as a traditional Software Engineering tool for helping to detect some IWA. Nevertheless, the results using this technique were not always accurate due to different combinations of IWA and the absence of some IWA in some candidate' responses.

There are many Knowledge Engineering tools that can be applied to detect this kind of fraud attempt with better accuracy. Among others, the main KE tools that can be used in this case are:

- Artificial neural networks (ANN).
- Artificial immune systems (AIS).
- Data mining.
- Case-based reasoning (CBR).

The proposed method is founded on applying case-based reasoning (CBR) as a data-mining tool. CBR is an artificial intelligence technique applied in solving problems and achieving learning, based on past experience such as the use of known cases to solve new cases [10].

CBR methodology fits the purpose of fraud detection proposed in this paper by presenting some features relevant to the problem presented. Among these characteristics, we can highlight the following [11]:

- A CBR system should be able to handle incomplete and highly specific queries.
- It can suggest appropriate cases, even when not all attributes are provided.
- It presents retrieved cases in a rational way; that is, avoiding excessive responses and respecting a limit of retrieved cases specified by the user.

These characteristics favor the application of CBR methodology in this type of fraud detection, since it allows retrieval of similar cases differently from traditional information retrieval, done through use of queries in relational databases.

The proposed method consists in designing a system of CBR for the identification of candidates with IWA above the minimum value of statistical probability (IWA = 3) for the retrieval of similar cases in an IWA file. The system starts out with a file containing all the wrong answers of several candidates, making an automatic sequential search of all similar cases until there is a recovery of more than one case where this similarity occurs. All cases recovered with high similarity will be listed for further investigation of attempted fraud.

As the volume of responses in a test can be quite high, it is necessary to adopt some criteria to restrict the sample studied in order to optimize queries. The first criterion to be adopted is to restrict the sample studied by eliminating the responses of candidates whose number of hits in the test is less than a minimum passing grade. Thus, all responses that have a

number of errors exceeding a certain percentage will be automatically discarded since these candidates failed to pass the competition. This measure considerably reduces the number of cases to be searched.

Another measure of restraint refers to the retrieval of cases in the database. It makes no sense to retrieve cases in which the number of IWA is less than a certain percentage; for example, 60%. The idea is to eliminate instances in which the number of IWA does not reach a certain percentage, which undermines the suspicion of fraud. Thus, we consider only the responses of the candidates whose percentage of IWA is equal to or exceeds 60%.

Looking closely at Figure 4, we note that there are some instances of IWA between the lines, as can be seen in Table 2.

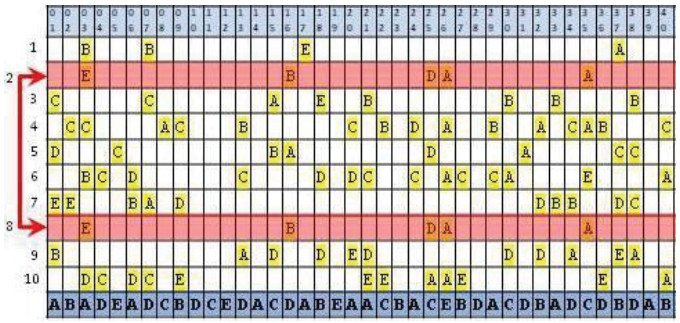

Figure 4. Relevant similar cases in the case base.

TABLE II. OCCURRENCES OF IWA IN THE FIGURE 4

Lines with IWA	Nº of IWA	% of IWA
2 and 8	5	100%
6 and 10	4	29%
7 and 9	1	10%

Although we have identified three instances (2-8, 6-10, 7-9) in which there is similarity among the cases of wrong answers, not all are relevant. If we consider the percentage of IWA in each of the events, we see that only one of them is of interest: line 2 with line 8 (Fig. 4).

The other events are not depicted with evidence of fraud since the percentage of IWA is less than a significant percentage. We can establish a minimum threshold value for this percentage (e.g., 60%), whereas in some cases the candidate who received a given template (crib note) can recognize that one of the answers is wrong and increased his or her number of correct answers or may even have tried to answer some questions on his or her own (chance), and it still is wrong, leading to wrong answers on the same issues but with different alternatives from the original source of cheat or crib.

The proposed method provides an algorithm to scan the responses meeting the restriction criteria predetermined. The process is sequential and begins with the first line, retrieving all its similar cases, then moving on to the next line (2) and doing new queries only from this starting point, reducing in every turn the universe to be searched and optimizing the process of the sequential search. Some CBR tools allow a case to be used as a query, facilitating the research process.

In a real application, we need the candidate identification number in addition to the answers of the multiple choice questions. This will enable us to identify those candidates who have a certain number of IWA.

To automate the fraud detection in an IWA file of multiple-choice questions, it is necessary to make a data-mining tool using an automatic scanning procedure on the IWA case base. As some CBR systems do not allow the creation of scripts to program this automatic scanning, one way to implement such a data-mining procedure would be through the creation of a similarity function, "Sim ()" in a relational database software, enabling the creation of an SQL script to perform the automatic scanning of all the IWA stored in the database, calculating their similarities, identifying which answers show a high similarity and, finally, retrieving them for inspection.

The similarity metric that best fits the proposed model is the average of similarities implemented in the CBR tool. Several simulations were conducted to find the best option for the case studied, including the codification of the alternatives as numeric values (ABCDE as 12345). None of them has better results than the model adopted.

VII. RESULTS AND DISCUSSION

The model simulated in the CBR tool has produced some excellent results in recovering similar cases of IWA. For testing the model, a query was created that had one more wrong answer than the similar cases in the case base, just in the initial position of the string (Fig. 5).

Figure 5. Graphical representation of the query.

This insertion of one more wrong answer in the initial position would make impossible the retrieval of similar cases by means of a SQL query in a relational database, since the blank character (or space) has a smaller value for its internal representation than the letter "A"; this fact increases the distance between the cases registered in the database and the query made. However, the model created with the CBR system proved excellent performance by retrieving all similar cases. Table 3 shows the similarity values calculated by the CBR tool in all the retrieved cases of the case base.

TABLE III. VALUES OF THE SIMILARITIES OF THE RETRIEVED CASES

Case	2	8	4	6	10	5	1	3	7	9
Sim()	1,00	1,00	0,50	0,25	0,25	0,20	0,00	0,00	0,00	0,00

The query on the case base done with the data shown in Figure 5 gives us the results returned by the CBR system used in this study, as presented in Figure 6.

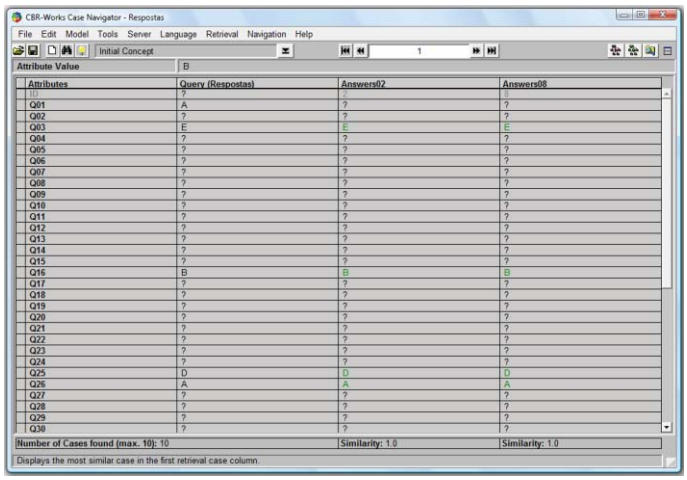

Figure 6. Cases retrieved bythe CBR tool.

Even when the query was submitted with one more wrong answer purposely introduced in the first column, it is clear that case numbers 2 and 8 were recovered with maximum similarity. The remaining cases that did not show a significant number of IWA had low similarity, proving the efficiency and effectiveness of the proposed model.

VIII. Conclusions and Future Work

The methodology of CBR showed excellent performance in the detection of IWA, identifying all the cases in the case base used as a test. While there are some differences between the values of the query with the values found in the case base, the CBR software used in this study correctly retrieved all cases that showed the highest similarity.

We conclude that the method proposed in this study can be applied in detecting and preventing fraud in selection examinations that use multiple-choice questions, allowing the adoption of countermeasures in a timely manner, thanks to its ease of modeling and application.

One limitation of this study is the lack of a more detailed analysis of the behavior of the CBR software with respect to its performance with a case base with thousands of answers from a large group of applicants. However, based on other authors' similar experiences with using bases of more than 200,000 cases [12], the CBR systems have a satisfactory performance. Thus, it is expected that the CBR solution here proposed presents a good performance even in the case of larger bases.

Future research could explore the application of the model proposed in this study for other kinds of questions and tests, adapting the methodology of CBR to the specificity of these applications. Others investigators can also expand this study, making the analysis of the behavior of other CBR software or others KE tools for a greater volume of data.

Acknowledgment

We want to thank Dr. Marcelo Sobottka of the Department of Mathematics at the Federal University of Santa Catarina (Brazil) for his valuable help in determining the probability of IWA in a test of multiple-choice questions.

***Abstract* — The great number of information available in different data sources requires increasingly of search engine system to retrieve as many relevant documents as possible. Clinical medical records contain a great number of information, normally written in free-text form and without a linguistic standard. The physicians do not write the patient's reports using style elements. Consequently, to retrieve the knowledge from these data is not an easy task for the search engine. In this paper we present the development of a model that allows recovering knowledge from textual information in medical documents. Query expansion techniques, which apply knowledge detection assets from the DeCS ontology and language dictionaries, will be used. The goal is to expand the user search and to create a knowledge base to allow its reuse. In order to improve the search results, semantic annotations and negation detection will be used to process medical texts. The case study presented at the end shows that the proposed model was able to achieve a mean accuracy of 90% in its first ten results, while the Boolean model was limited to only 60%. The conclusion is that the user will not need to search in different databases to find the necessary information.**

Keywords-Informartion Retrieval; Query expansion; Negation detection; Medical ontologies

I. INTRODUCTION

The electronic medical information is increasingly present in all hospital and medical clinic. The large number of data that contain medical information is available for researchers, medical institutions, patients and all types of people interested in this kind of information. More and more people can receive and share their information without any restrictions. However, the great number of information available in different data sources requires the use of more intelligent retrieval techniques, focusing on information content and semantic [1].

To demonstrate this requirement, we present a scenario from a typical medical expert task: some common tasks of medical research and clinical care involve, for instance, the checking of exam results, comparison with other reports or statistical analysis of disease patterns in medical records. When a large volume of information is captured and analyzed, the automation of this task is crucial for efficient processing. Medical concepts have to become easily extractable from medical records and they can be compared with other information in order to allow more effective searches[2]. Although the information is available from different forms, the medical texts need to be interpreted by computers in order that information can be processed and effectively shared. To enable this process, the users need to make use of tools in order to increase the accessibility and the data management [3]. On the other hand, to interpret medical text is a difficult task, but it can be easier in comparison as narrative speech, because the medical vocabulary is more restricted. Clinical medical records contain a great number of information, normally written in free-text form and without a linguistic standard. The physicians do not use elements of style for write the patient's reports. A physician can write a report using many ways, and each of them has its own writing style [4]. However, to manipulate these amounts of information is certainly one of the greatest challenges for modern health care search engine systems.

In this paper we describe the use of the knowledge extraction technique from medical ontology and negation detection procedures to define semantic annotation by expand the user's query and to improve the search engine process on medical reports. We describe how to connect the named entities from semantic descriptions on medical ontology DeCS [5] and expand the user's query from DeCS terms. Furthermore, we describe a method that automatic negation detection in medical reports using Natural Language Processing (NLP) techniques [6]. We understand that the use of these three techniques (semantic annotation, query expansion using medical ontology and detecting negated findings and diseases in medical reports), allow for semantically enriched Information Retrieval (IR), expands the user's queries with medical terms and improve the quality of a search in the search engine. In this paper, the search quality is typically described by the use of precision at ten (P@10) metrics.

This paper presents the problem of retrieval information from medical documents on Section 2. A background and related works for semantic search, medical ontologies, Semantic Annotation, Semantic repository and detecting negated phrases techniques are presents on section 3. In Section 4 we present a schema to define automatic annotation from medical ontology DeCS, expand the user query and detect

negative expressions on medical text reports. And finally, the conclusions and future works are discussed in Section 5.

II. PROBLEM

Just because the information does not have a specific standard, the information retrieval (IR) process from patient's medical records is in the most of cases, inefficient. The traditional search engine by using Boolean techniques, do not exploit all the potential existence in this domain-specific knowledge. Although the medical domain provides controlled vocabularies and tools that can be used to search and index documents according to a conceptual hierarchy (e.g. MeSH, DeCS, UMLS, etc.), these engines do not recovery the hierarchical relations among the concepts and semantic such the parents and children links. Sometimes, the medical expert needs to retrieval more relevant information about a specific term or expression. Therefore, this method does not necessarily improve the traditional methods of text search [3]. In order to all related information will be retrievable, it is necessary that the search engines are able to understand the user request and expand the search range, but without losing the quality of search described by precision and recall metrics.

III. BACKGROUND

Before we present our approach, we need to introduce some techniques most used for effective search and retrieval medical information in semantic context. We explain in more detail the methods used for semantic search using query expansion and medical ontologies on Subsection A. In particular, the Subsection B introduces the use of semantic annotation techniques in order to improve on free text search retrieval performance. The detection-negated phrases on medical reports are introduced in Subsection C.

A. Query expansion and ontologies

To solve the problem of semantic search, effective techniques are being widely developed to search and retrieve semantically the medical knowledge [1], [2], [3], [7], [6]. The resource most used is ontology. Ontology is a formal specification of shared conceptualization in order to represent concepts, relationships and rules that manage the relationships. It consists in a way to represent semantic relationships, such objects and relationships in a particular domain [8] and [9]. Ontologies and semantic approaches are used for the integration and IR from different databases [10]. The ontology structure is an important criterion to organize the knowledge and determine the semantic reusability and data interoperability [1].

An important use of the ontology is the query expansion from free textual documents in order to improve IR systems [10]. To expand a query, the user is guided to reformulate the search by add new meaningful terms to the initial query. The system extracts the similar terms from ontology and generates a new query to increase IR systems. The objective here is combining two independent subsystems to retrieval textual and visual information, using the integration of medical knowledge with term expansion they improve the results compared with the two techniques in separated way.

Other works address the problem of query expansion in order to enrich the information retrieval system [1], [7], [11]. A way to expand a query is the use of Term Frequency – Inverse Document Frequency (tf-idf) technique. In order to expand the search, this method includes new terms to the request using words or phrases having meanings similar or related to the original request [11]. In order to evaluate the importance of query expansion and manual indexing, Abdou and Savoy [11] develop a new query expansion model and evaluate the performance of ten different IR models, including probabilistic, language and vector-space models. The authors perform two IR tests (With and Without MeSH ontology) from Medline collection in order to measure retrieval performance. The method presented by authors is 170% more precise when compared to the classical tf-idf vector-space model. Including the MeHS when indexing scientific articles this work improve more 8.4% performance on the best IR scheme. Other way to expand a query is the use of ontologies. Bhogal et al.[7], presented a range of definitions of information retrieval focused on the use of context for query expansion. They have discussed the problem of the use of ontologies for a range of information retrieval tasks and their use in the area of query expansion. For more information see [7].

B. Semantic annotation

Important studies show that extract semantically the information providing semantic annotation using references from ontologies and knowledge databases, can improve more precision on IR systems [2], [12], [13]. In this research area, semantic text annotation is effective texts processing that map corresponding concepts from ontologies and annotate these concepts in the document [2]. Annotations generate and use a set of metadata that provide reference to named entities from ontology mentioned in the medical documents [12]. This metadata generate a knowledge database in order to support semantic search in document repositories. The unstructured medical text gain an important metadata supplied by the ontology. The Semantic annotation enable computer to understand the semantic meaning of a data set and increase the quality of retrieved information and system interoperability [14]. Gschwandtner et al. [2], presents a specific automatic semantic annotation system that maps the concepts from medical ontology to free medical text. They customize other annotation systems (annotating web-pages) to understand a specific medical domain. They develop an application that generates a map of concepts from medical terminologies and the medical concepts included in documents are annotated semantically by a metadata. The medical experts can visualize, control and correct all kinds of annotated information for processing a medical document. Her works show that mapping medical concepts from ontology can provide semantically accurate information for text processing and helps to removing ambiguity from different meanings.

Lourenco et al. [13], identifies relevant terms in documents based on a lexicon Named Entity Recognition (NER) process. The goal is annotate the occurrences of biological classes from abstracts or full-texts within PubMed library and implement the semantic indexing of documents and terms. The technique is used to extract the information from medical libraries, tokenize (pre-processing documents) and apply a lexical dictionary in order to perform the recognition of named entities. In their results obtained, the system is able to reduce significantly the

number of irrelevant documents without significant loss of irrelevant documents. Although the technique used was different, the two works aim to improve the indexing and semantic information retrieval from medical documents.

C. *Negative expressions*

Retrieval negative expressions is as important as retrieval any other information from the database. A negative expression can invalidate a search. Therefore, the system engine has to decide whether this expression contained in the database will be excluded or not from the search [15]. Negative phrases/expressions are used by doctors to write patient's diagnosis, medical procedures as well it helps the medical expert to identify the occurring symptoms and diseases from medical documents [6]. For instance, in medical document is common diagnosis that contains text like "the patient does not have hypertension", or "the patient has hypertension". These expressions create a problem to the search engine. If the engine detects the first expression as true, all documents that contain this kind of expression will be retrieved and the result will contain false information. Because of this, the process of negation detection requires a lot of knowledge about the language to correctly identify negated words or terms from an expression. The detection of negative statements in medical databases can reduce the search space thereby rendering the search process more agile.

Gingl et al. [6] developed a method to classify and detect negated information occurring in Clinical Practice Guidelines (CPG) on syntactical level using grammatical information of the English language. Her studies show that grammatical elements are used to decide whether a phrase is negated or not. The negation classification allows medical expert to decide which therapies or treatment options are best or not applied to the patients. Their syntactical methods detection improves the values in precision and recall. One previous study identifies concepts from a medical ontology UMLS and using a lexical scanner in order to recognize and classify a large set of negated patterns occurring in the text [15]. The authors developed a program based on existing technology for implementing parsers based on context-free grammar. The results of your study show that the system presented has a recall and precision between 91.8 and 95.7 percent in detecting negations on medical documents.

IV. METRHODS AND MODEL DESCRITION

Although, most of this works apply different techniques in order to retrieval the information from medical documents, all of these works have a very particular function: improve the search engine process on medical data. We understand that is not easy to improve the current process, but based on the union from these three previews presented techniques, we refine the actual approach.

Our work differs from the previous works, because we aim to provide to the medical user a document range much more extensive and effective. We want to present most relevant documents so that the user does not need to dispend too much time to find information or the user does not need to look in different databases in order to find the information. We aim also to provide a semantic list created from a knowledge database that is frequently updated in order to permit the user find the information in an intuitive way. The approach presented here is based on the query expansion technique using ontologies that defines the use of terms in hierarchical tree and by the use of synonyms. In order to improve the search, semantic annotations will be used in medical texts. This technique includes the use of named entities and the detection of negative phrases to increase the research universe and reduce the number of less relevant responses. We will create a metadata repository which be used to generate concepts from the ontology, extract the information from medical documents and make the text pre-processing.

In figure 1, we describe how the term is indexed and how the users receive de results. The most important component is the Query Engine module. It is responsible to access the semantic knowledge database and the text extraction modules (Semantic Annotation, Negation Detection and Query Expansion). The core of the query search engine is composed for two main elements: Indexing and Search. The Analyzer process is the conversion of texts in terms. The terms are used to determine which documents match a query during the search. The Analyzer is the component of the analysis process that performs a series of operations to facilitate the indexing. It converts the tokens to lowercase letter, removes stressed characters, and removes common words, like articles and pronouns (stop words) and extracts words root (stemming).

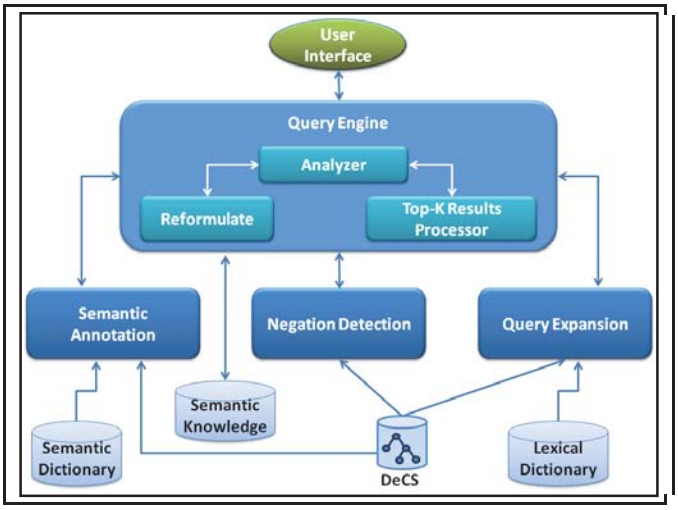

Figure 1. Semantic Information Retrieval from medical databases.

The Analyzer also uses NLP to extract terms from DeCS ontology, in order to classify and define the relationship between two terms, and extract the negative sentences. In our system, we assume that the knowledge database should be built and associated from information sources, which utilize medical ontologies, lexical dictionaries, and the analyzer component in order to describe concepts that appear in documents stored on medical database.

The Reformulate component is responsible to connect others text extraction modules, reformulate the query and store the results on the Semantic Knowledge database. The semantic annotation, query expansion and Negation Detection modules are used by the Top-k Results Processor in order to retrieval and ranking the information. The ranking method is an adaptation of the vector space model (Van Rijsbergen, 1975),

which defines keywords weights that appear in the document. The weights are computed automatically based on the frequency of instances in each document. The number of occurrences for a document instance is defined by the number of the times that an instance appears on text

The Negation Detection module is a NLP technique, which finds negations sentences into the medical text report in our database. As described in [6], we need to detect five negation classes (adverbial negation, intra-phrase triggered negation, prepositional negation, adjective negation and verb negation) in order to improve parameters of recall and precision by the user query. The first step in the detection process is to create a list of negative terms (not, ever, nerver, none, neither…). As a single word does not define a negative term, we need to analyze an expression. Furthermore, most of medical findings do not have 100% sure if a expression is affirmativ or negative, we created a list "hypothetical" terms, like, *cannot assert*, *cannot exclude, cannot completely rule out*…

Then we map biomedical text founded in DeCS ontology in order to create a negative expression dictionary with this five classes of negation expressions. We discovery this negated expressions on the medical report in order to refine the user query by sending to the query engine module. As a result, we generated a list that has been indexed with the terms found in order to facilitate further search. Figure 2 shows a list of excerpt from negative expressions indexed by the algorithm in the Portuguese language.

206876|Bloqueio divisional ântero-superior de ramo esquerdo, **<hypothetical>** nao se pode excluir **</hypothetical>** **<finding>** fibrose inferior **</finding>**
200330|Alterações da repolarização ventricular em parede inferior com onda T **<negation>** negativa **</negation>** em D3 e a Vf compatível com **<finding>** isquemia subepicárdica **</finding>**
295168|**<hypothetical>** Não se pode descartar **<hypothetical>** **<finding>** fibrose inferior **</finding>**
84079|**<finding>** taquicardia supraventricular **<negation>** não**</negation>** -sustentada **</finding>**

Figure 2. Stretch of annotated medical findings using our system.

The query expansion process uses the DeCS ontology by adding more medical information in the user research. The DeCS ontology is used for indexing the medical report text in database, because this ontology contains concepts, relations of synonymy and related concepts. This facilitates the expansion and extraction of terms from the DeCS Descriptors. If the set of terms have relation with the user query and DeCS descriptors, we generate a new query, which contain all terms presents on DeCS synonymous. Moreover, we use the lexical dictionary in order to find new synonymous expressions on medical reports. For instance, when a medical search for the disease "asthma", the DeCS ontology find four answer terms: "Asthma", "Asthma, Exercise-Induced", "Dyspnea, Paroxysmal" and "Asthma, Aspirin-Induced". If we use the lexical dictionary, we expand the results including three new terms: "Bronchitis", "Infectious bronchitis virus" and "Bronchitis, Chronic". It is happened because in our dictionary the term "Asthma" has relationship with the term "Bronchitis", but in DeCS ontology this connections does not exist in the same hierarchical tree.

To define semantic annotation, we use a lexicon dictionary, a list of stop words, and a dictionary of negative sentences for Portuguese language. Moreover, we use the DeCS ontology to create an automatic semantic annotation on text and to store on semantic repository. The purpose of the semantic repository is not only exact terms retrieval contained in the queries, but also retrieval related entities, as synonyms and related terms stored hierarchically on medical ontology. Using structural document similarities, we identified named entities, associate these entities with concepts, and define the semantic annotation. These annotations are stored on semantic repository for further future research.

V. RESULTS

In order to validate a knowledge base we needed a people who have a high knowledge degree in a specific area and ability to transfer this knowledge. These people are called domain specialist. The specialist help to structure the knowledge and allows to minimize the indexing errors of computer systems.

In this work we use an specialist in medical domain in order to validate the creation and the annotation of the knowledge base. This validation enable to the user to represent and communicate the knowledge in future search.

In order to validate our database, the specialist have select randomly 172 reports from computer tomography. Figure 3 shows the result of evaluating from the medical especialist in CTs findings. The specialist found 142 reports categorized as affirmative; 19 reports categorized as negative; four as ambiguous reports and seven reports are not found. In this case, we can see that only for these 172 reports, a traditional system would index those 19 reports (11%) as true and the traditional search engines would be unable to define if a report should be part of the response or not.

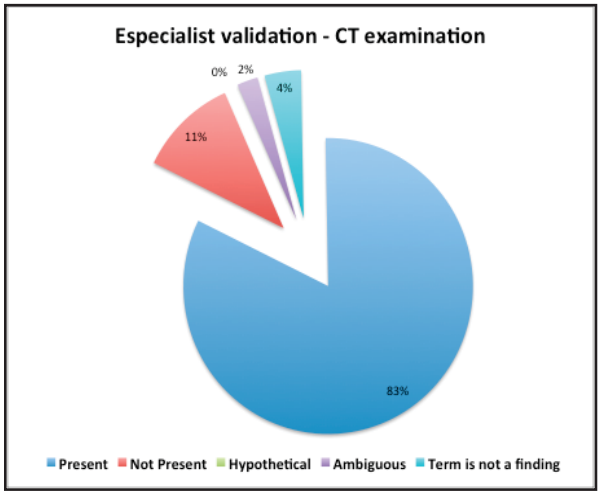

Figure 3. Validation reports for CT examination by medical specialist.

Once developed the prototype, several experiments were conducted to verify the conduct of the search system in real situations and in this case we verify the compliance with the model described here. The work tests were developed to validate the recovery process and communication of knowledge in health domain.

In this scenario, the user has done a search for reports that contain terms used in the ontology. We also investigated reports that contain negative expressions and reports that contain expressions, which are not known by the ontology. The aim of this study is show to the user the queries that he has required and similar terms. If the system does not find a result, the word or expression will be recorded in our daily database and indexed in the next interaction. This information is extremely valid, because the system can "learn" new terms, according users will use the system. And for users, they can learn more about the terms used by other professionals.

To illustrate the operation of our system, we developed a study case that considered four sentence searches:

Q1: "Presence of thyroid nodules"

Q2: "Absence of Lithiasis"

Q3: "popcorn calcification in the brain"

Q4: "Right MCA Aneurysm"

The query Q1 was done with terms that are present in domain ontology. In this case, the documents that are expected to answer to Q1 are all documents that contain *"thyroid nodules presence"* + *"Presence Thyroid Gland Nodule"* + *"presence Thyroid Neoplasms"* + *"presence Thyroid Disease"* + *Gland Thyroid presence"* (result of the research expansion). As the term "thyroid nodules" is known in ontology, the system returned all the documents that had some relation with the set of term listed in the expanded query. Still, the results may not contain negative expressions, because the user did not select the specific field to search for phrases with a negative sense. The queries results are described in Table 1.

TABLE I. CONSULTATION USING THE DEVELOPED METHODOLOGY

Query	Results	Time in ms	P@10
Q1 "Presence of thyroid nodules"	221	557	0,7*
Q2: "Absence of Lithiasis"	432	612	1,0
Q3: "popcorn calcification in the brain"	109	736	0,9*
Q4: "Right MCA Aneurysm"	79	589	1,0
* In this query we found hypothetical terms that can not be considered valid			

In order to validate this case study and define the system's accuracy, we used the metric of P@10. For each query defined in the beginning of this section, the result is shown in Table 1. For a better search, the queries was conduct after the validation by the specialist and the connection of the daily use terms with the ontology terms. The average precision of all queries was 0.9000.

The proposed methodology evaluated the accuracy of the first ten results (P@10) for the two research models: the traditional method (described here as IR) and the new model (IR+QE+Neg). We can notice that in all the submitted queries, the new research model had much better results than the traditional method. For the user to get a satisfactory result in the traditional method, we needed to perform various different queries, already in IR+QE+Neg method was carried out only one query for retrieve the results. Figure 4 show only the best results with the traditional IR compared with IR+QE+Neg model.

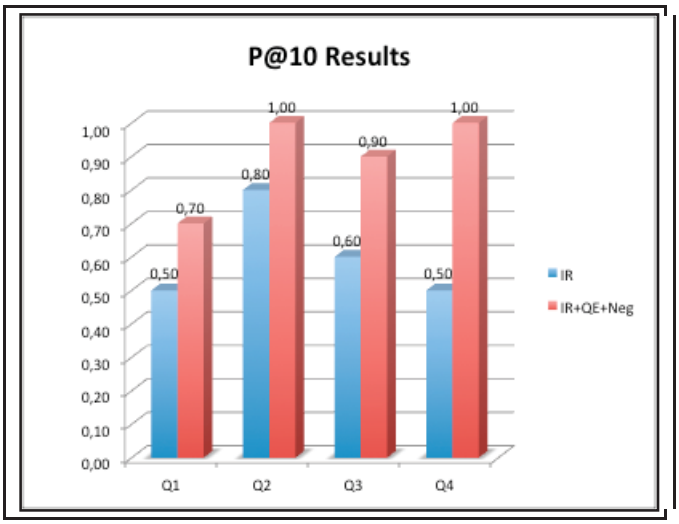

Figure 4. Comparison of traditional method with the proposed model.

With the exception of Q1, all other queries obtained accuracy equal to or above 90%. The accuracy rate is a little lower in Q1 due to the fact that the responses contain many hypothetical expressions. In this way, we cannot confirm the accuracy of the reports. But even so, the accuracy in Q1 was still much higher than the traditional IR method (50%).

As the average precision of the two models can be computed, we can also compare our model with the most important articles showed in section II. Figure 5 shows a comparison between our proposed systems with four others IR models. However, the average precision can only be considered in the expansion methods and in our method. Likewise, the overall precision was only available in works of detecting negative expressions. Because this work involves the use of two different models, it was difficult to define an efficient compared against the models available in literature. Still, the proposed model showed accuracy well above what is available in the literature.

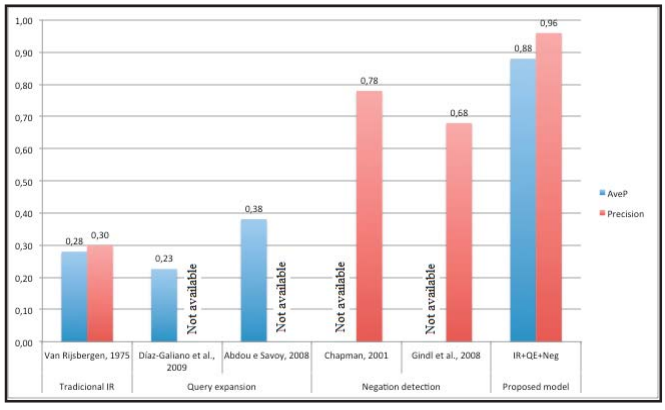

Figure 5. Results of average precision and overal precision compared with others important works.

The model presented by Díaz-Galiano *et al*. [1], uses the database of the Cross Language Evaluation Forum (CLEF) in 2005 and 2006. The base has 50,000 annotated images, which are available for testing accuracy. The other works have used a proper database for measuring the performance of its experiments. The traditional method was used to compute the 352 sentences accuracy rating, which reached 0.30. Dias-Galiano *et al.* [1] using 50,000 reports came annotated media accuracy of 0.23. Abdou and Savoy [11] were able to reach 0.38 of precision in their responses using a set of 1,000 reports. Chapman [16] and Gindl *et al.* [6] show only the total precision in their experiments. Chapman used a database of 1058 reports and came to a precision of 0.78. Gindl *et al.* [6] developed their research in a base of 558 awards and reached the total of 0.68 accuracy. Since our model, which uses three RI presented techniques, came to an accuracy rating of 0.88 and overall accuracy 0.96.

VI. CONCLUSIONS

In this paper we described a method that enables semantic search on medical text reports using ontologies in specific domains. We implemented a parser that extracts information from a database, normalize and store into an index database. In some searches conducted, it is possible to measure the functionality and applicability of the proposed architecture. Also we had used DeCS ontology for clinical toxicology area in order to classify the available information and establish well-defined relations between this information. The use of this ontology will optimize the process of care, increasing reliability and efficiency of medical professional.

In our approach the queries will be generated from keywords by a natural language query, or by form-based interface where the user can explicitly select ontological items. When a user performs a search, the queries are executed against the semantic repository, which returns a list containing instances that satisfy the search. If the required information is not indexed on semantic repository, the engine performs the search again directly to the medical database. The result is an index that is stored on semantic repository and is available for further queries. Before sending an answer to the user, the system retrieves the information, ranking and creates the top-k result list.

We also discussed three general data integrations approaches that use the DeCS ontology to provide access to medical database. According to an evaluation on the use of these three techniques, we believe that the use of this semantic information retrieval could assist the user to improve the results in your research, by expanding the query and enrich the values from precision and recall.

In future we aim to develop a semantic index that interprets the information received from a medical database. We will develop basic NLP techniques, in order to construct the semantic queries. An ontological process will be provided to map the word on the text with the ontology DeCS concepts.

For the handle of negative statements, we will develop a text-mining algorithm to extract medical terms from our medical diagnosis database. Then we need to classify the text, e.g., “the patient does not have hypertension”, “the patient has hypertension”, or “the patient has high blood pressure”. Furthermore, we need to make a relation between the terms on medical ontologies, with the terms founded in the medial report (e.g., symptoms and human body parts). The goal in the future is to define high weights for negative expressions, generate a dictionary that will be use for faster search and improve more precision and recall to the user queries.

***Abstract*—Approaches for measuring semantic similarity between words have been widely employed in various areas such as Artificial Intelligence, Linguistics, Cognitive Science and Knowledge Engineering. A new semantic similarity measure is proposed in this paper, which exploits the knowledge retrieved from a semantic network (i.e., WordNet) and the Internet. In particular, the structure information from WordNet and the statistic information obtained from the Internet are combined to quantify the semantic similarity between words. The new similarity measure is evaluated by comparing the rating results with two sets of human benchmark data. Experimental results indicate that, the proposed similarity measure outperforms previous WordNet-based semantic similarity measures.**

Keywords-semantic similarity; WordNet; Normalised Google Distance

I. INTRODUCTION

Measuring semantic similarity between words has been playing an important role in many research areas such as Artificial Intelligence, Linguistics, Cognitive Science and Knowledge Engineering [25]. The semantic similarity between words can be utilised to disambiguate word senses [15], detect malapropism [12] and improve the accuracy of ontology mapping [8]. Accurate estimation of semantic similarity can benefit all these applications in the aforementioned research areas and enhance their performances.

Measuring the semantic similarity or distance between words is a process of quantifying the relatedness between the words utilising the knowledge obtained from certain information sources. These information sources can be: (i) lexical recourses such as dictionaries, thesauri and semantic networks [16]; (ii) collections of documents such as corpus [25], and (iii) the Internet [3,5].

Semantic networks are considered as better choices for estimating semantic similarity than other lexical resources [2]. WordNet [4] is one of the most popularly used semantic networks for estimating semantic similarities [1,2,6,7,10,12,16, 19,20,24,26].

Based on the way of utilising WordNet, the WordNet-based semantic similarity measures can be classified into three categories: (i) *node-based methods*, which estimate the semantic similarity by computing the amount of information contained by related words in WordNet (e.g., [19]). (ii) *edge-based methods*, which assess the semantic similarity by calculating the length of edges on the shortest path between the words in WordNet (e.g., [26]). (iii) *hybrid methods*, which combine the information content theory and the structure information from WordNet to estimate the semantic similarity between words (e.g., [7]).

This paper proposes a hybrid method utilising the Internet as a corpus to overcome shortcomings of previous hybrid methods. In particular, our method utilises Normalised Google Distances (NGD) [3] to derive the semantic similarity between words combining with the structure information from WordNet. According to our experimental results, introducing the Internet knowledge to WordNet-based semantic similarity measures can increase the accuracy of estimating semantic relatedness between words.

The remainder of this paper is organised as follows. Section II provides a brief introduction on WordNet and reviews previous WordNet-based semantic similarity measures. Section III introduces our new WordNet-based semantic similarity measure, and the motivations of using the Internet as a corpus and NGD as a tool for estimating semantic relatedness between concepts. Section IV presents evaluation experiments and their results. Section V concludes the paper.

II. WORDNET AND WORDNET-BASED SEMANTIC SIMILARITY MEASURES

WordNet is a semantic network, which is organised in such a way that synsets and wordsenses are the nodes of the network, and relations among the synsets and wordsenses are the edges of the network. In WordNet, each meaning of a word is represented by a unique *wordsense* of the word, and a *synset* (stands for "synonym set") is consisting of a group of wordsenses sharing the same meaning. More than two thirds of the nodes in WordNet are synsets. *hyponymOf* is the key relationship for noun synsets in WordNet, which has been widely used to estimate the semantic relatedness among nouns.

WordNet has been commonly used to measure semantic similarity among words since it has the inherent advantages of being structured in the way of simulating human recognition behaviours [4]. The reminder of this section will give a brief review on previous WordNet-based semantic similarity measures organised in the aforementioned three categories.

A. Node-based methods

Node-based methods use the amount of information contained by related nodes (i.e., related concepts) in WordNet to estimate semantic similarity between the concepts of interest, i.e., c_1 and c_2. Thus, this kind of methods is also called as information-based methods.

Most of node-based methods employ the information content to quantify the amount of information that a concept contained. According the definition in the information theory [23], the *Information Content (IC)* of a concept c can be quantified by $IC(c) = -\log(P(c))$, where $P(c)$ is the probability of c appearing in a corpus.

Resnik [19] believed that the similarity of c_1 and c_2 is determined by the closest common superordinate concepts (i.e., hypernyms) of c_1 and c_2 in WordNet. Thus, Resnik proposed to use the IC of the lowest hypernyms of c_1 and c_2 to calculate the semantic relatedness between c_1 and c_2.

Richardson and Smeaton [20] amended Resnik's method [19] by using a different equation to calculate the IC of the lowest hypernyms of c_1 and c_2.

Banerjee and Pedersen [1] developed a score schema to estimate the relatedness through cross comparing the words being used in the definition of c_1 and c_2 and their hypernyms.

The drawbacks of node-based methods include: (i) it is a time-consuming work to analysis the corpora for estimating the IC values; (ii) unbalanced contents of the employed corpora may significantly decrease the accuracy of the IC values.

B. Edge-based methods

Edge-based methods utilise the shortest path between concepts (i.e., c_1 and c_2) in WordNet to estimate the semantic relatedness between c_1 and c_2. Lengths of all edges on the shortest path are accumulated to quantify the semantic similarity. It is the way of calculating the length of edges that differentiates methods in this category.

Sussna [24] proposed to use the depths of the taxonomy tree of WordNet that c_1 and c_2 are in, and the type-specific fanout factors to compute the semantic relatedness between c_1 and c_2. The *type-specific fanout factor* is defined by the type of the edges connecting c_1 and c_2, and the numbers of edges setting off from c_1 and c_2, respectively.

Leacock and Chodorow [10] suggested that the semantic relatedness between c_1 and c_2 can be estimated using the edge number of the shortest path between c_1 and c_2, and the depth of the involved taxonomy tree in WordNet.

Yang and Powers [26] proposed to utilise the properties of edges and the edge number of the shortest path to calculate the semantic similarity between c_1 and c_2. The properties of edges considered are: (i) the relation type of the edge, and (ii) the depth of the edge.

Hirst and St-Onge [6] utilised edge directions to estimate edge lengths of the shortest path. An edge direction is determined by the relation type of the edge. The directions of edges in a path between concepts are used to determine if the path is allowable, and to define the strength of turns in the allowable path. Hirst and St-Onge used the length of the shortest allowable path between c_1 and c_2, and the number of the direction turns in the path to estimate the semantic relatedness between c_1 and c_2.

The accuracy of the edge-based methods is significantly affected by the lack of considering the varieties of semantic distances between adjacent words, which is caused by the uneven word densities in WordNet. For instance, Sussna [24], and Leacock and Chodorow [10] did not consider the variety of all edge lengths; Hirst and St-Onge [6], and Yang and Powers [26] ignored the diversity of semantic distance among edges that are in a same type.

C. Hybrid methods

Hybird methods combine the information from different resources to estimate the semantic similarity between concepts, e.g., combining the IC of concepts with the structure information retrieved from WordNet to conduct the estimation.

Jiang and Conrath [7] accumulated the scaled length of all the edges in the shortest path between concepts to estimate the semantic similarity of the concepts. The edge length between concept c (a node in the shortest path) and concept p (the parent node of c in the shortest path) is calculated by $length(c, p) = \log(P(p)) - \log(P(c))$. Structure information from WordNet such as (i) local density of the nodes in the shortest path, (ii) depth of the nodes, and (iii) the relation type of edges are utilised to scale the edge length.

According to previous research [2,16], hybrid methods outperform the other two kinds of methods. However, hybrid methods share a common weakness with all node-based methods: the data sparseness of the employed corpus. This weakness can be caused by two reasons: (i) the size of the corpus is relatively undersized, and (ii) the coverage of the corpus is not well balanced. One possible way to complement the deficiency is to use a better corpus.

III. THE PROPOSED SEMANTIC SIMILARITY MEASURE

Our semantic similarity measure is a hybrid method combining the knowledge acquired from the Internet and the structure information from WordNet to quantify the semantic relatedness between concepts. In our method, the Internet is used as a corpus for estimating the semantic distance between adjacent concepts along the shortest path between the concepts of interest, i.e., c_1 and c_2, in WordNet.

A. The Internet as a corpus

We believe that the Internet is an ideal corpus for calculating IC of concepts. The reasons include: (i) the Internet is the current largest electronic text source; (ii) the Internet is a relatively balanced knowledge source; (iii) the knowledge in the Internet can be updated regularly and up-to-date.

Well-performed Internet search engines such as Google enable us to use the Internet as a huge corpus. With help from these search engines, the frequency of a word appearing in the

Internet can be easily estimated using the number of web pages that contain the word.

We use hypernyms as context words to tag word senses. A corpus with tagged word senses is one of the key requirements for semantic similarity measures to give accurate estimations on the similarities between concepts when corpora are involved. In word sense disambiguation area, context words are believed to share linguistic information with the word of interest and can be used as a word senses indicator [15]. Experimental results of *Clever Search* developed by Kruse et al. [9] show that hypernyms are effective to be used as context words to indicate word senses for querying the Internet.

B. Normalised Google Distance

We use Normalised Google Distance (NGD) [3] between the end nodes of each edge to estimate the edge lengths of the shortest path. The *NGD* utilises the numbers of Google search results to approximate the Kolmogorov Complexity [11] of words for calculating the semantic relatedness between the words. Given two words x and y, the NGD between x and y can be calculated by the following equation:

$$NGD(x, y) = \frac{\max\{\log f(x), \log f(y)\} - \log f(x, y)}{\log N - \min\{\log f(x), \log f(y)\}}$$

where $f(x)$, $f(y)$, and $f(x, y)$ are the numbers of web pages found by Google that contain x, y, and both x and y, respectively. N is a normalising factor, whose value is a reasonable large value that is larger than both $f(x)$ and $f(y)$.

C. Calculation of Semantic similarity

We employ the following structure information from WordNet to scale the edge lengths of the shortest path: (i) the relation type of the edges; (ii) the number of adjacent words that the end nodes have; (iii) the depth of the end nodes in their own taxonomy tree, and (iv) the maximum depth of the involved hierarchy structures.

Since Jiang and Conrath's method [7] outperforms other existed semantic similarity measures [2,16], we proposed an equation based on their equation to calculate the edge lengths of the shortest path:

$$wt(c, p) = \left(\beta + (1-\beta)\frac{\overline{E}}{E(p)}\right)\left(\frac{D}{d(p)}\right)^{\alpha} NGD(c, p)\ T(c, p)$$

where c is a node on the shortest path; p is the parent node of c; $\overline{E}$ is the average local density of all nodes; $E(p)$ is the local density of p (i.e., the number of its children nodes); D is the maximum depth of the hierarchy structure that c and p are in; $d(p)$ is the depth of p; α, β and $T(c, p)$ are the depth factor, density factor, and edge type factor, respectively; $NGD(c, p)$ is the Normalised Google Distance between c and p.

The semantic relatedness between c_1 and c_2 can then be calculated by the following equation:

$$rel(c_1, c_2) = \sum_{n \in \{S(c_1, c_2) - Sol(c_1, c_2)\}} wt(n, parentOf(n))$$

where $S(c_1, c_2)$ is the set of nodes in the shortest path between c_1 and c_2 ; $Sol(c_1, c_2)$ is the set of nodes in the shortest path which have no parent nodes in the path; n is a node included by $S(c_1, c_2)$ but excluded by $Sol(c_1, c_2)$.

IV. Evaluation

This section introduces the evaluation of the proposed semantic similarity measure. Similarity ratings computed by our method are compared with human judgement data in this evaluation. Two sets of prevalent human benchmark data are employed: (i) Rubenstein and Goodenough data set (RG-Set) [22] and (ii) Miller and Charles data set (MC-Set) [13]. The Pearson Product-moment Correlation Coefficient [21] is employed to calculate the consistency between similarity ratings.

Our method is compared with Jiang and Conrath's method [7] as well. Jiang and Conrath's method has been considered as one of the best semantic similarity measures [2,16]. In other words, we can believe our method is better than other methods if our method can outperform Jiang and Conrath's method.

Table I reports the similarity ratings on MC-Set computed by Jiang and Conrath's method and our method, respectively.

TABLE I. Human and computed rating on MC-Set

MC-Set	Human Ratings	Jiang and Conrath's Method	Our Method
car - automobile	3.92	3.409	3.473
gem - jewel	3.84	3.403	3.496
journey - voyage	3.84	3.062	3.303
boy - lad	3.76	2.899	3.256
coast - shore	3.7	3.402	3.172
asylum - madhouse	3.61	3.234	3.18
magician - wizard	3.5	3.433	3.445
midday - noon	3.42	3.402	3.472
furnace - stove	3.11	2.055	1.337
food - fruit	3.08	2.851	1.542
bird - cock	3.05	3.365	3.187
bird - crane	2.97	3.365	3.028
tool - implement	2.95	3.153	3.05
brother - monk	2.82	0.943	2.17
crane - implement	1.68	2.921	2.643
lad - brother	1.66	1.409	1.927
journey - car	1.16	0	0
monk - oracle	1.1	0.207	1.459
food - rooster	0.89	0.185	0.6
coast - hill	0.87	2.937	2.686
forest - graveyard	0.84	0.195	0.197
monk - slave	0.55	0.968	2.089
coast - forest	0.42	2.311	1.166
lad - wizard	0.42	1.363	1.466
chord - smile	0.13	2.193	1.117
glass - magician	0.11	0.032	1.019
noon - string	0.08	0	0
rooster - voyage	0.08	0	0
cemetery - woodland	0.95	0.178	0.185
shore - woodland	0.63	2.262	1.472

Table II shows that when MC-Set is used, the correlation coefficients between human rating and the ratings computed by Jiang and Conrath's method and our method, respectively. The correlation of human judgement replication listed in the table was reported by Miller and Charles [13].

TABLE II. THE CORRELATION COEFFICIENTS ON MC-SET

Methods	Correlation
Jiang and Conrath's and human rating	0.7509
Our method and human rating	0.8087
Human judgement (replication) [13]	0.8848

Because of the limitation of space, we will not report our similarity ratings on RG-Set in this paper. Table III reports when RG-Set is used, the correlation coefficients between the human ratings and the ratings computed by each of Jiang and Conrath's method and our method.

TABLE III. THE CORRELATION COEFFICIENTS ON RG-SET

Methods	Correlation
Jiang and Conrath's and human rating	0.7129
Our method and human rating	0.7634

The above experimental results indicate that our method outperforms Jiang and Conrath's method. Since Jiang and Conrath's method is one of the best existed semantic similarity measures [2,16], we believe that our method can provide better estimations on semantic similarities than previous methods.

V. CONCLUSIONS

In this paper, we proposed a new hybrid method for semantic similarity measure by combining the structure information from WordNet and the statistic information obtained from the Internet.

In our method, the length of the shortest path between two concepts in WordNet is used to measure the semantic similarity of the two concepts. The Internet is used as a corpus for estimating the length of each edge on the shortest path. Previous methods usually employ stand alone corpora to estimate the edge lengths, and their performances are limited by the data sparseness or unbalanced knowledge of the employed corpus. Our experimental results show that the Internet can overcome the drawbacks that stand alone corpora brought to semantic similarity measures. We use context words to tag word senses and Normalised Google Distance (NGD) to calculate the length of edges on the shortest path.

The proposed semantic similarity measure has been evaluated by comparing the rating results with human benchmark data. We also compare our results with the results returned by Jiang and Conrath's method, which, according to [2,16], provides one of the best results on measuring semantic relatedness. The experimental results indicate that employing the Internet as a corpus and using NGD to compute the edge lengths enable our method to outperform previous semantic similarity measures.

Abstract

Wireless Sensor Network (WSN) systems have become more and more popular in our modern life. They have been widely used in many areas, such as smart homes/buildings, context-aware devices, military applications, etc. Despite the increasing usage, there is a lack of formal description and automated verification for WSN system design. In this paper, we present an approach to support the rigorous verification of WSN modeling using the Semantic Web technology. We use Web Ontology Language (OWL) and Semantic Web Rule Language (SWRL) to define a meta-ontology for the modeling of WSN systems. Furthermore, we apply ontology reasoners to perform automated verification on customized WSN models and their instances. We demonstrate and evaluate our approach through a Light Control System (LCS) as the case study.

1. Introduction

Wireless Sensor Network (WSN) systems have become more and more popular in our daily life [6]. It can be found in many areas, such as industrial plants, residential buildings, smart portable devices, as well as military fields, etc. For example, in a chemical plant, sensors are used to monitor the leaking of toxic materials. In a smart building, sensors are used to detect the motions inside secured facilities. However, the cost of developing a WSN is relatively expensive. Once the sensors have been deployed, it is very hard to change and reconfigure them. Therefore, a good initial design prior to the implementation is essential, which can make the system more reliable and fault tolerant.

With regard to initial designs, there are many approaches that can be used to model WSN systems. For instance, the Unified Modeling Language (UML) was used to specify the WSN design [9]. Despite the semi-formality of UML, the weak ability in modeling WSN instances and the lack of support for automated verification hinder the approach. Recently, Dong et. al. [1] proposed a process algebra based notation, i.e., Active Sensor Process (ASP) for the modeling of WSN systems. However, there has been no automated verification support to facilitate the promised reasoning. On the other hand, there are mature formal techniques from the Semantic Web community that can be effectively applied to this domain. Recently, Web Ontology Language (OWL) has been used to model the knowledge base of WSN and semantic technologies has been widely accepted as important components of complex, cross-jurisdictional, heterogeneous, dynamic sensor network systems [3, 8, 4]. For example, OntoSensor [8] is one of such approaches, where a knowledge base for WSN was developed using OWL. As a forerunner, OntoSensor provides a comprehensive model for WSN system specifications. It covers most of the concepts and properties that can be used in a WSN design. However, one weakness of the approach lies in that it has not fully utilized the reasoning functionalities of the ontology models. Hence, OntoSensor lacks of the capability of analyzing and verifying the correctness of its WSN specifications. As a matter of fact, ontology reasoning could greatly assist the users in creating high quality WSN models as well as further exploring the hidden knowledge, checking the correctness and minimizing redundancies.

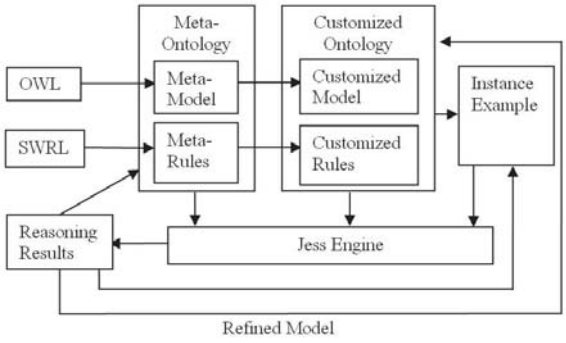

Figure 1. Overall approach to WSN design.

In this research, we aim at fully utilizing the reason-

ing functionalities of the ontology approach in verifying the correctness of WSN design and managing WSN models. We use rule-based notations, i.e., Semantic Web Rule Language (SWRL) [5] to capture complicated constraints among different concepts of a WSN system. Moreover, automated verification can be carried out to check whether these constraints are correctly enforced by the design, in terms of the WSN model and its specific configurations (instances). The users can apply generalized rules of WSN systems that are encoded in the meta-ontology, as well as they can define new rules for a customized WSN system by extending the meta-model. Figure 1 presents an overview of our ontology-based approach. Firstly, a WSN meta-model is defined using the OWL/SWRL languages. The meta-model is designed specially for the WSN context, which includes most of the conceptual terminologies that can be used in a WSN system design. In the meta-model, we also defined additional constraints among different concepts using SWRL rules, which capture complicated relationships among the entities. The meta-model plus the rules form the WSN meta-ontology that can be used to create customized WSN system specifications. When users declare their own customized WSN specifications by extending the meta-model, all the meta-level rules are automatically enforced upon the customized model. The customized WSN ontology also consists of model specific terminologies and the rules. For example, we can customize the meta-ontology into defining a specific light control sensor network system of a smart building. The terms used in the light control system extend the meta-ontology, e.g., specific motion sensors and light devices. The rules used in the customized model further constrain the requirements of the specific system, such as the conditions for a light to be turned on, the light illumination in a room in relation to the sunlight intensity readings of the out-door sensor and so on. After defining the customized WSN ontology, we can create instance configurations from the ontology, e.g., specific numbers of offices and lights in a light control system configuration. At this stage, we can perform reasoning tasks on the ontology and its instances to check the correctness of design. The Jess [2] is a rule engine that can be used for such a purpose.

The rest of the paper is organized as follows. Section 2 presents the modeling and reasoning of the WSN meta-ontology. Section 3 presents a Light Control System (LCS) as a case study to demonstrate the usage of the WSN meta-ontology and the reasoning on customized WSN designs. Section 4 concludes the paper and discusses the future work.

2. Ontological Meta-model for WSN Systems

A WSN structure can be divided into three levels, i.e., node level, group level and network level. Our model concentrates on the group level, which means the ontology is built based on how sensors are managed into different groups to provide specific functions and how they interact with each other. We can view a WSN system as a service orientated network, where each group provides services to other groups as well as works collaboratively together. A group consists of two different types of sensors, i.e., leader sensors and normal sensors. A leader sensor acts as the leader of the group that controls other sensors.

$$
\begin{array}{ll}
Group \sqsubseteq \top & Sensor \sqsubseteq \top \\
Service \sqsubseteq \top & \\
LeaderSensor \sqsubseteq Sensor & NormalSensor \sqsubseteq Sensor \\
Group \sqsubseteq \forall\, hasId.int & Group \sqsubseteq = 1\, hasId \\
Group \sqsubseteq \forall\, hasLeaderSensor.LeaderSensor & \\
Group \sqsubseteq \exists\, hasLeaderSensor.LeaderSensor & \\
Group \sqsubseteq \forall\, hasNormalSensor.NormalSensor & \\
Group \sqsubseteq \exists\, hasNormalSensor.NormalSensor & \\
Group \sqsubseteq \forall\, hasService.Service & \\
Group \sqsubseteq \exists\, hasService.Service &
\end{array}
$$

As defined above, a group has an *id* that is used to uniquely identify itself. Each group consists of `Leader Sensors`, `Normal Sensors` and `Services`. We do not restrict the number of services that a group can provide, as a group may provide more than one services to others. For example, a sensor can be used to detect both temperate and altitude at the same time, thus the group that the sensor belongs to can provide two kinds of services simultaneously. Note that the '$\forall$' and '$\exists$' combinations in the above definition represent closure axioms on the entities through their corresponding properties. They are useful in performing automatic classification on the ontology with the Open World Assumption (OWA) of DL. For example, the above states that a group must have a non-empty set of lead sensors through the `hasLeadSensor` property, and the only things that a group can related to through the `hasLeadSensor` property are lead sensors. Similar closure axioms can be defined on the normal sensor and service.

Sensors are used to receive and send data, which are formed in groups to accomplish specific tasks in a WSN system. Our WSN ontology model focuses on the group level of WSN design. For example, the distance of a signal can travel is directly proportional to the power consumption of a sensor node. Therefore, a signal that travels 10 meters in distance consumes more energy than that of the same signal propagates through a neighboring sensor with two 5 meters distance. Thus the cooperation among the sensors in a group is a typical behavior in WSN systems. Sensor grouping can be divided into two main categories, i.e., location groups and logical groups. A location group simply indicates that all the sensors in the group are organized by their physical positions, which can be further divided it into three different types, i.e., a planar mesh group, a geographic group and a spanning tree group. We use the planar mesh groups as examples to demonstrate the modeling. The geo-

graphic and spanning tree groups can be modeled in a similar way.

The planar mesh group is a commonly used structure in WSN systems, where there is no centralized communication and the sensors in the group only sends signals to its nearest neighboring sensors. The structure forms a planar mesh network. This is known as an ad-hoc network where each sensor is willing to propagate the information. One advantage of such a network is its fault tolerance, where broken nodes should not effect the functionalities of the system as a whole, since the data information can always find an alternative path to eventually reach its destination. A planar mesh network is typically deployed into harsh environments. For example, a planar mesh WSN group can be applied in a forest surrounding to collect the soil and weather information. As the sensors need to withstand all sorts of weather conditions, such as rain, wind, frost, snow, etc., fault tolerance is essential. The planar mesh location group can be defined in OWL as follows.

$$
\begin{aligned}
&\mathit{PlanarMeshGroup} \sqsubseteq \mathit{LocationGroup}\\
&\mathit{PlanarMeshGroup} = 1\,\mathit{hasStartingSensor}\\
&\mathit{PlanarMeshGroup} \sqsubseteq \forall\,\mathit{hasStartingSensor}.\\
&\qquad\qquad \mathit{PlanarMeshLeaderSensor}\\
&\mathit{PlanarMeshLeaderSensor} \sqsubseteq \mathit{LeadSensor}\\
&\mathit{PlanarMeshLeaderSensor} \sqsubseteq \forall\,\mathit{hasNeighbour}.\\
&\qquad\qquad \mathit{PlanarMeshNormalSensor}\\
&\mathit{PlanarMeshLeaderSensor} \sqsubseteq \exists\,\mathit{hasNeighbour}.\\
&\qquad\qquad \mathit{PlanarMeshNormalSensor}\\
&\mathit{PlanarMeshLeaderSensor} \sqsubseteq \geq 1\,\mathit{hasNeighbour}.\\
&\qquad\qquad \mathit{PlanarMeshNormalSensor}\\
&\mathit{PlanarMeshNormalSensor} \sqsubseteq \mathit{NormalSensor}
\end{aligned}
$$

The leader sensor still acts as the coordinator of the group. It has at least one normal sensor as its neighbor and manages other normal sensors in the group. A normal sensor in a planar mesh group can have more than one neighboring sensors (leader or normal). The size of the network can be quite large depending on the number of sensors in the group. The group only needs to know the location of the leader sensor, as all other sensors belongs to the group can eventually be reached from it.

A logical group represents a group of sensors that are organized by certain business logic, e.g., temperature, pressure, humidity, altitude, etc. Therefore, strictly speaking, a location group can be considered as one type of logical group, where the physical position is its logic. Logical groups can be defined similarly as the location group. In addition, a logical group can be used in conjunction with other logical groups or location groups. For example, a group can extend both a geographic group and a humidity group in its hierarchy, which means that the group is used for humidity measuring purpose and its sensors are managed through the geographic structure. For interested readers, the complete WSN meta-ontology definition can be found online at: `http://www.cs.auckland.ac.nz/~jingsun/WSN/SensorNetwork_3_4.owl`

One of the distinguishing features of logic based ontology languages is that it has good reasoning support to perform desired verification. Designed as a web ontology language, the full-automatic, high efficiency and large scalability are the most important requirements for OWL and SWRL reasoning services. Ontology reasoning can be used to verify the WSN design at both the conceptual level and the instance level. It can assist users to reduce the amount of work needed in building a good WSN specification. For example, we can define a WSN model partially and use ontology reasoners to infer the rest of the knowledge about the model. Moreover, ontology reasoning can be used to check constraints (relationships) among different instances. Such additional constraints can be captured by the SWRL rules in the ontology and enforced upon the instances by reasoning. In general, the use of OWL reasoners for WSN systems includes but is not limited to the following.

Composition – is a fundamental advantage of using ontology reasoners. OWL provides the ability to specify sets of *sufficient and necessary* conditions to recognize members of a class and infer that one class must be a subclass of another. Classes for which there is at least one set of sufficient conditions are known as "defined" classes. (The symbol $\equiv$ is used in the DL syntax to denote defined classes.) By using the necessary and sufficient conditions defined in OWL, new concepts can be defined systematically from existing concepts. This can result in a dramatic reduction in the number of facts that have to be maintained explicitly. In OWL, complex expressions can be built up using restrictions and logical operators without having to name each intermediate concept before use. This embedding of 'anonymous concepts' allows more expressive representations to be built easily and naturally. For example, we might define *SensoriaPressureGeographicGroup* as pressure sensor groups which are organized geographically and led by a sensor produced by *Sensoria*.

$$
\begin{aligned}
&\mathit{SensoriaPressureGeographicGroup} \equiv\\
&\quad \mathit{PressureGroup} \sqcap \mathit{GeographicGroup} \sqcap\\
&\qquad \forall\,\mathit{hasCenterSensor}.(\mathit{Sensor} \sqcap\\
&\qquad\quad \exists\,\mathit{hasManufacturer}.\mathit{Sensoria})
\end{aligned}
$$

Poly-hierarchy – represents the structure of a knowledge base. As we mentioned before, a sensor or sensor group can be organized into different classes based on its properties and usages. Managing and maintaining such complex poly-hierarchy of concepts is hard. Changes often need to be made in several different places, and keeping everything in step is error prone and laborious. For example, the property values of a sensor in WSN might change over time and its network system has to be reconfigured dynamically. Using a classifier, we can develop normalized knowledge models. In a normalized ontology, even the most complex poly-hierarchies are built out of simple non-overlapping trees. The OWL class definitions are used to define concepts bringing the trees. The reasoners can maintain the relationships amongst defined concepts auto-

matically. Changes are always made in exactly one place. The new poly-hierarchy relationship can be computed on the fly. For example, if we set up a new type of pressure geographical sensor group using *WINSNG*2, which is one kind of sensor produced by *Sensoria*. This can be modeled as the following.

$$WINSNG2 \sqcap Sensor \sqcap \exists\, hasManufacturer.Sensoria$$
$$TestSensorGroup \equiv PressureGroup \sqcap GeographicGroup \sqcap \forall\, hasCenterSensor.WINSNG2$$

Note that there is no need to assert *TestSensorGroup* is a subclass of *SensoriaPressureGeographicGroup*. OWL reasoners will automatically infer this relationship, as the sufficient and necessary condition of *SensoriaPressureGeographicGroup* has been satisfied. If later we update the leading sensors of *TestSensorGroup* to *MPS-D3*, which is a product of *SEBA*, we only need to modify the class *TestSensorGroup*. The reasoners will update the class hierarchy automatically, i.e., removing the subclass relationship between *TestSensorGroup* and *SensoriaPressureGeographicGroup*.

Instantiation – is the process of matching instances against classes. By using instantiation, we can define a general individual, and the reasoning can classify which specific concept it belongs to. The following example illustrates how it works. For example, if we would like to further restrain that a lead sensor can only control normal sensors, not other lead sensors. We specify the following SWRL rule.

$$Sensor(?y) \wedge controlSensor(?x, ?y) \wedge LeaderSensor(?x) \rightarrow NormalSensor(?y)$$

`Sensor(?y)` and `LeaderSensor(?x)` define the types of individuals `x` and `y`. Note that we define `y` as a generalized sensor instead of a specific type of sensor. The `controlSensor(?x, ?y)` indicates the relationship between `x` and `y`. `NormalSensor(?y)` is the result of this rule. The whole rule can be understood as '*if y is a sensor and it is controlled by a leader sensor x, then y must be a normal sensor*'.

Property inference – is used to derive the existence of a certain property in the ontology. With inference, we can build a partial WSN model, and use reasoning to derive the rest of the knowledge. For example, the following SWRL rule captures that '*if a group x has a leader sensor y, y controls z, then z must belongs to group x*'.

$$Group(?x) \wedge LeaderSensor(?y) \wedge NormalSensor(?z) \wedge hasLeaderSensor(?x, ?y) \wedge controlSensor(?y, ?z) \rightarrow hasNormalSensor(?x, ?z)$$

From the above, we specified three entities, i.e., a `Group x`, a `LeaderSensor y` and a `NormalSensor z`. If there is a relationship `hasleaderSensor` between `x` and `y` and another relationship `controlSensor` between `y` and `z`, we can infer that there must be a relationship `hasNormalSensor` exists between `x` and `z`. Similarly, instances can be checked in Protégé through the Jess engine. The above rule illustrates the inference property of ontology reasoning. The user only needs to define the relationships from a group to a leader sensor and from a leader sensor to a normal sensor. The rule can infer the relationship between the group and the normal sensor automatically.

Consistency Checking – is the process of detecting violation of constraints (inconsistency) in a model. After we define the WSN ontology, we can create specific WSN instances (configurations) and use reasoning to check whether the instances are consistent with respect to the model. For example, the following rule captures that a normal sensor can only be controlled by at most one lead sensor.

$$LeaderSensor(?x) \wedge NormalSensor(?y) \wedge controlSensor(?x, ?y) \rightarrow controlledBySensor(?y, ?x)$$

The rule states if a `LeaderSensor x` control a `NormalSensor y`, then `y` must be only controlled by `x`, not any other lead sensors. If we have an instance that states `y` also controlled by another leader sensor z, then there is an inconsistency (conflict) in the model. Similarly, this can be checked in Protégé through Jess.

The above examples illustrate different types of reasoning that can be performed by the WSN meta-ontology model. The most important strength and purpose of logic-based ontology approach is that they allow classes to be defined by complex class expressions built recursively from previously defined classes and properties using constructors provided by the ontology language. In the next section, we demonstrate the modeling and verification of a customized WSN that extends the meta-ontology.

3. Case Study - A Light Control System (LCS)

In this section, we extend the above defined WSN meta-ontology to design a Light Control System (LCS) [7] as a case study of WSN modeling and apply reasoning to enhance the design. LCS is a context-aware system that uses sensors to detect the motions of people and decide whether it should turn on/off the lights inside the facilities. It also has a set of outdoor sensors to detect the intensity of the day light in order to automatically adjust the illuminations of the lights inside the facilities. Detailed LCS requirements can be found in [7]. Due to the space limit, we can not list all of them, as our goal is to use it as an examples to demonstrate the verification.

In the LCS, room, hallway and wall can be defined as subclasses of the Geographic Group, where the diameters of those groups represent the physical space. Our design is based on a building structure of a university facility, where the types of rooms included are computer labs, hardware labs, meeting rooms, offices and peripheral rooms. For each

group, we defined a controller that acts as the leader sensor. There are three types of controllers specified, i.e., room controller, hallway controller and wall controller. Let's consider the room controller as an example.

$$RoomController \sqsubseteq LeaderSensor$$
$$RoomController \sqsubseteq \forall controlElectricalDeviceGroup.LightGroup$$
$$RoomController \sqsubseteq \geq 1\ controlElectricalDeviceGroup$$
$$RoomController \sqsubseteq \forall controlSensor.MotionSensor$$
$$RoomController \sqsubseteq \geq 1\ controlSensor$$
$$LightSensor \sqsubseteq NormalSensor$$
$$LightSensor \sqsubseteq \forall hasMeasurand.LightDetector$$
$$LightSensor \sqsubseteq = 1\ hasMeasurand$$

The above syntax states that a room controller is one type of leader sensor that can control at least one light group and at least one motion detector. After we created the controllers, we need to deploy some sensors into the system. In the LCS, we mainly have two types of sensors, i.e., motion sensor and light sensor. The motion sensor is used to detect if there is any movement in a certain area. The light sensor is installed on the facility wall to detect the intensity of the outdoor day light. Light sensor and motion sensor both extend from a normal sensor. For example, the eighth line constrains that a light sensor can only be used for detecting light intensity; while the ninth line constrains that light sensor can only have one measurand. Other entities of the LCS, such as offices, meeting rooms, hallways, etc., can be defined in a similar way. For interested readers, the complete LCS model can be found online at: `http://www.cs.auckland.ac.nz/~jingsun/WSN/LightSystem_3_4.owl`

In this section, we used SWRL rules to specify some of the LCS functional requirements that were listed in [7] and demonstrate how the ontology reasoning can help us to build a high quality specification. Note that because the LCS model extends the WSN meta-ontology defined in Section 3, the meta-level reasoning we demonstrated in Section 3.3 can be automatically applied on the LCS model. However, here we would like to focus more on examples of the LCS specific reasoning as follows.

"*The illumination value of the lights in a room plus the day light intensity detected by the light sensors outside the room should be equal to a certain value, for instance 100.*"

$$Office(?x) \wedge Wall(?y) \wedge besideWall(?x, ?y) \wedge RoomController(?w) \wedge WallController(?z) \wedge hasLeaderSensor(?x, ?w) \wedge hasLeaderSensor(?y, ?z) \wedge LightGroup(?c) \wedge LightSensor(?a) \wedge Light(?d) \wedge controlElectricalDeviceGroup(?w, ?c) \wedge controlSensor(?z, ?a) \wedge LightDetector(?b) \wedge hasMeasurand(?a, ?b) \wedge detectLightIntensity(?b, ?e) \wedge deviceGroupHasSomeDevice(?c, ?d) \wedge swrlb : subtract(?f, 100, ?e) \rightarrow lightHasIntensity(?d, ?f)$$

In the above, we demonstrate a SWRL representation of the illumination requirement in LCS. It simply specifies that if an outdoor sensor detects the daylight intensity value, say 20, then the lights in the office should have an illumination value of 100-20 = 80 (if we assume that the safe illumination value is 100). Note that the `swrlb:subtract(?f, 100, ?e)` is a built-in mathematic rule in SWRL that expresses 'f = 100 - e' [5]. With this constraint enforced, it can provide two kinds of reasoning, i.e., inferring new knowledge and checking inconsistency. Firstly, if we knew the outdoor daylight intensity reading, we can automatically derive the light illumination value in the room. Secondly, if a user wrongly specified a value of the light illumination inside a room with respect to its outdoor daylight intensity reading, the reasoning can easily detect such inconsistent instances.

"*When a room/hallway is occupied by a person, the lights inside the facility must be kept on.*"

$$MotionDetector(?x) \wedge MotionSensor(?y) \wedge hasMeasurand(?y, ?x) \wedge controlSensor(?z, ?y) \wedge controlElectricalDeviceGroup(?z, ?u) \wedge deviceGroupHasSomeDevice(?u, ?v) \wedge detectMotion(?x, true) \rightarrow isDeviceTurnedOn(?v, true)$$

The above rule states that a room controller `z` controls both the motion sensor `y` and light group `u`. If the motion sensor detects some movement from the motion detector `x`, then the lights `v` that belong to the light group `u` should be turned on. Again, this rule enforces the availability of lights according to the motion detectors in the facility and also checks (maintains) the correct status of the lights in the system. Other LCS requirements in [7], e.g., '*if a room/hallway is unoccupied for a certain time the lights in the facility need be switched off automatically*', etc., can be modeled and verified using the Jess rule engine in a similar manner. In the following section, we demonstrate another type of reasoning that can be used to monitor the behavior patterns of a WSN system.

Besides the reasoning examples demonstrated above, SWRL rules can also be used to determine dynamic actions in a WSN system. For example, we define the following two SWRL rules in the LCS.

Rule-1 :
$$MotionDetector(?x) \wedge MotionSensor(?y) \wedge hasMeasurand(?y, ?x) \wedge controlSensor(?z, ?y) \wedge controlElectricalDeviceGroup(?z, ?u) \wedge deviceGroupHasSomeDevice(?u, ?v) \wedge detectMotion(?x, true) \rightarrow isDeviceTurnedOn(?v, true)$$

Rule-2 :
$$MotionDetector(?x) \wedge MotionSensor(?y) \wedge hasMeasurand(?y, ?x) \wedge controlSensor(?z, ?y) \wedge$$

$controlElectricalDeviceGroup(?z, ?u) \wedge$
$deviceGroupHasSomeDevice(?u, ?v) \wedge$
$detectMotion(?x, false) \wedge detectNothing(?x, 10)$
$\rightarrow isDeviceTurnedOn(?v, false)$

Rule-1 states if a room or hallway is occupied by someone, the lights in that room or hallway should be turned on. And rule-2 is the reverse case of rule-1, which states if a hallway/room is not occupied for more than 10 seconds, the lights belong to that hallway/room should be turned off. Now, if we have two hallways connecting to each other, namely hallway a and b, as show in Figure 2.

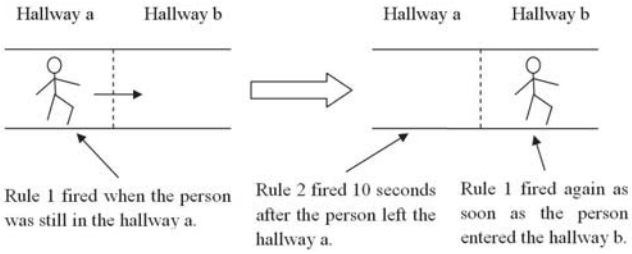

Figure 2. Movement from hallways a into b.

If a person goes into hallway a, it will trigger Rule-1 to be fired. We can record as ⟨Rule-1, a⟩. Suppose this person moves from hallway a into hallway b, the sensor installed in hallway b detect this person and Rule-1 is fired again. We record as ⟨Rule-1, b⟩. If there is no one else in hallway a at that moment, after 10 seconds, Rule-2 will be fired. We can record ⟨Rule-2, a⟩. Finally, we can write the rule invocation sequence for this person (instance) as: ⟨Rule-1, a⟩ → ⟨Rule-1, b⟩ → ⟨Rule-2, a⟩. Now, suppose if this sequence has occurred for the same instance and no other direct connected sections are involved during the same period, we can conclude that there must have been a person moved from hallway a to hallway b in that duration period. Hence, we can define a set of control sequences in the WSN system (in the forms of rule actions), where each sequence represents a behavior pattern that could be engaged by the individuals (instances) in the system. By monitoring these sequences (patterns) occurred in the system, we can come to aware of the basic activities happened during a certain period of time. Moreover, these behavior pattern recognition results can be used to make further context-aware decisions in the WSN system, e.g., for security or patient monitoring purposes.

4. Conclusion

In this paper, we proposed a formal ontological approach for WSN modeling and verification. We defined an WSN meta-ontology in the OWL/SWRL language, which specifies the basic terminologies and relationships that captures the fundamental requirements of a WSN design. These rules can provide subsumption, inference and consistency reasoning on the WSN instances. When users design a WSN model using our approach, they can create customized WSN specifications by extending the top level meta-ontology. In addition, they could initialize parts of the specification and use the ontology reasoner to automatically infer the rest of the knowledge in the design. Furthermore, the rules and their invocation sequences in our approach can be effectively used as action patterns in monitoring the dynamic behaviors of a WSN system implementation. Finally, we demonstrated the design and verification of the Light Control System (LCS) as a case study.

In the future, we plan to develop a Graphical User Interface (GUI) that aims at assisting a user-friendly creation and verification of WSN designs. The purpose of the GUI is to allow the designers to build their WSN models in transparent of the underlying OWL/SWRL syntaxes.

***Abstract* — Requirements change for a variety of reasons and at different stages of the project development. Changes to items in a requirements document must be propagated to other items that depend on the changed items in order to maintain their consistency. This paper explores the use of semantic annotations in requirements document templates to support requirements evolution.**

Keywords – Requirements evolution; requirements documentation; semantic documentation.

I. INTRODUCTION

The Requirements Engineering (RE) process plays a key role to ensure that software products will fully support and evolve with the business processes. It is the process by which requirements are gathered, analyzed, documented, and managed throughout the software lifecycle [1]. During the RE process, elicited requirements need to be precisely specified and documented. Moreover, requirements change for a variety of reasons. Such changes may be required at various stages of the software lifecycle, and must be propagated through other items that depend on the changed items. In order to maintain their mutual consistency, we need to manage traceability links among items and to propagate changes along such links [2].

Requirements are usually recorded in one or more documents, which are used to communicate requirements to different stakeholders. There are many different ways to structure requirements documents, depending on, among others, the type of the system being developed, the target audience, the level of detail to be considered, and organizational practices. To ensure that the essential information is included in each document, organizations should define their own standards for requirements documents. If an organization works with different types of requirements documents, it should define an appropriate template for each requirements document type [3, 4].

Despite its shortcomings, structured natural languages, augmented with graphical models, remains the most practical way for most software organizations to document their requirements [4]. Moreover, despite the current advances in electronic documentation along with the boom of collaborative text edition tools (such as wiki engines), desktop text editors are still the most frequently solution used by software organizations when it comes to electronic documentation [5,6]. Whether on the use of wiki engines or the use of desktop text editors, documents produced by these tools are still the main vehicle for knowledge dissemination [5,7,8]. This is the case of software engineering in general, and RE in particular.

Requirements documents hold a considerable amount of information that are to be mainly interpreted by human readers, such as requirements statements, use case descriptions, and so on. Managing requirements evolution requires reading different versions of different documents, in a task that is often dull and error prone. In addition, gathering relevant information contained in different documents spread through the organization's repositories demands a considerable effort and, because of that, this activity is often skipped [5].

Requirements traceability can be more easily achieved if the semantic content of the requirements documents could be exposed in order to allow visibility of the data and the relationships embedded in the document, and if the semantic content of each document version is extracted and registered into a version control system. In order to make these scenarios possible, it is essential to allow semantic metadata annotation into documents, turning requirements documents into semantic requirements documents.

For dealing with theses problems, Arantes and Falbo [9] developed an Infrastructure for Semantic Document Management (ISDM) [9] that presents the following features: semantic annotation of document templates; traceability support; searching based on extracted semantic content; and change notification subscription.

This paper discusses how this infrastructure is used to support requirements evolution, and is organized as follows: Section II talks briefly about requirements evolution, and semantic documentation; Section III shortly presents the ISDM and its main components; Section IV addresses the use of ISDM in the requirements management context, and presents some preliminary results from using ISDM in practical situations. Section V compares our work with some related ones. Finally, Section VI presents our conclusions.

II. REQUIREMENTS EVOLUTION AND SEMANTIC DOCUMENTATION

Two important activities of the RE process are requirements documentation and evolution. The results of requirements development should be documented for latter

agreement between customers and developers about the software to be built, and to serve as basis for further development and evolution.

As said before, requirements can be recorded in one or more documents, each one devoted to different classes of stakeholders. Pfleeger and Atlee [10], for instance, suggest the use of two different types of documents: the requirements definition, which is written in terms of the customer's vocabulary, and the requirements specification, which is written in terms of the system's interface.

There are many different ways to structure these documents. Ideally software development organizations should define templates for different types of requirements documents, imposing a standard structure on them [2,4].

With regard to the requirements definition document, it should specify the agreed requirements statements in a language that supports communication with stakeholders. The most obvious option is to document these statements using free prose in natural language. However, this approach is prone to several defect types, such as ambiguity. To overcome these problems, we may adopt a disciplined approach for documentation, using structured natural language. In such approach, stylistic rules on how statements should be written, and predefined statement templates, among others, are used to discipline writing the statements [2].

The agreed statements posed in a requirements definition document are subject to change. In order to maintain consistency, these changes must be propagated through other items that depend on the changed item. Since evolution is inevitable, we must prepare for change, and traceability is one of the most important ingredients for this. Consistency maintenance requires managing traceability links among items. However, traceability management is not an easy task. To take full advantage of its benefits, we need to reduce the complexity and cost of establishing and maintaining the traceability graphs [2].

A way of addressing this issue is applying a semantic documentation approach to requirements documentation. Allowing users to add metadata annotations to documents can improve the understanding and accessibility of the data contained on it. Features such as document annotation, data extraction from metadata, and data indexing and searching, are somehow the basis for semantic documentation [7,8,9].

III. An Infrastructure for Semantic Document Management

In essence, the Infrastructure for Semantic Document Management (ISDM) provides: (i) a way to semantically annotate document templates; (ii) a mechanism for controlling versions of the semantic content extracted from semantic document versions, and therefore providing a way for tracking the evolution of the data embedded inside a semantic document; and (iii) data visibility to end-users, allowing searches and data-change notification subscription, to aid developers to get an up-to-date information about something he/she is interested in [9].

As shown in Figure 1, the ISDM architecture is composed by two main elements [9]: the Semantic Document Repository (SDR), which is responsible for storing semantic documents; and the Main Module, which is composed by three sub-modules: (i) the Semantic Annotation Module is responsible for allowing users to semantically enrich a document template; (ii) the Data Extraction and Versioning Module is responsible for extracting the semantic content from an annotated document whenever a new version of that document is checked into the SDR. After extraction, the semantic content of the version is stored in another repository, called Data Repository, that is also part of this module; (iii) the Search and Traceability Interface Module is responsible for providing an API (Application Programming Interface) that allows users and other systems to perform ontology-based searches and data traceability towards the Data Repository.

In a nutshell, document engineers annotate document templates using the Semantic Annotation Module. Later on, developers and analysts may instantiate that template, generating semantic documents. These semantic documents are checked into the SDR. When a new version of a semantic document is available at the SDR, the Data Extraction and Versioning Module unwraps the semantic content of that version and stores it into the Data Repository, making the information of that version available. At this point, it is possible to further enhance the integration of information scattered throughout various semantic documents contained in the SDR. This is done by merging the graphs corresponding to the last versions of the documents contained in the repository. Finally, users and other systems may interact with the Search and Traceability Interface Module in order to perform queries about the evolution of a particular semantic content stored in the Data Repository.

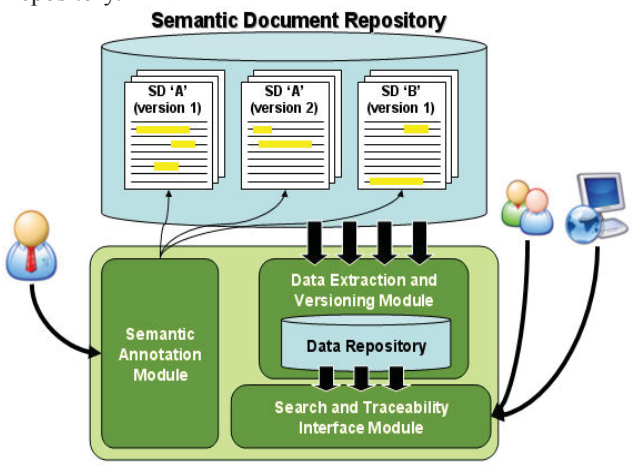

Figure 1. ISDM Architecture.

For annotating document templates, domain ontology-based annotations are used. ISDM works with templates and

documents written in Open Document Format (ODF) [11], and Open Office [12] was chosen as the document editor for composing annotations in document templates. In order to allow template annotation, specialized instructions for annotating text fragments and tables were developed. These kinds of annotations encapsulate annotations directed for document instances, allowing document engineers to add a set of instructions directly in these document elements (tables and text fragments). These instructions are processed when a document instance is analyzed by the Data Extraction and Versioning Module that will ultimately generate instances and relations accordingly. For more details, see [9].

IV. SUPPORTING REQUIREMENT EVOLUTION WITH SEMANTIC ANNOTATIONS

During the software life cycle, changes in requirements are quite common. New requirement dependencies are discovered, requirements statements are rewritten and priorities change. If a change is propose in a requirement, we need to identify how this change affects others requirements. In this scenario, the traceability matrix is an important artifact that is used to analyze the impact of changing requirements. Defining a network of requirement dependencies is the starting point for creating the requirements traceability matrix. Moreover, the use of a requirements management tool can support developing traceability matrices.

To deal with this, we are currently using the ISDM for supporting some tasks of the RE process at NEMO (Ontology & Conceptual Modeling Research Group). In NEMO, we use two types of documents for documenting requirements: a Requirements Document (RD) and a Requirements Specification (RS). The first is directed to clients and users, and captures user requirements. It is written in natural language, following rules defined for writing requirements statements. The second details the user requirements into systems requirements, and serves as basis for further development. It is mainly composed by models (use case diagrams, class diagrams, state diagrams, among others), although there are also some textual parts, especially the ones related to use case descriptions. Due to space limitations, in this paper we only discuss how we are using semantic annotations in RDs.

A. Annotating the Requirements Document Template

The NEMO's RDs are composed by some preliminaries, and four sections. For elaborating a RD, developers should follow the RD template shown in Figure 2.

First of all, there are two important information placed in text fragments: the name of the project, and the names of the responsible for the document. For capturing them, the ISDM provides annotations for annotating text fragments. Following we present the text fragment annotations added to the RD template. These annotations are done based on the requirements ontology proposed in [13].

Requirements Document

Project : <<project name>>
Responsible: <<names of the responsible analysts, separated by commas>>

1. Introduction

This document presents the user requirements of the <<system name>>. It is organized as follows: Section 2 describes the system purpose; Section 3 presents a description of the problem domain; Section 4 presents the user requirements elicited from clients and users.

2. System Purpose

<<one paragraph describing the system purpose>>.

3. Domain Description

<<a free text briefly giving an overview of the domain, describing the problem to be solved and business processes to be supported>>

4. User Requirements

Functional Requirements

Id	Statement	Priority	Depends on
FRXX	<<sentence following defined pattern>>	<<possible values: High, Medium, Low>>	<<ids of the requirements on which the requirement depends>>

Business Rules

Id	Statement	Priority	Depends on
BRXX	<<idem FR>>	<<idem FR>>	<<idem FR>>

Non Functional Requirements

Id	Statement	Priority	Category	Depends on
NFRXX	<<idem FR>>	<<idem FR>>	<<type of the NFR>>	<<idem FR>>

Figure 2. Requirements Document Template

[[completeText]];instance({content},http://localhost/ontologies/SE/onto.owl# Project,$project);

[[break with ',']];
instance({slice},http://localhost/ontologies/SE/onto.owl#Person, $person);

property($person,http://localhost/ontologies/SE/onto.owl#involvedIn,$project);

The first annotation is added in the place marked with the <<project name>> tag; the second is added in the place marked with the <<names of the responsible analysts, separated by commas>> tag. The third annotation is done based on the requirements ontology, and says that the people informed as responsible analysts are involved in the project. Other tags shown in text fragments, such as the one related to the system purpose, are annotated in a similar way.

ISDM also provides annotations for annotating tables, which were used in the RD template for annotating the Domain Description table, the Functional Requirements (FR) table, the Business Rules (BR) table and the Non Functional Requirements (NFR) table. In the case of FR table, as shown in Figure 2, the first column refers to the FR id; the second to the FR statement, the third to its priority, and the last one to a list of the ids of the requirements (FRs, BRs and NFRs) on which it depends, separated by comma. Annotations in tables allow that each column has a different set of instructions.

The following annotations were added to the FR table in the semantic template:

[[ignorerow0]];

[[at0]];instance({content},http://localhost/ontologies/SE/onto.owl#FunctionalRequirement,#req);
property(#req,http://localhost/ontologies/SE/onto.owl#artifactProducedIn,#project);

[[at1]];property(#req,http://localhost/ontologies/SE/onto.owl#description,{content});

[[at2]];property(#req,http://localhost/ontologies/SE/onto.owl#priority,{content});

[[at 3 break with ','];instance({slice},http://localhost/onto.owl#Requirement,#reqline);
property(#req,http://localhost/ontologies/SE/onto.owl#relatedWith,#reqline);

The first annotation only says to ignore the first row in the table, since it does not contain data (it is a header). The annotations that begin with *[[at]]* are used for annotating the content from a column. The second annotation indicates that the content of the first column is a FR and that this FR is produced in the project informed before. The third annotation points out that the content of the second column is the statement of the FR captured in the first column. Finally, the last annotation says that the current FR depends on the requirements informed in the fourth column.

The other tables and their annotations are quite similar to the FR table. Thus, making use of the semantically anotated template, it is possible to the Data Extraction and Versioning Module to extract the semantic content present in the requirements document, as explained next..

B. Extracting and Visualizing Information from the RDs

Once the RD template is instantiated and a new version of the RD is produced, it should be committed in the corresponding Semantic Document Repository (SDR) (see Figure 1), in order to the Data Extraction and Versioning Module (DEVM) process the semantic document. DEVM generates instances and relations accordingly to the contents of the document in the Data Repository, in an OWL format.

Whenever a new version of a semantic document is commited in the repository, a new version of the document content is generated in the Data Repository, and it is possible to use the services from the platform.

Figure 3 presents part of the tables concerning functional requirements and business rules, produced in the context of the Cargo Delivery Control Project. The versions of the RDs of this project are stored in the the repository /home/nemo/reposg7. Taking the third verson of this RD into account, it is possible to generate the traceability matrix shown in Figure 4. The full matrix is not presented in this paper due to space limitation. It is worthwhile to point out that as the data is stored in OWL format, we can make some inferences using the JENA engine.

Functional Requirements

Id	Statement	Priority	Depends on
FR01	The system shall control types of cargos.	High	
FR02	The system shall control transportation rates.	High	FR01, FR12, BR03, BR05
FR03	The system shall allow the customer to make a request to transport a cargo from a quotation previously made.	High	FR02, BR02, NFR02, NFR06
…	…	…	…

Business Rules

Id	Statement	Priority	Depends on
BR01	Clients who have hired a service can not be excluded.	High	
BR02	The system must generate a unique identifier for each quotation.	High	
BR03	Each cargo type has a procedure to be followed to be transported.	High	

Figure 3. Part of a Requirements Document.

As the dependency relationship (the last column of the requirements tables) is transitive, we can infer, for instance, that if FR03 depends on FR02 and FR02 depends on FR01, then FR03 depends on FR01. Direct dependencies are shown in the figure with the flag "D"; inferred dependencies, on the other hand, are marked in the table with the letter "I". Such information is very important, since it is useful for analyzing the impact of a change. Inferring requirements dependencies in large projects can be difficult, laborious and error prone to perform manually.

Req	FR01	FR02	FR03	...	BR01	BR02	BR03
FR01				...			
FR02	D			...			D
FR03	I	D		...		D	I
…				...			

Figure 4. Part of the Traceability Matrix.

Another service provided by ISDM is to trace the differences between versions of a document. Using this service, a developer may look for the changes made in a specific document. Figure 5 shows the results from a query for providing the differences between versions 2 and 3 of the RD partially presented in Figure 3. This document was modified, for instance, by changing the statement of FR03 and the requirements on which it depends. Such changes are preceded by "(CHANGED)" in the figure. Moreover, there were three FRs added and one removed, which are represented in the figure by lines beginning with the words "(ADDED)" and "(REMOVED)", respectively. Using this service, we can follow up requirements evolution, as they are listed when they are added, removed or modified in a new version of the RD.

On the other hand, during the execution of the project, a developer may want to know the history of a specific requirement. To this end, the developer can use the service for visualizing the evolution of a requirement, illustrated in Figure 6. As we can see in this figure, *FR04* was added in the Revision 1. The requirements on which it depends were changed in the Revision 2, when two related requirements

were added (*BR03* and *NFR01*). Finally, in revision 3, *FR04* was removed from the RD. With this service, a developer can trace the evolution of a specific requirement, detailing how it was related to other requirements and the values of its properties along the project.

C. *A Preliminary Evaluation*

ISDM has been used to trace the requirements of projects performed at NEMO. Up to now, 7 projects used it. In 4 of these projects, the RDs evolved in two versions. In the other 3 projects, there were three versions. The various versions of these documents were added to the Semantic Document Repository (SDR), and each project had its own version control repository. The three tables shown in Figure 7 present data regarding the evolution of the RDs of these projects, including how many requirements were added, changed or removed in each version of each project.

Revision 1

Project	Added	Changed	Removed	Sum
Project 1	29	-	-	29
Project 2	10	-	-	10
Project 3	25	-	-	25
Project 4	29	-	-	29
Project 5	13	-	-	13
Project 6	10	-	-	10
Project 7	24	-	-	24

Revision 2

Project	Added	Changed	Removed	Sum
Project 1	11	16	12	24
Project 2	16	10	-	26
Project 3	3	22	3	25
Project 4	2	27	1	30
Project 5	11	12	-	24
Project 6	14	10	-	24
Project 7	9	17	5	28

Revision 3

Project	Added	Changed	Removed	Sum
Project 4	9	9	4	35
Project 6	13	15	2	35
Project 7	2	11	10	20

Figure 7. Changes of requirements in numbers.

The numbers shown in Figure 7 give an idea of how the use of ISDM for managing requirements has proved to be useful in NEMO. Since many requirements are added, removed and changed, especially at the beginning of the projects, controlling their changes and impacts in other artifacts are essential. The use of ISDM has speeded the impact analysis and, as a consequence, the time spent in performing changes. Before the use of ISDM at NEMO, those analyses were done by humans, using only the functionalities provided by OpenOffice for comparing documents. By showing the changes done and generating traceability matrices, ISDM provided a very useful basis for impact analysis.

V. RELATED WORK

Since evolution is inevitable, there are several works that aim at minimizing evolution efforts. Special attention has being devoted to requirements traceability management.

Rochimah et al. [14] evaluated seven traceability approaches focusing on their contributions to simplify software evolution tasks. Three of them generate traceability

links in an automated way, while other three are semi-automated, in the sense that they combine a manual and automated way in obtaining the traceability links. Regarding the degree of automation, our approach can be classified as semi-automated, since templates are annotated manually and the links between requirements are informed by the analysts when the templates are filled in. On the other hand, the traceability matrices are automatically generated, and the changes done can be queried. Concerning the degree of formality, Rochimah et al. consider that the seven evaluated approaches are semi-formal. This is also the case of our approach, which uses an ontology as basis for the template annotations. Finally, regarding the change type, as the other approaches, ours allows to identify additions, deletions, and modifications. A distinguishing feature of our approach is that analysts work in the same way they have always done, i.e. filling templates in a text editor, and committing them in the project's repository. In this way, our approach is in line with the "support in-place traceability" best practice, defined by Huang et al. [15] as traceability being provided to the artifacts residing within their native environments.

There are several requirements engineering tools, such as TRACE [16], that provide various forms of traceability and support to change. However, at the best of our knowledge, none of them uses a semantic documentation approach, and thus users have to interact with the tool, instead of writing requirements documents in a text editor. In our work, the idea is just to allow the analysts to continue using a desktop text editor and, by means of semantic annotations made in templates, extract and track requirements in a transparent way to the user.

VI. CONCLUSIONS

In this paper we discussed the use of ontology-based annotations in semantic Requirements Document (RD) templates for supporting requirements managing and evolution. Our strategy was to instantiate and to extend the Infrastructure for Semantic Document Management (ISDM) [9], developing functionalities that address important issues for requirements management, such as automatic generation of traceability matrices. The annotations are done in RD templates, and they are based on the conceptualization defined in the Software Requirements Ontology proposed in [13]. It is important to highlight that, since we annotate templates, the effort spent with annotations is very small compared with the benefits obtained.

The resulting tool was used to support requirements management in 7 projects. From this preliminary use, we have already glimpsed some improvements to be done. First, we need to develop a more user-friendly interface for performing searches and for displaying traceability matrices. Second, ISDM provides other features that can be explored in the context of Requirements Management. This is the case of the change notification subscription functionality. This feature allows notifying users when a given individual in a document changes. This could be useful to notify stakeholders when a requirement that they are interested in changes. Third, although our approach has shown to be useful for organizations that use a desktop text editor for documenting requirements, we know that, ideally, software organizations should use requirements management tools for that. Thus, we are working on integrating ISDM with the requirements management tool of ODE (Ontology-based Development Environment) [17], a Software Engineering Environment developed at NEMO.

Abstract

Software architecture plays an essential role in the high level description of a system design, where the structure and communication are emphasized. Despite its importance in the software engineering process, the lack of formal description and automated verification hinders the development of good software architecture models. In this paper, we present an approach to support the rigorous design and verification of software architecture models using the semantic web technology. We view software architecture models as ontology representations, where their structures and communication constraints are captured by the Web Ontology Language (OWL) and the Semantic Web Rule Language (SWRL). Specific configurations on the design are represented as concrete instances of the ontology, to which their structures and dynamic behaviors must conform. Furthermore, ontology reasoning tools can be applied to perform various automated verification on the design to ensure correctness, such as consistency checking, style recognition, and behavioral inference.

1. Introduction

Software architecture plays an essential role in the high level design of a software system. Analogy to civil engineering, it represents the fundamental structural and behavioral descriptions of the system under design. Despite its importance in the software engineering process, the lack of formal description and automated verification hinders the development of good architecture models. Traditionally, software architectures are specified using diagrammatic and textual notations [8, 9]. However, architecture models defined in this manner are likely to be inconsistent and error prone due to the informality of the description and the lack of means of rigorous verification to ensure the correctness. As a result, formal modeling techniques have been applied to software architecture descriptions [1, 4], which is aimed at achieving precise specification and rigorous verification of the intended structures and behaviors in the design. The main advantage of such verifications is the ability to determine whether a modeled structure can correctly satisfy a set of given properties in the requirements of a system in order to assure quality of design. However, one drawback of many existing approaches in the automated verification of software architecture models is their limited scalability, as large architecture models are computationally expensive to process. For example, a recent work by Kim and Garlan [7] proposed the modeling and verification of architecture styles using the Alloy language and its analyzer. In their approach, a few architecture styles based on ACME descriptions were translated and verified using the Alloy analyzer. Although it offers a useful insight to the ability of applying formal modeling in automating the verification of architecture descriptions, the performance issue is a practical limitation of the research. The problem arose from that large-sized architecture models dramatically expand the search spaces of the verification in the Alloy SAT solver. To overcome this problem, Wong et al. [11] recently proposed a model splitting approach for the parallel verification of Alloy based architecture models using their underlying styles. The approach improved the performance of the verification. However, the overheads of the model decomposition as well as the dependency issues among the sub-models during the parallel verification phase still remain as challenges.

On the other hand, there are mature large-scale reasoning means from the Semantic Web [2] technology that can be adopted to provide more promising solutions towards the problem, both in terms of knowledge representation and automated verification. The semantic web vision recommended by the World Wide Web Consortium (W3C) has emerged as the next generation of the web from the late

nineties. It extends the current web by assigning web content with a well-defined meaning, aimed at enabling intelligent machine processing of web resources. Description Logic (DL) based ontology languages, such as the Web Ontology Language (OWL) [6] and Semantic Web Rule Language (SWRL) [5], have been proposed to meet the needs of representing the complicated relationships among different entities. One of the advantages of the ontology languages, such as OWL and SWRL, is that DL reasoning engines, such as Pellet [10] and Jess [3], can be effectively used to perform large-scale automated reasoning on ontologies and their instances, e.g., subsumption reasoning, consistency checking, classification and knowledge inference. The scale of such verifications is usually in terms of thousands of ontological individuals (instances). To a certain extent, the semantic web approach is essentially an application of formal methods into the web community, where web resources are formally specified using description logic notations and rigorously verified using ontological reasoning engines.

In this paper, we explore the synergy between software architecture modeling and the semantic web ontological reasoning. We view software architecture models as ontology representations, where their structures and communications must hold. The overall approach of our ontological based software architecture modeling and verification is presented in Figure 1. As shown from the diagram, we

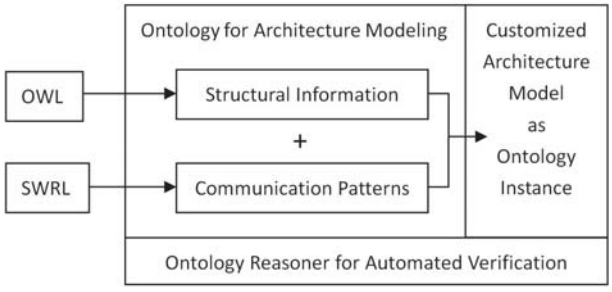

Figure 1. Overall Approach of Ontology-based Architecture Modeling and Verification.

first define ontology models that are specific to software architecture design using the OWL/SWRL languages based on different architecture styles. OWL is used to specify the structure and relationship constraints among the architecture terminologies, e.g., the participating components, connectors and their connections. SWRL is used to capture the dynamic interactions within the architecture models as additional constraints, e.g., the requester and provider communication protocol of a Client and Server style. The OWL ontology plus the SWRL rules form the meta-ontology that can be used to create customized architecture specifications. When users define their own customized architecture models by extending the meta-ontology (styles), all the meta-level rules are automatically enforced upon the customized models, i.e., the particular structures and communications are carried over onto the new design. A customized ontology can also consist of system specific terminologies and rules. For example, we can customize the meta-ontology into defining the architecture model of a specific internet application that extends the Client and Server style and yet has its own additional communication behaviors. After creating the customized ontology, architecture configurations can be defined as instances of the underlying ontology design, e.g., specific numbers of web servers and named clients involved in the system layout, etc.

Furthermore, there are two levels of verification that can be performed in our approach to ensure the correctness of an architectural design, namely, the ontology and the instance levels. The former ensures the correctness of the architecture model itself, e.g., no conflicting connection and communication constraints among the components. The latter ensures the conformance of a particular configuration with respect to its design, e.g., a certain configuration should always have its pre-defined structures and perform its own communication protocols. Moreover, ontology reasoners can be used to fully automate the verification process. For example, the Pellet reasoner can be used to check the consistencies of the ontology and instance models, and the Jess rule engine can be used to automatically derive the communication sequences on configurations, etc. In addition, ontology classifiers can be used to automatically recognize the style patterns that are used in a design at the ontology level.

The remainder of the paper is organized as follows. Section 2 presents ontology definitions for software architecture modeling which includes commonly used architecture styles. Section 3 illustrates the use of the architecture ontology in modeling and verifying a customized Three-Tier network architecture as a case study. Finally, section 4 concludes the paper and discusses the future work.

2. Ontology for Software Architecture Design

Software architecture modeling focuses on the high level description of a system in term of the elements in the system and the interactions among the elements. Components and connectors are two fundamental units in an architecture description [1]. Components describe the identifiable computation entities of a system, where connectors specify the patterns of communication among these entities. Each component consists of a set of ports as its external visible interfaces. A connector consists of a set of roles that are used to describe the patterns of a particular kind of communication. In order to establish a connection between different components of the system, the roles of a connector must be attached to the ports of the participating components.

The use of connectors separates the concern of computation from communication in a system description.It further promotes encapsulation and reusability in architecture modeling. In OWL, we define the following classes and properties to represent the different entities and their relationships in an architectural design.

$$\begin{array}{ll} \mathit{Component} \sqsubseteq \top & \mathit{Connector} \sqsubseteq \top \\ \mathit{Port} \sqsubseteq \top & \mathit{Role} \sqsubseteq \top \\ \mathit{Process} \sqsubseteq \top & \mathit{Id} \sqsubseteq \top \end{array}$$
$$\mathit{Component} \sqcap \mathit{Connector} \sqcap \mathit{Port} \sqcap \mathit{Role} \sqcap \mathit{Process} \sqcap \mathit{Id} = \bot$$

The above defines `Component`, `Connector`, `Port`, `Role` and `Process` as mutually disjoint classes. They are top level entities in the architecture description, where the `Process` represents an atomic behavior that a port or a role can perform. The `Id` defines the message identification number that is shared by different processes involved in a communication. For example, the processes in a client and server communication, e.g., sending a request, invoking the server, server returning the result, receiving the result back by the client, may share the same message id for referring to the same client request interacting through the client and the server.

$$\begin{array}{ll} \geq 1\, \mathit{hasPort} \sqsubseteq \mathit{Component} & \top \sqsubseteq \forall\, \mathit{hasPort}.\mathit{Port} \\ \geq 1\, \mathit{hasRole} \sqsubseteq \mathit{Connector} & \top \sqsubseteq \forall\, \mathit{hasRole}.\mathit{Role} \\ \geq 1\, \mathit{hasAttachment} \sqsubseteq \mathit{Role} & \\ \top \sqsubseteq \forall\, \mathit{hasAttachment}.\mathit{Port} & \top \sqsubseteq \leq 1\, \mathit{hasAttachment} \end{array}$$
$$\mathit{isAttachedTo} = (^{-}\mathit{hasAttachment})$$
$$\geq 1\, \mathit{hasAction} \sqsubseteq (\mathit{Port} \cup \mathit{Role})$$
$$\top \sqsubseteq \forall\, \mathit{hasAction}.\mathit{Process}$$
$$\geq 1\, \mathit{hasCommunication} \sqsubseteq \mathit{Process}$$
$$\top \sqsubseteq \forall\, \mathit{hasCommunication}.\mathit{Process}$$

After defining the basic entities, we use OWL property definitions to further capture the relationships among them. For example, the `hasPort` is a relation from a `Component` as its domain to a Port as its range, which simply denotes that a component has a set of ports as its interfaces. Similarly, the `hasRole` represents that a connector has a set of roles as its participating parties in the connection. The attachment of a role to a specific port is defined as the property `hasAttachment`. Note that `hasAttachment` is defined as a functional property from a role to a port, which means that a port can be attached to different roles, but not vise versa. The relation `isAttachedTo` is an inverse relation to the `hasAttachment` function, which maps a port back to its attached role. We also define two more relationships to capture the dynamic interactions within a component or a connector and their communications. The property `hasAction` describes the set of atomic processes that a port or a role is able to perform. The property `hasCommunication` captures the interaction sequences of a particular communication (protocol). In addition, the connectivity constraint need to be enforced upon the model, i.e., in order to establish a valid attachment between a role and a port, the port must be able to perform the behaviors (actions) that the role has. Otherwise, the port can not 'play' the role in the connection due to behavior mismatch. This can be easily specified using a SWRL rule as follows.

$$\mathit{hasAttachment}(?r, ?p) \wedge \mathit{hasAction}(?r, ?x) \rightarrow \mathit{hasAction}(?p, ?x)$$

The above states that if a role `?r` is attached with a port `?p` and the role has a process `?x` in its action, then the port must also have the same process `?x` in its action set. Note that a port may have more behaviors than that of its attached role, which is allowed during an attachment. This also gives the flexibility for a port to be able to participate in different roles of connections. The ontology reasoning engine asserts the above rule when checking the correctness of the attachments in the architecture design.

After defining an ontology for the component and connector model, we will further demonstrate the construction of commonly used software architecture styles by extending this base ontology. In the following subsection, we use the Client and Server style as an example to illustrate the modeling. Other styles can be defined in a similar manner.

2.1. Ontology for the Client and Server style

The Client and Server structure is one of the most widely adopted styles in software architecture description, especially in distributed and network based computer systems. It offers a loosely coupled multi-connection mechanism in a consumer and provider fashion. A server is a component that provides a set of services that are exposed to various clients for consumption. A client is a component that acts as a consumer to those services. We define the following OWL classes for the Client and Server style by extending the component and connector ontology.

$$\begin{array}{ll} \mathit{Client} \sqsubseteq \mathit{Component} & \mathit{Server} \sqsubseteq \mathit{Component} \\ \mathit{Request} \sqsubseteq \mathit{Port} & \mathit{Provide} \sqsubseteq \mathit{Port} \\ \mathit{CnS} \sqsubseteq \mathit{Connector} & \\ \mathit{Provider} \sqsubseteq \mathit{Role} & \mathit{Consumer} \sqsubseteq \mathit{Role} \\ \mathit{SendRequest} \sqsubseteq \mathit{Process} & \mathit{ReceiveResult} \sqsubseteq \mathit{Process} \\ \mathit{InvokeServer} \sqsubseteq \mathit{Process} & \mathit{ServerReturn} \sqsubseteq \mathit{Process} \end{array}$$

The above extends the component and connector model and defines the basic entities involved in a Client and Server structure, i.e., client, server, connector, ports, roles and participating processes. Note that the `Request` port belongs to the `Client` component and the `Provide` port belongs to the `Server` component. `CnS` is a connector that has a `Provider` role and a `Consumer` role. We refined the basic behaviors of the style into four communication processes, i.e., `SendRequest`, `ReceiveResult`, `InvokeServer` and `ServerReturn`, where the first two belongs to the consumer and the last two belongs to the provider. These relations are specified using OWL properties as follows.

$Client \sqsubseteq \exists hasPort.Request \quad Server \sqsubseteq \exists hasPort.Provide$
$CnS \sqsubseteq \exists hasRole.Provider \quad CnS \sqsubseteq \exists hasRole.Consumer$
$CnS \sqsubseteq \forall hasRole.(Provider \sqcup Consumer)$
$Request \sqsubseteq \exists isAttachedTo.Consumer$
$Request \sqsubseteq \forall isAttachedTo.Consumer$

In addition, we defined a necessary and sufficient condition for the `CnS` connector, where there is a closure axiom on the `hasRole` property. This enforces the classification on any connector that only has a provider and a consumer as its roles to be a connector of the Client and Server style. Note that the necessary and sufficient conditions contribute to the automatic recognition of architecture styles through ontology classification, which will be demonstrated later.

With the structure information of the Client and Server style defined, we then use SWRL rules to capture its dynamic communication behaviors (protocol) as follows. We divided the entire communication of the Client and Server style into two parts, i.e., the communication of the connector and the internal behaviors within the server. The former consists of two action sequences - (1) receive a request from the consumer role and invoke the server through the provider role, (2) receive a server return value from the provider role and send the result back through the consumer role. This is captured by the first SWRL rule below using the `hasCommunication` property. The latter represents the internal actions of a server that contributes to the overall communication of the service consumption, i.e., whenever there is an invocation of request on the server, there should always be a corresponding response returned from the server. This is captured using the second SWRL rule shown below.

$$CnS(?cn) \wedge Consumer(?cr) \wedge Provider(?pr) \wedge$$
$$p1 : Id(?id) \wedge SendRequest(?r) \wedge InvokeServer(?i) \wedge$$
$$ServerReturn(?ret) \wedge ReceiveResult(?res) \wedge$$
$$p1 : hasRole(?cn, ?cr) \wedge p1 : hasRole(?cn, ?pr) \wedge$$
$$p1 : hasAction(?cr, ?r) \wedge p1 : hasAction(?cr, ?res) \wedge$$
$$p1 : hasAction(?pr, ?i) \wedge p1 : hasAction(?pr, ?ret) \wedge$$
$$p1 : hasId(?r, ?id) \wedge p1 : hasId(?i, ?id) \wedge$$
$$p1 : hasId(?ret, ?id) \wedge p1 : hasId(?res, ?id)$$
$$\rightarrow p1 : hasCommunication(?r, ?i) \wedge$$
$$p1 : hasCommunication(?ret, ?res)$$

$$Server(?s) \wedge Provide(?p) \wedge InvokeServer(?i) \wedge$$
$$ServerReturn(?r) \wedge p1 : hasPort(?s, ?p) \wedge$$
$$p1 : hasAction(?p, ?i) \wedge p1 : hasAction(?p, ?r) \wedge$$
$$p1 : Id(?id) \wedge p1 : hasId(?i, ?id) \wedge p1 : hasId(?r, ?id)$$
$$\rightarrow p1 : hasCommunication(?i, ?r)$$

After completing the ontology definition for the Client and Server style, we can invoke the Pellet reasoner to check the consistency on the ontology. In addition, we can create particular configurations of the style and infer new knowledge on the models. We will demonstrate these verification aspects with an example in the next section.

3. A Three-Tier Network Architecture

In this section, we demonstrate the modeling and verification of a Three-Tier network example by using the architecture style ontology that we defined earlier. In modern web applications, the systems are constructed using a multi-layered structure, where a middle-ware layer is introduced to encapsulate the business logics. The middle layer is named as the 'Application Server', which can be considered as a mediator between the clients and the data storage facilities. The application server acts as both a server to the user requests and a client to the database server for data manipulations. We model the Three-Tier architecture using the following OWL classes by extending the style ontology that we defined in the previous sections.

$ThinClient \sqsubseteq Component$
$ApplicationServer \sqsubseteq Component$
$DatabaseServer \sqsubseteq Component$
$CnA \sqsubseteq Connector \quad AnD \sqsubseteq Connector$
$AppRequest \sqsubseteq Port \quad AppProvide \sqsubseteq Port$
$AppConsumer \sqsubseteq Role \quad DBProvider \sqsubseteq Role$
$SendApp \sqsubseteq SendRequest \quad AppResult \sqsubseteq ReceiveResult$

We define the `ThinClient`, `ApplicationServer`, `DatabaseServer` as basic components involved in the structure. In addition, `CnA` is a connector that connects the thin client with the application server, while `AnD` is the connector that relates the application server to its database server. The above also gives the definitions of the ports used in the model, i.e., `AppRequest`, `AppProvide`, `DBRequest`, and `DBProvide`. The roles used in the structure include `AppConsumer`, `AppProvider`, `DBConsumer` and `DBProvider`. Finally, we define the processes that involved in the communication of the structure, e.g., `SendApp` extends the `SendRequest` process of the Client and Server style ontology, which denotes the client sending a request to the application server. Other processes, such as `AppResult` extends the `ReceiveResult` process, `AppReturn` extends the `ServerReturn` process, and so on, can be defined in a similar manner. With the entities of the Three-Tier ontology specified, we can add property definitions to relate the classes, e.g., the client only has application request ports, the application server has both a provide port to its client and a request port to the database server, and so on. Due the space limit, we can not list all of them here. Furthermore, the communication behaviors of the Three-Tier architecture need to be redefined in terms of the specific processes used in the new structure. For example, the interactions of the application server are defined using the following SWRL rule.

$$ApplicationServer(?as) \wedge AppProvide(?ap) \wedge$$
$$DBRequest(?dr) \wedge AppAccess(?aa) \wedge AppReturn(?ar) \wedge$$
$$SendDB(?sd) \wedge DBResult(?dres) \wedge p1 : Id(?id) \wedge$$

$$p1 : hasId(?aa, ?id) \wedge p1 : hasId(?sd, ?id) \wedge$$
$$p1 : hasId(?dres, ?id) \wedge p1 : hasId(?ar, ?id) \wedge$$
$$p1 : hasPort(?as, ?ap) \wedge p1 : hasPort(?as, ?dr) \wedge$$
$$p1 : hasAction(?ap, ?aa) \wedge p1 : hasAction(?ap, ?ar) \wedge$$
$$p1 : hasAction(?dr, ?sd) \wedge p1 : hasAction(?dr, ?dres)$$
$$\rightarrow p1 : hasCommunication(?aa, ?sd) \wedge$$
$$p1 : hasCommunication(?dres, ?ar)$$

The above states that `ApplicationServer` has two ports i.e., `AppProvide` and `DBRequest`. The `AppProvide` port acts as the interface for providing services to the client and has `AppAccess` and `AppReturn` as its actions, while the `DBRequest` port acts as the interface for requesting data access service from the database server and has `SendDB` and `DBResult` as its actions. The behavior of the application server mainly consists of two types of communication sequences, i.e., (1) $\langle AppAccess, SendDB \rangle$ - invokes service from a client request via `AppAccess` and sends the converted data request to database server via `DBRequest`; (2) $\langle DBResult, AppReturn \rangle$ - receives data result from the database server via `DBResult` and returns the converted result to the client via `AppReturn`. This concludes the dynamic behaviors of the application server. Similarly, the communication behaviors of other entities in the model, such as, the `ThinClient` and `DatabaseServer` components, the `CnA` and `AnD` connectors can be redefined by simply cloning the server and connector communication rules from the Client and Server style ontology.

3.1. Styles recognition via classification

Up to now, we have completed the ontology definition of the Three-Tier network architecture model. Careful readers might have already noticed that the entities of the Three-Tier ontology mainly extend the component and connector model, apart from its specific process definitions. This was 'deliberately' chosen to demonstrate the automatic style recognition via ontology classification. In Section 3.2, we mentioned that the necessary and sufficient conditions with closure axioms can contribute to the automatic recognition of different architecture styles through ontology classification. Figure 2 represents the inferred hierarchy of the classes in the Three-Tier example after running the 'classify taxonomy' function of the Pellet ontology reasoner. As shown in the diagram, the left-hand side panel contains the asserted (original) class hierarchy of the Three-Tier ontology by directly extending the component and connector model, the right-hand side panel contains the inferred class hierarchy after the classification. We can see that except for the `ApplicationServer`, all other classes that we defined in the Three-Tier ontology have been re-classified into the corresponding categories under the Client and Server ontology. For example, the `ThinClient` is moved to a subclass of the `Client`, and the `DatabaseServer` is now under the `Server` class. The `CnA` and `AnD` connectors have both been moved to subclasses of the `CnS` connector. Similarly, the ports and roles that we defined earlier have also been re-classified under the specific ports and roles of the Client and Server style ontology. Note that in this example, because we defined a server to be only having the 'Provide' ports and a client to be only having the 'Request' ports, the `ApplicationServer` in Figure 2 was not classified as either a client or a server, since it has both an `AppProvide` port to the thin client and a `DBRequest` port to the database server.

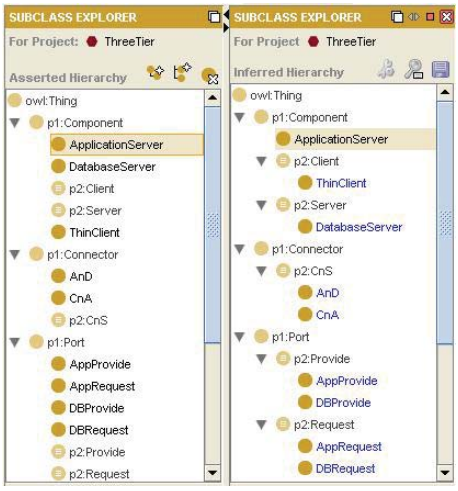

Figure 2. Automated style recognition of the Three-Tier architecture via classification.

Effectively speaking, the above indicates that the ontology classifier have automatically recognized the Three-Tier ontology to be composed of two basic Client and Server structures. We believe that this kind of automated style recognition can be very useful during software architecture modeling. The users only need to create their customized architecture models by extending the top level component and connector ontology, and let the ontology classifier to automatically recognize the styles that involved in the design. It not only helps the users to realize the architectural design patterns, but also assists the designers in decomposing a complex system into clear structured and verifiable sub-models.

3.2. Communication generation via inference

With the Three-Tier ontology defined, we can create specific configurations of this structure through the instance declarations. For example, we defined a network configuration with twenty thin clients, two application servers and one database server. Each application server

handles about ten clients and they both connected to the same database server. Note that such a configuration involves 294 instances in total, which consists of the instances for all the components, connectors, ports, roles, processes, and client identifiers. Once the instances are created, we attach the desired roles to their corresponding ports to form the communication topology. When ports and roles are connected, we can then invoke the Jess rule engine to automatically infer the communication sequences on the instance configuration. For example, a typical inferred communication sequence for $Client_1$ could be – '$\langle SendApp_1, AppAccess_1\rangle$, $\langle AppAccess_1, SendDB_1\rangle$, $\langle SendDB_1, DBAccess_1\rangle$, $\langle DBAccess_1, DBReturn_1\rangle$, $\langle DBReturn_1, DBResult_1\rangle$, $\langle DBResult_1, AppReturn_1\rangle$, $\langle AppReturn_1, AppResult_1\rangle$'. This effectively illustrates exactly what happened in the model in terms of communication interactions among the entities, i.e., starting from the client submits a request to the server until the client receives the corresponding result. The Jess rule engine generates 300 inferred axioms on the configuration model, which includes twenty separately identified communication sequences with respect to the number of clients involved in the configuration (each contains the above seven communication pairs with different client identifier labeled) to simulate the interactions among the instances of the clients and servers.

4. Conclusion

In this paper, we proposed a formal approach to software architecture modeling and verification using the semantic web technology. We represented architecture models as ontology descriptions and applied DL reasoners to perform automated verification on the design. The OWL definitions specify the structure information of the model, where the SWRL rules capture the dynamic communication in the styles. Users can easily extend the style ontology in defining their customized architecture models. In the aspect of automated verification, we demonstrated two levels of reasoning, i.e., style recognition via ontology classification and communication sequences generation using rule inference. The former works on the ontology level and can automatically recognize the style patterns used in the design, where the latter applies to the instance level and enables the users to automatically derive the interactions within the configuration of a design. As a complex architecture model usually consists of a combination of different architecture styles, these two levels of verification can be effectively used together to enhance the quality of a design. For example, when creating a customized architecture ontology model, the user only needs to define the model by extending the top level component and connector ontology and then invoke the classifier to automatically recognize the architecture styles used in the design. Once the customized architecture model is classified into recognizable styles, the users can then create specific configurations (e.g., partially) of the design (ontology) and invoke the rule engine to automatically infer new knowledge and derive the communication sequences on the model. To demonstrate the effectiveness of our approach, we illustrated the design and verification of a Three-Tier network architecture model as the case study.

In the future, we plan to develop a visual tool support that aims at assisting the design and verification of architecture models based on the proposed ontology approach. The tool should allow the designers to build their architecture models graphically without knowing the underlying syntax and knowledge of OWL/SWRL. It should integrate all the ontology definitions and verification steps described in the paper and automated them in one coherent visual interface.

***Abstract*—Programmers tend to spend a lot of time debugging code. They check the erroneous phenomena, navigate the code, search the past bug fixes, and modify the code. If a sequence of these debug activities can be automated, programmers can use their time for more creative tasks. To address this problem, this paper proposes *dcNavi* (Debug Concern Navigator), a concern-oriented recommendation system for debugging. The *dcNavi* provides appropriate hints to programmers according to their debug concerns such as *"how to handle this exception"* and *"how to use this API"*. We propose the notion of DCG (Debug Concern Graph), an extension of the *Concern Graphs*. A DCG appends a set of debugging information such as past bug fixes and test results to a concern graph. Debug hints are provided in the form of code snippets showing the sample code modification before and after a bug fix.**

***Keywords*-debug, concern graph, recommendation**

I. Introduction

In many software development projects, programmers tend to spend a lot of time debugging code [5]. They check the erroneous phenomena, navigate the code that may include bugs, and search external useful resources such as API specifications and documents. It is effective if IDEs (Integrated Development Environments) provide programmers with advices summarized by these external resources. However, it is not clear which kind of information navigation should be provided to the programmers because these external resources provide only indirect hints for debugging and do not always resolve the bugs.

It is favorable if IDEs can provide the code snippets before and after similar bug fixes by searching past repositories because programmers can understand how to fix a bug by referring concrete examples. Especially, it is useful for novice programmers. To achieve this goal, we have to develop the following mechanisms because the code in the repositories should be associated to the debugging activities in order to provide effective hints: 1) a mechanism for collecting and archiving the debugging activities from IDEs; 2) a mechanism for associating the debugging activities to the program structures; and 3) a mechanism for retrieving the code snippets advising bug fixes from the repositories.

To deal with this challenge, this paper proposes *dcNavi* (Debug Concern Navigator), a concern-oriented recommendation system for debugging. The *dcNavi* provides appropriate hints to programmers according to their debug concerns by using a repository containing not only program information but also past test results and their bug fixing history. We propose the notion of DCG (Debug Concern Graph), an extension of the *Concern Graphs* [10], [11] that helps programmers identify and reason about concerns in programming and maintenance tasks by abstracting the implementation details of a concern and makes explicit the relationships among concerns. A DCG appends a set of debugging information such as bug fixes and test results to a concern graph.

The remainder of this paper is structured as follows. In Section 2, we point out the issues on debugging. In Section 3, the concept of DCGs is illustrated. In Section 4, an overview of *dcNavi* is shown. In Section 5, the effectiveness of *dcNavi* is evaluated. In Section 6, related work is introduced. Concluding remarks are provided in Section 7.

II. Motivation

In this section, we discuss the problems on debugging by showing a typical debugging scenario.

A. A typical debugging scenario

We consider a situation in which a student is debugging a Java program handling file operations such as *read* and *write*. The student with insufficient programming skills tends to make a mistake because these file operations interact with external resources. The code below shows the student's program that reads a text file. In this program, the *readFile* method reads a text line from a file specified by the parameter. In the case of *read* failure, null is returned.

```
[List 1]
01: public class Property {
02:   public String readFile (String pathname)
03:     throws IOException {
04:       String val = null;
05:       File file = new File(pathname);
06:       FileReader fr = new FileReader(file);
07:       BufferedReader br = new BufferedReader(fr);
08:       val = br.readLine();
09:       return val;
10:   }}
```

The code below shows a unit test program for the *readFile* method. While the *testReadFile* method is successfully ter-

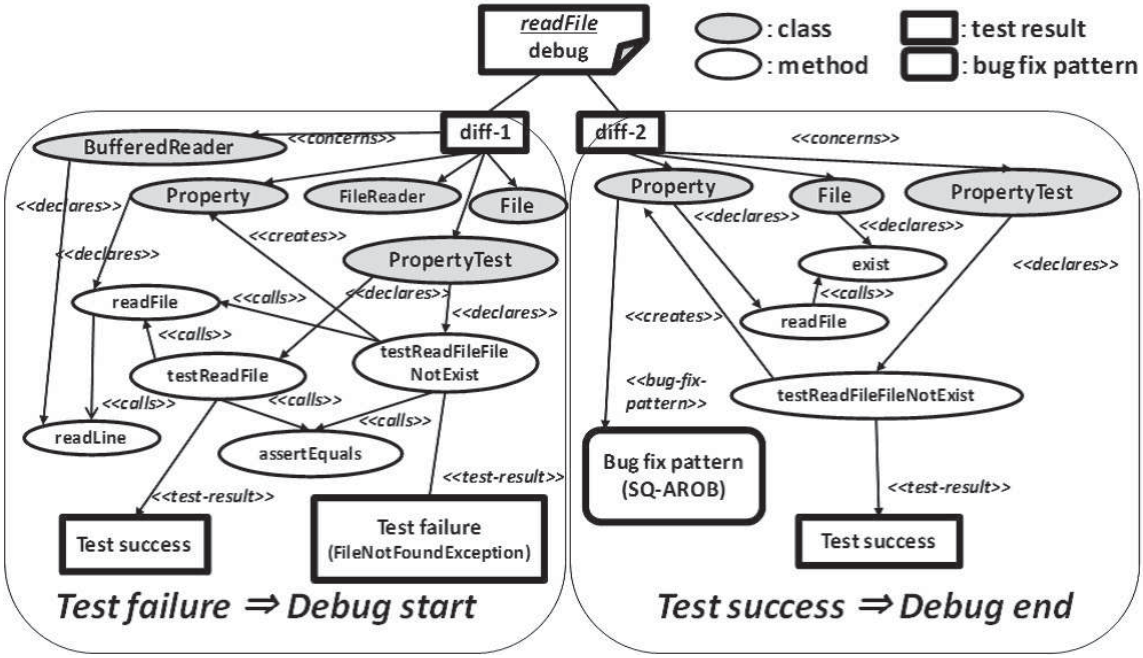

Figure 1. DCG: Debug Concern Graph

minated, *FileNotFoundException* is thrown in the case of the *testReadFileFileNotExist* method execution (line 13).

```
[List 2]
01: public class PropertyTest extends TestCase {
02:   public void testReadFile()
03:     throws IOException {
04:       Property property = new Property();
05:       assertEquals("true",
06:         property.readFile("property.txt"));
07:   }
08:   public void testReadFileFileNotExist()
09:     throws IOException {
10:       Property property = new Property();
11:       // property2.txt does not exist !!
12:       assertEquals(null,
13:         property.readFile("property2.txt"));
14:   }}
```

The student begins to debug the program and is faced with the following three problems: 1) although the programmer guesses that he or she has to append the code for dealing with the case in which a file does not exist, the programmer does not know how to write the code avoiding *FileNotFoundException* because it is an unfamiliar exception for the programmer; 2) the programmer cannot be convinced of the correctness of the API usage (*BufferedReader*) because it is an unfamiliar library; and 3) the programmer does not know whether other test cases are needed.

Although it might not be difficult for professional programmers to predict the cause of a bug by referring to their experience, many beginners are faced with the various difficulties when they debug a program. For example, it is not easy for a beginner to use program exceptions or test failures as a hint for fixing a bug because they do not have enough experience and knowledge for programming languages, library usages, and source code reviews. Even if a programmer has a long career, he or she will be faced with the similar difficulties when the programmer works for unfamiliar new projects, languages, and frameworks.

B. Our approach

Many programmers tend to make the same kind of bugs concerning API usages, exception handling, and domain knowledge [4], [8], [9], [12]. It is effective to provide hints from past bug fix data.

This paper proposes *dcNavi*, a recommendation system for giving an answer to the programmer's questions such as *"how to handle this exception"* and *"how to use this API"*. We call these questions *debug concerns*. The *dcNavi* provides hints for bug fixes by reusing debug experience and knowledge archived in the graph structures, DCGs, containing not only source code but also static analysis information, test results, and revision numbers before/after bug fixes. By using graph structures as knowledge bases, it becomes easy to navigate and search related information that may be hints for debugging. In *dcNavi*, a hint is provided in the form of code snippets showing the code modification before and after a bug fix because the correct code samples are effective for program understanding.

III. Debug Concern Graph

In this section, we explain the notion of DCG in detail.

A. Graph structure

Figure 1 illustrates two DCGs showing before and after debugging the *readFile* method from Section 2. The root

node *readFile debug* indicates the name of a debug activity consisting of sub-activities related to a test failure (*diff-1*) and a test success (*diff-2*). We consider *test failure time* and *test success time* as *debug start point* and *debug end point*, respectively.

The DCG consists of element nodes and edges. The nodes include not only program elements such as classes and methods, but also a variety of debugging activities annotated with applied bug fixes and test results. Each node is connected to other nodes by edges annotated with stereotypes such as *calls* (method call), *creates* (object instantiation [some edges are omitted in Figure 1 for simplicity]), *declares* (method declaration), and three kinds of relations: 1) *concerns* (relation between a debug activity and a class concerned by a programmer); 2) *test-result* (relation between a test class and its execution result); and 3) *bug-fix-pattern* (relation between a modified class and an applied bug fix pattern).

The bug fix patterns are the code modification catalogues for fixing a variety of bugs and can be considered hints for debugging. We adopted the bug fix patterns proposed in [9]. The patterns are well documented and consist of twenty-seven catalogues such as MC-DAP (Method Call with Different Actual Parameter Values), SQ-AROB(Addition or Removal of Method Calls in a Short Construct Body), and IF-CC (Change of If Condition Expression). The *dcNavi* detects the applied bug fix pattern by comparing the code before debugging with the code after the bug fix. In Figure 1, the SQ-AROB pattern is applied.

B. Graph evolution

A DCG is created and expanded automatically as a programmer debugs a program. First, a sub-activity-node is created when a test is executed. The structure of the *diff-1* node is fixed and the *diff-2* node is created at the time of test failure. If the test fails, a programmer begins to browse classes, methods, and fields that might include a bug. These browsed program elements are automatically added to a DCG. The result of the test execution is also added to the DCG. After the code modification is completed, the test is executed again. If the test succeeds, the bug fix pattern node is added to the DCG.

Our approach is integrated with TDD (Test-Driven Development) [2]. The TDD events such as test execution, fail, success can be good triggers for enriching concern graphs with debugging activities that are automatically associated to program elements such as classes and methods.

C. Concern query

It is a difficult problem to translate a programmer's debug concern to a query for obtaining the code snippets showing the program modification before and after the bug fix because searching only keywords (e.g., *FileNotFoundException*) included in the debug concern matches with many code fragments that are not relevant to the bug fix. To deal with this problem, *dcNavi* searches a sub graph that matches the bug fix patterns and includes the specified keywords. The bug fix patterns show not only how to fix bugs but also the reasons of the bugs. The bug fix patterns play an important role in our recommendation system because many bug fixes can be categorized into the patterns, the advice can be generated from actual code snippets annotated with the bug reasons, and the recommendation mechanism is implemented by simple pattern matching.

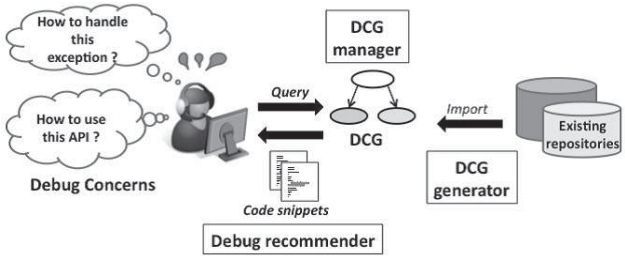

Figure 2. dcNavi

IV. DCNAVI

The *dcNavi* consists of three facilities including *DCG manager* for supporting graph construction and evolution, *DCG generator* for importing existing repositories, and *debug recommender*. Figure 2 illustrates the outline.

The *dcNavi* supports debugging in Java and is implemented as an Eclipse plug-in by using Mylyn and JUnit. Mylyn [7], [3] monitors programmer's activities, creates a *task context* that focuses his or her workspace, and automatically links all relevant artifacts to the task context. JUnit is a unit testing framework for Java.

A. DCG manager

DCG manager creates and expands DCGs as follows: 1) program elements related to debug concerns are automatically captured and added to DCGs by using Mylyn's task-focused interface (*concern* edges in DCGs are also appended automatically); 2) structural associations among program elements such as *declares*, *creates*, and *calls* are added to DCGs by analysing source code; 3) test results are added to DCGs by monitoring JUnit test executions; and 4) the applied bug fix patterns are added to DCGs by checking the *diff* before and after bug fixes determined by test failure and success events.

Programmers do not have to be aware of creating DCGs because the *dcNavi* automatically constructs DCGs based on Mylyn. Using Mylyn, the information only related to the debug activities is added to the DCGs. The static program analysis information, test results, and applied bug fix patterns are merged with Mylyn and Eclipse. Programmers can browse the debug information from the IDE because the *dcNavi* is tightly integrated to Eclipse.

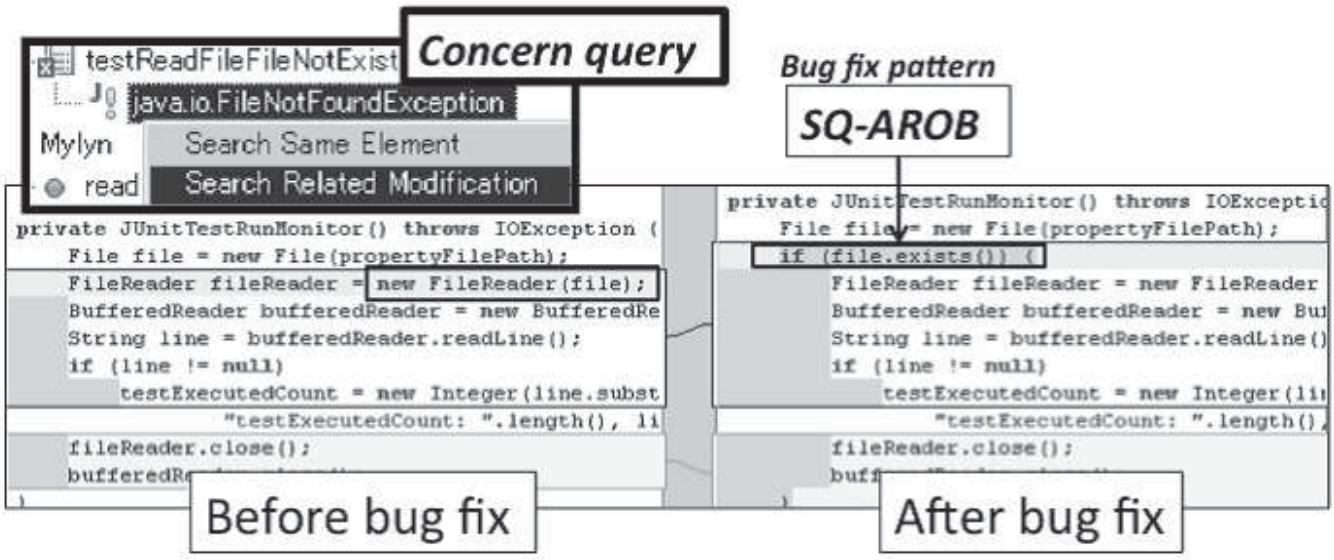

Figure 3. Recommendation result

B. DCG generator

Although our approach is effective for debugging, it needs a repository in which past debugging information is archived. This is not realistic because there are many repositories that do not take into account debugging activities.

To deal with this problem, we developed the DCG generator to convert a set of existing *Subversion* (SVN) repositories such as open source projects into DCGs. The DCG generator uses commit-log keywords such as *bug*, *fix*, and *patch* to define test success or failure, because a sub-activity node (e.g., *diff-1*) in a DCG has to be created per each debugging process staring from a test failure and terminating by a test success. Although a DCG construction is based on TDD in *dcNavi*, there are no data concerning TDD activities in most existing repositories. We have to predict and compensate this data. Moreover, we have to add program elements only concerning to the debug activities because a concern graph is automatically expanded by using the facility of Mylyn. The DCG generator links only program elements related to the bug fixes appearing in the commit-logs to the corresponding sub-activity node by analysing the program structures. That is, *concerns* edges are automatically added to DCGs.

C. Debug recommender

Figure 3 illustrates an example of a concern query *"Search Related Modification" of FileNotFoundException* and its recommendation result. The *dcNavi* explores a DCG from the *testReadFileFileNotExist* node (see Figure 1) and traverse connected nodes such as *Property* and *readFile* with comparing past bug-fixed graphs. The recommendation in Figure 3 shows that a file existence check should be inserted. In this case, the SQ-AROB pattern indicates that *"Addition of Method Calls [file.exists()]"* is needed for this bug fix. This recommendation shows that programmers tend to forget to write this checking code.

The recommendation algorithm is as follows.

Step1) Search a method to be modified: The *dcNavi* searches the test target method because our approach is based on TDD. This method needs to be modified. In this case, we have to find *readFile*, a method that throws the *FileNotFoundException* exception by tracing the *call* edges in the DCG from the *testReadFileFileNotExist* node.

Step2) Obtain recommendation candidates: The *dcNavi* obtains all the tests failing to handle the *FileNotFoundException* exception from the DCG. Next, the *dcNavi* finds the test target methods whose *after-modification* include the bug fix patterns that can be reached from the starting node such as *FileNotFoundException*. These test target methods are recommendation candidates. In the case of Figure 3, *JUnitTestRunMonitor*, a candidate of debug recommendation, includes the SQ-AROB pattern. Currently, the *dcNavi* does not search the IF-CC pattern because it matches with many bug fixes and is not appropriate for obtaining essential bug causes.

Step3) Recommend code snippets: The *dcNavi* recommends the code snippets ranked by the graph similarity metric:

```
Similarity(G1, G2) =
 #common_node / (#G1_node + #G2_node) / 2).
```

This metric indicates the degree of the similarity between two graphs *G1* and *G2*. #common_node is the number of nodes commonly appearing in *G1* and *G2*. This metric becomes high if the number of the nodes commonly shared between a current graph and a past bug-fixed graph is large.

Table I
EVALUATION OF NINE ECLIPSE PLUG-IN PROJECTS

In the case of Figure 3, *readFile* (before modification) and *JUnitTestRunMonitor* (before modification) correspond to *G1* and *G2*, respectively. The code snippet of the *JUnitTestRunMonitor* (after modification) is useful for fixing the bug of the *readFile* method. As shown in Figure 3, it is easy for programmers to fix bugs by referring to concrete code snippets. Currently, the *dcNavi* supports several concern queries such as *"Search Related API Usages"*, *"Search Test Cases"*, and *"Search Review Points"*.

V. EVALUATION

In this section, we evaluate the effectiveness of our approach in terms of the recommendation quality.

A. Test data and Criteria

We generated DCGs by using nine open source repositories created in the Eclipse plug-in projects. We selected a set of repositories related to Mylyn because we predicted that there were similar bug trends in the same domain. First, we collected 4/5 revisions from each project and all revisions of other eight projects as the training data. Next, using this data, we checked how many recommendations were provided to the bugs contained in the remaining 1/5 revisions of each project. After that, we compared correct bug fix set with recommendations provided by *dcNavi*.

We consider that a recommendation is correct when the *dcNavi* recommends a bug fix pattern that is used in the real bug fix. More concretely, we define the criteria of correct recommendation as follows: 1) the bug fix pattern applied to the real debugging is the same as that of recommendation; and 2) all the method calls related to the bug fix pattern must be included in the method to be modified. We think that a past bug fix dealing with the same method calls can be a hint for debugging and the applied pattern indicates the reason of the bug. In this evaluation, we used the value 0.20 as the minimum graph similarity metric. Precision becomes high if we use a large value as the similarity metric. On the other hand, recall becomes low in this case. The average F-measure in all nine projects becomes most favorable when the value of the similarity metric is 0.20.

B. Evaluation results

Table I shows the results of the recommendations. The rough precision (the fraction of the correct recommendations among all recommendations) ranges from 15% to 35%. The rough recall (the fraction of the correct recommendations among all correct bug fixes) ranges from 20% to 50%. In case of *qcMylyn* (HP Quality Center Mylyn Connector), 174 (= 223 * 4/5) revisions and 10,035 revisions (other eight projects) are used as the training data. There are 54 methods including bugs and the average number of the provided recommendations per method (ANR) is 5.70. Precision and recall are 34.42% and 50.24%, respectively.

C. Discussion

Our criteria of the correctness is slightly rigorous because all the method calls related to the bug fix pattern must be included in the method to be modified (see condition 2). However, it is effective to reuse the code with the same structure in which only the called methods are different (e.g., code templates). Although *dcNavi* recommends this kind of code, the code is not treated as a correct answer in our evaluation because the condition 2 is not satisfied. On the other hand, there may be too many recommendations if the condition 2 is deleted. We have to relax the condition 2 in order to regard this type of code as a correct answer.

Someone might think that the percentage of correct recommendations provided by *dcNavi* is not high. One reason is the rigorous criteria used in this evaluation as mentioned above. However, it is not easy to define the *correctness* in essence because the usefulness of recommendations varies according to the programmer's debug situation and skills.

To deal with this problem, we plan to introduce the recommendation options such as name matching and the value of minimum graph similarity metric. It would be better if programmers can specify the category of recommendations: API, exception handling, project-specific library, and so on. We think that the debug advice will be right to the point if the scope of the recommendation is explicitly specified. By introducing the recommendation options, we expect that we

can define the *correctness* suitable to each option. This is our future work.

VI. Related Work

Debugging is one of the crucial issues in software engineering and many researchers have proposed a variety of support tools such as debuggers and static analysis tools. Although the information provided by these tools is effective, they cannot directly advise programmers on the bug fixes. Recently, several recommendation systems for debugging have been proposed to deal with this problem.

The *Whyline* [6] is a debugging tool that allows programmers to ask *"Why did" and "Why didn't"* questions about the bugs. Programmers choose from a set of questions generated by static and dynamic analyses, and the tool provides answers of the bug causes. While *Whyline* uses static and dynamic analysis information of the target program, *dcNavi* uses not only program analysis information but also past bug fix information. We admit that fine-gained dynamic analysis information is effective for detecting the fault location and we plan to add the information to DCGs. If *Whyline* and *dcNavi* are integrated, we can provide more appropriate debug hints to the programmers.

The *DebugAdvisor* [1] is a search tool that allows programmers to express the context of the bugs and search through diverse data such as natural language text and core dumps. The *DebugAdvisor* allows programmers to search using a fat query, which could be kilobytes of structured and unstructured data. The *dcNavi*, which can be considered one of the search tools, explores structured DCGs focusing debugging. Although the goal of our approach is different from that of *DebugAdvisor*, we admit that large-scale searching is essential for the practical debug support.

The *FixWizard* [8] supports the tasks that identify the code peers existing in the program and recommend the similar fixes to its peers. Although *FixWizard* is similar to our approach, *dcNavi* focuses on the notion of *Concern* that can be related to a variety of debugging knowledge.

In *dcNavi*, the algorithm for searching the recommended methods is simple and general. It is effective that we can use the algorithm specific to the debug concern. The *CAR-Miner* [12] provides an approach for mining exception-handling rules as sequence association rules. These rules are specific to exception-handling.

The *BugMem* [4] provides a bug finding algorithm using bug fix memories consisting of project-specific bugs and fix knowledge. These bug fix memories use a learning process to extract project-specific bugs.

VII. Conclusions

This paper proposed a new concept, *debug recommendation based on Concern Graphs*, for providing the appropriate hints to programmers according to their debug concerns. Adopting our approach, programming, testing, and debugging can be systematically integrated based on the *Concern Graphs*. Although our approach is effective as demonstrated in Section 5, we have to improve the quality of the recommendation. As the first step, we plan to integrate *dcNavi* with runtime verification and dynamic analysis.

***Abstract*—Coverage-based fault localization techniques assess the extent of how much a program entity relates to faults by contrasting the execution spectra of passed executions and failed executions. However, previous studies show that different test cases may generate similar or identical coverage information in program execution, which makes the execution spectra of program entities indistinguishable to one another, thus involves noise and decreases the effectiveness of existing techniques. In this paper, we use the concept of coverage vector to model program coverage in execution, compare coverage vectors to capture the similarity among test cases, reduce noise by removing similar coverage vector to refine the execution spectra, and based on them assess the suspicious basic blocks being related to fault. We thus narrow down the search region and facilitate fault localization. The empirical evaluation using Siemens programs and realistic UNIX utilities shows that our technique effectively addresses the problem caused by similar test cases and outperforms existing representative techniques.**

Keywords-fault localization; execution path; noise reduction

I. INTRODUCTION

Coverage-based fault localization (CBFL) techniques have been proposed to support software debugging [8][11] [13]. By contrasting the coverage statistics of program entities (such as statements, blocks and predicates) between passed executions and failed executions, CBFL techniques can locate the program entities which exercising are strongly correlated to the program execution failures observed. Previous studies showed that CBFL techniques are effective in locating faults [8][13].

Since test cases may not always be generated to satisfy some coverage criteria, and there is no guarantee that the test suite reduction task is always conducted, it is common that different executions may cover similar and even identical execution paths [4]. Similar coverage information makes the execution spectra of program entities indistinguishable in passed and failed executions and thus decreases the effectiveness of previous fault localization techniques or even makes them lose effect, especially when coincidental correctness occurs [5]. For example, suppose a faulty statement is exercised in the program execution of all passed and all failed executions, it is hard to pinpoint it by contrasting its execution spectra in passed and failed executions. Such a case may have a high chance to happen in real life programs (e.g., a faulty statement may exist in the main method of a program and must be exercised by all the executions). Previous study also shows that execution similarity and coincidental correctness occurs frequently in realistic programs [12].

In this paper, we propose to use the concept of coverage vector to count the distinct execution paths, to capture the happening of execution similarity. We first calculate the failing rate of each coverage vector as the ratio of the number of failed executions covering it to the number of all executions covering it. For each basic block, we then calculate two numbers, the number of coverage vectors exercising that basic block and covered by failed executions, and the number of coverage vectors either exercising that basic block or covered by failed executions. We then use the ratio of the former to the latter as the suspiciousness score of that basic block. We next sort all the basic blocks in the descending order of thus calculated suspiciousness scores. In case of a tie, which means two or more blocks sharing identical suspiciousness scores, we try to use the average failing rate of coverage vectors exercising a block to further determine the order of the blocks.

We use seven Siemens programs and three UNIX utilities to evaluate our technique, and compare it with five representative techniques, namely, Tarantula [7], Jaccard [1], SBI [13], SAFL [4], and ICST10 [10]. The empirical results show that our technique is promising on the studies subject programs. Further analysis show that our technique is promising to alleviate the impact of execution similarity.

The contributions of this paper are twofold. (i) We propose to use the concept of coverage vector to count the distinct execution paths, and make use of it to estimate the occurring of similarities from the coverage information. (ii) We propose a new fault localization technique, PAFL, which is empirically evaluated to be promising in locating fault, especially in case of high execution similarity.

II. MOTIVATING EXAMPLE

In this section, we use an example to demonstrate previous techniques and motivate our approach.

The code excerpt in Figure 1 finds the middle value in three given numbers. A fault exists in statement s_2, which accesses the variable x instead of z. We choose six test cases to demonstrate in this example. The mark "•" in each cell indicates that a statement is exercised in the program

Figure 1. Motivating example – the program Mid

execution with respect to a test case. The execution results (*P* for pass and *F* for fail) are shown in table header.

We apply previous techniques Tarantula [7], Jaccard [1], SBI [13], SAFL [4], and ICST10 [10] to locate fault (statement s_2) in this example. For example, Tarantula assigns suspiciousness score 0.50 to statement s_2, and finally needs to examine 66% of all code to locate the fault. The results of Jaccard, SBI, SAFL, and ICST10 can be similarly explained. Unfortunately, none of them can locate the fault with somehow affordable code examining efforts (e.g., less than 50%). This is because that the faulty statement (s_2) happen to be exercised in all passed and failed executions, so that they are indistinguishable in execution spectra. On the other hand, Statements s_4 and s_6 are given higher suspiciousness scores than statements s_8 and s_{10} because the former happen to be exercised in relatively more failed executions than the latter. Note that statements s_4 and s_6 are exercised in one failed execution (t_5) and one passed execution (t_6), while statements s_8 and s_{10} are exercised in one failed execution (t_1) and three passed executions (t_2, t_3, and t_4). Among the two passed test cases (t_5 and t_6), which exercise the former (statements s_4 and s_6), 50% of them are failed ones. While only 25% of the test cases that exercise the latter (statements s_8 and s_{10}) are failed ones. As a result, statements s_4 and s_6 are given higher suspiciousness scores because of such imbalance.

Execution similarity may frequently occur in realistic programs [12]. We could not expect to always benefit from the imbalance observed in previous paragraph. To measure the execution similarity, we design to use the coverage information. In addition, we also measure the execution similarity to estimate the occurring of coincidental correctness in passed executions and manage to alleviate the impact of coincidental correctness to execution spectra of statements.

From Figure 1, we observe that there are in total two distinct paths covered by the six test cases [2], which are denoted as $p_1 = \langle b_1, b_2, b_4, b_{10}\rangle$ and $p_2 = \langle b_1, b_3, b_7, b_{10}\rangle$. After that, we adopt SBI's formula $\frac{\text{failed(p)}}{\text{failed(p)+passed(p)}}$ to estimate the failing rate of a path, which means the probability of an execution (covering that path) revealing a failure. Note that, here we use a path, rather than a statement, as the program entity in the formula. Since p_1 is covered by one failed test case and three passed test cases, the failing rate of p_1 is 0.25. Similarly, the failing rate of p_2 is 0.5. A path with a positive failing rate means that the corresponding execution can reveal failures. A path with failing rate zero means that the corresponding execution reveals no failure. We then adopt Jaccard's formula $\frac{\text{failed(b)}}{\text{totalfailed+passed(b)}}$ to calculate the suspiciousness score for each block. Here, *failed*(*b*) means the number of distinct paths, which have positive failing rates and exercise block *b*; *passed*(*b*) means the number of distinct paths, which have failing rates of zero and exercise block *b*; *totalfailed* means the number of distinct paths, which have positive failing rates. Thus, the suspiciousness score of block b_1 is calculated as $\frac{2}{2+2} = 0.50$. As a result, we finally take 33% code examining effort to locate the fault.

The above example has interestingly demonstrated that previous techniques may not be effective in a common case, while our approach has the potential to address it. In the next section, we will elaborate on our model.

III. OUR APPROACH

In this section, we introduce the problem settings, give definitions, and elaborate on our model PAFL.

A. Definitions

We use the definition of "coverage vector" to formally describe the concept of "distinct path" used in Section II.

[Definition I] *An **original coverage vector** $ocv_i = \langle b_1, b_2, ..., b_n\rangle$ ($b_j \in \{0, 1\}$ for $j = 1, 2, ..., n$) of program execution $P(t_i)$ is a tuple. We use $ocv_i(b_j)$* to retrieve the *j*-th element in the tuple, *where $ocv_i(b_j) = 1$ means the basic block b_j is exercised in the execution, $ocv_i(b_j) = 0$ means b_i is not exercised in the execution. For the coverage vector ocv_i with respect to execution $P(t_i)$, we also say $P(t_i)$ covers ocv_i.*

In Figure 1, there are six original coverage vectors. The coverage vector with respect to test case t_1 is $ocv_1 = \langle 1, 0, 0,$

0, 0, 1, 0, 1, 0, 1⟩. Apparently, an original coverage vector can be covered by many different executions (even by both some passed executions and some failed executions). So let us move to Definition II.

[Definition II] *The **distinct coverage vector set** $CV = \{cv_1, cv_2, ..., cv_p\}$ is the distinct set (with no repeating elements) of all original coverage vectors ocv_i with respect to the program execution $P(t_i)$ of each test case t_i. Each element $cv_i \in CV$ is called a **coverage vector**. Similarly, we use $cv_i(b_j)$ to retrieve the j-th element in the tuple of cv_i.*

By such definition, we know that we have $cv_i \neq cv_j$ for any two coverage vectors cv_i and cv_j ($1 \leq i < j \leq p$). In Figure 1, there are two coverage vectors, namely, cv_1 = ⟨1, 0, 0, 0, 0, 1, 0, 1, 0, 1⟩ and cv_2 = ⟨1, 1, 0, 1, 0, 0, 0, 0, 0, 1⟩.

B. Failing Rate of Coverage Vector

Since a coverage vector may be covered by both passed executions and failed executions, we are also interested in the ratio of failed executions that covers the coverage vector (to all executions that covers the coverage vector). We use the term *failing rate of a coverage vector* to denote such a ratio, which is calculated using equation (1).

$$\theta(cv_i) = \frac{failed(cv_i)}{failed(cv_i) + passed(cv_i)} \quad (1)$$

In equation (1), *failed* (cv_i) and *passed* (cv_i) respectively refer to the number of failed and passed executions that cover cv_i. They are calculated using equation (2) and (3).

$$failed(cv_i) = \left|\{v_j | P(v_j) \text{ covers } cv_i\}\right| \quad (2)$$

$$passed(cv_i) = \left|\{u_j | P(u_j) \text{ covers } cv_i\}\right| \quad (3)$$

Here, we adopt the formula of SBI in equation (1) because it gives a best estimation to the probability of an exercised program entity causing a failure [14].

For a coverage vector cv_i with $\theta(cv_i)$ greater than zero, it indicates that cv_i is covered by at least one failed execution, and it is also denoted as a *failed coverage vector*. For a coverage vector cv_i with $\theta(cv_i)$ equals to zero, it indicates that cv_i is covered by no failed execution, and it is also denoted as a *passed coverage vector*.

According to equation (1), the failing rates of cv_1 and cv_2 are $\theta(cv_1) = 0.25$ and $\theta(cv_2) = 0.50$, respectively. Both of them are failed coverage vectors.

C. Suspiciousness Scores of Blocks

After we have identified all the coverage vectors, we also need to calculate suspiciousness scores for basic blocks. Inspired by previous study [6], we employ the Jaccard similarity coefficient to evaluate the suspiciousness scores for basic blocks, by contrasting the execution spectra of basic blocks on the coverage vector level. In this paper, we use the term $susp(b_i)$ to denote such suspiciousness score of basic block b_i, which is calculated using equation (4).

$$susp(b_i) = \frac{\left|\{cv_j | \theta(cv_j) > 0 \wedge cv_j(b_i) = 1\}\right|}{\left|\{cv_j | \theta(cv_j) > 0 \vee cv_j(b_i) = 1\}\right|} \quad (4)$$

The numerator represents the number of failed coverage vectors that cover b_i, the denominator represents the number of coverage vectors that are either failed coverage vectors or cover b_i. Here, we adopt the similarity coefficient Jaccard because it has mature mathematical basis. Further, it has been used in previous techniques and empirically shown effective in locating faults in programs [1].

Equation (4) estimates the extent of how much a basic block is related to faults. The greater the value, the more the basic block will be related to fault. According to equation (4), we can recall the motivating example in Section II and revisit the suspiciousness scores calculated in Section II. The suspiciousness scores for b_1 is calculated as $\frac{2}{2+2} = 0.50$.

D. Tie breaking

After all the blocks are sorted according to their suspiciousness of relating to fault and form a list, programming may search along the generated list for the fault. Particularly, when some basic blocks have identical suspiciousness scores, we use equation (5) to break tie.

$$conf(b_i) = \frac{\sum_{cv_j(b_i)=1}[\theta(cv_j)]}{\left|\{cv_j | \theta(cv_j) > 0, cv_j(b_i) = 1\}\right|} \quad (5)$$

Equation (5) calculates the average failing rate of the coverage vectors that exercising basic block b_i. The rational is that for two basic blocks having identical probability of causing failure, we deem the one whose appearance in a path has higher chance to reveal a failure as more related to faults.

For example, in Figure 1, basic blocks b_1 and b_{10} form a tie. We calculate that $conf(b_1) = conf(b_{10}) = \frac{0.25+0.5}{2} = 0.375$ so that the tie still cannot be break and thus b_1 and b_{10} are evaluated as a whole. Finally, we need to examine 33% of all code to locate the fault.

IV. EVALUATION

A. Experiments Setup

In this paper, we use the 7 Siemens programs and 3 UNIX utilities to evaluate our technique. Each of them has several faulty versions (downloaded from the SIR repository [3]). They have been used in previous studies [9][13][14]. Table 1 shows the statistics of the subject programs used in the experiments.

In our experiment, we select techniques Tarantula [7], Jaccard [1], SBI [13], SAFL [4], and ICST10 [10] to compare with. Tarantula is an old technique and has a lot of variants [7][13]. Jaccard is evaluated very effective in

Table 1. Statistics of subjects

Subjects	# of faulty versions	# of test cases	Description
print_tokens	7	4130	lexical analyzer
print_tokens2	10	4115	lexical analyzer
replace	32	5542	pattern replacement
schedule	9	2650	priority scheduler
schedule2	10	2650	priority scheduler
tcas	40	1578	altitude separation
tot_info	23	1054	information measure
flex	56	567	lexical parser
grep	21	809	text processor
gzip	18	213	compressor
in total	226		

previous studies [10][14]. SBI is the statement-level version of CBI [9], while the latter is a classic predicate-level technique. SAFL and ICST10 investigate execution similarity to reduce the noise from coincidental correctness and relates to them.

B. *Effectiveness on Subject Programs*

To know the overall effectiveness of the studied techniques, we take the average of the 10 programs to show in Figure 2. In Figure 2, the x-coordinates mean the percentage of code examined in each faulty version; the y-coordinates show the percentage of faulty versions, in which, faults can be located within the code examining effort specified by the x-coordinates.

From Figure 2, we observe that at most checkpoints (except the 50% checkpoint), PAFL is more effective than, or at least comparable to, the other techniques. For example, on average, by examining up to 5% of all the code in faulty versions, PAFL can locate faults in 34% of all faulty versions, Jaccard can locate 33%, Tarantula can locate 23%, SBI can locate 22%, SAFL can locate 6%, and ICST10 can locate 26%. It shows that PAFL has an overall better effectiveness than the other techniques studied.

Table 2 shows the mean effectiveness of these techniques on each program. Limited by the space, we cannot show results of the minimum, maximum, and standard deviation measurements. This table shows that for these programs, PAFL is often, but not always, the best among the four techniques.

V. CONCLUSION

In this paper, we demonstrate that frequently occurred execution similarity may affect the effectiveness of existing fault localization techniques and propose PAFL to alleviate the impact of coincidental correctness. We use the concept of coverage vector to count distinct execution paths, and calculate failing rate for each coverage vector, thus refine the executions spectra to reduce noise. The empirical study shows that our technique outperforms five previous techniques on Siemens and UNIX programs. The experiment also shows that our technique is particularly effectiveness to alleviate the impact of execution similarity and coincidental correctness. The future work is to investigate the impact of test case selection to PAFL and adapt PAFL to locate faults in multi-fault programs.

Abstract

The testing of concurrent software is a challenging task. A number of different research approaches have investigated adaptation of the techniques and the criteria defined for sequential programs. A major problem with the testing of concurrent software that persists is the high application cost due to the large number of the synchronizations that are required and that must be executed during testing. In this paper we propose a complementary approach, using reachability testing, to guide the selection of the tests of all synchronization events according to a specific coverage criterion. The key concept is to take advantage of both coverage criteria, which are used to select test cases and also to guide the execution of new synchronizations, and reachability testing, which is used to select suitable synchronization events to be executed. An experimental study has been conducted and the results indicate that it is always advantageous to use this combined approach for the testing of concurrent software.

1. Introduction

Concurrent applications are inevitably more complex than sequential ones and, in addition, all concurrent software contains features such as nondeterminism, synchronization and inter-process communication which significantly increase the difficulty of validation and testing.

For sequential programs, many testing problems were simplified with the introduction of testing criteria and the implementation of supporting tools. A testing criterion is a predicate to be satisfied by a set of test cases which can be used as a template for the generation of test data [10].

Extending previous work on sequential program structural testing criteria, we have proposed structural testing criteria for the validation of concurrent programs, applicable to both message-passing software [14] and shared-memory software [12]. These testing criteria are designed to exploit information about the control, data and communication flows of concurrent programs, considering both sequential and parallel aspects.

The use of these criteria significantly improves the quality of the test cases, providing a coverage measure that can be used in two important testing procedures. In the first one, the criteria can be used to guide the generation of test cases, where the criteria are used as guideline for test data selection. The second testing procedure is related to the evaluation of a test set; in this case, the criteria can be used to determine when the testing activity can be terminated based on sufficient coverage of the required elements. The main contribution of the proposed testing criteria is to provide an efficient coverage measure for evaluating the progress of the testing activity and the quality of test cases.

This approach uses static analysis of the program under test to extract relevant information for testing, which is straightforward to apply and generate relevant information for coverage testing. The problem is the large number of infeasible elements generated that must be analyzed. An element is infeasible if there is no set of values for the parameters (the input and global variables) that cover that element. Complete determination of infeasible elements is an extremely difficult problem and it is not possible to determine them automatically.

Lei and Carver [7] proposed a method (based on reachability testing) to obtain all of the executable synchronizations of a concurrent program (from a given execution of the program) in a way that reduces the number of redundant synchronizations. As this method uses dynamic information, only feasible synchronizations are generated, which

is a considerable advantage. However, a difficulty with this method is the high number of possible combinations of synchronization that are generated. For complex programs, this number is very high, which limits the practical application of this approach. In [1], Carver and Lei proposed a distributed reachability testing algorithm, allowing different test sequences be executed concurrently. This algorithm reduces the time to execute the synchronizations, but the authors do not comment about the effort necessary to analyze the results from these executions.

Lei and Carver's [7] method is essentially complementary to our approach. They do not address how to select the test case which will be used for the initial run, while we use the static analysis of the program to select the optimum test cases in advance.

In this paper we propose a complementary approach, using reachability testing to target coverage testing for synchronization events. The idea is to take appropriate advantage of both approaches: information about synchronizations provided by the coverage criterion are used to decide which race variants will be executed, selecting only synchronizations that have not already been covered by existing test cases. It is therefore possible to execute each synchronization at least once and to use reachability testing to select only those synchronizations that are feasible.

This paper is structured as follows. In Section 2 we describe related work on the testing of concurrent software, presenting more details on the coverage testing and reachability testing approaches. In Section 3 we present the test strategy proposed in this paper. In Section 4, an experimental study to evaluate our test strategy is presented and the results obtained are discussed. Finally, in Section 5 we present our conclusions together with future work.

2. Concurrent Program Testing

Traditional testing techniques are often not well-suited to the testing of concurrent or parallel software, in particular when nondeterminism and concurrency features are significant. Many researchers have developed specific testing techniques addressing such issues and in addition there have been initiatives to define suitable testing criteria [16, 18, 17, 8, 11, 15]. The detection of race conditions and mechanisms for replay testing have also been investigated [4, 7, 2, 3].

Yang [18] describes a number of challenges for the testing of parallel software: 1) developing static analysis; 2) detecting unintentional races and deadlock in nondeterministic programs; 3) forcing a path to be executed when nondeterminism might exist; 4) reproducing a test execution using the same input data; 5) generating the control flow graph for nondeterministic programs; 6) providing a testing framework as a theoretical base for applying sequential testing criteria to parallel programs; 7) investigating the applicability of sequential testing criteria to parallel program testing; and 8) defining test coverage criteria based on control and data flow.

Lei and Carver [7] proposed the *reachability testing* for generating all feasible synchronization sequences (and only them). This method guarantees that every partially-ordered synchronization will be exercised exactly once without repeating any sequences that have already been exercised. The method involves the execution of the program in a semi-deterministic way; the execution is deterministic up to a given point, from which it runs nondeterministically. The resulting synchronization sequence (sync-sequence), which is feasible, is analyzed and a new feasible sequence (if possible) is computed. The authors employ a reachability schema to calculate the synchronization sequence automatically. The reachability testing uses dynamic information to execute all feasible synchronization sequences, generating all *race variants* from one particular execution.

The reachability testing process is illustrated in Figure 1 (extracted from [7]). The figure shows a space-time diagram in which vertical lines represent four threads of a concurrent program. The interaction between processes is represented by arrows from a send event to a receive event. Diagram Q_0 shows the one execution of the program, generating the synchronizations: (s_1^{T1}, r_1^{T2}), (s_2^{T4}, r_2^{T2}), (s_3^{T2}, r_3^{T3}), (s_4^{T4}, r_4^{T3}). V_1, V_2 and V_3 are *race variants* of Q_0 and feasible executions generated during reachability testing execution. A problem here is the high number of possible combination of synchronization that are generated and (for complex software) this number can be very high, restricting any practical application of the strategy. This approach has the important advantage that it will generate only feasible synchronization sequences, which is an important consideration when reducing the cost of the testing activity.

2.1. Structural Testing for Concurrent Programs

In this section we describe our test model and criteria for validation of message-passing software [14]. The test model captures control, data and communication information. The model considers that a fixed and known number of processes n is created at the initialization of the concurrent application. These processes may each execute different programs. However, each one executes its own code in its own memory space. The concurrent program is defined by a set of n parallel processes $Prog = \{p^0, p^1, \ldots p^{n-1}\}$. Each process p has its own Control Flow Graph CFG^p, that is built using the same concepts as traditional software [10]. In other words, a CFG of a process p is composed of a set of nodes N^p and a set of edges E^p. Each node n in the process p is represented by the notation n^p and corresponds to a set of commands that are sequentially executed or can be

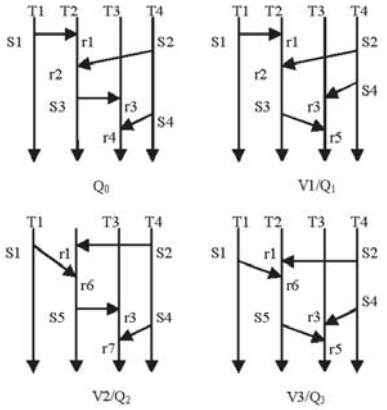

Figure 1. Example of reachability testing [7]

associated to a communication primitive (send or receive). The model considers both blocking and non-blocking receives, such that all possible interleaving between send-receive pairs can be represented. $Prog$ is associated with a Parallel Control Flow Graph ($PCFG$), which is composed of the CFG^p (for $p = 0 \ldots n-1$) and by the representation of the communication between the processes. A synchronization edge (sync-edge) (n_i^a, n_j^b) links a *send* node in a process a to a *send* node in a process b. These edges represent the possibility of communication and synchronization between processes.

A set of coverage testing criteria is defined, based on ($PCFG$): All-Nodes; All-Edges; All-Nodes-R; All-Nodes-S and All-Edges-S (related to control and synchronization information) and All-C-Uses; All-P-Uses; All-SUses; All-S-C-Uses and All-S-P-Uses (related to data and communication information) [14]. The All-Edges-S criterion requires that the test set executes paths that cover all the sync-edge associations of the concurrent program under testing; the All-S-uses criterion requires that the test set executes paths that cover all the *s-use* associations. An *s-use* is an association between a node n^p, that contains a definition of a variable x, and a sync-edge that contains a communications use of x.

An example of a $PCFG$ is shown in Figure 2. There are four processes, consisting of two different codes. Synchronization pairs are represented by dotted lines — for example, the pair $(2^0, 2^m)$ is one sync-edge between process p^0 and p^m. Each sync-edge is associated with one or more s-use associations, and related to a variable represented in $PCFG$.

Nondeterminism is the key issue addressed in this test model. As it is impossible to determine statically when a synchronization is feasible, a conservative approach is assumed, where every pair of send and receive events which have the appropriate types are considered

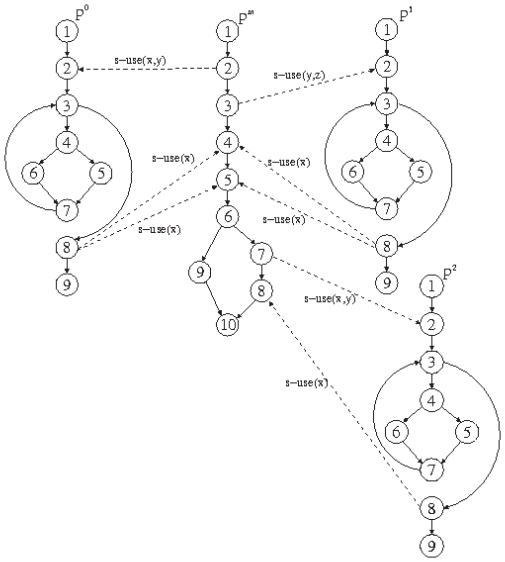

Figure 2. Example of a Parallel Control Flow Graph

as a possible matching. Considering the example of Figure 1, the required sync-edges are: (s_1^{T1}, r_1^{T2}), (s_2^{T4}, r_1^{T2}), (s_4^{T4}, r_1^{T2}), (s_1^{T1}, r_2^{T2}), (s_2^{T4}, r_2^{T2}), (s_4^{T4}, r_2^{T2}), (s_1^{T1}, r_3^{T3}), (s_2^{T4}, r_3^{T3}), (s_3^{T2}, r_3^{T3}), (s_4^{T4}, r_3^{T3}), (s_1^{T1}, r_4^{T3}), (s_2^{T4}, r_4^{T3}), (s_3^{T2}, r_4^{T3}), (s_4^{T4}, r_4^{T3}). Some sync-edges are infeasible (e.g., (s_1^{T1}, r_3^{T3})) but are required. Using controlled execution [2], it is possible to force the execution of feasible sync-edges.

It is not necessary to execute all combinations of possible synchronization as long as at least one execution of each sync-edge pair is included. A problem in this approach is the high number of infeasible sync-edges that are generated and need to be analysed. Nevertheless, it is interesting because it uses information generated statically to direct the selection of test cases and to assess the coverage of the program under test. We believe that the choice of the test case can influence the results obtained, improving the overall testing activity quality. This has led directly to the test strategy presented in the next section.

3. Proposed test strategy

In this paper we propose a test strategy that combines both reachability testing and coverage testing to execute synchronization events. The main motivation of this strategy is to improve coverage testing; however, the approach can also be applied to improve reachability testing perfor-

mance. In this case, reachability testing can be applied using an approach that selectively exercises a set of sync-sequences according to a specified coverage testing criterion. Exhaustive testing is not always practical and they pointed out the need to use mechanisms to guide the selection of the sync-sequences during reachability testing [7].

In Figure 3 the proposed test strategy is illustrated. This figure does not show all the steps necessary to apply the coverage testing criterion, only those important to our strategy.

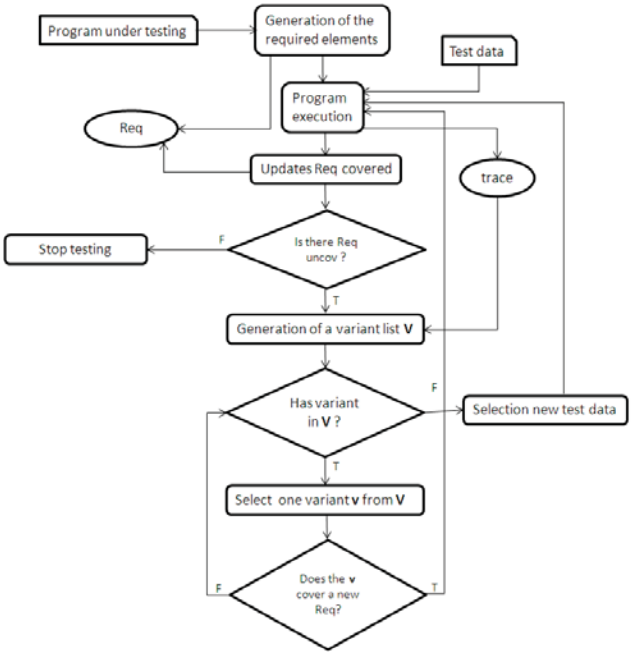

Figure 3. Test Strategy using Reachability Testing and Coverage Testing Criterion

First, a required elements list Req is generated from a given concurrent program, based on the all-s-uses and all-edges-s criteria. An initial test dataset is produced and the program is executed to generate an execution trace, containing a record of all the nodes and the sync-edges executed by the test dataset. The elements covered by the test dataset execution are marked in Req and any required element not yet covered identified. Usually, a procedure is used to select a new test dataset to improve the coverage of Req.

Considering reachability testing in this context, the next step is the generation of a list V of the variants, based on the sync-edges executed. For each sync-edge all possible variants are then generated. The difference here from reachability testing, is that only the variants required to cover a required element that is not yet covered are included. Therefore, when a new variant v is selected from V, it is verified only if it executes a new requirement of Req. Otherwise, another variant is selected or a new test dataset is generated (when V is empty). The procedure to execute a variant v is the same as that defined by Lei and Carver [7]: the controlled execution ensures that the synchronization of the v always occurs during the execution. After execution of the variant v, the execution trace is obtained and the required elements covered for this execution are marked in list Req. Considering now the variant v, new variants are generated and added to the list of the variants V. The procedure to execute variants or new test datasets is repeated while any required elements remain to be covered.

4. Experimental Study

In this section, we present an experimental study that indicates that the approach combining reachability and coverage criteria testing improve overall testing quality. The ValiMPI tool was used to conduct this study. ValiMPI is a tool developed to test concurrent programs implemented in MPI (Message Passing Interface), proposed originally to support the coverage testing mentioned in Section 2 [13, 6]. ValiMPI functionality has been extended to implement the reachability testing strategy proposed by Lei and Carver [7] and hence test the strategy proposed in this paper.

Eight different MPI programs were used in this study, implementing classical concurrency algorithms. The complexity is given by the number of sends s and receives r of each program: **sieve of Eratosthenes** - (7s and 9r) an algorithm for finding all prime numbers up to a specified integer [9]; **gcd** - (7s and 7r) to calculate the greatest common divisor of three numbers, using successive subtractions between two numbers until one of them is zero; **mmult** - (15s and 27r) to implement matrix multiplication using domain decomposition; **philosophers** - (11s and 10r) to implement the dining philosophers problem; **pairwise** - (16s and 16r) where each process n_i receives a data X_i and is responsible for computing the interactions $I(X_i, X_j)$,for $i \neq j$. For this, a structure with N channels is used, where each communication channel represents a pair source-destination — these channels are used to connect the N tasks into a unidirectional ring; **reduction** - (4s and 4r) to implement the reduction operation of distributed data, considering add, multiplication, greater than and less than operations; **qsort** - (28s and 52r) to implement quicksort, based on the parallel algorithm presented in Grama [5]; and **jacobi** - (23s and 37r) to implement Jacobi-Richardson iteration for solving a linear system of equations.

Three different test scenarios were executed:

1. **Selection of adequate test case using coverage criteria (CovT)**: using the criteria all-s-uses and all-edges-s, test cases were manually generated to exercise the required elements of these criteria, s-use associations

and sync-edges, respectively. Infeasible elements were identified to evaluate the coverage of an initial test set.

2. **Application of reachability testing (RT)**: using the initial test set generated during Scenario CovT, reachability testing was undertaken, according to the algorithm proposed by Lei and Carver [7].

3. **Application of our test strategy (RTCovT)**: using the criteria all-s-uses and all-edges-s, (related to synchronization), reachability testing was executed guided by the required elements of these criteria, following the steps discussed in Section 3.

Table 1 presents the sync-sequences generated by Reachability Testing (column RT) and by our test strategy (column RTCovT), using two different test sets: T_1, generated by CovT and containing test cases adequate to execute both sync-edges and s-uses; and T_2, which is a subset of T_1 containing only effective test cases (i.e. T_2 contains only test case contributing to the execution of the sync-edges). RT executes, for each test case, all variants of the each sync-edge, even those variants already executed previously. For this reason, the number of the sync-sequences generated by RT is higher than the sync-sequences generated by our test strategy. These results indicate that is possible to reduce the cost of the reachability testing using coverage testing. A fundamental problem with reachability testing is to decide when the testing activity can be considered complete; our test strategy contributes to the work on this problem. We compared the advantages of using our test strategy compared to the alternatives discussed previously.

Table 1. Number of the sync-sequences executed

Programs	T1	T1		T2	T2	
		RT	RTCovT		RT	RTCovT
sieve	10	60	13	4	20	7
gcd	13	24	14	7	14	9
mmult	8	48	11	4	24	5
philosophers	1	1680	2	1	1680	2
pairwise	4	4	4	1	1	1
reduction	4	4	4	1	1	1
qsort	3	794	18	3	266	16
jacobi	9	1710	13	6	377	11

Table 2 shows the results of the coverage obtained using the coverage testing (CovT) and our test strategy (RTCovT) for all-edges-s and all-s-uses criteria. For this analysis, for each program, the same test set T (generated on an *ad-hoc* basis) was used to execute the two test scenarios and the two coverage criteria. Our test strategy (RTCovT) indicates the potential to improve the criteria coverage because our strategy executes a greater number of sync-edges and s-uses than the traditional coverage testing, establishing that it is a good strategy to reduce the overall application cost of the test. Some of the programs in the test had no improvement in coverage because in these cases the T set already covered all feasible elements for the criteria.

Table 2. Coverage using coverage criteria and the test strategy

Programs	All-Edges-S		All-S-Uses	
	CovT	RTCovT	CovT	RTCovT
sieve	80.95%	90.48%	56.67%	76.67%
gcd	100.00%	100.00%	80.00%	85.00%
mmult	93.33%	93.33%	94.74%	94.74%
philosophers	100.00%	100.00%	75.00%	75.00%
pairwise	100.00%	100.00%	83.33%	83.33%
reduction	100.00%	100.00%	100.00%	100.00%
qsort	51.61%	89.25%	43.54%	67.35%
jacobi	100.00%	100.00%	84.06%	85.51%

Table 3 shows the results for the Jacobi algorithm example as different test cases ($tc1$ to $tc9$) are processed. Our testing strategy always provides better test coverage and maximal coverage is achieved after only five test cases have been considered. Table 4 provides similar results for the mmult algorithm example with test cases $tc1$ to $tc8$. For this example maximum coverage is achieved after only two of the test cases have been considered.

Table 3. Evolution of the jacobi program coverage

testcases	All-Edges-S		All-S-Uses	
	CovT	RTCovT	CovT	RTCovT
$tc1$	19.30%	19.30%	8.70%	8.70%
$tc2$	38.60%	49.12%	26.09%	34.78%
$tc3$	82.46%	94.74%	60.87%	71.01%
$tc4$	84.21%	96.49%	68.12%	78.26%
$tc5$	94.74%	100.00%	78.26%	82.61%
$tc6$	94.74%	100.00%	78.26%	82.61%
$tc7$	94.74%	100.00%	78.26%	82.61%
$tc8$	100.00%	100.00%	82.61%	84.06%
$tc9$	100.00%	100.00%	84.06%	85.51%

5. Conclusions

In this paper we have presented a new test strategy to validate concurrent programs, using a combination of coverage criteria and reachability testing. The coverage criteria are used both to select test cases and to determine the execution of new synchronizations, while the reachability testing is used to select appropriate synchronizations to be executed.

Table 4. Evolution of the mmult program coverage

testcases	All-Edges-S		All-S-Uses	
	CovT	RTCovT	CovT	RTCovT
$tc1$	60.00%	93.33%	63.16%	89.47%
$tc2$	60.00%	93.33%	68.42%	94.74%
$tc3$	73.33%	93.33%	78.95%	94.74%
$tc4$	86.67%	93.33%	89.47%	94.74%
$tc5$	86.67%	93.33%	89.47%	94.74%
$tc6$	86.67%	93.33%	89.47%	94.74%
$tc7$	86.67%	93.33%	89.47%	94.74%
$tc8$	86.67%	93.33%	94.74%	94.74%

The combination of the two approaches has the potential to deliver significant reduction in the overall testing cost. Due to the high number of synchronizations in a typical concurrent program, the execution of these synchronizations using reachability testing alone can be impractical; while in the case of the coverage criteria used by itself, these synchronizations generate a high cost because of the number of infeasible synchronizations that must be analyzed.

The test strategy described in this paper contributes in two ways: 1) by using structural criteria to minimize the number of sequences in reachability testing; and 2) by guiding the generation of test cases based on the structural criteria, using reachability testing to increase the test coverage. An experimental study has been undertaken to evaluate this approach. The results indicate that is promising to adopt this test strategy, with an improvement in test coverage in every case considered.

Finally, we plan to evaluate the proposed test strategy in terms of revealing faults. Preliminary results have demonstrated that our strategy is effective in detecting faults. The test sets discussed above were evaluated using the fault taxonomy presented in [4] and 84.8% of the seeded defects were revealed on average. Further studies are being developed using different fault taxonomies and comparing the effectiveness of our strategy with the effectiveness of reachability testing.

Abstract

Spectrum-based fault localization technique mainly utilizes testing coverage information to calculate the suspiciousness of each program element to find the faulty element. However, this technique does not fully take consideration of dependences between program elements , thus its capacity for efficient fault localization is limited. This paper combines program slicing with program spectrum technique, and proposes a program slicing spectrum-based software fault localization (PSS-SFL) technique. Firstly, PSS-SFL analyzes dependences between program elements, and deletes some elements unrelated to the failed test outputs; then it builds the program slicing spectrum model and defines a novel suspiciousness metric for each slice element; finally, the faulty element is located according to the suspiciousness metric results. Experimental results show that PSS-SFL can be effective and more precise to locate the fault than program spectrum-based Tarantula technique.

***Keywords*-Fault localization, program slicing spectrum, program slicing, program spectrum**

I. Introduction

A software fault is an incorrect step, process, or data definition in a computer program [1]. Software fault localization is to locate the fault that cause software failure. According to Collofello's research, in an attempt to reduce the number of delivered errors, it is estimated that most companies spend between 50% and 80% of their software development effort on testing [2], while software fault localization is one of the most complex and difficult tasks during the process of reducing the number of errors. There are two traditional ways to locate software faults: the first way is to insert print statements into the program, and then analyze the suspicious statements according to the print result; the second way is to set a breakpoint at some statement, and then single step to the next statement and determine whether the statement is faulty or not. Both ways above have to be performed manually. When the program is complex and large-scale, it is difficult to fully analyze the fault and the work will be very huge. So these two traditional ways above are not very efficient.

Program slicing technique was firstly proposed by Weiser [3]. It can abstract program's statements according to a specific criterion, so the fault in the program can be limited to a small region, that is, a relevant slice. Program slicing technique includes static program slicing technique and dynamic program slicing technique. Software fault localization based on static program slicing [4][5] analyzes the data flow and control flow of the program statically to reduce the search domain of faults. However, because the static program slicing is overly conservative, the precision of locating fault is very low. Based on static program slicing technique, dynamic technique [6][7] introduces more precise slicing criterion and the search domain of faults can be further reduced.This paper firstly abstracts the dynamic slicing criterion according to the failed test information, then constructs a fault-related slice to locate the fault.

In recent years, program spectrum-based software fault localization [8][9] was proposed, which can be applicable to the large-scale program and easy to implement. A program spectrum characterizes, or provides a signature of a program behavior [10]. Generally speaking, the collection of program spectrum is very simple, moreover, its storage is easy, so it can be suitable for situations with limited resources. Program spectrum-based software fault localization technique first statistically analyzes program spectrum and computes the probability that each

program element may include faults, commonly known as suspiciousness; then program elements are checked according to the descending order of the suspiciousness until the fault is found. Researches show that even for the lowest quality of programs, only 20% of the program code remains to be investigated to locate the fault with the program spectrum-based technique [9][11]. However, this technique does not fully take consideration of dependences between program elements, thus its capacity for efficient fault localization is limited. This paper combines program slicing with program spectrum technique, and proposes a program slicing spectrum-based software fault localization (*PSS-SFL*) technique. The main contributions of this paper are as follows:

(1) We delete program elements that have no dependence with the fault program elements by program slicing technique and construct a fault-related slice according to the test information,and then propose a program slicing spectrum-based software fault localization model.

(2) Based on the popular suspiciousness metric technique, we propose a new suspiciousness metric technique by introducing the frequency and contribution of each program element.

(3) We verify the effectiveness of *PSS-SFL* technique with our experiment and compare *PSS-SFL* technique with the popular Tarantula technique based on program spectrum.

II. Preliminaries

A. Dynamic program slicing

A dynamic program slice [6][7] consists only of statements that influence the value of a variable for a specific program input. The location, variable and input are referred as the dynamic slicing criterion as Definition 1, then a dynamic program slice is abstracted from the program dependence graph as Definition 2 [6][12].

Definition 1 (Dynamic slicing criterion): Given a program P, P's variable set V and input set I, a dynamic slicing criterion C of the program P is a triple $< s, v, i >$, where $s \in P$ is a specific statement in P, $v \in V$ denotes a subset of the program variables and $i \in I$ means a specific input to the program P.

Definition 2 (Program dependence graph): Given a program P,P's program dependence graph is a two-tuple $< N, E >$, where N is a set of nodes which denote the statements in P, E is a set of edges which consist of control dependence edges and data dependence edges. A control dependence edge $< v_i, v_j > \in E$ shows node v_i is executed depending on the output of the predicate expression at node v_j and a data dependence edge $< v_i, v_j > \in E$ indicates that the computation performed at vertex v_i directly depends on the value computed at vertex v_j.

Table I. *PSS-SFL* **model**

Program	Test cases						Suspiciousness
	Failed			Passed			
	T_1	...	T_s	T_{s+1}	...	T_m	
e_1	$b_{1,1}$	...	$b_{1,s}$	$b_{1,s+1}$	...	$b_{1,m}$	p_1
e_2	$b_{2,1}$	...	$b_{2,s}$	$b_{2,s+1}$	...	$b_{2,m}$	p_2
...	...	...	...	...	...	...	...
e_n	$b_{n,1}$	...	$b_{n,s}$	$b_{n,s+1}$	...	$b_{n,m}$	p_n

B. Program spectrum-based software fault localization

Recently, many researchers have proposed various fault localization techniques based on program spectrum[8][9][10][11][13][14][15][16]. Generally speaking, these techniques mainly include three steps: (1) collect coverage information of program elements based on test executions; (2) compute the element suspiciousness based on coverage information; (3) locate the fault according to the suspiciousness in a descending order. Program spectrum is usually defined as follows:

Definition 3 (Program spectrum): Given a program P, n is the number of elements in P and $T = T_F \cup T_P$ is a set of test executions where $T_F = \{T_1, ..., T_s\}$ is the set of failed test executions and $T_P = \{T_{s+1}, ..., T_m\}$ is the set of passed ones, then program spectrum is a two dimensional matrix $M_{n,m}$: $\forall b_{i,j} \in M_{n,m}$,

$$\mathrm{b}_{i,j}=\begin{cases} 1 & T_j \text{ covered } e_i \\ 0 & \text{otherwise} \end{cases}, (1 \leq \mathrm{i} \leq \mathrm{n}, 1 \leq \mathrm{j} \leq \mathrm{m})$$

A visual model of program spectrum-based software fault localization is shown in the following table. Rows of the table denote corresponding elements in the program and columns $T_1, \ldots, T_m$ indicate the number of test executions is m including s failed ones and $m-s$ passed ones. $b_{i,j}$ is the element of program spectrum matrix with value 1 or 0 which indicates whether T_j executed the element e_i or not. The last column is the suspiciousness of its corresponding element. The metric of suspiciousness is usually based on the following assumptions: the more failed tests and the less passed ones that executed the element e_i, the greater likelihood that e_i is faulty, that is, in the table, the larger value of $\sum_{i=1}^{s} b_{i,j}$ and the smaller value of $\sum_{i=s+1}^{m} b_{i,j}$, the greater value of suspiciousness(e_i). So $suspiciousness(e_i)$ is generally defined as follows [8]:

Definition 4 (Suspiciousness):

$$suspiciousness(e_i) = \frac{failed(e_i)\%}{failed(e_i)\% + passed(e_i)\%}$$

In the definition above, $failed(e_i)\%$ is the percentage of failed tests that executed e_i in total failed tests, and $passed(e_i)\%$ is the percentage of passed tests that executed e_i in total passed tests. In general, different researchers have different definitions to $failed(e_i)\%$ and $passed(e_i)\%$, but their targets are all to locate

the faulty element more precisely by the computation of $suspiciousness(e_i)$. This paper defines a new suspiciousness metric based on popular Tarantula's suspiciousness metric by defining a different $failed(e_i)\%$ and $passed(e_i)\%$.

III. program slicing spectrum-based software fault localization

A. Program slicing spectrum model

Traditional program spectrum-based fault localization technique considers all elements of a test execution, but the elements are not all related to the test output,so we introduces the program slicing technique to delete the unrelated elements to the fault and improve the precision of fault localization.

To more effectively locate faults, we firstly collect fault related slice according to the failed test executions:

Definition 5 (Fault-related slice): Given a set of test executions T=$T_F \cup T_P$, where T_F =$T_1, \ldots, T_s$ is the set of failed test executions and T_P=$T_{s+1}, , T_m$ is the set of passed ones, Let $Slice(T_i)$ $(i = 1, \ldots, m)$ be the dynamic slice corresponding to the test execution T_i, then fault-related slice is an elements set $Slice = Slice(T_1) \cup Slice(T_2) \cup \ldots \cup Slice(T_s)$.

Based on the above definition, program slicing spectrum is defined as follow:

Definition 6 (Program slicing spectrum): Given a set of test executions $T = T_F \cup T_P$, where $T_F = \{T_1, \ldots, T_s\}$ is a set of failed test execution and $T_P = \{T_{s+1}, \ldots, T_m\}$ is the set of passed ones, let the number of elements in $Slice$ be n, that is n=$|Slice|$, then program slicing spectrum is a two-dimensional $M_{n,m}$: $\forall f_{i,j} \in M_{n,m}$(1≤i≤n, 1 ≤j≤m), $f_{i,j}$=$\begin{cases} k & \text{the frequency that } T_j \text{ exceuted } e_i \text{ in } Slice \\ 0 & \text{otherwise} \end{cases}$

B. suspiciousness model

Program spectrum-based software fault location technique is performed based on the suspiciousness metric. Definition 4 gives a popular suspiciousness model. This paper improves the traditional computing algorithm of $failed(e_i)\%$ and $passed(e_i)\%$ by introducing the execution frequency and contribution of each program element. The popular definition of $failed(e_i)\%$ and $passed(e_i)\%$ is proposed in Tarantula technique as follows:

$$failed(e_i)\% = \frac{a_{11}(e_i)}{a_{11}(e_i)+a_{01}(e_i)}, passed(e_i)\% = \frac{a_{10}(e_i)}{a_{10}(e_i)+a_{00}(e_i)}$$

In the formula above,$a_{11}(e_i)$ represents the number of failed tests that executed the element e_i,$a_{01}(e_i)$ represents the number of failed tests that didn't execute the element e_i,$a_{10}(e_i)$ represents the number of passed tests that executed the element e_i, $a_{00}(e_i)$ represents the number of passed tests that didn't execute the element e_i. Obviously, Tarantula technique computes the suspiciousness of each program element by counting the number of failed tests and passed tests that executed the element. When different tests executed the same element, the contribution of the element to each test result is considered to be equal. That is, in Table I, Tarantula technique just considers if e_i was executed by each test and just counts the number of 1 of the line e_i. In reality, the number of program elements that each test executed is different and the frequency that each program element is executed is also different, so the contribution of a program element to different test result is unequal. For example, if a test just executed a program element, then the contribution of this program element to the test result is 100%; while this test executed two program elements and each element was executed one time, the contribution of each program element to the test result is 50%. The contribution can be computed from the column of program spectrum matrix. Below is our definition of $failed(e_i)\%$ and $passed(e_i)\%$:

$$failed(e_i)\% = \frac{\sum_{j=1}^{m} P_{T_j} \times C_{i,j}}{\sum_{j=1}^{m} P_{T_j}}, passed(e_i)\% = \frac{\sum_{j=1}^{m} (1-P_{T_j}) \times C_{i,j}}{\sum_{j=1}^{m} (1-P_{T_j})},$$

$$\text{where } C_{i,j} = \frac{f_{i,j}}{\sum_{k=1}^{n} f_{k,j}}, P_{T_j} = \begin{cases} 1 & T_j \text{ is failed} \\ 0 & T_j \text{ is passed} \end{cases}$$

In the formula above, $C_{i,j}$ represents the contribution of the program element e_i to the test execution T_j where $f_{i,j}$ is the frequency of e_i that is executed by T_j and details are shown in Definition 6. P_{T_j} with value 1 represents that T_j is a failed test execution, otherwise P_{T_j} is assigned a value 0. Denominators of $failed(e_i)\%$ and $passed(e_i)\%$ represent the number of failed test executions and the number of passed ones; their numerators represent the sum of the contributions of program elements to each failed test execution and passed one. These are different from the suspiciousness metric in Tarantula technique.

When the suspiciousness of each program element is obtained, the fault can be located according to the suspiciousness in a descending way.

C. Program slicing spectrum-based software fault localization model

According to the definition of program slicing spectrum and suspiciousness model, a visual model of program slicing spectrum-based software fault localization is shown in Table II. Rows of the table denote corresponding elements in the fault-related slice $Slice$ and columns $T_1, \ldots, T_m$indicate m test executions where the number of failed ones is s and passed ones is $m - s$. $f_{i,j}$ (1 ≤i≤n, 1 ≤j≤m) is the element of program slicing spectrum matrix with value k or 0 which means the

Table II. *PSS-SFL* **model**

Slice	Test cases						Suspiciousness
	Failed			Passed			
	T_1	...	T_s	T_{s+1}	...	T_m	
e_1	$f_{1,1}$	...	$f_{1,s}$	$f_{1,s+1}$	...	$f_{1,m}$	p_1
e_2	$f_{2,1}$	...	$f_{2,s}$	$f_{2,s+1}$	...	$f_{2,m}$	p_2
...	...	...	...	...	...	...	...
e_n	$f_{n,1}$	...	$f_{n,s}$	$f_{n,s+1}$	...	$f_{n,m}$	p_n

frequency that T_j executed the element e_i . The last column is the suspiciousness of each corresponding element by the computation in the above section. Obviously, *PSS-SFL* technique greatly improves traditional program spectrum-based technique. It reduces the scale of the traditional spectrum, introduces the frequencies of program elements and defines contributions for suspiciousness metric.

Program slicing technique firstly abstracts corresponding slicing criterion, and then generates the slice by traversing program dependence graph. *PSS-SFL* technique generates the fault-related slice according to the failed test executions information, and then constructs program spectrum according to history test executions and finally computing the suspiciousness of each element in the fault-related slice.

IV. Experiment

In this section, we will verify the effectiveness of *PSS-SFL* and compare its precision of locating faults with popular Tarantula techniques.

A. Object of analysis

Many current researches on software fault localization use siemens suite as their object. Siemens suite consists of seven C programs and each program has several hundred lines of code. Because each program in siemens suite is mainly composed of branch structures, program spectrum-based software fault localization techniques generally have a high precision on these programs and *PSS-SFL* has not obvious advantages. This section uses a practical JAVA tool program *JAVA Hierarchical Slicing and Applications* (*JHSA*) as our object of analysis.*JHSA* program includes three packages, twenty-six classes and 11201 lines of code in all, which is used to construct a hierarchical system dependence graph for JAVA program, and to compute its hierarchical slice. We totally select 178 faulty versions for this experiment.

B. Experiment design and analysis

In this study, experiment data collection and analysis are conducted in four steps: first, collect program elements

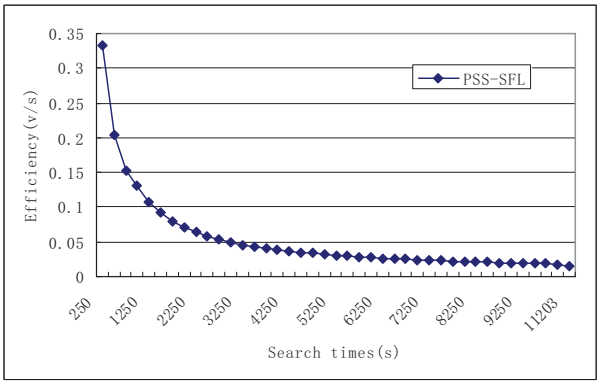

Figure 1. The effectiveness of *PSS-SFL*

coverage information by the tool eclemma and count the frequencies of the program elements; second, abstract the fault-related slice by a slicing tool *JHSA* according to the failed tests; third, construct the program slicing spectrum matrix based on the steps above; finally, compute the suspiciousness as depicted in the above section and locate faults according to the suspiciousness of each program element in a descending order.

To evaluate the effectiveness of *PSS-SFL*, an efficiency score is used in this experiment. Given v is the number of versions in which faults have been successfully located and s is the number of program elements that have been searched for locating faults in each version.we evaluate the effectiveness with following formula:

$$Efficiency = \frac{v}{s}$$

In the formula above, efficiency means that the number of versions in which faults have been successfully located when searching s elements in each version. Here, s can be also referred as search times. In the ideal case, if the value of s is 1 and the value of v is the number of total versions, efficiency denotes that this technique can once find faults in all versions and its efficiency is the highest.

C. Result and analysis

In this section, we verify the effectiveness of *PSS-SFL* and compare its precision of locating faults with popular Tarantula techniques with the above efficiency score.

Figure 1 shows the relation between the efficiency of *PSS-SFL* and search times. In the figure, with the increase of search times, the efficiency reduced. This implies *PSS-SFL* technique can quickly locate most faults at the beginning, and only a small number of faults need to be searched many times further, so the technique is very effective.

Figure 2 shows the relation between search times and the number of versions and compares *PSS-SFL* with Tarantula technique. In the figure, when the value of search times

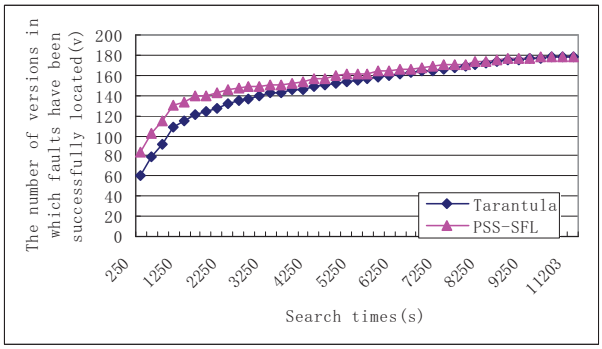

Figure 2. The comparation between *PSS-SFL* and Tarantula technique

is about 250, the number of versions in which faults have been found with *PSS-SFL* is nearly 80, while the value with Tarantula is about 60. In this experiment, the number of all versions is 178, so when searching 250 times, *PSS-SFL* can find faults in nearly half versions and Tarantula about one third. Moreover, Figure 2 shows *PSS-SFL* can be more effectively and precisely locate faults most of the time than Tarantula technique.

D. Threads to validity

According to the experiment above, *PSS-SFL* technique can effectively and precisely locate faults. However, there are some threads to the experiment.

First, the scale of the object of analysis is still relatively small. It is a real application program, so, to some extent, it can verify the effectiveness and precision of *PSS-SFL*. However, it still needs to be verified for the larger scale program. In addition, with the increase of sequential structures in programs, the precision of Tarantula technique will reduce. Although *PSS-SFL* introduce program slicing technique to reduce this degradation to some extent, but this degradation also exists in the *PSS-SFL* technique.

Second, if program fault is caused by the omission of some element, we can locate the fault to its prior element close to the position of omission element. Then, we can find the corresponding fault from this prior element, but this needs some manual analysis.

Third, because suspiciousness metric is based on the statistical number of failed test executions and passed test executions, the precision of suspiciousness will be reduced with the increase of the number of faults in a version. This problem exists in traditional program spectrum-based software fault location technique and also exists in *PSS-SFL* technique.

V. Related work

Because of the importance and difficulty of software fault localization, more and more software engineering researchers pay attention to this field. They proposed various techniques for locating faults such as techniques based on program slicing [3][4][5][17][18][19][20][21] and program spectrum [8][9][10][11][13][14][15][16]. This paper combines the program slicing and program spectrum, and proposes *PSS-SFL* technique, which can more effectively locate faults.

Most of program slicing based-software fault localization techniques locate faults using set operation between slices. Dicing technique [17] computes the difference between a failed slice and a passed slice to confine the fault to a small region; execution slice [18][19] is some program execution blocks according to some specific inputs, it can be abstracted more effectively than traditional slice, and this slicing technique generally computes the intersection and union between slices to locate faults. The idea of the union is first to compute the union of all passed slices, then to get the difference between a failed slice and the union; the way of the intersection is first to compute the intersection of all passed slices, then to obtain the difference between the intersection and a failed slice. Renieris proposed another difference between a failed execution slice and a passed slice that has a closest distance to the failed slice [20]. In addition to set operations, DeMillo proposed a critical slicing for locating faults based on ”statement deletion” mutant operation [21]. *PSS-SFL* technique is different from these techniques: Although this technique abstracts dynamic program slice for fault-related slice, it constructs a program slicing spectrum model and finally computes the suspiciousness to locate faults. *PSS-SFL* technique is more suitable for general cases.

Program spectrum includes program frequency spectrum and program hit spectrum. Their difference is that a frequency spectrum introduces the execution frequency of each program element and a hit spectrum only considers if program elements are covered or not. Traditional program spectrum-based software fault localization is mainly based on program hit spectrum. There are usually two methods to improve the effectiveness of program hit spectrum-based software fault localization. One is to improve the suspiciousness model. The common suspiciousness models mainly have Tarantula [8],Jaccard [9],Ochiai [9],etc. In addition, Wong [13] introduced the weight of test cases into the suspiciousness metric to improve the effectiveness. The other is to optimize the test cases by deleting unrelated or redundant test cases [22][23][24]. *PSS-SFL* technique is different from these techniques: *PSS-SFL* introduces program slicing technique to delete elements that have no dependence with faults; moreover, *PSS-SFL* is based on program frequency spectrum and has a different sus-

piciousness model by introducing the contribution of each program element.

VI. Conclusion and future work

This paper proposed an effective fault location technique, *PSS-SFL* technique. First, this technique abstracts fault-related slice and deletes elements that have no dependences with faulty elements to improve the precision of locating faults; second, it introduces the execution frequency and the contribution of each program element to improve the traditional suspiciousness metric; finally, an experiment is conducted to verify the effectiveness of this technique.

Although our experiment has verified the effectiveness of *PSS-SFL* on a practical program, the efficiency will be reduced with the increase of faults in a single program as other software fault localization technique, so our future work will focus on improving the efficiency of locating faults in multi-faults program.

Abstract— **One of several obstacles in automated test generation is the presence of dependencies among test data where not all combinations of test parameter values are feasible. In previous attempts, a subgraph splitting algorithm has been suggested where a graph model is created for test generation in order to reflect dependencies among test data. This paper extends these results and considers a new improvement of the algorithm that can significantly simplify the final model. We investigate this approach in a case study of an interface test case generation for the VirtualECU software system. Detailed graph models are developed to reflect all dependencies and generate all feasible test cases during VirtualECU interface testing.**

Keywords-testing; dependencies; subgraph splitting

I. INTRODUCTION

Testing of modern software systems is a complex process that requires a high level of automation, which is why the development of methods and tools for automated testing has become an important research area. One major obstacle to automated test generation is the presence of dependencies in test data, where not all combinations of test parameter values are feasible.

Different approaches to test generation with dependencies exist in the literature [1-4]. In previous works [6, 7], the first author of this paper has suggested a subgraph splitting algorithm, which reflects dependencies among test data in terms of a graph model. A tool for automatic model construction [8] was also developed. The graph model is used as a basis for test case generation then. Generation of test cases from the graph can be done manually or automatically using existing out-of-the-shelf tools, such as JUMBL [5]. This paper extends the previous results taking into consideration the following new materials:

- Improvement of the subgraph splitting algorithm by adding a new step (merging nodes), which can significantly simplify the final model.
- Application of the algorithm during interface testing.
- Reflection of more complex "one-on-two" dependencies.
- Practical application of the algorithm and interface test case generation for a real case study: VirtualECU [9] software system.

The rest of this paper is organized as follows: In Section 2.A, the specifics of dependencies during interface testing is analyzed. Section 2.B reviews the subgraph splitting algorithm and suggests a new step for merging nodes. VirtualECU, the software system that is used as a case study for the application of our approach, is described in Section 3. Section 4 contains detailed diagrams of graph models, created by the subgraph splitting algorithm for dependencies between interface options of the VirtualECU. Generation of test cases from these models is also considered in this section. Conclusions are presented in Section 5.

II. PROPOSED APPROACH

A. Dependencies During Interface Testing

In [6, 7], a graph input space model for test case generation and a subgraph splitting algorithm for creation of this model are suggested. Different types of input variables (discrete and continuous numerical data, symbols, strings, etc.) are considered and used as test parameters. The model reflects dependencies between values of input variables and is used for generation of feasible test cases.

For many types of software, a direct use of input variables is unnatural. Rather, a user chooses some interface options from menu bars, tool bars, buttons, etc., to actuate software functionalities. However, from the point of view of testing, these situations are very close. Similar to input variables, interface options can also be considered as values of test parameters. The choice of one interface option can affect possibilities for another. In other words, it is possible to have dependencies between interface options. Based on this, we can conclude that the subgraph splitting algorithm can be applied for interface testing.

Input information for the algorithm includes a list of test parameters and their values, and dependencies between these values. For interface testing, the test parameters are not directly defined and will be determined at the first stage of modeling. Some values of the test parameters may not be defined explicitly by the user. For example, some software functionalities can be different across user categories, but the category itself is not chosen explicitly. Users do not need to have any knowledge about the used gradation, and the users' category can be determined automatically based on user IDs during the log-in process.

Each dependency for the subgraph splitting algorithm should be described using "if-then" implications for test parameters values. Because of the presence of dependencies, some user actions that correspond with test parameters can be restricted or not even be applicable. A general description of the subgraph splitting algorithm is given in Section 2.A and a detailed example of the use of this algorithm for interface testing is discussed in Section 4.

B. Subgraph Splitting Algorithm

The initial start point of the algorithm is a linear direct labeled graph, which describes values of test parameters but does not include any dependencies between them. Any node in the graph corresponds with one test parameter. An ingoing edge of this node is labeled with values of this parameter. The subgraph splitting algorithm then uses a four-step approach to reflect each dependency at a time. The main step is subgraph splitting after which one test parameter corresponds with several nodes. The labels of edges are then changed according to dependency restrictions.

It is necessary to mention that the constructed graph does not coincide with other type of graphs widely used in software engineering and testing. It is not a control-flow or data-flow graph, neither is it a dependency graph used in constraint programming. Connected nodes do not represent any relationships between test parameters; rather they just reflect some arbitrary predefined order of the parameters. The graph represents dependencies between test parameters in such a way that

- Each path through the graph correlates with a set of independent feasible test cases.
- Fixing one value from the label of each edge of some path gives a feasible test case, i.e., a test case that satisfies all dependencies.
- The set of test cases, generated from all paths of the graph is a complete set of all feasible and only feasible test cases.

The algorithm contains the following four steps for each dependency. A more detailed description of the first three steps can be found in [7]. The fourth step is the new improvement of the algorithm, which allows simplifying a graph model in some situations. The steps of the algorithm are explained below for the dependency between test parameters $a \in A$ and $d \in D$: If $a \in A1$ then $d \in D1$, if $a \in A2$ then $d \in D2$, where A and D are sets of interface options, $A = A1 \cup A2$, $D = D1 \cup D2$, and $A1 \cap A2 = \emptyset$.

- *Step 1: Splitting a subgraph.* The subgraph includes all nodes for test parameters between a and d, including a but not including d. The subgraph is splitting (duplicating) and the new subgraph is connected with other nodes in the same way as the original subgraph. Adding the split subgraph creates new paths in the graph mode, which reflects the dependency between parameters.

- *Step 2: Labeling ingoing and outgoing edges of split subgraphs.* If some ingoing edge is labeled with a set I, then the label for this edge for the original subgraph changes to $I \cap A1$ and the label for the corresponding edge for the duplicated subgraph changes to $I \cap A2$. In much the same way, if some outgoing edge is labeled with a set O, then the label for this edge for the original subgraph changes to $O \cap D1$ and the label for the corresponding edge for the duplicated subgraph changes to $O \cap D2$.

- *Step 3: Eliminating dead nodes and edges.* After step 2, some edges can be labeled with the empty set. Such edges are considered as dead and should be eliminated from the graph model. After eliminating edges, some nodes can be without ingoing or outgoing edges. Such nodes are considered dead and also should be eliminated together with corresponding edges. This cycle should be repeated until all dead edges and nodes are eliminated.

- *Step 4: Merging nodes.* We suggest here this new step because it is possible that after Step 2, outgoing edges from two nodes may go to the same node and have the same labels. In such situations, these two nodes should be merged. This action simplifies the graph model and reduces the number of paths through the graph, eliminating paths that generate the same sets of test cases.

III. A Case Study: VirtualECU Software

VirtualECU is a software system for educational support processes developed in the Computer Science (CS) Department at East Carolina University (ECU), North Carolina. The system is composed of two different parts. The first part can be accessed by all visitors and serves as an informational site for the graduate programs offered by the CS department. The other part is designed to establish connections between the students and faculty of the department. It facilitates delivering course materials, lecture sharing, quiz and test taking, grade recording, etc. Accessing the latter part is restricted by user accounts and their special privileges. This second part of VirtualECU is our focus point in the case study.

There are three different user groups in VirtualECU: administrators, instructors, and students. Each group is assigned specific access levels and permissions. Users need to log into the system before being able to access the services. VirtualECU functions with a bidirectional interactive mechanism. Instructors design, create, and upload course materials such as lectures, quizzes, and tests. They may also put a time limit on those materials. Students have access to these materials; they take quizzes, submit assignments, etc. Instructors review and grade student submissions and update records, which can also be checked by students. There are two presentation modes in VirtualECU: List view (Figure 1) and Calendar view (Figure 2). In the List view, a list of existing materials is shown to the user as hyperlinks to allow access to details about course components. The Calendar view helps users access course materials using date tags (upload date, due date, etc.).

The system interface allows users doing typical actions, such as "open," "download," "upload," "delete," etc. Some scenarios may include a sequence of actions. Availability of actions depends on the group of users and course objects. For example, a student can download a lecture, but not a quiz, an administrator or instructor can change the date and time of some course objects, but a student cannot perform this action, etc. A more detailed discussion of the actions and their inter-dependencies are considered in the next section.

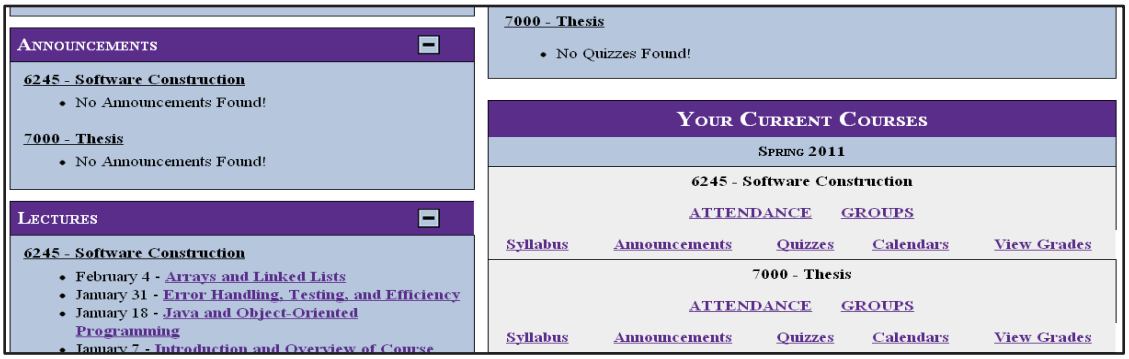

Figure 1. Fragment of VirtualECU List view

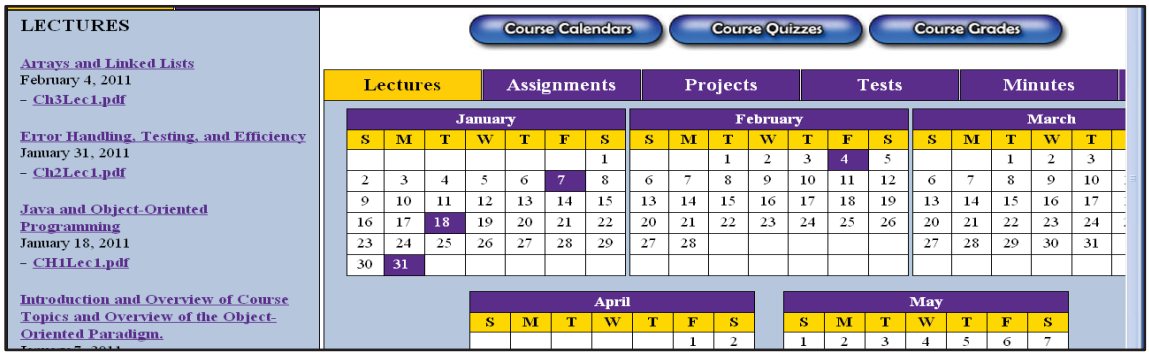

Figure 2. Fragment of VirtualECU Calendar view

TABLE I. TEST PARAMETERS AND THEIR VALUES

N	Test parameter	Values
1	User (*user)*	U={Student (std), Instructor (instr), Administrator (adm)}
2	Course object (*object)*	O={Quiz (q), Lecture (lec), Project (pr), Assignment (as), Announcement (an), Test (test), Note (note), Grade (grade), Attendance (at), Course Listing (col), Groups (gr)}
3	Time (*time*)	T={Passed (p), Ready(r), Waiting (w), not exist (ne), time independent (ind)}
4	Presentation (*pres*)	P={List (list), Calendar (cal)}
5	Action 1 (*act1*)	A1={Download (dw), Upload (up), Delete (del), Rename (ren) , Edit (ed), Open (op), N/A (na)}
6	Action 2 (*act2*)	A2={Select answer and save (ss), Select answer and continue (sc), Jump (jum), N/A (na)}
7	Action 3 (*act3*)	A3={Close (cl), Submit (sub)}

IV. VIRTUALECU TEST SPACE MODELING

A. Test parameters and dependencies

As a first stage of modeling, we grouped all interface options into eight test parameters. The parameters and their values are presented in Table 1. Provided in brackets are short identifiers that are used later in graph diagrams (Section 4.B).

There are two types of dependencies between VirtualECU test parameters: "one-on-one" and "one-on-two" dependencies. For the "one-on-one" dependency, values of one specific test parameter depend only on values of another one parameter. For example, parameter *time* depends on parameter *object*. For the "one-on-two" dependency, values of one specific test parameter depend on values of two other parameters at the same time, and this dependency cannot be presented as a composition of two "one-on-one" dependencies. For example, parameter *action1* depends on parameters *user* and *object*, but dependencies *user-action1* and *object-action1* do not exist separately.

There are two ways to deal with "one-on-two" dependencies. As a first approach, instead of two separate dependees, we can create one derived parameter-vector. For example, we can consider one parameter *user&object* with Cartesian product $U \times O$ as a set of values and then directly apply the subgraph splitting algorithm. The second approach is possible when a number of possible values of one of dependee is small. In this case, instead of one model with "one-on-two" dependency, it is possible to create several models (separately for each value of this parameter) with "one-on-one" dependency. In our case study, parameter *user* has only three values, so the second approach is applicable. Because of the limited space of the paper, we consider here graph models only for *user*=instructor. However, model for other users are similar; therefore, the models provided here fully illustrate the method of model creation by the subgraph splitting algorithm.

There are six dependencies among VirtualECU test parameters (Table 2). Dependencies 1, 2, 4, and 5 are for all users and dependencies 3 and 6 are formulated only for instructors.

TABLE II. DEPENDENCIES AMONG TEST PARAMETERS

N	Dependency	Values of dependee	Values of dependant
1	*object - time*	O_1={q, pr, as}	{p, r, w, ne}
		O_2={ lec, an, note, grade, at, gr, test}	{r, ne}
		{col}	{ne, ind}
2	*pres - act1*	{list}	A1\{up}
		{cal}	A1
3	*time - act1*	{p, w, r}	A1\{up}
		{ne}	{up}
		{ind}	{del, ed}
4	*user – act1*	{instr, adm }	A1\{na}
		{std }	A1
5	*user – act2*	{instr, adm }	{na}
		{std }	A2
6	*act1 – act3*	{dw, del, ren, up, na}	{cl}
		{op, ed}	A3

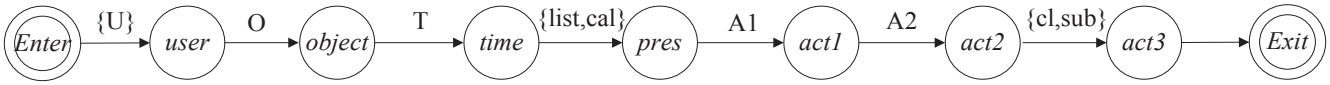

Figure3. Model for test parameters and their values (without dependencies)

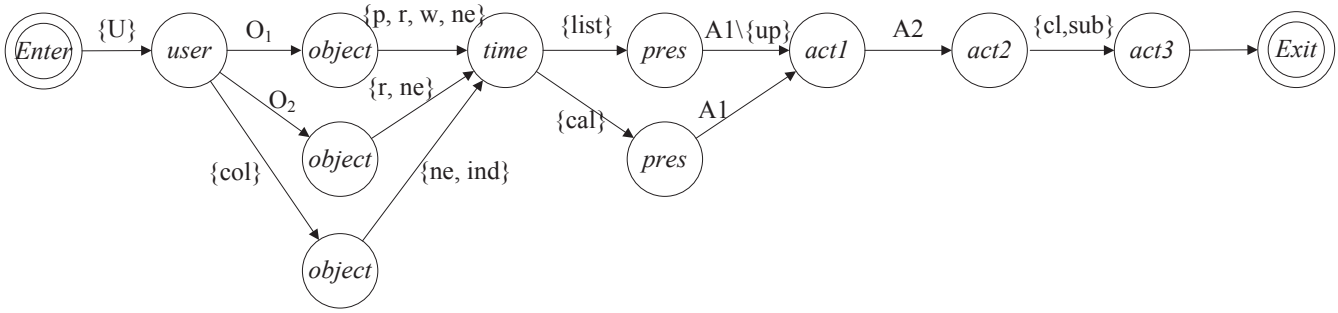

Figure 4. Model for dependencies 1 (between *object* and *time*) and 2 (between *pres* and *act1*)

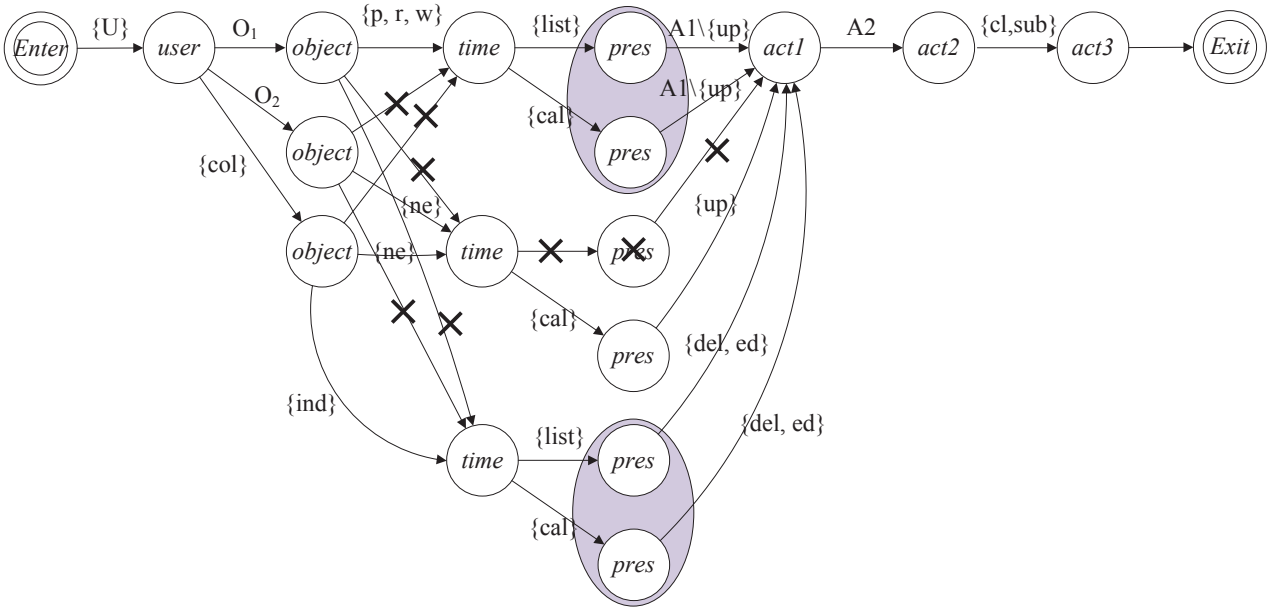

Figure 5. Model for dependency 3 (eliminating dead nodes and edges and merging nodes)

B. Graph models for dependencies

A graph model for dependencies is based on a simple linear graph where nodes represent test parameters, and ingoing arcs are labeled with all possible values of these parameters (Fig.3).

To reflect dependency 1 between and *time* parameters, *object* node should be split. For dependency 2 between *pres* and *act1* parameters, *pres* node should be split. Dependency 1 is described by three "if-then" implications (Table 2); therefore, there are three nodes for *object*. Dependency 2 is described by two "if-then" implications, and so *pres* node should be duplicated (Figure 4). There are no dead arcs, dead nodes, and nodes that should be merged.

For dependency 3 between *time* and *act1* parameters, the subgraph with nodes *time* and *pres* should be split into three identical subgraphs. After labeling ingoing arcs, some of the arcs are dead and should be eliminated (marked with crosses in Fig. 5). Also, there are two pairs of *pre* nodes, which outgoing arcs have the same labels (oval forms in Fig. 5). According to step 4 of the subgraph splitting algorithm, these nodes should be merged. The model for dependencies 1, 2, and 3, after eliminating dead nodes and edges and merging nodes, is given in Fig. 6.

Dependency 4 restricts the value of *act3* for instructors to be "na." Dependency 5 shows that the value of *act1* for instructors cannot be "na." Both these dependencies require only relabeling of the ingoing arc of *act1* and *act3* without splitting subgraphs. For dependency 6 between *act1* and *act3* parameters, one cycle of step 3 of the subgraph splitting algorithm is necessary for eliminating dead edges (we skip this diagram because of the limited space of the paper). The final model for dependencies 1 - 6 is presented in Fig. 7.

C. Test case generation

The final model in Fig. 7 contains six different paths through the graph. Each path represents a group of test cases, where the values of test parameters are labels of arcs of this path (Table 3).

The values of different parameters are independent and can be combined in any combinations. Together, these test cases form a set of all feasible and only feasible tests that satisfy all dependencies. For instructor mode, the total number of feasible test cases is 140.

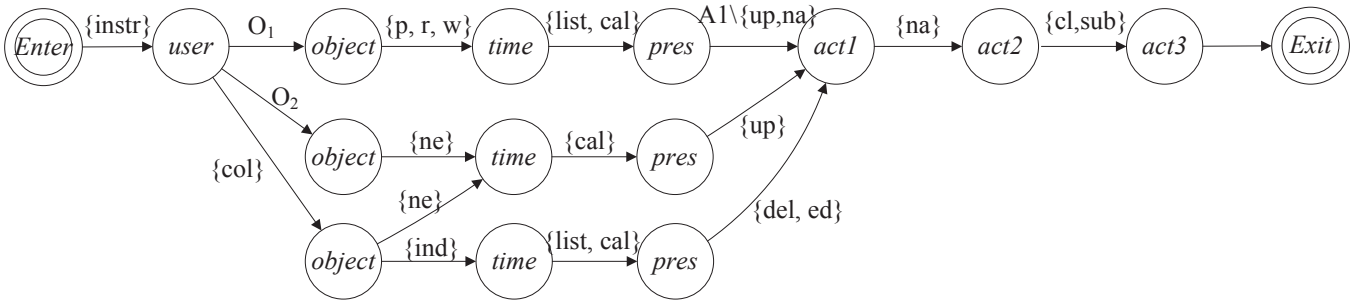

Figure 6. Model for dependency 3 between *time* and *act1* parameters

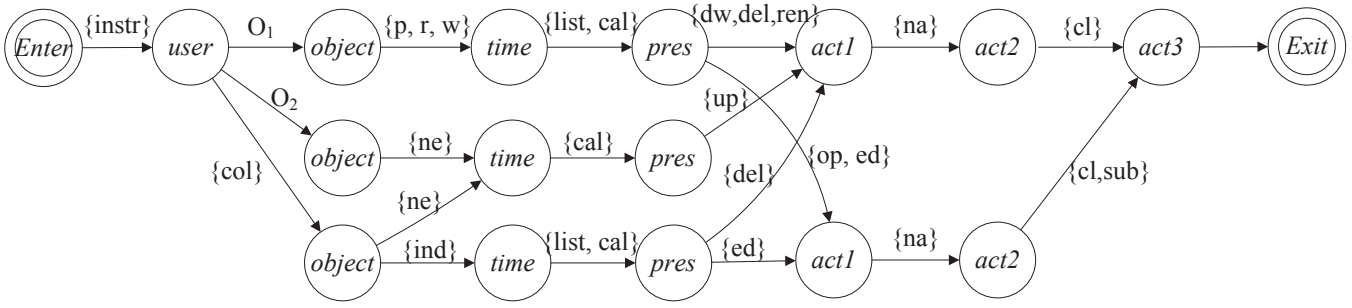

Figure 7. Final model for dependencies 1 - 6

TABLE III. FEASIBLE TEST CASES

Path	user	object	time	pres	act1	Act2	Act3	Number of tests
1	instr	O1	{p, r, w}	{list, cal}	{dw,del, ren}	{na}	{cl}	54
2	instr	O1	{p, r, w}	{list, cal}	{op, ed}	{na}	{cl, sub}	72
3	instr	O2	{ne}	{cal}	{up}	{na}	{cl}	7
4	instr	{col}	{ne}	{cal}	{up}	{na}	{cl}	1
5	instr	{col}	{ind}	{list, cal}	{del}	{na}	{cl}	2
6	instr	{col}	{ind}	{list, cal}	{ed}	{na}	{cl, sub}	4
Total								140

The benefit of using the created model is that this model allows generation of the test cases according to different strategies. Applying existing tools (i.e. JUMBL) to our model, it is possible to randomly generate any fixed number of feasible tests, or provide path/node/arc coverage, or generate test cases with highest probabilities according to a user profile, etc. The model can also be successfully used for statistical testing.

V. CONCLUSIONS

A subgraph splitting algorithm is a method for software input space modeling and test case generation. In this paper, a new area of this algorithm application, specifically interface testing, is considered. The main challenge for such application is representing all interface options as a set of test parameters and their values. The subgraph splitting algorithm then allows us to create a graph model, which reflects all dependencies between interface options and generates only feasible test cases.

The improved algorithm makes the model more compact and convenient for practical applications, as illustrated for a case study of the VirtualECU software. The model developed here presents all 140 feasible test cases for VirtualECU and allows further test selection according to various test criteria.

***Abstract*—Software Testing (ST) processes attempt to verify and validate the capability of a software system to meet its required attributes and functionality. As software systems become more complex, the need for automated software testing methods emerges. Machine Learning (ML) techniques have shown to be quite useful for this automation process. Various works have been presented in the junction of ML and ST areas. The lack of general guidelines for applying appropriate learning methods for software testing purposes is our major motivation in this current paper. In this paper, we introduce a classification framework which can help to systematically review research work in the ML and ST domains. The proposed framework dimensions are defined using major characteristics of existing software testing and machine learning methods. Our framework can be used to effectively construct a concrete set of guidelines for choosing the most appropriate learning method and applying it to a distinct stage of the software testing life-cycle for automation purposes.**

I. Introduction

Software Testing (ST) is an investigation process which attempts to validate and verify the alignment of a software system's attributes and functionality with its intended goals. Software testing is a labour intensive and costly process and as mentioned in [2], [3], a testing process may require up to 50% of the development resources. Due to this fact, automated testing approaches are desired to reduce this cost and time. Besides, automation can significantly enhance the testing process performance. Hence, for future software systems development, steps need to be taken towards the development of automated testing strategies [4].

Several interesting attempts have already been made for automating the software testing process. Machine Learning (ML) as a sub domain of AI [12] is widely used in various stages of the software development life-cycle [19], especially for automating software testing processes [5]. In [1], [17], evolutionary algorithms have been employed for automating test case generation. In [16], Artificial Neural Networks (ANN) have been used to build a model for estimating the effectiveness of the generated test cases. Briand *et al.* in [8] has proposed a method based on the C4.5 decision tree algorithm for predicting potential bugs in a software system and localizing the bugs in order to reduce the debugging process time. All research works show that the employment of machine learning techniques is a promising approach for automating testing processes. But, still some major questions remain that need to be addressed and further investigated such as:

- What types of machine learning methods can be effective in different aspects of software testing?
- What are the strengths and weaknesses of each learning method in the context of testing?
- How can we determine the proper type of learning method for the stages of a testing process?
- Where are the critical points in a software testing process in which ML can positively contribute?

The general purpose of our ongoing research is to provide a specific set of guidelines for automating software testing processes with the aid of machine leaning techniques. To come up with such set of guidelines, it is required to systematically analyse the current research work and find answers to some of the abovementioned questions.

In the first step, we propose a framework which can be used to classify the current research work in the conjunction of ML and ST. In addition, to support our framework, some works are reviewed. This classification framework can assist ST practitioners to analyse and understand the emerging applications of the ML-ST domain. Such structured classification framework can be useful for defining and constructing a set of guidelines for automating software testing processes.

The reminder of this paper is as follows. In Section II , the proposed classification framework is presented. In addition, the dimensions of the framework are discussed in detail. Section III is devoted to presenting some work in the area of ML and ST. In Section IV we discuss how this set of representative work can be classified according to our proposed framework. We conclude the paper with conclusions and direction for future work in Section V.

II. The Proposed Framework for Classification

During the past decade, several works have been introduced based on machine learning techniques where learning algorithms have been applied to the various stages of software testing. In order to clarify the stand point of ML in the area of ST, we propose a classification framework. In this section, we take a look at the proposed framework and its dimensions.

A. The Framework's Dimensions

The most important factors that can be used to distinguish the current research work are represented in Fig. 1. In its highest layer, the framework consists of two main categories

TABLE I
TESTING GENERAL ACTIVITY DIMENTION

Sub-dimension	Possible value
A: Test Planning	Testing cost estimation [9]
B: Test Case Management	Test case prioritization [1] Test case design [1] Test case refinement [6] Test case evaluation [16]
C: Debugging	Fault localization [18] Bug prioritization [18] Fault prediction [15]

(Testing and ML). According to the defined categories, six main dimensions and some sub-dimensions are obtainable in the classification framework. The framework's dimensions are as follows:

Dimension 1-Testing approach: According to the older testing terminology [2], we define the *testing approach* dimension with three possible values: black-box, white-box, and gray-box [2]. Based on the black-box approach, testing can be performed using the external description of a software system such as the software specification. In a white-box approach, the internal properties of a software system like source code can be used for testing purposes. The grey-box approach is a combination of the two, which considers both internal and external properties at the same time.

Dimension 2-Testing general activity: In the second dimension, the standard testing process life-cycle [13] inspired us to define the *a) test planning*, *b) test case management*, and *c) debugging* sub-dimensions. With respect to the testing process life-cycle, we found out that these three phases are critical and that automation can effectively assist them in order to reduce the cost and time of the whole testing process. The possible activities that can be automated based on ML in *a*, *b*, and *c* are presented in Table I.

In the *test planning* sub-dimension, *testing cost estimation* can help test managers to predict testing process cost and time and provide good testing plan to manage the testing process efficiently. *Test case management* includes several tasks such as *test case prioritization*, which intends to prioritize the test input space in terms of test case effectiveness; *test case design*, which intends to generate high quality test cases; *test case refinement*, which intends to map the current specification of a software system to the existing test cases in order to reuse the available test cases; and *test case evaluation* which intends to measure the quality of the generated test cases. In the *Debugging* sub-dimension, *fault localization* can help to find the exact location of the program that is defected. In addition, *bug prioritization* intends to prioritize the revealed faults based on their severities; later test engineer can focus on more critical faults accordingly. *Fault prediction* can assist test engineers in the debugging stage, in the sense that potential faults for a given program are predicted.

Dimension 3-Testing level: Software development process includes a range of stages form "requirement analysis" to "implementation" [13]. The development process goes further even after the implementation stage and concentrates on software maintenance. In Dimension 3, we have employed the following widely accepted testing levels in order to classify existing work: *acceptance testing*, *system testing*, *integration testing*, *module testing*, *unit testing*, and *regression testing*, which refer to requirement analysis, architectural design, subsystem design, detailed design, implementation, and maintenance in the software development stages, respectively.

Dimension 4-Learning technique: In the machine learning area, various types of learning methods have been introduced and each of them has its own specific characteristics. We adopt Mitchel [12] learning method classification and define *learning technique* dimension values as follows: Decision Trees (DT), Artificial Neural Networks (ANN), Genetic Algorithms (GA), Bayesian Learning (BL), Instance Base Learning (IBL), Clustering, and Hybrid methods, which can be combination of several other learning methods.

Dimension 5-Learning property: Each learning method has its own specific characteristics. This dimension is devoted to evaluating learning methods properties in various aspects. To do so, three sub-dimensions; *Training data properties*, *Supervision*, *Time generalization* are defined. The *Training data properties* evaluate the properties of a data set. The gathered data for learning process can be small or large in terms of its quantity. Data can be noisy or accurate in terms of errors that might exist in a data set. In addition, learning can be supervised or unsupervised; therefore, the *Supervision* sub-dimension is defined. For a given target function the *time generalization* sub-dimension exposes how its generalization is; which can be either eager (at learning phase) or lazy (at classification phase). In terms of online and offline learning, also *time generalization* shows how a learning system updates its approximation of the target function after the initial training data are used. The last sub-dimension, *automation degree*, is responsible for addressing the learning system in terms of the degree of automation. The designed system can be fully or partially automatic.

Dimension 6-Elements learned: In each learning system for software testing automation, various types of data can be used to build the target function. The training data can be collected in different stages of the software testing process or software development life-cycle. The learning elements could be *software metrics*, *software specification*, *CFG (control flow graph)*, *call graph*, *test case*, *execution data*, *failure reports*, and/or *coverage data*. The *elements learned* dimension is defined to distinguish the type of learning element that being used for an individual learning model in the testing process.

Fig. 1 shows the framework dimensions, their sub-dimensions and some possible values for them. The main dimensions are shown with ellipse and numbered from 1 to 6. The sub-dimensions are represented with ellipse as well. In addition, the possible values of each dimension are shown with rectangles.

III. THE EXAMPLES OF ML IN SOFTWARE TESTING

In this section, some research work in the area of ML and ST has been selected for supporting the proposed classification framework. In Section IV, we discuss how this work can be classified with proposed framework. Note that, Dimension

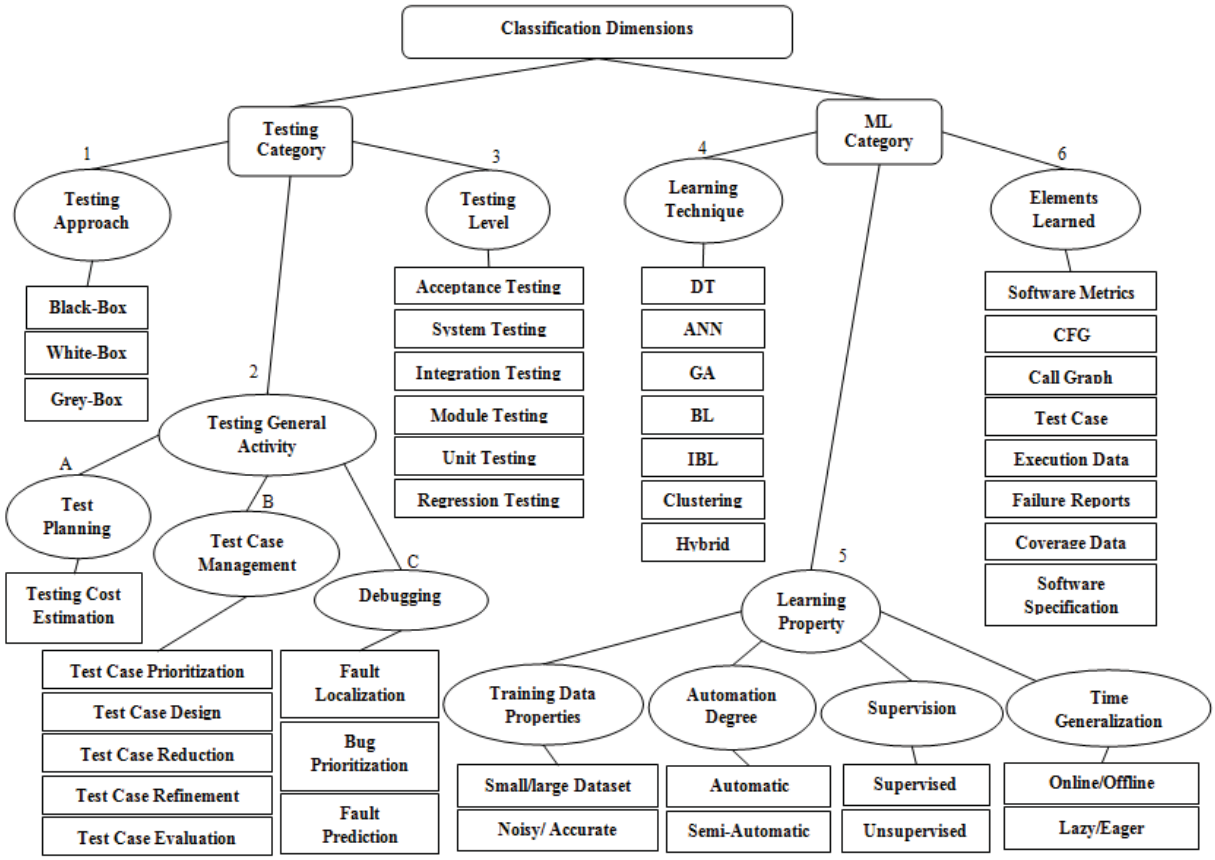

Fig. 1. Classification framework dimensions.

2 has been chosen as the main dimension for classification purposes. We have tried to select and present at least one work according to sub-dimensions *a*, *b*, and *c*. In the following three subsections, we have chosen and briefly introduced three interesting works (due to space limitation) that have employed machine learning techniques for test planning, test case management, and debugging, respectively. Later, we will show how these three works that fall under different aspects of software testing can be effectively described using our proposed classification framework. In our future longer publication, we will comprehensively classify the relevant related literature within our proposed framework. The following three works are only introduced to show the potential of our framework.

A. Test planning

In [9], machine learning techniques have been used to identify the main factors of software testing where they have been employed to predict the testing process time. Understanding the important factors of software under the test can help test managers to prepare a good test plan. The developed methodology consists of four phases; 1) Database formation; 2) Data collection; 3) Classification of software and 4) Analysing the results. In the first phase, databases of 25 software systems were constructed. The sample software were collected from various sources with different attributes. The second phase is devoted to real data extraction form software systems. According to the predefined factors and for a given software system, values were extracted for each individual factor. The list of determined factors included code complexity measures, measures of programmer and tester experience, testing time and a number of other attributes. The complete attributes list includes twenty-seven attributes. In the third phase, COBWEB/3 [11] was used to classify the software systems and build a model to predict the cost of testing for the new software system. COBWEB/3 builds a decision tree. In the last phase, the classification results need to be analyzed to get specific time prediction.

B. Test Case Management

In the context of software evolution, sometimes the available test cases need to be refined to address the current test requirements of the software system. The process of test case refinement is called *test case re-engineering* [6]. In [6], [7], a semi-automatic methodology based on a machine learning approach is provided to explore the limitations and find the possible redundancies of the available test cases and then refine them for future usage. As illustrated in Fig. 2, the MELBA (MachinE Learning based refinement of BlAck-box test specification) methodology is an iterative process and it consists of five main activities.

In the Activity 1, test cases are transformed into the abstract level using the Category-Partition (CP) strategy [14], so they would be ready to be used by the machine learning method in Activity 2. The CP method helps to model the input domain

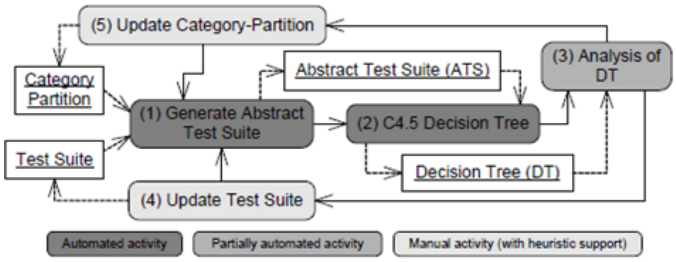

Fig. 2. Overview of the MELBA process [6].

and as discussed in [14], CP requires defining the sets of categories and choices. The categories are the properties of the input and environment parameters of the software system and the choices are the possible values for each category. The abstraction process is conducted using the defined categories and choices. An abstract test case shows an output equivalence class and the pairs of (category, choice). In Activity 2, the machine learning algorithm (C4.5 decision tree) is used to learn the rules for classifying the abstracted test cases. Activity 3 is the important part of MELBA, which is devoted to analysing the learnt rules. The results of the analyzed tree could lead to determine the problems that cause the redundant test cases or the needs for adding new test cases (Activity 4). In addition, the learnt rules may indicate that CP needs to be updated (Activity 5). This iterative process will continue until no more problems could be identified in the trees.

C. Debugging

In software debugging, fault localization refers to process of finding the exact locations of the program that are defected and contain faults. In [18], the Back-Propagation (BP) neural network method [10] is used to effectively pinpoint the program faults. According to proposed approach, first the BP neural network is trained with both the coverage data and the execution result, then the trained network is used to predict and rank the suspicious statements of the code, in terms of its potential to have faults. The proposed method for fault localization consists of the following steps:

1) Building up the dataset: In order to create dataset, it is required to run the program with several test cases and collect the coverage data for each execution. Beside this, the execution results are also need to be collected. This coverage data (coverage vectors) and its execution results can be used for training phase.

2) Training of the BP neural network: In this stage BP neural network is built with k input-layer neurons, three hidden-layer neurons, and one output-layer neuron. The sigmoid function is used as the transfer function. In order to perform training process, coverage vector of each test cases $t_1...t_n$ is used as input data and their corresponding $r_1...r_n$ testing result is used as expected output.

3) Prioritizing the defected statements in program: the trained network can be used for prioritization purpose. Assume, we have a set of virtual test cases $v_1...v_n$ which they cover statements $s_1...s_n$ respectively. It means that, the execution of virtual test case v_i *(i=1...m)* covers only s_i statement. With respect to this assumption, we can say that if the execution of test case v_i fails, then the probability that s_i is defected is high. Here, the trained network can be used to predict the expected output for each virtual test case (r_{vi}). The value of r_{vi} is between 0 and 1. The larger the value of r_{vi}, the more probable s_i is defected. Hence, the statements $s_1...s_m$ can be ranked based on $r_{v1}...r_{vm}$ values in descending order. At the end, the bugs can be identified by examining statements one by one form top of the list.

IV. Classification based on Proposed Framework

In Section II, we introduced a classification framework. There, we discussed the framework's dimensions, sub-dimensions, and some possible values of them. This framework can be used to classify and highlight the main features that need to be considered in the junction of ML and ST area. Following that, in Section III, we presented some representative work in the ML and ST domains.

In this section, we show how the proposed framework can be applied on the three sample presented works. Table II summarizes the results of this classification for each individual work that we have reviewed. In this table, the columns show the dimensions and the related sub-dimensions of the framework and the rows represent the research work that we reviewed. In addition, each cell in the junction of a column and a row indicates the value(s) of that dimension for the corresponding research work.

To clarify, from Table II it can be understood that the automation in [18] has been done in the *debugging* stage of testing process and the *task type* was *fault localization*, which *automatically* finds the suspicious statements in the source codes. In addition, in terms of testing level, this work has been conducted at the *unit testing* level. With respect to the *testing approach* dimension, this work was carried out based on the *white-box* approach, because the statements of the source code are considered for testing purposes. From the ML perspective it can be derived that this work has benefited from the *ANN* learning algorithm which is a *supervised* learning method. Furthermore, the elements which were used as input in the learning process were *coverage data*.

For the work presented in [9], automation has been performed in the *test planning* stage whose *task type* is *testing cost estimation*. The *DT (Decision Tree)* type learning algorithm was used to build a model for estimating testing process cost. From the *automation degree* point of view, this work proposed a *semi-automatic approach*, since in some parts of this method we can see the need for test engineer's intervention. Furthermore, *software metrics* have been employed as input for the learning process. In this work, the learning task has been conducted using a *small size* of dataset, which can considerably decrease the learning process time.

Finally, in [6], [7], *testing general activity* is addressed by *test case management* value, which means, for automation purposes the learning method was applied in the *test management* stage in the software testing life-cycle. The *task type* in this work was *test case refinement*. The proposed method in

TABLE II
CLASSIFICATION OF SOME RESEARCH WORK IN ML AND ST BASED ON PROPOSED FRAMEWORK

Research Work	Testing Category				ML Category					
						Learning Property				
	Testing General Activity	*Task Type*	*Testing Level*	*Testing Approach*	*Learning Technique*	*Training data properties*	*Automation Degree*	*Supervision*	*Time generalization*	*Elements Learned*
[9]	Test planning	Testing cost prediction	-	-	DT	Small dataset	Semi-automated	Unsupervised	Offline/Eager	Software metric
[6][7]	Test case management	Test case refinement	Regression testing	Black-box	DT	Small dataset	Semi-automated	Supervised	Offline/Eager	Test Case/software specification
[18]	Debugging	Fault localization	Unit testing	White-box	ANN	-	Automatic	Supervised	Offline/Eager	Coverage data

this work, in terms of testing level, can be categorised in the *regression testing* level, because this work focused on reusing the existing test cases for new updated version of the current software system. With regards to the *testing approach*, this work used the *black-box* method, since it considers only the software specification for testing purposes. From the machine leaning point of view, this work employed a *semi-automatic* approach using *DT*- based learning technique. The dataset size was quite small and the elements which have been used to build dataset were *test cases* and *software specification documents*.

Table II and the above classification show how our proposed framework is useful in categorizing and explaining work in the intersection of ML and ST.

V. Conclusion and Future work

Testing is critical task in the software development process and considerably imposes cost and time restrictions on the development process. Therefore, automating the testing process can significantly increase testing process performance. In the context of software testing, different types of data can be collected in various stages of testing. Machine learning techniques can be used to find patterns in this data and use them for automation purposes.

In this paper, we have introduced a framework for classifying the current research works in ML and ST. Some sample works of ML in ST have been reviewed and appropriately classified according to the proposed framework. The proposed framework provides us with the opportunity to systematically investigate and extract the prominent information from existing research works in ML and ST.

Considering the introduced framework, our main attempt for future research is reviewing and classifying all current work in the area of ML and ST. The collected information from classification process will assist us to construct the sets of concrete guidelines for applying ML methods in the ST process. These guidelines will help test engineers to choose the most efficient and appropriate learning method for automation of a target testing stage. Our initial probe has shown that our classification framework is quite strong in providing the means to capture various aspects of work in ML and ST.

***Abstract*—Component-based software systems consist of various components, such as third-party components and in-house built components. Due to the component changes, a software system is usually affected at both component level and system level. Related existing research does not address the issue of systematic regression testing of component-based software, especially at system level. This paper proposes a systematic regression testing method from components to system. The paper discusses component API changes, interaction changes, and architecture changes. In addition, it presents a component-based change impact analysis method based on the proposed component firewalls and uses a decision table as its test model. The provided approach is applied throughout the regression testing process. Finally, the paper reports our case studies based on a realistic component-based software system. The study results show that the approach is feasible and effective.**

***Keywords*-component-based software regression testing; software maintenance; retest model; change and impact analysis; test cases update**

I. Introduction

Component-based software is widely used nowadays. The modern software system is primarily constructed based on reusable components, such as third-party components and in-house built components. During software maintenance, when a component is updated or upgraded, it must be retested. This refers to regression testing, which is an important task of software maintenance. Its major objective is to gain the quality confidence for the updated software whenever it is changed. According to [1], regression testing is a major task of software maintenance and it accounts for more than one-third of its total costs. For any component-based software, its regression testing can be conducted in a hierarchical manner that is from the component-level unit retest, component reintegration, to the system level regression testing.

In regression testing of component-based software, the research topics still focus on *re-test model*, *change impact analysis* and *test case update*. However, changes made to a component could bring impact on the other parts of the component, which means the change impact could affect other components of the system or the whole system behaviors. In addition, component-based regression testing should take practical test models into account. For instance, if a decision table-based method has been selected as a test model to generate test cases, regression testing should consider how to identify test cases change and impact based on the decision table.

*Supported partially by the National Natural Science Foundation of China under Grant No. 60773105 and no. 60973149, and partially Supported by Doctoral Fund of Ministry of Education of China under Grant No. 20100092110022, and partially by National High Technology Research and Development Program under Grant No. 2007AA01Z141 and No. 2008AA01Z113.

Research in the past seldom discussed how to identify component changes and impacts in component-based software. Although some papers discussed regression testing of component [2–5], these papers didn't address regression testing at different levels from component to system. Nowadays, practitioners in the real world are looking for systematic solutions to support component and system regression testing and component evolution.

This paper addresses those needs above by providing a systematic approach to regression testing of component-based software based on re-test models. Re-test models are usually used to present the dependency relationships amongst components, assist engineers to define re-test criteria and re-integration strategies, and facilitate automatic test generation. To support regression testing, related modes need to be chosen. This paper proposes several models according to diverse views of component testing. In those models, the relationships between functions or data at component level, between components at system level are all taken into account.

Change identification is the first step of regression testing. A clear classification of change types can support effective impact analysis. The various change types are summarized at different levels in this paper. Impact analysis is an important task in regression testing. The component firewall concept is utilized as a primary method for our change impact analysis. This paper presents diverse firewalls based on the re-test models at both component level and system level. Test case update is one of the goals of regression testing. As a complete regression testing solution, the original test cases should be updated for reusable test cases, obsolete test cases and new test cases. To identify the affected test cases, the affected components or parts should be mapped into the corresponding test cases. Thus, the test models which are used for generating test cases need to be analyzed. Since the *decision table*-based testing is an important component testing method and the project of our case study also utilizes *decision table* as the major testing method, therefore, we regard *decision table* as a basic test model for our regression testing in this paper. The related test case update is based on the *decision table*. Therefore, the process to perform regression testing of component-based software from component to system is as following steps:

Step 1 Change identification at component level, which refers to API function changes, API data changes, structural changes, etc.

Step 2 Impact analysis at component level, which refers to component function firewall, component data function firewall and component API function firewall.

Step 3 Test cases update at component level, which refers to component decision table-based test cases reused, deleted and added.

Step 4 Change identification at system level, which refers to component interaction changes and architecture changes.

Step 5 Impact analysis at system level, which refers to extended composition tree firewall and component interaction firewall.

Step 6 Test cases update at system level, which refers to system decision table-based test cases reused, deleted and added.

The major contributions of this paper are summarized below:

(1) A systematic solution to regression testing of component-based software from component level to system level is presented, including the process of regression testing : change identification, change impact analysis and test cases update.

(2) Several new component firewalls are introduced for component change impact and test case reuse in component-based software regression testing.

(3) Practical application experiments are performed in our case studies. Nearly a hundred students joined related empirical studies.

This paper is organized as follows. Section 2 introduces a brief review of the related work in regression testing of component-based software. In section 3, the re-test models are presented. Section 4 analyzes the change types and provides a systematic approach to component-based software change impact analysis using firewall. Section 5 discusses test cases update. Section 6 reports the case study. Conclusion and future work are summarized in the end.

II. Related Work

In the past decades, a number of papers have been published for regression testing issues for conventional programs and object-oriented software. Those papers primarily focus on three issues: regression test selection techniques [6, 7, 9, 10], regression testing cost-effectiveness analysis [11, 12], and object-oriented re-integration [13–15].

A lot of papers focus on the component-based software testing issues. Currently, component-based software testing mainly focuses on component testability, component test adequacy and coverage, component-based software integration, performance testing, and configuration testing. Recently, a few papers addressed the regression testing problems existed in component-based software [2, 3, 16–18]. They can be generally classified into the following three groups.

The first group is regression test selection of component-based software. For example, Harrold et al. proposed an approach to regression testing of COTS components using component meta-data [16]. They utilized three types of meta-data to perform the regression test selection. However, the method needs additional information from component which may be not available in practice. Similarly, Orso et al. also discussed two techniques for regression testing of component-based software [2]. The first is code-based and the second is specification-based. Both techniques are based on the provided component meta-data. To support the approach, the additional information is needed, including the version information, change data and coverage measurement facilities. Zheng et al. proposed an *Integrated-Black-box Approach for Component Change Identification* for COTS(Commercial-off-the-shelf) software [17]. For the third-party component, the internal software information could be available from component specification, user interface and reference manual. To support the approach, binary code and document should be visible. They assumed that when components change and only binary code and documentation are available, regression test selection can safely be based upon the glue code that interfaces with sections of the component that changed. Robinson et al. proposed a firewall method for regression testing of user-configurable software. They constructed a firewall to identify the impacted area in system based on setting changes and configurable element changes respectively, then created or selected test cases to cover the impacts [19].

The second group is UML-based. For instance, Wu et al. presented a UML technique for regression testing of component-based software [4]. They adopted UML diagrams, which represent changes to a component, to support regression testing. Class diagrams, Collaboration diagrams, and Statechart diagrams are considered to be as the re-test models.

The third group is the systematic method based on API models. Gao et al. focused on component API-based changes and impacts, and proposed a systematic re-test method for software components based on a component API-based test model [3]. In addition, Mao et al. proposed an improved regression testing method based on built-in test design for component-based system [5].

The open questions and challenges of regression testing of component-based software are primarily as follows.

-How to identify the diverse component changes in a systematic way?

-How to do impact analysis from component to system?

-How to update both component and system test cases?

This paper addresses those problems above. Unlike previous work that only focused on component change analysis and impact at the component level, this paper proposes a model-based approach for regression testing. A firewall approach is utilized for impact analysis from component to system to find out ripple effects on other components and system behaviors. Moreover, this paper also introduces a systematic methodology for regression testing of component-based software from component to system.

III. Component-based Software Re-test Models

Component and system can be viewed from different perspectives for testing. For instance, a component can have *white-box* view, *black-box* view, *API* view or *performance* view. A system can have *integration* view, *configuration* view, *function* view or *performance* view. Component testing researchers can choose different views according to their test plan and test goal. Various views of components correspond to different re-test models.

At component level, the changes could be structure changes or internal logic changes. If each updated component is assumed to provide the component internal information as its meta-data, from the white-box view, the white-box re-test models like *data function dependency* or *function dependency* could be adopted for component re-test. Since component function is usually used through API function or data call, the API models can be borrowed for component re-test. From the black-box view, the component could be tested using *decision table-based* testing or *state-based* testing. Hence, the related test models could be adopted for component testing. In addition, from the performance view, the scenario-based testing models can also be applied. However, performance is out of the scope of this paper.

At system level, the relationship between components could be *interaction*, *composition*, *message communication*, etc. Thus, re-

lated system-level models are proposed for system regression testing. For example, from the integration view, *component interaction graph* can be used as interaction models for system. As component system is usually configurable, the *composition* and *configuration* models are needed to support the system testing. From the *function* view, *decision table-based* or *state-based* methods could also be adopted for system function testing.

The reason why we adopt those models to support the regression testing of component-based software from component to system is explained above. In the next few subsections, we will define and introduce those models in detail.

A. System-level Re-test Models

At the system level, from the integration view and configuration view, we propose two re-test models. Now we introduce those two models in detail.

1) ***Extended Composition Tree****: Extended Composition Tree* (*ECT*) describes the *composition* and *configuration* relationship amongst components or inside sophisticated components. *ECT* extends traditional *composition tree* through adding the *configuration* relationship [20]. For instance, an elevator system is composed of the *car*, the *floor panel*, the *controller*, and etc. Sophisticated component *car* contains *user panel*, *door*, *car controller*, etc. Regarding configuration, a *door* component can be configured with *Single door* or *Double door*.

ECT consists of tree nodes and links. Tree nodes present single or sophisticated components including configurable components. Tree links in *ECT* present the composition relation or configuration relation between tree nodes.

Definition 1 An *Extended Composition Tree(ECT)* can be defined a directed graph $ECT = (N, E, R)$, *where* $N = \{N_1, N_2, ..., N_n\}$ *is a finite set of nodes,* $R = \{POW, EXT, EOR, AND, Switch, Multiplex\}$ *is the set of relations,and* $E = E_{POW} \cup E_{EXT} \cup E_{EOR} \cup E_{Multiplex} \cup E_{AND} \cup E_{Switch}$ *is the set of edges.*$E_{POW} \subseteq N \times N \times R$ *is the set of directed edges representing the* part-of-whole *relation between the components. For any two components* $C_1, C_2 \in N$, $\langle C_1, C_2, POW\rangle \in E_{POW}$ *indicates that component* C_2 *is a part of* C_1. $E_{EXT} \subseteq N \times N \times R$ *is the set of directed edges representing the* extend *relation between the components. For any two components* $C_1, C_2 \in N$, $\langle C_1, C_2, EXT\rangle \in E_{EXT}$ *indicates that component* C_2 *extends* C_1 *through composition.*

Regarding *configuration* relation, we already defined the related models in our previous work [20].

2) ***Component Interaction Graph****:* Wu et al. introduced the *component interaction graph* to depict interactions and dependance relationships among components , which is mainly call relationship [21]. Here, *Component Interaction Graph (CIG)* addresses the relationships include *message-communication*, *usage*, etc. Component interaction graph is defined as *Definition 2* below.

Definition 2 *Component interaction graph(CIG) for software components is a directed graph* $CIG = (N, E, R)$, *where* N *is the set of nodes representing the components,* $R = \{MSG, USA\}$ *is the set of interaction relations, and* $E = E_{MSG} \bigcup E_{USA}$ *is the set of edges defined below.* $E_{USA} \subseteq N \times N \times R$ *is the set of directed edges representing the* usage *interaction relation between the components.* $E_{MSG} \subseteq N \times N \times R$ *is the set of directed edges representing the* message-based *interaction relation between the components.*

	Precondition				Action				Postcondition			
	$prec_1$	$prec_2$	·····	$prec_m$	A_1	A_2	·····	A_k	$postc_1$	$postc_2$	·····	$postc_n$
T1	T	F	·····	–	X		·····		T	–	·····	–
T2	F	T	·····	–		X	·····	X	–	F	·····	T
···			·····				·····				·····	
Ti	T	T	·····	F		X	·····		T	F	·····	T

Figure 1. A Sample of Component Semantic Decision Table

For instance, *For any two components* $C_1, C_2 \in N$, $\langle C_1, C_2, MSG\rangle \in E_{MSG}$ *indicates that component* C_1 *sends message to* C_2.

B. Re-test Models for Test Cases Reuse

1) ***Component Semantic Decision Table Test Model****: Decision Table* is a black-box testing method focusing on validating business rules, conditions, constraints and corresponding responses and actions of a software component [22, 23]. The basic approach is to identify and list all possible conditions and their combination cases as well as responding actions and outputs for each case, then define test cases to cover each case. In this paper, we propose a new *Component Decision Table* for component. We call this *Component Semantic Decision Table* (*CSDT*). For each case, there exists *precondition*, *action* and *postcondition*.

According to *component black-box view*, the data value of *preconditions* could be *Incoming data*, *Incoming message*(such as GUI input data or component internal data) or *API call parameter*, and the data value of *postcondition* could be *Outgoing data*(such as database table, GUI output, output data file, etc.), *Outgoing message* or *Outgoing call data*. All these *preconditions* and *postconditions* could be obtained from component specification. *Action* in *CSDT* stands for component *function*. Figure 1 shows a sample component semantic decision table. The *precondition*, *postcondition* and *action* are explained in *Definition 3*.

Definition 3 *The CSDT includes three sets, which is presented below.* $prec = \{prec_1, prec_2, ..., prec_m\}$, $postc = \{postc_1, postc_2, ..., postc_n\}$, *where* prec *denotes a* precondition *set, which includes precondition* $prec_1, prec_2, ..., prec_n$, *and* postc *denotes a* postcondition *set, which includes postcondition* $postc_1, postc_2, ..., postc_n$. $action = \{A_1, A_2, ..., A_l\}$, *where* action *denotes a* action *set, which includes action* $A_1, A_2, ..., A_l$.

2) ***System Semantic Decision Table Test Model****:* In our component system specification, there is a *feature-component table*. The table describes the relation between system features and corresponding components. These features can be observed at the system level. For each feature, there is a corresponding *decision table*.

The system features can be defined as a set Ft, $Ft = \{ft_1, ft_2, ..., ft_n\}$, where Ft denotes the function feature set of component-based system, which includes feature $ft_1, ft_1, ..., ft_n$. Each *feature* is supported by a set of components. The relation between feature and components can be expressed below.

$ft_i \longrightarrow C(ft_i) = \{C_1, C_2, ..., C_m\}$, *where* $C(ft_i)$ *denotes the set of components which support feature* ft_i.

Each system decision table can be used for each feature, which is presented below.

$ft_i \longrightarrow SDT_i$, where SDT_i stands for system decision table.

$SDT_i \longrightarrow STd_i$, *where* STd_i *stands for test case set for decision table* SDT_i.

Type	Specific Changes
ADP	Add a data parameter
AF	Add a function
ARD	Add a 'return' data
DDP	Delete a data parameter
DF	Delete a function
DRD	Delete a 'return' data
CDT	Change data type or name
CFL	Change the function logic
CFS	Change the interface signature

Type	Specific Changes
AMO	Add Message-based (MB) relation (outgoing)
AMI	Add MB (incoming)
AMB	Add MB (both way)
AU	Add Usage relation
DMO	Delete MB (outgoing)
DMI	Delete MB (incoming)
DMB	Delete MB (both way)
DU	Delete Usage relation
CMS	Change MB semantic

Figure 2. Component Function and Interaction Change Types

Type	Specific Changes
APW	Add a 'part of whole' relationship (add C1 as a part of C2)
AE	Add an 'extends' relationship (add C1 to extend C2)
ACDV	Add a 'configurable' data value
ACDT	Add a 'configurable' data type
ACF	Add a 'configurable' function
DPW	Delete a 'part of whole' relationship (delete C1 from C2)
DE	Delete an 'extends' relationship (delete C1 from C2)
DCDV	Delete a 'configurable' data value
DCDT	Delete a 'configurable' data type
DCF	Delete a 'configurable' function
CCDV	Change a 'configurable' data value
CCDT	Change a 'configurable' data type
CCF	Change a 'configurable' function

Figure 3. Architecture Change Types

IV. Change Impact Analysis

We have summarized the common changes existed in component-based software in Figure 2 and 3. Component changes could be classified at two levels: **a)** the component level, and **b)** the system level. Change impact analysis is based on the models proposed in section 3. We introduce several component change firewalls, which include change, add and delete firewalls. The basic procedure to perform a component change impact consists of the following steps:

1) Identify the impacts of a changed component function or data on other component functions at component level; 2) Identify the component change impacts on its API; 3) Identify the component change impact on its precondition, action, and postcondition; 4) Identify the component change impact on other components based on architecture at system level; 5) Identify the component change impact on other components based on interaction at system level.

For any component, we assume $ECT = (N, E, R)$ be the old version of its *Extended Composition Tree*, $ECT' = (N', E', R')$ be its new version, $CIG = (N, E, R)$ be the old version of its *Component Interaction Graph*, and $CIG' = (N', E', R')$ be its new version.

A. Component function, precondition and post-condition Firewall

Through the computation of *CFFW* and *CDFW*, we can get the affected component functions based on invocation dependencies and data *define-use* dependencies [3]. Various change types correspond to different impact. Now we try to present the change impact analysis corresponding to the summarized component level change types in Figure 2 using firewall.

- For ADP or ARD (the changed data is assumed as D_i):
  $CDFW_{add}[D_i] = \{F_j | (\exists F_j)(\exists F_k)((\langle F_k, F_i, du\rangle \in R'_d - R_d) \wedge (F_k \in F) \wedge (\langle F_j, F_k, du\rangle \in R'_d *))\}$
  Where R'_d is the data define-use relation derived from DFDG'.
- For AF (the changed function is assumed as F_i):
  $CFFW_{add}[F_i] = \{F_j | (\exists F_j)(\exists F_k)((\langle F_k, F_i\rangle \in E' - E) \wedge (F_k \in F) \wedge (\langle F_j, F_k\rangle \in R'_f *))\}$
  Where R'_f is the dependence relation for FDG'.
- For DDP and DRD (the changed data is assumed as D_i):
  $CDFW_{delete}[D_i] = \{F_j | (\exists F_j)(\exists F_k)((\langle F_k, F_i, du\rangle \in R_d - R'_d) \wedge (F_k \in F) \wedge (\langle F_j, F_k, du\rangle \in R' *_d))\}$
- For CDT (the changed data is assumed as D_i):
  $CDFW_{change}(D_i) = \{F_i | (\langle F_i, D_j\rangle \in R_{def}) \wedge ((\langle F_j, D_j\rangle \in R_{use}) \wedge (\langle F_j, F_i, du\rangle \in R *_{dr})\}$
  Where $R *_{dr}$ is the transition closure of R_{dr}, which is the binary relation that define the data define-use relation between the residual component functions. R_{dr} can be defined as:
  $R_{dr} = R_d \cap (F \times F \times \{du\}) \cap (F' \times F' \times \{du\})$
- For CFL and CFS (the changed function is assumed as F_i):
  $CFFW_{change}(F_i) = \{F_j | (F_j, F_i \in F) \wedge (\langle F_j, F_i\rangle \in R *_{fr})\}$
  Where $R *_{fr}$ is the transition closure of R_{fr}, which is the binary relation that define the dependencies between the residual component functions. R_{fr} can be defined as:
  $R_{fr} = R_f \cap (F \times F \times \{du\}) \cap (F' \times F' \times \{du\})$, where x is the Cartesian product operation.

Regarding API function firewall, our previous work already discussed it [3]. The definition is as follows.

$CAW_{API}(C) = \{F_i | \forall F_i((F_i \in F'_{API} - F_{API}) \wedge ((F_i \in CFFW(C)) \vee (F_i \in CDFW(C))))\}$

Where $CAW_{API}(C)$ includes all API functions which may be affected by component function changes, deletions and additions, as well as alters in the *data-define-use* relations between them.

Now we extend $CAW_{API}(C)$ by adding the *precondition*, *post-condition*, and *action*. Here, action corresponds to API function. *precondition* and *postcondition* change information can be obtained from the component requirement. The new firewall is called ECAW(*extended component API function firewall*). Thus, the new firewall set can be represented as below.

$ECAW(C) = \{\langle prec_i, postc_j, action_k\rangle | (prec_i$ is changed, added or deleted) $\vee (postc_j$ is changed, added or deleted) $\vee (action_k \in CAW_{API}(C))\}$

Where $prec_i$, $postc_j$, $action_k$ denote *precondition*, *postcondition* and *action* respectively. $\langle prec_i, postc_j, action_k\rangle$ stands for a vector set, which include the affected *preconditions*, *postconditions* and *actions*.

B. Extended Composition Tree Firewall

Extended Composition Tree Firewall (ECTF) in *Extended Composition Tree* after changing components or configurations, refers to a set of components which might be affected by changing, adding and deleting components or configurations based on composition

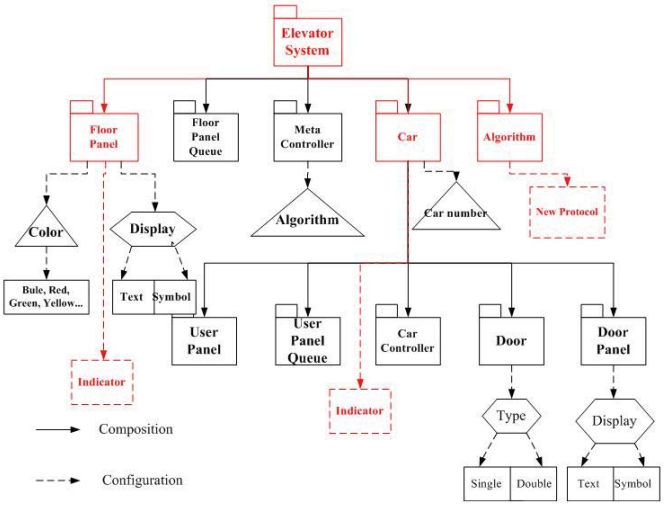

Figure 4. A Sample Extended Composition Tree Firewall in the Elevator System

and configuration dependencies. *ECTF* is performed on architecture. Thus, it is used for identifying the affected architecture at the system level. For instance, in the elevator system, if the *door* component is changed, then the *car* component, which has the composition relation with *door*, will be affected. The affected test cases corresponding to this change mainly refers to unit test cases.

The *Extended Composition Tree Firewall* can be computed based on *Extended Composition Tree*. Now we introduce changed, added and deleted extended composition tree firewalls respectively.

The firewall for a changed, added, and deleted component C_i can be computed below.

$ECTF_{change}[C_i] = \{(C_j | C_j \in C) \wedge (\langle C_j, C_i \rangle) \in R_{ECTr}*\}$

Where $R_{ECTr}*$ is the transitive closure of R_{ECTr}, which is the binary relation that defines the composition dependencies between the components. R_{ECTr} can be defined as follows:

$R_{ECTr} = R_{ECT} \cap (N \times N) \cap (N' \times N')$

Where $\times$ is the Cartesian product operation.

$ECTF_{add}[C_i] = \{C_j | (\exists C_j)(\exists C_k)((\langle C_k, C_i \rangle \in E' - E) \wedge (C_k \in N) \wedge (\langle C_j, C_k \rangle \in R'_{ECT}))\}$

Where R'_{ECT} is the composition dependence relation for *ECT'*.

$ECTF_{delete}[C_i] = \{C_j | (\exists C_j)(\exists C_k)((\langle C_k, C_i \rangle \in E - E') \wedge (C_k \in N) \wedge (\langle C_j, C_k \rangle \in R'_{ECT}))\}$

Now we present the change impact analysis corresponding to the summarized architecture change types in Figure 3 using firewall. The left side of arrow represents change type set and the right side of arrow denotes the corresponding firewall.

$(APW, AE, ACDV, ACDT, ACF) \rightarrow ECTF_{add}[C_i]$

$(DPW, DE, DCDV, DCDT, DCF) \rightarrow ECTF_{delete}[C_i]$

$(CCDV, CCDT, CCF) \rightarrow ECTF_{change}[C_i]$

For instance, in the elevator system, after adding an *indicator* in the *car* component and the *floor panel* component and a new protocol , the *extended composition tree firewall* (ECTF) is shown in highlighted in Figure 4.

C. *Component Interaction Graph Firewall*

Component Interaction Graph Firewall (CIGF) in *Component Interaction Graph* after changing components, refers to a set

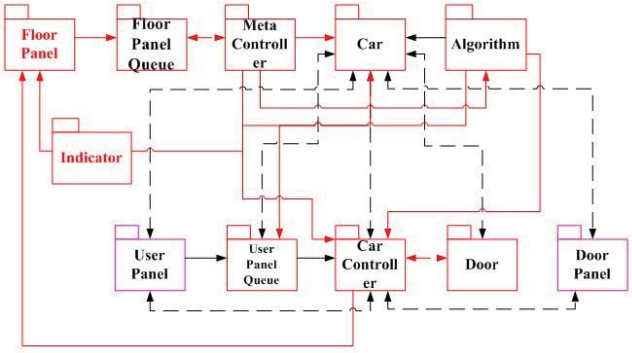

Figure 5. A Sample Component Interaction Graph Firewall in the Elevator System

of components which maybe affected by changing, adding and deleting components based on interaction dependence. The *Component Interaction Graph Firewall* can be computed based on given *Component Interaction Graph*. For instance, in the elevator system, after adding an *indicator* in the *car* component and the *floor panel* component, the *component interaction graph firewall* (CIGF) is shown in highlighted in Figure 5. However, if we only consider component changes, the size of the *Component Interaction Graph Firewall* could be very large. Some components might be redundant for regression testing. API is the function interaction for other components to call. The Algorithm is shown in Algorithm 1. In the case of the interaction change types in Figure 2, the firewall could be computed by algorithm of *Component Interaction Graph firewall*.

Algorithm 1 Component Interaction Graph Firewall

Declare: C_0: changed component;

then
$CIGF_{API}(C_j.F_j, CIG, CIG')$
}
}

V. Test Cases Update

The final goal of regression testing is to refresh the existing test cases for the previous version, which means selecting reusable test cases and scripts, deleting out-of-date test cases and scripts, and adding new test cases and scripts.

As we mentioned above, *decision table* based testing is the primary method to generate test cases in this paper. Now we need to analyze how to map the change impact firewall into affected test cases in the given test suite. We introduce the concept of test firewall to emphasis the test cases updating. The procedure to perform test firewall analysis can be divided in two steps: 1) Identify the change impacts on component decision table-based test cases at component level; 2) Identify the change impacts on system decision table-based test cases at system level.

A. Decision table-based test firewall at component level

In any of the given *component semantic decision table* (CSDT), if any of the *preconditions*, *postconditions* and *actions* are added, deleted or changed, then the corresponding test cases could be affected.

According to the requirement changes, we can identify the *component semantic decision table* (CSDT) changes easily. As the test model defined in section 3, the CSDT changes could come from three sets: *precondition*, *action* and *postcondition*. The problem here is how to identify the reused, changed and new test cases according to the changes.

Each entry value in a row of a given decision table CSDT could be "True", "False", or "-". "True" means the corresponding *precondition* or *postcondition* has to be true; "False" means the corresponding *precondition* or *postcondition* has to be false. "-" means the corresponding *precondition* or *postcondition* could be either true or false. The table includes three sets, which is presented below. The entry value of precondition and postcondition can be defined as a set respectively like below.

$vprec = \{vprec_1, vprec_2, ..., vprec_m\}$, where *vprec* denotes the entry value set of *precondition*.

$vpostc = \{vpostc_1, vpostc_2, ..., vpostc_n\}$, where *vpostc* denotes the entry value set of *postcondition*.

Assumptions *The value of precondition associated with test cases could be* $vprec_i(i \leq m) =$ "T"or"F"or" − ". *The value of postcondition associated with test cases could be* $vpostc_j(j \leq n) =$ "T"or"F"or" − ". *Assuming* $T_p \longrightarrow \langle vprec, A, vpostc \rangle$, *where* T_p *stands for decision table based test case. Vprec,* $A(A \subseteq action)$ *and* $vpostc_j$ *stand for the associated precondition prec, action A and postcondition postc respectively.*

Through the computation of ECAW, we can get the firewall at component level. Assuming CTd_{v1} denotes the original component decision table test cases set, now we need to get the updated version CTd_{v2}. According to the assumptions, we have the following rules for component decision table test firewall.

Rule 1 (corresponding to change firewall):
For any i, j, k
(1)**If** $((prec_i$ or $postc_j \in ECAW_{change}(C)) \wedge (T_p \rightarrow vprec_i =$ "T"or"F" $\vee\ T_p \rightarrow vpostc_j =$ "T"or"F"$))\vee\ (T_p \rightarrow A_k \in ECAW_{change}(C))$
then T_p need to be changed in CTd_{v2}.

(2) **If** $((prec_i$ or $postc_j \in ECAW_{change}(C)) \wedge (T_p \rightarrow vprec_i =$ " − " $\wedge\ T_p \rightarrow vpostc_j =$ " − "$))\wedge\ (T_p \rightarrow A_k \notin (ECAW_{change}(C) \cup ECAW_{add}(C) \cup ECAW_{delete}(C)))$
then T_p need to be reused in CTd_{v2}.
Rule 2 (corresponding to add firewall):
For any i, j, k
(1)**If** $((prec_i$ or $postc_j \in ECAW_{add}(C)) \wedge (T_p \rightarrow vprec_i =$ "T"or"F" $\vee\ T_p \rightarrow vpostc_j =$ "T"or"F"$))\vee\ (T_p \rightarrow A_k \in ECAW_{add}(C))$
then new test case T_p need to be added in CTd_{v2}.
(2) **If** $((prec_i$ or $postc_j \in ECAW_{add}(C)) \wedge (T_p \rightarrow vprec_i =$ " − " $\wedge\ T_p \rightarrow vpostc_j =$ " − "$))\wedge\ (T_p \rightarrow A_k \notin (ECAW_{change}(C) \cup ECAW_{add}(C) \cup ECAW_{delete}(C)))$
then T_p need to be reused in CTd_{v2}.
Rule 3 (corresponding to delete firewall):
For any i, j, k
(1)**If** $((prec_i$ or $postc_j \in ECAW_{delete}(C)) \wedge (T_p \rightarrow vprec_i =$ "T"or"F" $\vee\ T_p \rightarrow vpostc_j =$ "T"or"F"$))\vee\ (T_p \rightarrow A_k \in ECAW_{delete}(C))$
then T_p need to be deleted in CTd_{v2}.
(2) **If** $((prec_i$ or $postc_j \in ECAW_{delete}(C)) \wedge (T_p \rightarrow vprec_i =$ " − " $\wedge\ T_p \rightarrow vpostc_j =$ " − "$))\wedge\ (T_p \rightarrow A_k \notin (ECAW_{change}(C) \cup ECAW_{add}(C) \cup ECAW_{delete}(C)))$
then T_p need to be reused in CTd_{v2}.

B. Decision table-based test cases firewall at system level

At the system level, we still adopt decision table model to perform test case update. In component-based system, there is a *feature-component* table, which describes the relation between system feature and corresponding components. These features can be observed at the system level. For each feature, there is a corresponding *decision table*. Here, the proposed firewall like *component interaction graph firewall* could be used to compute the affected components at the system level.

First we need to analyze if the changes affect the corresponding components. If so, then we find out the affected system features corresponding to the affected components. According to the relation between features and decision table, the affected decision table at feature level can be identified. Then, we analyze the changes to precondition, postcondition and action of decision table, and identify the test cases firewall at system level.

According to the *System Semantic Decision Table Test Model*, we propose the following formulas to compute the test cases firewall at system level. Here, C_o denotes modified component. CIGF and ECTF represent related change impact firewalls which are introduced above. Assuming the original system test cases set is STd_{v1}, we need to obtain the updated version STd_{v2}.

$STd_{reuse} = \{STd_i | (\forall C_k (k \leq m) \in C(ft_i))(C_k \in CIGF_{reuse}(C_o) \vee ECTF_{reuse}(C_o))\}$

Where SDT_{reuse} could be reused in SDT_{v2}. C_o denotes modified component. $C(ft_i)$ denotes the set of components that support feature ft_i. SDT_i represents the decision table corresponding to feature ft_i. The number of total components is m.

$STd_{delete} = \{STd_i | (\forall C_k (k \leq m) \in C(ft_i))(C_k \in CIGF_{delete}(C_o) \vee ECTF_{reuse}(C_o))\}$

Where STd_{delete} could be deleted in STd_{v2}.

$STd_{change} = \{STd_i | (\exists C_k (k \leq m) \in C(ft_i))(C_k \in CIGF_{change}(C_o) \vee ECTF_{reuse}(C_o))\}$

Where STd_{change} need to be changed in STd_{v2}.

$STd_{new} = \{STd_i | (\forall C_k (k \leq m) \in C(ft_i))(C_k \in CIGF_{add}(C_o) \vee ECTF_{reuse}(C_o))\}$

Where STd_{new} need to be added in STd_{v2}.

VI. Case Study Report

To better understand our approach, we have performed a case study by applying the systematic regression testing from component level to system level onto a real component-based elevator system. We have used two software testing classes and two master project teams in San Jose State University (SJSU) to perform the related experiments. To make the study more typical, we conducted a complete component-based software testing process, including the original test cases design, test strategy, test coverage, etc. The decision table-based test cases are designed for both component and system. All of the test cases were executed adequately.

A. Study Objectives

The case study focuses on the following items: (a) Perform a systematic regression testing of the new component system version using the proposed approach, to verify the feasibility of the approach; (b) Check the effectiveness of the proposed approach; (c) Discover bugs after regression testing.

B. Study Subject

We have performed some case studies by applying the proposed approach in a component-based software, which is a component-based elevator system. The elevator system consists of several components, which are *car*, *user panel*, *door*, *door panel*, *userpanel queue*, *car controller*, *floor panel* and *metacontroller*. We have used two software testing classes and two master project teams in San Jose State University (SJSU) to perform the related experiments. The test cases are decision table-based. In the new version, we have made some changes such as adding a component 'Indicator' in the component 'Car' to show the current floor where the car locates, adding a component 'Indicator' in the component 'Floor Panel' to show the current floor where the car locates, adding another kind of elevator algorithm to current system, like FCFS, SCAN, etc., to make elevator scheduling configurable, and so on. The original version of the system is well designed with adequate decision table-based component test cases and system test cases. In the new system version, we conducted regression testing from component level to system level, to obtain updated decision table-based test cases, including reused test cases, deleted test cases and new test cases.

C. Study result report and discussion

Since we have many testing groups to work on the case study, we selected some good study results from four groups to report the test case reuse and bug checking. Those groups performed the experiments strictly using our approach. To perform a complete regression testing process, we classified the regression test cases into newly created test cases, reusable test cases and deleted test cases. Those groups also reported the bugs found in regression testing.

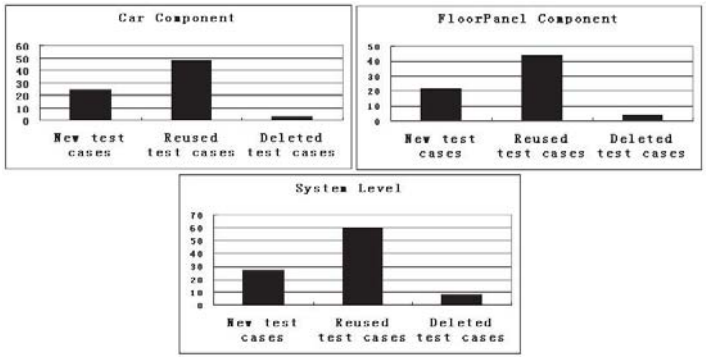

Figure 6. Regression Testing Result

Table I
Bug Report of Group 1

Level	*Test case design*	*Test case executed*	*Test coverage*	*Bugs*
Car	*79*	*79*	*100%*	*5*
Floor Panel	*59*	*59*	*100%*	*4*
System	*159*	*159*	*100%*	*11*

Figure 6 shows the regression testing results. We have obtained test cases update results from component level, i.e. *car* component and *floor panel* component to system level.

In the figure, there are three subgraphs, which represents the study results of car component, floor panel component and system respectively. The horizontal axis represents new test cases, reused test cases and deleted test cases respectively. The data of test cases are represented by a vertical bar. The height of the bar depicts the number of new, reusable, and deleted test cases.

From the figure, we can find, after regression testing, some of the original test cases could be reusable and some could be deleted. In addition, new test cases need to be created for the new version system to achieve adequate testing. For instance, in Figure 6, 25 test cases for *car* component, 23 test cases for *floor panel* component and 29 test cases for system level are newly created. This is because we have added a new component *indicator* in the elevator system. The *indicator* is added to both *car* component and *floor panel* component.

We also find most of the test cases are reusable. For instance, 48 test cases for *car* component, 44 test cases for *floor panel* component and 60 test cases for system level are reusable. The explanation is that most of the components in the system are reused in the new version. Several test cases are obsolete and deleted after regression testing due to the program changes.

Table 1 represents the bug report. The test case design includes all the new test cases and reused test cases. All of those test cases are executed with a 100% coverage. The bugs come from both component level and system level. For example, 4 bugs in *floor panel* component and 5 bugs in *car* component are found. In addition, 11 bugs are found in *system*. Thus, the modification does bring affection and impact on both the component and system.

From the result of case study, we can see the proposed approach can obtain reusable, deleted and new test cases at both levels. In addition, we also have bug reports. Hence, our approach is feasible when applied to real component-based software system.

In the case study, Most of the test cases are reusable. In terms

of the statistics of studies, nearly over 70% of the test cases are reusable. That means most of our original test cases are kept for further testing. Thus, we still can achieve a relatively high test coverage. Some test cases are deleted after regression testing, which meets the demand of reducing the number of obsolete original test cases for cost-effectiveness. Moreover, in the case study, several program bugs are reported by many groups. We also found the bugs do existed in the system after modifications. This indicates that our approach is effective.

VII. Conclusions and future work

This paper has presented a systematic regression testing technique for component-based software from component level to system level. We analyzed the whole process of regression testing, including change identification, change impact analysis and test case updating.

We proposed several re-models to support regression testing. The diverse types of changes are considered in this paper, such as component level API changes, interaction changes, and system level architecture changes. For impact analysis, the firewall concept is borrowed and extended to analyze affected program parts according to the proposed re-test models. For test models, we provide a commonly used component testing method-decision table-based testing. The change types are mapped to impact analysis, and then the affected parts are mapped to the affected test cases which are decision table-based. In addition, we performed case studies on a realistic component-based software system. The studies results show that our approach is feasible and effective.

The future extension of this research is to apply the approach into different component testing methods and models, such as state-based testing, scenario-based testing, etc. In addition, we will study how to use the approach to address automation regression test issues and develop automatic component-based regression testing tools.

***Abstract*—We propose an interactive fault localization method based on two data mining techniques, formal concept analysis and association rules. A lattice formalizes the partial ordering and the dependencies between the sets of program elements (e.g., lines) that are most likely to lead to program execution failures. The paper provides an algorithm to traverse that lattice starting from the most suspect places. The main contribution is that the algorithm is able to deal with any number of faults within a single execution of a test suite. In addition, a stopping criterion independent of the number of faults is provided.**

I. Introduction

Executing a test suite can be very costly, especially when the test oracle, that tells whether a run is correct, is not fully automated. In the multiple fault localization context, being able to explain as many as possible of the failures detected by the test suite execution is therefore an important property. However, it is in general impossible to tell how many faults are present in a buggy program. In order to deal with multiple faults, Liblit *et al.* [11] propose a ranking based on a statistic treatment of inserted predicates. Zheng *et al.* [16] propose a method based on bi-clustering in order to group failed executions and to identify one feature that characterizes each cluster. Jones *et al.* [9], with their *parallel debugging*, propose to cluster failed executions in order to distribute each cluster of executions to different debuggers. Ideally, one cluster should represent one fault, and instead of searching the faults one by one, what the authors call *sequential debugging*, the faults can be searched in parallel by different persons. In all those methods, there is, however, no guaranty that each cluster represents only one fault. Furthermore, the dimension used to measure suspicion tends to ignore the actual structure of the program. On the one hand, lines with close suspicion scores may be uncorrelated; on the other hand, correlated lines may have very different suspicion scores (e.g, a condition and the branches it controls).

In a previous work [4], we have proposed a new data-structure that can organize program elements in a multi-dimensional space: the *failure lattice*. The failure lattice is a partial ordering of the elements of the traces that are most likely to lead to failures. The traces can contain different kinds of information called *events*, for instance, executed lines or variable values. We assume that each execution trace contains, in addition to the events, the verdict of the execution, $PASS$ if the execution produces the expected results, and $FAIL$ otherwise. In a previous work [5], we have compared the exploration of the failure lattice with existing approaches that handle only a single fault. We have shown, in particular, that the method gives a comparable number of lines to analyze while providing a richer environment for the analysis.

Fig. 1. Trityp Java program.

In this paper, we propose an interactive fault localization algorithm that explores the *failure lattice* and can deal with multiple faults. The contribution of this paper is twofold. Firstly, the exploration stops when all the detected failures are explained. That stopping criterion is independent of the number of faults. Secondly, a programmer can exploit all the results of a single execution of a test suite, thus reducing the number of executions of the test suite.

In the remaining of the paper, Section II presents the running example. Section III presents the failure lattice introduced in [4]. Section IV introduces an extended labelling of the failure lattice for the multiple fault problem. Section V defines the proposed algorithm to explore the data structure and locate multiple faults in a program. Section VI and Section VII discuss the characteristics of the algorithm with respect to fault dependencies and statistical indicators. Finally Section VIII presents the related work.

II. Running Example

To illustrate our method, we use a classical benchmark for test generation methods, the Trityp Java program shown in Figure 1. It classifies sets of three segment lengths into four categories: *not a triangle*, *scalene*, *isosceles*, *equilateral*. The program contains one class with 130 lines of code. The

III. DATA MINING AND FAILURE LATTICE

In this section, we give background knowledge about two data mining techniques in order to explain how to read a failure lattice. The construction is explained in [4].

Data mining is a process to extract relevant information from a huge amount of data. Two data mining techniques are used to compute the failure lattice: Association Rules and Formal Concept Analysis (FCA). The input of those techniques is a *formal context*, i.e. a binary relation describing elements of a set of *objects* by subsets of a set of *attributes*. Table II is an example of context. The objects are the executions. The attributes are the program lines and the verdicts. Each execution is described by its execution trace.

1) Association Rules: Searching for association rules [1] allows interesting regularities to be found. An *association rule* has the form: $P \rightarrow C$, where P and C are sets of attributes. P is called the *premise* of the rule and C the *conclusion*. Any pair of premise and conclusion forms an association rule, but some of them are more relevant than others. In order to measure the relevance of computed rules, statistical indicators are used. In the following, we use two indicators, *support* and *lift*, that will be defined when they are actually needed.

2) Formal Concept Analysis (FCA): Formal Concept Analysis [7] allows relevant clusters to be computed. In FCA, the set of all objects that share a set of attributes is called the *extent* of the set of attributes. For example, in the context of Table II, $extent(\{line\ 57, line\ 58\})$ is the set of executions that execute $line\ 57$ and $line\ 58$ and $extent(\{FAIL\})$ denotes all failed executions. The set of all attributes shared by all elements of a set of objects is called the *intent* of the set of objects. For instance, the intent of a set of executions, S, is the set of lines that appear in the traces of all executions of S and the verdict if it is the same for all executions of S. In FCA, a *formal concept* is defined as a pair (O, A), where the set of objects, O, is the extent of the set of attributes, A, and A is the intent of O. The set of concepts of a context can be represented by a concept lattice where each attribute and each object labels only one concept[2]. Namely, each concept is labelled by the attributes and the objects that are characteristic to its intent and extent.

The failure lattice is computed thanks to combining association rules and formal concept analysis. The set of execution traces is a context where the objects are the executions and where each execution is described by the events occuring during the execution. From that context, association rules are computed: $e_i,\ e_j, \cdots \rightarrow FAIL$. Those rules can be read as "when events $e_i,\ e_j, \cdots$ appear in a trace most of the time the execution fails". Those rules, extracted from the execution trace context, form the context used to compute the failure lattice. In that second context, the objects are the association rules and each rule is described by the events that appear in its premise. Some rules are more specific than others and that partial order is highlighted in the failure lattice. Figure 2 displays an example of failure lattice for the faulty Trityp program which is obtained by combining faults 1, 2 and 3. Note that, in the sequel, for the examples, the events in execution traces are the executed lines and verdicts.

The premise of a rule r, in the failure lattice, can be obtained by collecting the attributes labelling all the concepts above the concept that is labelled by r. In our particular case, there is only one rule with a given premise, so a concept can only be labelled by one rule in the failure lattice. We will therefore give the same number to a concept and the rule that labels it. In Figure 2, r_3 is $line\ 105, line\ 97, line\ 93, line\ 58, ... \rightarrow FAIL$. Two pieces of information are added to the rule: support and

[1]http://www.irisa.fr/lande/gotlieb/resources/Java_exp/trityp/

[2]There are some tools that automatically compute concept lattices and their labelling. For instance, ToscanaJ (http://toscanaj.sourceforge.net/) is used for the lattices that appear in this paper.

lift values. The support of a rule is the number of failed executions that have in their trace all events of the premise of the rule. The support of r_3 means that 116 failed executions execute lines 105, 97, 93, 58, ... The lift of a rule indicates if the occurrence of the premise in a trace increases the probability to fail. A lift value greater than 1 means that the observation of the premise in a trace increases the probability to fail.

In Figure 2, we see that r_2 is more specific than r_3, indeed its premise contains the premise of r_3. It is denoted by $r_2 < r_3$. Therefore, c_3 is a superconcept of c_2.

Note that in the illustrations, the red ellipses point to the concepts labelled by faulty lines. Note also that we illustrate the method with pictures of concept lattices, but it is only for the sake of exposing the logic of the process. In fact, failure lattices are in general very large and are not legible. They however need not to be computed in totality, neither need to be globally exposed to the user.

IV. The Failure Lattice for Multiple Faults

This section presents how the labelling of the lattice is extended by failure concepts and support clusters. Properties for the multiple fault problem are given.

A concept c is a *failure concept* of the failure lattice if there exists some failed execution that contains all events of the intent of c in their trace but not all the events of the intent of subconcepts of c. For instance in Figure 2, concept 5 is a failure concept, indeed it covers 40 failed executions that are not covered by a more specific concept. We also say that those 40 failed executions are *covered* by rule 5. Concept 4 is not a failure concept because the 40 failed executions that it covers are already covered by concept 5 which is a more specific concept. In the same way, concept 2 is not a failure concept because among the 116 failed executions that are covered by it, 40 are already covered by concepts 4 and 5 and the remaining 76 are covered by concept 10, which are all more specific concepts than concept 2. In the example, there are four failure concepts: 5, 13, 12 and 9. We note $FAILURES$ the set of failure concepts.

We call *support cluster* a maximal set of connected concepts labelled by rules which have the same support value. We note $cluster(c)$ the support cluster that contains c. For instance, in Figure 2, concepts 4 and 5 belong to the same support cluster. It means that lines 71 and 74 are executed by exactly the same 40 failed executions. Note that there is at most one failure concept by support cluster.

The failure lattice has two properties which are essential for the design of the algorithm of next section.

*Property 1 (**global monotony of support**):* Let c_i and c_j be two concepts of a failure lattice. If $c_j < c_i$ then $sup(r_j) \leq sup(r_i)$. For instance, in Figure 2, concepts 11 and 13 are ordered, $c_{13} < c_{11}$ and $sup(r_{13}) = 16 < sup(r_{11}) = 76$.

Proof: The fact $c_j < c_i$ implies that the intent of c_j strictly contains the intent of c_i. The intent of concept c_i (resp. c_j) is the premise, p_i (resp. p_j), of rule r_i (resp. r_j), thus $p_i \subset p_j$. Conversely $extent(p_j) \subset extent(p_i)$. Thanks to the definition of the support $sup(r_j) \leq sup(r_i)$ holds. □

*Property 2 (**local monotony of lift**):* Let c_i and c_j be two concepts of a failure lattice. If $c_j < c_i$ and $sup(r_j) = sup(r_i)$ then $lift(r_j) > lift(r_i)$. For instance, concept 4 and 5 are ordered, $c_5 < c_4$, $sup(r_5) = sup(r_4) = 40$ and $lift(r_5) = 2.38 > lift(r_4) = 1.19$. It means that r_5 and r_4 cover the same failed executions but r_5 covers less passed executions than r_4.

Proof: In the previous proof we have seen that $c_j < c_i$ implies that $extent(p_j) \subset extent(p_i)$. The definition of the lift of a rule $r = p \rightarrow FAIL$ is $lift(r) = \frac{sup(r)}{\|extent(p)\|\|extent(FAIL)\|} * \|\mathcal{O}\|$. As $sup(r_j) = sup(r_i)$, and $\|extent(p_j)\| < \|extent(p_i)\|$, $lift(r_j) > lift(r_i)$ holds. □

V. Exploration of the Failure Lattice for Multiple Faults

In this section, we propose an algorithm to explore the failure lattice in order to find clues to understand faults. The algorithm presents events to a *debugging oracle*, currently most likely a human person. We assume *the competent debugger hypothesis*, namely when a set of events that indicates a fault is presented to the debugging oracle he will detect the fault. The same kind of hypothesis is assumed in [2].

When locating faults in a program, relevant parts of the program are the ones specific to failed executions. In the failure lattice, that information belongs to the most specific rules which label concepts at the bottom of the failure lattice. Furthermore, as stated by Property 1, the bottom concepts are the ones with the lowest support and, as stated by Property 2, the bottom concepts inside a support cluster are the ones with the highest lift. As a consequence, the rule lattice is explored bottom-up, starting from the more specific rules with the lowest support and highest lift.

We define the *fault context* of a concept c as the set of events that label strict subconcepts of c. For example, in Figure 2 the fault context of concept 11 is lines 64, 79, 87 and 90. For the localization task, as the lattice is traversed bottom-up, when exploring concept c, the events of its fault context have already been explored. Each time a concept c is explored, the debugging oracle has to say if the lines that label c, in addition to the fault context of c, indicates a fault. In that case we say that the failed executions that label c (and thus subconcepts of c) are *explained* by that fault. By definition, the concepts belonging to the support cluster of c are also *explained*, indeed, the concepts of a same support cluster cover exactly the same failed executions.

The exploration of the failure lattice stops when all failure concepts in $FAILURES$ are explained by at least one fault. Namely, when all failed executions that are covered by a concept in the failure lattice are *explained*.

The exploration strategy is specified by Algorithm 1. The failure lattice is traversed bottom-up, starting with the failure

5	$\{c_{11}, c_8\}$	$\{\}$

TABLE III
EXPLORATION OF THE FAILURE LATTICE OF FIG. 2.

concepts (step 1). At the end of the failure lattice traversal, $C_{failure}$ - the set of failure concepts not *explained* by a fault (step 2) - is empty or all concepts have been already explored (step 3). When a concept, c (step 4), is chosen among the concepts to explore, C_{next}, the events that label the concept, are explored. Note that the selection of that concept is not deterministic. If no fault is located, then the upper neighbours of c are added to the set of concepts to explore (step 7). If, thanks to those new clues, the debugging oracle understands mistakes and locates one or several faults then all subconcepts of c and all concepts that are in the same support cluster are *explained*. Those concepts do not have to be explored again (step 10). The failure concepts that are subconcepts of c are *explained* (step 11).

At each iteration, $C_{failure}$ can only decrease or remain untouched. The competent debugger hypothesis makes sure that $C_{failure}$ ends at empty when min_sup is equal to 1.

For the example of Figure 2, the support threshold, min_sup, is equal to 4 failed executions (out of 400 executions, of which 168 failed executions) and the lift threshold, min_lift, is equal to 1. There are four failure concepts: 5, 13, 12 and 9. Table III presents the values of C_{next} and $C_{failure}$ at each iteration of the exploration. We choose to explore the lattice with a queue strategy, namely first in C_{next}, first out of C_{next}. Note that the stopping criterion of the algorithm depends only of the failure concepts, it is therefore valid whatever the chosen strategy.

At the begining, C_{next} and $C_{failure}$ are initialized as the

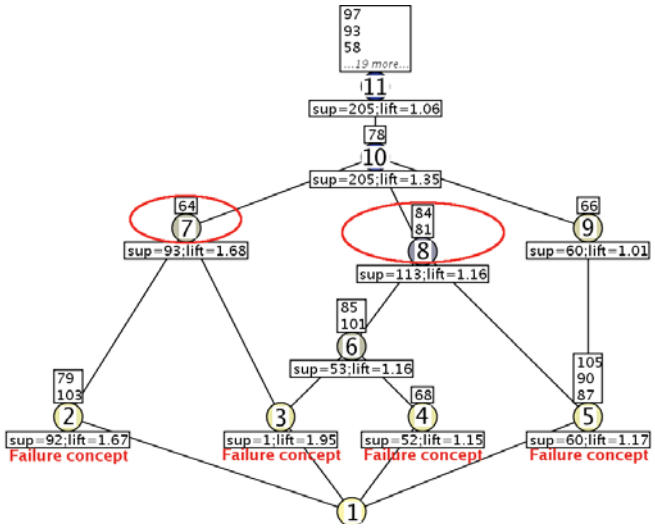

Fig. 3. Failure lattice for program Trityp with faults 1 and 6

set of all failure concepts (Iteration 0 in Table III). At the first iteration of the while loop, concept 5 is selected ($c = c_5$). That concept is labelled by line 74. Line 74 actually corresponds to fault 3. The debugger oracle locates fault 3. Concept 5, 4 and 14 are thus tagged as *explained*. The new values of C_{next} and $C_{failure}$ are presented at iteration 1 in Table III. At the second iteration, concept 13 is selected ($c = c_{13}$). That concept is labelled by lines 64 and 79. Line 79 actually corresponds to fault 2; the debugging oracle locates fault 2. Concept 13 is tagged as *explained*. At the third iteration, concept 12 is selected. That concept is labelled by lines 87 and 90. No fault is found. The upper neighbours, concepts 7 and 11, are added to C_{next} and $C_{failure}$ is unchanged. At the next iteration, concept 9 is selected. As in the previous iteration no fault is found. The upper neighbour, concept 8, is added to C_{next}.

Finally, concept 7 is selected. That concept is labelled by lines 81 and 84. By exploring those lines (new clues) in addition with the *fault context*, i.e. lines that have already been explored: 87, 90, 101 and 85, the debugging oracle locates fault 1 at line 84. The fault is the substitution of the test of trityp equal to 2 by a test of trityp equal to 3. Concepts 12 and 9 exhibit two concrete realisations (failures) of the fault at line 84 (Concept 7). Concepts 7, 12, 9 are tagged as *explained*. The set of failure concepts to explain is empty, thus the exploration stops. All four failures are explained after the debugging oracle has inspected nine lines.

VI. FAULT DEPENDENCIES

This section discusses the behavior of the algorithm with respect to fault dependencies. In the following, a fault is identified by its faulty line. We call *fault concept* of a fault F the most specific concept, c_F, such that it is labelled by the faulty line of F.

When two faults are independent, the execution of one fault implies that the other fault cannot be executed. The fault concepts of both faults thus appear in different support

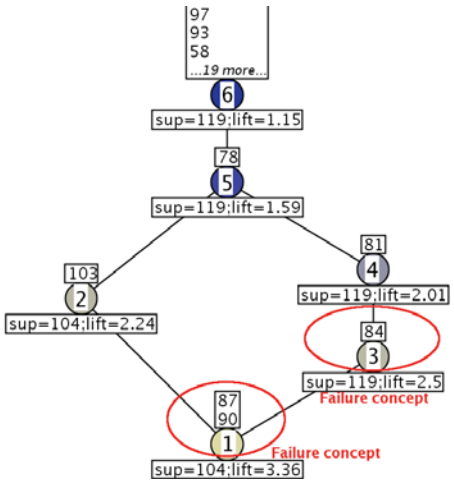

Fig. 4. Failure lattice for program Trityp with faults 1 and 4

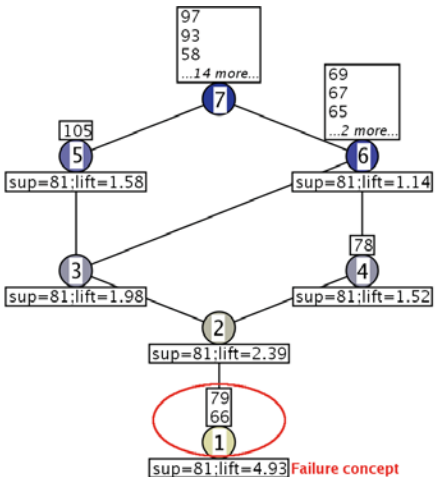

Fig. 5. Failure lattice for program Trityp with faults 2 and 5

clusters. That case is illustrated in Figure 2 which shows an example of three independent faults. The previous section has shown how the algorithm helps a debugging oracle locate the faults.

Two faults can be partially dependent, it means that some failed executions execute both faults. For example, Figure 3 presents the failure lattice for the Trityp program with faults 1 and 5. Fault 1 is at line 84, fault 6 is at line 64. The failure lattice contains four failure concepts: 2, 3, 4 and 5. There are also 8 support clusters. Running Algorithm 1, the exploration of concepts 2 and 3 does not allow a fault to be located, but gives clues when exploring concept 7. Concept 7 is labelled by line 64. Fault 6 is located. In the same way, exploring concepts 3, 4, 5 and 6 is not sufficient to locate a fault, but gives clues when exploring concept 8. Concept 8 is labelled by lines 84 and 81. Fault 1 is located. The two faults are not independent but they are represented separately, and can be distinguished.

Another example of partially dependent faults is given in Figure 4 that presents the failure lattice for the Trityp program with faults 1 and 4. Fault 1 is at line 84 and fault 4 is at line 90. Executing faulty line 90 implies to have executed faulty line 84 before, but executing line 84 does not always imply executing line 90. Fault 4 strongly depends on fault 1. The failure lattice contains two failure concepts, concepts 1 and 3. There are two support clusters. One support cluster has its support value equal to 104 failed executions. The second support cluster has its support value equal to 119 failed executions (all executions). Running Algorithm 1, concept 1 is explored. It is labelled by two lines: 87 and 90. Line 90 is fault 4. Concept 3 is labelled by line 84 then fault 1 is located. All failure concepts are tagged as *explained*. The search is finished, the two faults are located. The two faults are dependent but they are represented in different support cluster, and can be distinguished.

The last case is when the faults are always executed together in failed executions. From the point of view of the failed executions, they cannot be distinguished. Figure 5 presents the failure context for the Trityp program with faults 2 and 5. Fault 5, at line 66, sets triptyp to a value above 20, trityp is tested at line 78, with the value set at line line 66 the execution necessarily goes to line 79 which contains fault 2. The failure lattice contains only one *failure concept*, concept 1. All concepts belong to the same support cluster. The support value of that cluster is equal to 81, which is the number of failed executions. Running Algorithm 1, concept 1 is explored. It is labelled by two lines: 79 and 66. No distinction is done between both faults in the failure lattice. They are seen as a unique fault. Therefore, if the debugging oracle stops diagnosing when he finds one fault without exploring all the lines presented at that step, only one fault is found. Note, that the lines related to the other fault, are nevertheless present at that step and that the oracle can still find both faults in this example. However, in the worst case, when faults are executed by the same failed executions but by some different passed executions, the fault concepts are two different concepts in the same support cluster. It implies that when one of the faults is found, the search stops. All concepts in the support cluster are *explained*. In that case the first found fault hides the second one and the program has to be executed again after the correction of the first fault.

VII. Statistical Indicators

Computing association rules w.r.t. a support threshold (min_sup) filters out some rules. For example, rules that stress very specific lines may have a support under the threshold because they are present in a small number of failed traces. Those rules do not appear in the failure lattice. The failed executions that are covered by only pruned rules may not label concept in the failure lattice. The proposed process helps drawing conclusions from failures that label concepts in the failure lattice. A run of the fault localization process draws every conclusion from the failures that have a sufficient support. A new run can safely considers only the low support failures. This suggests a progressive approach for fault localization as successive runs of rule exploration with decreasing supports.

When the program contains a single fault, a rule is relevant with a lift value greater than 1. When the program contains several faults the lift threshold can be lower. Indeed, when a program contains several faults, verdict $FAIL$ is used as an abstraction of several more specific verdicts. All failures are not caused by the same faults, nevertheless we consider only one attribute, $FAIL$, to characterize failed executions when searching for association rules ($? \rightarrow FAIL$). If the failures were tagged by the faults that cause them, for example $FAIL_{F_i}$, the searched association rules would be $? \rightarrow FAIL_{F_i}$. However, we cannot assume that failures are tagged. When a rule $F_i \rightarrow FAIL_{F_i}$ would have a lift greater or equal to 1, the rule $F_i \rightarrow FAIL$ can have a lift lower than 1. The lift threshold can thus start equal to 1 at the beginning of the localization process and decrease below 1 if some faults remain hidden.

Note that, in both the above cases, the test suite does not need to be re-executed.

VIII. Related Work

In [5], we have compared our data structure, the failure lattice, with existing fault localization methods. In this section, we briefly recall the main results and further our navigation into the failure lattice, with the strategies of other methods. Renieris and Reiss [15] as well as Cleve and Zeller [6] have proposed four methods based on the differences between executions traces. In those cases, navigating is the action to explore the whole set of events without guide whereas our approach is guided by the structure of the failure lattice. The statistical methods, Tarantula [10], parallel debugging [9], Falcon [13], SBI [11], the bi-clustering method [16] and SOBER [12] rank events and there is not necessarly a relation between an event and the following one in the ranking. On the contrary, our proposed approach gives a context to understand the faults thanks to a partial ordering of the events, which takes into account their dependencies. In [3], the authors takes into account the program dependence graph in their scoring function thanks to the causal-inference theory, but as previously seen with the other methods, no context is provided with each statement.

For multiple faults, Jiang *et al.* [8] propose a method based on traces whose events are predicates. The predicates are clustered, and the path in the control flow graph associated to each cluster is computed. In the failure lattice, events are also clustered in concepts. The relations between concepts give information about the path in the control flow graph and highlight some parts of that path as relevant for debugging without computing the control flow graph. Other methods group together failed executions to separate the effects of different faults ([16], [9]). Those methods do not take into account the dependencies between faults whereas our method does. Finally, SBI [11] has a stopping criterion. SBI wants to take advantage of one execution of the test suite. SBI ranks predicates. When a fault is found thanks to the ranking, all execution traces that contain the predicates used to find the fault are deleted and a new ranking on predicates with the reduced set of execution traces is computed. Deleting execution traces can be seen as equivalent to tagging concepts, and thus the events of their labelling. The difference between SBI and our approach is that our approach does not need to compute the failure lattice several times.

IX. Conclusion

In this paper, an algorithm to locate multiple faults in programs is proposed. It is based on a data structure, the failure lattice, that gives a partial ordering of the events of the traces. At each step of the proposed algorithm, a debugging oracle, for example the human debugger, has to say if a fault is found given a set of events. The advantage of our algorithm is that the debugging oracle knows when to stop the exploration of the program.

Constructing Subtle Concurrency Bugs Using Synchronization-Centric Second-Order Mutation Operators

Leon Wu Gail Kaiser

{leon,kaiser}@cs.columbia.edu

Abstract

Mutation testing applies mutation operators to modify program source code or byte code in small ways, and then runs these modified programs (i.e., mutants) against a test suite in order to evaluate the quality of the test suite. In this paper, we first describe a general fault model for concurrent programs and some limitations of previously developed sets of first-order concurrency mutation operators. We then present our new mutation testing approach, which employs synchronization-centric second-order mutation operators that are able to generate subtle concurrency bugs not represented by the first-order mutation. These operators are used in addition to the synchronization-centric first-order mutation operators to form a small set of effective concurrency mutation operators for mutant generation. Our empirical study shows that our set of operators is effective in mutant generation with limited cost and demonstrates that this new approach is easy to implement.

1 Introduction

Mutation testing is a white-box fault-based software testing technique that uses mutants, slightly modified variants of the program source code or byte code, to characterize the effectiveness of a testing suite and locate weaknesses in the test data or program that are seldom or never exposed during normal execution [9]. Mutation testing is based on the *Competent Programmer Hypothesis* and the *Coupling Effect Hypothesis*. The *Competent Programmer Hypothesis* assumes that programmers are competent and normally write programs that are close to perfect; program faults are syntactically small and can be corrected with a few small code modifications [1, 9]. The *Coupling Effect Hypothesis* states that complex bugs in software are closely coupled to small, simple bugs. Thus, mutation testing can be effective in simulating complex real-world bugs [9, 23].

Mutation testing typically involves three stages: (1) Mutant generation, the goal of which is the generation of mutants of the program through inserting bugs. (2) Mutant execution, the execution of test cases against both the original program and the mutants. (3) Result analysis, to check the *mutation score*, *i.e.*, the percentage of nonequivalent mutants that are *killed* by the test suite [26, 23]. A mutant is *equivalent* to the original program if the mutant and the original program always produce the same output, hence no test case can distinguish between the two [8]. A mutant is considered *killed* by the test suite if the execution result of the mutant is different from the result of the original program [25]. A test data set is said to be *adequate* if its mutation score is 100% [8, 24].

For the first stage, a predefined set of mutation operators are used to generate mutants from program source code or byte code. A *mutation operator* is a rule that is applied to a program to create mutants [25]. Mutants containing one simple fault are called *first-order mutants* and mutants containing two simple faults are called *second-order mutants* [26]. Researchers have developed many sets of mutation operators [25, 17], targeting a variety of programming languages. For example, Delamaro *et al.* and Bradbury *et al.* have proposed different set of mutation operators for concurrent Java programs [7, 4]. Our empirical study and analysis shows that some subtle concurrency bugs are not generated by any of these proposed first-order mutation operators. Our study further shows that a large portion of these operators are not effective in mutant generation: the majority of the mutants are generated by a small subset of the mutation operators, generally those that are synchronization-centric, *i.e.*, directly relating to the synchronization of different processes or threads. Based on a general fault model for concurrent programs and our analysis of the limitations in prior work, we present our new mutation testing approach, which employs synchronization-centric second-order mutation operators that are able to generate subtle concurrency bugs not

represented by the first-order mutation. These operators are used in addition to the synchronization-centric first-order mutation operators to form a small set of effective concurrency mutation operators that can be used in mutant generation. Our empirical study shows that our small set of operators is effective in mutant generation with limited cost and demonstrates that this new approach is easy to implement. The initial analysis of the possible implications of our results has potential impact on the Coupling Effect Hypothesis, indicating that possibly the coupling effect is weaker in concurrent programs than in sequential programs.

The remainder of this paper is structured as follows. In Section 2, we describe our fault model for concurrent programs. In Section 3, we present the limitations of some previous work. In Section 4, we present our new approach. In Section 5, we present our empirical study. Lastly, we discuss the related work before we conclude.

2 Fault Model for Concurrent Programs

Testing concurrent programs is difficult. It is generally impossible or impractical to exhaustively test all combinations of input values or cover all possible control or data flow paths in sequential programs but even more so in concurrent programs; nevertheless, test suites can and must be constructed according to various criteria to attempt to find bugs. In order to develop a set of concurrency mutation operators that are able to model subtle concurrency bugs, we employ a general fault model that is based on the concurrency bug patterns and the synchronization mechanisms. Our definition of *fault* is a programming error that leads to an erroneous result in some programs during execution.

2.1 Concurrency Bug Patterns

Some prior research on concurrency bug patterns has been done. [13] and [20] described taxonomy of common concurrency bugs. [12] compiled a benchmark of concurrency bugs. [6] and [21] described some empirical studies on concurrency bugs. We consolidate the common concurrency faults from these prior research that we consider for mutation operators to model and present them below.

- Data Race: *Data race* condition happens when multiple threads read and write the same data, and the outcome of the execution depends on the particular order in which the accesses happen [6]. It is also called *thread interference*.
- Memory Inconsistency: *Memory inconsistency* errors occur when different threads have inconsistent views of the same variable.
- Atomicity Violation: *Atomicity violation* error is caused by concurrent execution of multiple threads violating the atomicity of a certain code region [21].
- Deadlock: *Deadlock* happens when multiple threads are blocked forever, waiting for each other.
- Livelock: *Livelock* happens when two threads are busy responding to each other and make no progress.
- Starvation: *Starvation* happens when a thread is unable to gain regular access to shared resources and is unable to make progress.
- Suspension: *Suspension* happens when a thread suspends or waits indefinitely.

2.2 Synchronization Mechanism

Concurrent programs rely on synchronization to ensure correct program execution. There are two main synchronization mechanisms: synchronization using shared memory and synchrnonization using message passing. For programming models that use shared memory synchronization (*e.g.*, Java and C#), the threads communicate primarily by sharing access to fields and the objects reference fields refer to. The synchronization aims to avoid thread interference and memory consistency errors. For programming models that use message passing (*e.g.*, Erlang [3] and Microsoft Asynchronous Agents Library [22]), the concurrent agents or actors in the programs communicate with each other through exchanging messages and use the synchronization to avoid problems in the message communications.

3 Limitations of First-Order Concurrency Mutation Operators

To measure the testability of concurrent Java programs, Ghosh described mutation based on two mutation operators that remove the keyword `synchronized` [14]. Long *et al.* tested mutation-based exploration for concurrent Java components [19]. Delamaro *et al.* proposed a set of 15 concurrency mutation operators for Java [7]. Later, Bradbury *et al.* proposed a new set of 24 concurrency mutation operators for Java [4]. The operators they proposed are all first-order mutation operators. We have investigated these mutation operators in our empirical study and identified some of their limitations.

3.1 Subtle Concurrency Bugs Are Not Generated

The first important limitation we found is that some subtle concurrency bugs are not generated by any of these proposed first-order mutation operators. This limitation could lead to loss of comprehensive representation of common concurrency bugs by the mutants, thus reducing the reliability of the mutation score that follows. We give two examples in the following subsections.

3.1.1 Data Race Example

The following code fragment from the *LinkedList* program, a Java program from the IBM concurrency benchmark programs repository [12], inserts an element to the end of a

list. Another process, not shown here, reads the list. The synchronized method first starts from the top of the list (line 4), then moves to the end of the list via a loop (line 5) before inserts the object `x` to the end (line 6). Suppose we only apply first-order mutation operators (*e.g.*, removing `synchronized` keyword from line 2 or deleting a statement from line 4 to 6), the mutant does not represent a feasible programming error that line 2 is not synchronized and line 5's error causes the node index `itr` does not move to the end of the list properly. The combined error in line 2 and line 5 would potentially cause data race because multiple threads would try to write to the header of the list without synchronization and other threads might read the list at the same time. The outcome of the execution would depend on the thread schedule and which thread made the last call to the method because different threads all try to update the header of the list. By definition, this is a data race condition. To apply either operator independently is not going to create the same fault because under single application of either first-order mutation operator, data race would less likely happen and their mutants would represent different kind of faults.

```
1   /* Inserts element to the end of list */
2   public synchronized void addLast( Object x )
3   {
4      MyListNode itr = this._header;
5      while( itr._next != null ) itr = itr._next;
6      insert(x,new MyLinkedListItr(itr));
7   }
```

3.1.2 Deadlock Example

Incorrect use of synchronization can result in two or more threads waiting for each other to release the locks on the synchronized objects, forming a deadlock circle. As shown in the following example code for money transfer between two accounts, the line 5 and 6 in the original code may be incorrectly programmed in a nested synchronized block, which makes the deadlock possible. For example, two threads with execution of line 9 and 10 simultaneously would lead to deadlock since each thread will be waiting in a circle for the other thread to release required lock. This kind of deadlocks that require changes in more than one place are not generated by any first-order operator.

```
1   void TransferMoney(Acct a, Acct b, int amount) {
2      synchronized(a) {
3         a.debit(amount);
4      }
5       synchronized(b) {
6         b.credit(amount);
7      }
8   }
1   void TransferMoney(Acct a, Acct b, int amount) {
2       synchronized(a) {
3         synchronized(b) {  //first change
4            a.debit(amount);
5            b.credit(amount);  //second change
6         }
7      }
8   }
9   Thread1.run() { TransferMoney(a,b,10); }
10  Thread2.run() { TransferMoney(b,a,20); }
```

3.2 A Large Portion of Mutation Operators Do Not Generate Any Mutant

Our empirical study show that a large portion of existing mutation operators are not effective in generating mutants. For example, several previously proposed mutation operators for concurrent Java, including MSF, MXC, MBR, RCXC, ELPA, EAN, RSTK, RFU, RXO and EELO [7, 4], did not generate any mutants in our experiments. Some others, including MXT, RNA, RJS, InsNegArg, and ReplTargObj [7, 4], generated very few mutants. In our assessment, over half of the total number of operators are non-performing mutation operators, *i.e.*, operators that do not generate any new mutant. Most of the performing ones are related to mutation of a synchronized method or block.

4 Approach

4.1 Synchronization-Centric Second-Order Concurrency Mutation Operators

Our new mutation testing approach is based on our fault model and our analysis of the limitations of some previous work. We use synchronization-centric second-order concurrency mutation operators to construct subtle concurrency bugs that are not represented by the first-order mutation. While, a random and brute-force approach without any reduction would lead to $n * n$ second-order mutation operators based on n first-order mutation operators. To reduce the number of second-order mutation operators and mutant execution cost, we employ two steps of reduction. We first choose one of the two first-order mutation operators to be a synchronized method or block related modification and the other first-order operator to perform code changes related to the same synchronized method or block. For example, in concurrent Java, there are five first-order mutation operators related to synchronized methods [7, 4], we choose two out of the five in the same category. Then we evaluate the chosen two first-order mutation operators to see if their combination can generate mutants that resembles some possible faults due to programming mistakes and only keep those meaningful combinations. This second reduction step through selection based on domain knowledge further reduces the amount of second-order mutation operators and leads to fewer unnecessary or redundant mutants.

After the set of synchronization-centric second-order concurrency mutation operators are chosen, they are combined with the synchronization-centric first-order mutation operators to form a smaller set of mutation operators for mutant generation.

4.2 Example Mutation Operators for Java

Table 1 lists the synchronization-centric second-order concurrency mutation operators for Java, as an example of synchronization using shared memory. We describe each operator with example code in the following subsections.

Table 1. Second-Order Concurrency Mutation Operators for Java

sync method	RKSN+RSSN	Remove `synchronized` Keyword and a Statement from Synchronized Method
	AKST+MASN	Add `static` Keyword and Modify Argument with Constant to Synchronized Method
	RKSN+MASN	Remove `synchronized` Keyword and Modify Argument with Constant
sync block	RSNB+RSSB	Remove `synchronized` Block and a Statement from Synchronized Block
	MOSB+RSSB	Modify `synchronized` Object and Remove a Statement from Synchronized Block
	MOSB+MVSB	Modify `synchronized` Object and Move Statement(s) Out of Synchronized Block

4.2.1 RKSN+RSSN

The RKSN+RSSN operator removes a `synchronized` keyword and a statement from a synchronized method. This operator simulates programming errors that can potentially lead to data race, memory inconsistency, and deadlock. The data race described in Section 3.1.1 can be constructed by this operator.

```
/* Original Code */
public synchronized void proc(Object A) {
   <statement 1>
   <statement 2>
}
/* RKSN+RSSN Mutant 1 */
public void proc(Object A) {  // sync removed
   ...// statement removed
   <statement 2>
}
/* RKSN+RSSN Mutant 2 */
public void proc(Object A) {  // sync removed
   <statement 1>
   ...// statement removed
}
```

4.2.2 AKST+MASN

The AKST+MASN operator adds a `static` keyword and modifies an argument with a constant to a synchronized method. This operator simulates programming errors that can potentially lead to data race and memory inconsistency.

```
/* Original Code */
public synchronized void send(String m) {...}
/* AKST+MASN Mutant */
public static synchronized void send(String n) {...}
```

4.2.3 RKSN+MASN

The RKSN+MASN operator removes a `synchronized` keyword and modifies an argument with a constant to a synchronized method. This operator simulates programming errors that can potentially lead to data race and memory inconsistency.

```
/* Original Code */
public synchronized void send(String m) {...}
/* AKST+MASN Mutant */
public void send(String n) {...}
```

4.2.4 RSNB+RSSB

The RSNB+RSSB operator removes the synchronized block and a statement from a synchronized block. This operator simulates programming errors that can potentially lead to data race, memory inconsistency, and deadlock.

```
/* Original Code */
synchronized (this) {
   <statement 1>
   <statement 2>
}
/* RSNB+RSSB Mutant 1 */
... // removed
    ... // removed
   <statement 2>
...
/* RSNB+RSSB Mutant 2 */
... // removed
   <statement 1>
    ... // removed
...
```

4.2.5 MOSB+RSSB

The MOSB+RSSB operator modifies a synchronized object and removes a statement from a synchronized block. This operator simulates programming errors that can potentially lead to data race and memory inconsistency.

```
/* Original Code */
synchronized(obj1) {
   <statement 1>
   <statement 2>
}
/* MOSB+RSSB Mutant */ // object modified
synchronized(newobj) {
   <statement 1>
    ... // removed
}
/* MOSB+RSSB Mutant */
synchronized(newobj) { // object modified
    ... // removed
   <statement 2>
}
```

4.2.6 MOSB+MVSB

The MOSB+MVSB operator modifies a synchronized object and moves statement(s) out of a synchronized block. This operator simulates programming errors that can potentially lead to data race, deadlock, memory inconsistency, and atomicity violation. The deadlock described in Section 3.1.2 can be constructed by this operator, *i.e.*, moving two lines of code including the synchronized block.

```
/* Original Code */
synchronized(obj1) {
   <statement 1>
   <statement 2>
    ...
}
/* MOSB+MVSB Mutant 1*/
<statement 1>  // moved
synchronized(newobj) { // object modified
   <statement 2>
    ...
}
/* MOSB+MVSB Mutant 2*/
<statement 1>  // moved
<statement 2>  // moved
synchronized(newobj) { // object modified
    ...
}
```

4.3 Example Mutation Operators for Erlang

Table 2 lists the synchronization-centric second-order concurrency mutation operators for Erlang, as an example of synchronization using message passing. The CRT (*i.e.*,

Change Reference Type) refers to changing a message reference from *Send by Ref* to *Send by Val*, and vice versa [15]. The CST (*i.e.*, Change Synchronization Type) refers to changing a message's synchronization method from *Sync Send* to *Async Send*, and vice versa. Since these mutation operators are self-explanatory, we do not give detailed example code here.

Table 2. Second-Order Concurrency Mutation Operators for Erlang

Messaging	CRT+MMP	Change reference type and modify message parameter
	CRT+RMP	Change reference type and reorder message parameter
	CRT+MMN	Change reference type and modify message name
	CRT+MMR	Change reference type and modify message recipient
	CST+MMP	Change sync type and modify message parameter
	CST+RMP	Change sync type and reorder message parameter
	CST+MMN	Change syn type and modify message name
	CST+MMR	Change syn type and modify message recipient
Constraint	CRT+RC	Change reference type and remove constraint
	CRT+MC	Change reference type and modify constraint
	CST+RC	Change syn type and remove constraint
	CST+MC	Change syn type and modify constraint

5 Empirical Study

5.1 Implementation

We developed an Eclipse Plug-in [11] named BUGGEN that is able to automate mutant generation after the specific mutation operator is selected. Eclipse is a popular integrated development environment (IDE) with an extensible plug-in system. Building BUGGEN as an Eclipse Plug-in leverages the functionalities of the Eclipse and simplifies software development. During our implemention, we found our set of mutation operators are easy to implement. In our empirical study, we focus on concurrent Java.

5.2 Example Programs

We use the following four example programs in our experiments to study mutant generation, as well as the cost and effectiveness of each proposed operator,

- *Webserver*, a Java web server program that supports concurrent client connections and synchronization [2].
- *Chat*, a Java chat program that supports multiple clients exchanging messages [10].
- *Miasma*, a graphical Java applet program from the NIH web-site [18]. It supports synchronization and uses `wait(t)` for prior pixels to be accepted before triggering another one.
- *LinkedList*, a modified Java program from the IBM concurrency benchmark programs repository [12]. The original program was developed to emulate the concurrency bug in using Java linked list, which is a non-synchronized collection.

We select the above example programs because they all employ different concurrency features and these programs are diversified in terms of type, size, coding style, applied field, and developer. These programs are representive in demonstrating common programming practices using concurrent Java. Table 3 lists some statistical information for each program's source code.

Table 3. Example programs

Program Name	LOC	classes	sync methods	sync blocks
Webserver	125	6	11	2
Chat	482	4	10	2
Miasma	360	1	0	2
LinkedList	421	5	1	1
Total	1,388	16	22	7

5.3 Mutant Generation Results and Analysis

In our experiments, we apply each of the mutation operators listed in Table 1, along with the synchronization-centric first-order mutation operators, on the example programs, count the number of mutants generated by each operator for each program, and then examine these mutants. From our experiments, we found that over half of the first-order mutation operators, especially those that are not related to synchronization, are not effective in generating mutants. The majority of the mutants are generated by synchronization-centric mutation operators. Our quantitative data and summations for each category are recorded in the histogram chart presented in Figure 1. Details for each operator and the example programs can be found in our technical report [27]. The vertical axis shows the number of mutants. Most synchronization-centric mutation operators, in particular the second-order ones, are effective in mutant generation.

Our empirical study demonstrates that subtle concurrency bugs not represented by the first-order mutation are generated by the second-order mutation operators; our mutant generation effort is limited; fewer percentage of equivalent mutants are generated. Second-order operators tend to decrease the percentage of equivalent mutants [26].

6 Related Work

Some prior studies have been done on mutation testing for concurrent programs [17]. Carver described deterministic execution mutation testing and debugging of concurrent programs using synchronization-sequence [5]. Researchers have developed many sets of mutation operators [25, 17], targeting a variety of programming languages. Other than the mutation operators for concurrent Java, Jagannath *et al.* have proposed a set of mutation operators for actor programming model [15]. Our synchronization-centric second-order mutation operators for message passing also apply to the actor programming model.

For higher-order mutation, Polo *et al.* studied mutation cost reduction using second-order mutants [26]. Jia *et al.* described some general cases of higher-order mutation and related algorithms [16]. In our approach, we used second-order mutation to construct some subtle concurrency faults.

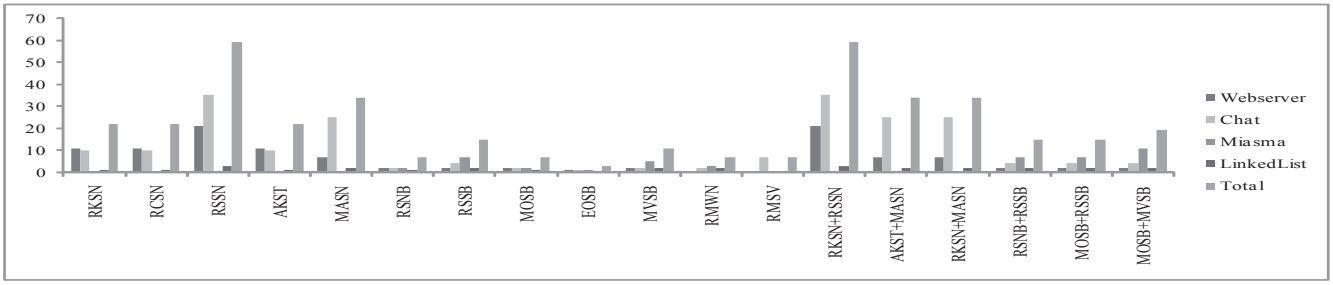

Figure 1. Number of mutants generated per operator

By keeping a small number of second-order mutation operators based on synchronization and reduction through domain analysis, we avoided the drastic growth of the number of mutants, thus avoiding higher computing cost in mutant execution. To the best of our knowledge, our work is the first study of the second-order mutation operators specifically for concurrent programs.

7 Conclusion

This paper first described a general fault model for concurrent programs and some limitations of previously developed sets of first-order concurrency mutation operators. We then presented our new mutation testing approach, which employs synchronization-centric second-order mutation operators that are able to generate subtle concurrency bugs not represented by the first-order mutation. These operators are used in addition to the synchronization-centric first-order mutation operators to form a small set of effective concurrency mutation operators that can be used in mutant generation. We developed an Eclipse Plug-in named BUGGEN to automate the mutant generation using these operators. Our empirical study showed that our set of mutation operators is effective in mutant generation with limited cost and this new approach is easy to implement. For future work, we plan to evalute some concurrency testing suites using the set of mutation operators.

***Abstract*— In general, test generation tools receive as input either requirements or use case specifications. However, in most companies these specifications are written in free natural language (NL), and the lack of standardization may become a problem for the generation tools and testers. A promising solution is to use a Controlled NL (CNL) to write software specifications. We present here the ucsCNL for the authoring of Use Case specifications. The ucsCNL is implemented as a plug-in of TaRGeT, a tool for the automatic generation of feature test cases based on use case scenarios written in English. The ucsCNL is already in use, and has achieved satisfactory results.**

I. Introduction

Software Testing has grown in importance in recent years, as a way to increase quality and reliability of the final product. Several tools to automate software testing tasks have been proposed, from test generation to its execution. In particular, automatic test generation has been the focus of several works [1], due to the drawbacks of manual test design, which is time-consuming, and not always systematic and precise.

Usually, test generation tools receive as input either requirements or use case (UC) specifications, from which the test cases are derived. This input should be unambiguous, to preserve the quality of the testing process. However, in most companies requirements and use cases are written using free natural language, and the absence of standardization may become a problem both for the generation tool, and for the professionals who manually execute the test suits.

A promising solution is to use a Controlled Natural Language (CNL) to restrict the creation of requirements and/or use cases. A CNL is a subset of natural language that uses a restricted set of grammar rules and a predefined vocabulary, in order to avoid textual complexity and ambiguity [2].

We present here the ucsCNL, a subset of English language designed for the authoring of UC specifications. The ucsCNL counts on two knowledge Bases: a Lexicon, with the domain-specific vocabulary; and a Grammar, used to restrict the sentence constructions allowed for writing the UC specifications.

The ucsCNL is implemented as a plug-in of TaRGeT [3], a tool for the automatic generation of feature (black box) test cases based on use case scenarios. The ucsCNL is already in use, and has achieved satisfactory results. Initial experiments showed a better performance of testers when manually executing test generated from UCs written using the ucsCNL *versus* UCs written in free English. This is an original work which combines techniques from Software Engineering, Artificial Intelligence and Natural Language Processing.

Section II discusses research in the CNL field. Section III presents the ucsCNL in detail, section IV shows implementation details, and section V brings conclusions and future work.

II. Controlled Natural Languages and Software Specifications

In order to safeguard the quality of the input specifications in the software development process, some companies use a Controlled Natural Language specially designed to address their particular communicative needs. A CNL [2] is a subset of some NL which uses:

(1) a domain-specific vocabulary (Lexicon), in order to avoid *synonymy* (i.e., two different terms referring to the same entity) and *lexical ambiguity* (i.e., the same term referring to two or more entities in the application domain); and

(2) a restricted set of grammar rules, which can be general (e.g., 'write short and simple sentences'), or more formal, counting on grammar rules to constrain the accepted syntactic structures (in order to avoid *structural ambiguity* - a sentence being mapped into two or more different syntactic structures).

It is possible to identify two major groups of CNLs, aimed at different purposes. The most basic goal of a CNL is to define a standard to be followed throughout an organization, in order to provide for unambiguous and clear technical documentation (e.g., ASD-STE100 Simplified Technical English [4]). These CNLs are also known as 'simplified', or 'technical languages', since their Grammar is basically a set of general writing rules (e.g., 'write short and grammatically simple sentences', 'use active instead of passive voice' [5]).

The second group of CNLs is at the more formal side. In case a mapping from CNL specifications to a formal representation is desired, the CNL must use a precise syntax and semantics. Based on a formal grammar and a controlled lexicon, it is then possible to define a mapping from CNL sentences into a more formal representation (such as First-Order Logic - FOL) - e.g., PENG [6]. These formal representations

can be used for further processing, such as model checking [7], automatic test generation [8], and so on.

We highlight here the Attempto project[1] and works derived from the Attempto Controlled English (ACE) [9], such as the work of [10], which focuses on Requirement specifications.

Finally, [11] presents a tool for modal-based test generation from 'natural-language-like' functional specifications. Requirements are represented using a Template Based Natural Language Specification (TBNLS), where each requirement corresponds to a TBNLS representation. These TBNLSs are mapped into a Formal Requirement Language in which requirements are represented as tuples: (start-condition (if), consequence (then), end-condition (until)). Clearly, this is a too restricted grammar for our purposes.

III. A Controlled Natural Language for Use Case Authoring

This section presents the ucsCNL developed for the authoring of use cases specifications. Our CNL is not merely a technical language, since we are interested in the automation of the whole testing process. This way, we designed a more formal CNL, counting on a Lexicon with pre-defined word types and terms, and a Grammar, used to restrict the sentence constructions allowed for writing the UC specifications.

The ucsCNL version presented in this paper was developed for the mobile phone domain. However, our CNL can be adapted to different application domains. In this work, UC specifications consist of three basic fields:

(1) *Initial Condition*, stating the system's state before the test takes place (e.g., 'The phone is in data connection screen');

(2) *User Action*, stating the test steps to be executed by the tester (e.g., 'Cancel the operation pressing END key'); and

(3) *System Response*, stating the result of an action or the system state after the test was completed (e.g., 'The operation was successfully canceled').

The ucsCNL Grammar provides rules for the three UC fields (section III-B). Section III-A presents the ucsCNL Lexicon.

A. The ucsCNL Lexicon

The Lexicon contains the ucsCNL vocabulary, whose terms are classified into 7 different lexical classes (also known as 'parts of speech') [12]: noun (representing the domain entities), verb (representing an action or an event that may occur in the domain), determiner (a noun modifier - detailed below), adjective, adverb, preposition, and conjunction.

Determiners include articles (a, the), quantifiers (every, all, some), and numerals (cardinals and ordinals). Pronouns such as 'this', 'that' or 'it' are not allowed, in order to avoid ambiguity caused by pronominal reference (i.e., anaphora).

Determiners, prepositions and conjunctions are closed word classes, that is, they contain a stable (fixed) set of words which do not depend on the application domain. Terms belonging to these categories are already provided by the ucsCNL initial vocabulary, and cannot be added or erased by the user. Only the system's administrator is allowed to edit these classes. The user is free only to add nouns, verbs, adjectives and adverbs.

Verb entries contain the infinitive form plus inflections: present; past simple; past participle (also used as adjective); and gerund form, also used as a noun. Modal verbs (e.g., may, can, could) are not allowed, since they express the idea of 'possibility', and we need precise statements regarding Use and Test Cases, in order to avoid misinterpretations.

B. The ucsCNL Grammar

The ucsCNL grammar consists of a set of rewriting rules used to restrict the sentence constructions allowed for writing UC specifications. We work within the Immediate Constituents Grammar approach [12], according to which a sentence can be analyzed as a combination of units - immediate constituents- (e.g., sentence = noun phrase + verb phrase + prepositional phrase). These constituents can, in turn, be analyzed as smaller constituents (e.g., noun phrase = article + noun), until reaching irreducible constituents (such as nouns, verbs, etc).

Sentences in the different UC fields are based on different syntactic structures. To specify the *User Action* field, imperative sentences are used (e.g., 'Press the END key'). On the other hand, *Initial Condition* and *System Response* sentences convey, respectively, the system state before and after an action is taken. Here, active and passive sentences are used.

In order to simplify the parsing process, two separate grammars were defined (sections III-B.2 and III-B.3). This way, the parsing of each UC field is guided by a different set of rules. The ucsCNL also counts on a Base Grammar, which defines rules for basic constituents (section III-B.1).

The ucsCNL *parser* receives an input sentence and returns its grammatical structure, according to the Lexicon and Grammar under use (section IV-A). The process starts by attributing the input sentence to the token 'Sentence', which is the root of the parsing tree. Thus, the UA and IC-SR grammars start with a rewriting rule for this token (see tables III and IV).

1) Base Grammar: The Base Grammar defines rules for the basic constituents, namely: noun phrase, determiner, qualifier, prepositional phrase, relative clause, verb phrase and gerund phrase. These basic constituents are used by all other ucsCNL grammars, which actually extend the Base Grammar with field-specific rules built upon these general constructions.

A noun phrase (NP) is "a group of words in a sentence which together behave as a noun" [13]. Qualifiers are defined as "a word or phrase which limits the meaning of another word or phrase, or makes it less general, such as an adjective or adverb" [13]. An NP may end with a Prepositional Phrase or a Relative Clause, to add more information about the preceding noun. A Prepositional Phrase consists of a preposition followed by an NP.

Table I presents some rules for NP, Determiner and other constituents. The comma sign represents the 'AND' connector, and the vertical bar represents the 'OR' connector. Constructions ending with a question mark are optional, and brackets indicate that only one of the constructions between

INITIAL CONDITION AND SYSTEM RESPONSE GRAMMAR RULES.

Sentence = SRSentence, [‘and’, SRSentence]?
SRSentence = SRNucleus, SRComplementList?
SRNucleus = ActiveVoiceSentence | PassiveVoiceSentence | ThereBeSentence | VerbToBeSentence
ActiveVoiceSentence = NounPhrase, Neg?, ADV?, ActiveVerbPresent, ADV?, SimpleVC?, ADV?
PassiveVoiceSentence = NounPhrase, VerbToBe, ADV?, VBN, ADV?
VerbToBeSentence = NounPhrase, VerbToBePresent, (NounPhrase | PrepositionalPhrase | QualifierList)
SRComplement = ToComplement | [PrepositionalPhraseList, ADV?] | [CJ, SRNucleus]

the signs can be used. Finally, ‘[]’ indicates that all constructions between the signs must occur together. Some sentence formations require a particular word occurring in a given position (rather than any word from a particular class). Words between quotation marks must be literally interpreted by the rules (e.g., ‘and’ in Table I).

We introduce now the acronyms (tokens) used to represent the Lexicon entries: noun = Noun, verb = VB and other tokens (see below), determiner = DT, adjective = ADJ, adverb = ADV, preposition = PP, and conjunction = CJ. Numerals have their own entries: ordinals = OD and cardinals = CD. The main Verb entries are: VB (infinitive form) and VTB (verb to be). The verb conjugations are represented by adding suffixes to these acronyms: D - past tense; N - past participle; P - non-3rd person singular present; Z - 3rd person singular present. Finally, the gerund form is represented by G suffix.

A verb phrase (VP) is a group headed by a verb and may consist of a single verb, or auxiliary and main verbs, with optional complements and adjuncts (e.g., ‘The agenda *has three entries*’). Table II brings some rules for verbs.

2) User Action Grammar: User Action (UA) sentences are *imperative sentences* that convey an action to be executed by the tester (for manual test execution). UA sentences may also state how the action should be executed (e.g., ‘Send a message *by pressing the SEND key*’). This grammar allows imperative sentences in the *negative form*, as well as *subordinate clauses* to an imperative sentence (e.g., ‘*After creating a message with 100 characters*, go to the drafts folder’).

Note that imperative sentences do not have an explicit subject, since UC actions are commands to the tester. This way, the UA rules do not accept an NP in the beginning of the sentence (see Table III).

3) Initial Condition and System Response Grammar: Initial Condition (IC) sentences are statements defining the system state before a test is started. In turn, System Response (SR) sentences convey messages stating how the system is expected to behave after some action has been taken by the tester. We observed that IC and SR sentences have similar grammar structures. This way, the ucsCNL uses the same grammar rules for the parsing of both IC and SR fields (Table IV).

The IC and SR fields convey four different kinds of sentences: active and passive voice sentences, existential sentences, and the so-called ‘verb To Be’ sentences. The ‘verb to be’ sentences are simple formations that denote the state of a domain entity, or better describe it (e.g., ‘The imported media file is a music file’).

IV. Implementation Details

The ucsCNL is implemented as plug-in of a larger system for feature (black box) test cases generation, the TaRGeT (Test and Requirements Generation Tool) [3]. TaRGeT was developed as a software product line, and its main purpose is to automate a systematic approach to generate feature test suites from use case specifications written in the ucsCNL.

TaRGeT receives as input use cases scenarios written in CNL, thus aiding the test designers/engineers, who are more familiar with NL sentences than with formal specification languages. The system model and test suites are automatically derived from these UC scenarios.

A. The ucsCNL Advisor

The ucsCNL plug-in is implemented as the TaRGeT *CNL Advisor* view at the workbench. This advisor gives support to the process of UC authoring, obeying the ucsCNL Grammar and Lexicon (in order to minimize possible mistakes in the testing phase). In order to conform with TaRGeT's software product line approach, the ucsCNL Lexicon and Grammar bases are represented as XML files.

The CNL Advisor counts on 3 modules: a pre-processing module, a POS-tagger and a context free parser. Initially, the pre-processing module verifies whether all words in the sentence are included in the Lexicon. When a new word is detected, the user receives an error message. If the word belongs to an open class (noun, verb), the user will able to add it to the Lexicon via a simple user interface. When the word belongs to a closed class, the user receives a message advising him/her to modify the input sentence, or to contact the system's administrator, who has special priority to edit the Lexicon and the Grammar.

Following, the POS-tagger tags all words in the input sentence with their lexical class. Words that belong to more than one class are tagged with all possibilities, and the parsing process will disambiguate the double categorization based on the available grammar rules. The parser receives a list of words with their lexical class, and builds one tree for every possible syntactic structure. Sentences that could not be correctly parsed are returned to the user. In the case of syntactic error, the Advisor indicates the word categories that were expected instead, and gives examples of correct sentences. The Advisor also allows the user to filter the errors, displaying only the user action, initial condition or system response sentences.

B. Empirical tests

Empirical tests were performed to evaluate the impact and the benefits of the ucsCNL for text standardization. Although this is not the unique aim of our CNL, this preliminary test already indicated the benefits of text standardization. This case study was executed in the context of a mobile device testing company. The aim was to compare the gains of manually executing TC suites created using the ucsCNL versus suites written in free natural language. We considered here: (1) the execution time (the ucsCNL performed better in 35% of the TCs); and (2) number of detected defects/bugs (the ucsCNL detected one extra bug, and avoided a false defect accused by the free LN TCs). The results demonstrate a slight advantage of the use of ucsCNL in relation to free natural language. New tests will be performed in order to confirm this advantage, as well as to identify other gains with the use of the ucsCNL.

V. Conclusion and Future Work

This paper presented the ucsCNL for the authoring of Use Case specifications, from which test cases can be automatically derived by TaRGeT. The main aim of this work was to aid users (in particular, test designers) who are more familiar with natural language descriptions than with formal specifications.

We are currently developing a mechanism for the automatic mapping from ucsCNL sentences into a formal language representation, to automatically generate test scripts from these formal specifications. Another future work is the inclusion of ontology-based semantic analysis to check the coherence of the UC input specifications according to the specific domain application being tackled.

Abstract

A common problem in object-oriented software integration testing is to determine the order in which classes are integrated and tested. In this paper, we first overview some related work based on their objectives in current literature and then provide some analysis and evaluation.

***Index Terms*—object-oriented; integration test order; coupling measurement; graph-based algorithm; search-based algorithm**

I. Introduction

During object-oriented software integration testing, an important problem is to determine the order in which classes are integrated and tested, which is called class integration test order (*CITO*) problem. When integrating and testing a class that depends on other classes that have not been developed or tested, some stubs must be developed to simulate these other classes. There are two types of stubs: specific stub and realistic stub [16] (or generic stub [9]). It is very error-prone and costly to construct stubs. All related papers tried to find a (optimal) test order using minimal stubbing cost which is usually modeled as the number of stubs to be constructed or modeled as the overall stub complexity.

Many approaches proposed to solve this problem can be divided into two categories based on their objectives: minimizing the number of stubs [2], [5], [7], [11], [12], [13], [14], [15], [16] and minimizing the overall stub complexity [1], [3], [4], [6], [17]. If the objective is to minimize the number of stubs, there are two key steps which are modeling and breaking cycles. A dependency model which can be created from *UML* diagrams or source code is used to represent classes and inter-class dependency relationships using nodes and edges, respectively. In current literature, there are two kinds of dependency models which are object relationship diagram (*ORD*) [12] and test dependency graph (*TDG*) [16]. If a dependency model has no cycles, a test order can be generated by using a simple reverse topological sorting algorithm based on inter-class dependency relationships, otherwise all existing approaches tried to design an effective and efficient algorithm to break cycles. In current literature, there are two types of typical algorithms for breaking cycles which are graph-based algorithm (*GBA*) and search-based algorithm (*SBA*). If the objective is to minimize the overall stub complexity, one extra step must be introduced to measure each stub complexity based on inter-class coupling information before breaking cycles.

The rest of this paper is organized as follows: Section II overviews some existing approaches for minimizing the number of stubs. Section III overviews some existing approaches for minimizing the overall stub complexity. Section IV provides some analysis and evaluation. Section V draws some conclusions.

II. Minimizing the Number of Stubs

A. Minimizing the Number of Specific Stubs

Kung et al. [12] used an *ORD* as a dependency model which was created from source code and had three types of dependency relationships: inheritance, aggregation and association. They used a *GBA* to break cycles by selecting and removing association edges. Their algorithm did not use any heuristic information to select association edges

Correspondence to: bx.li@seu.edu.cn

to break cycles. The time complexity of their algorithm is O(n^4).

Tai et al. [15] used an *ORD* as a dependency model which was created from *UML* class diagrams and had three kinds of dependency relationships: inheritance, aggregation and association. They determined major level numbers of classes based on inheritance edges and aggregation edges and determined minor level numbers of classes based on association edges. If the classes with the same major level number contained cycles, they used a *GBA* to break cycles. Their algorithm preferred to select and remove an association edge (u,v) with the highest weight to break cycles. The weight was defined as the sum of in-degree of u and out-degree of v. The time complexity of their algorithm is O(n^4).

Briand et al. [5] used an *ORD* as a dependency model which was created from *UML* class diagrams and had five kinds of dependency relationships: inheritance, aggregation, association, composition and usage. They used a *GBA* to break cycles. Their algorithm preferred to select and remove an association edge (u,v) with the highest weight to break cycles. The weight was defined as the product of in-degree of u and out-degree of v. The time complexity of their algorithm is O(n^4).

Malloy et al. [13] and Kraft et al. [11] used an *ORD* as a dependency model which was created from source code and had six types of dependency edges: inheritance, composition, association, dependency, polymorphism, and ownedElement. They used trial-and-error method to assign different weights to different edges based on their types and then used a *GBA* to break cycles. Their algorithm preferred to select and remove an edge with the lowest weight to break cycles. The time complexity of their algorithm is O(n^4).

Mao et al. [14] used a weighted *ORD* (*WORD*) as a dependency model which was created from *UML* class diagrams and had three types of dependency relationships: inheritance, aggregation and association. They used a triple (cycle weight, direction factors of edges, association intensity) to represent weight for each association edge. They defined the cycle whose length is two as a cycle pair. They first selected and removed association edges to break all cycle pairs, then used a *GBA* to break other types of cycles. Their algorithm preferred to select and remove an association edge with the highest cycle weight to break cycles. The time complexity of their algorithm is O(n^4).

Hashim et al. [8] used an *ORD* as a dependency model which was created from source code and had five types of dependency edges: inheritance, composition, aggregation, association and dependency. They used coupling between objects as a new cost function instead of Malloy et al's parameterized cost function to assign weights to all types of edges with a deterministic way. They used a *GBA* to break cycles. Their algorithm preferred to select and remove a node with the lowest weight to break cycles. The time complexity of their algorithm is O(n^3).

Bansal et al. [2] used an *ORD* as a dependency model which was created from source code and had eight types of dependency edges: inheritance, composition, association, dependency, polymorphism, ownedElement, friend and exception. They used Malloy et al.'s idea [13] to assign weights to all types of edges and used Abdurazik et al.'s method [1] (discussed in Section III) to break cycles.

B. Minimizing the Number of Generic Stubs

Traon et al. [16] used a *TDG* as a dependency model which was created from *UML* diagrams. They used a *GBA* to break cycles. Their algorithm preferred to select and remove a node with the highest weight to break cycles. The node weight was defined as the sum of the number of incoming back edges and the number of outgoing back edges. The time complexity of their algorithm is O(n^3). The number of generic stubs depended on the starting node of deep first search (*DFS*).

Hanh et al. [7] used a *TDG* as a dependency model which was created from *UML* diagrams. They provided two different types of strategies to break cycles. The first called *Triskell* used a *GBA* to break cycles. They preferred to select and remove a node with the highest weight to break cycles. The weight was defined as the number of cycles the node appeared in. The second used a *GA* to break cycles. The time complexity of *Triskell* strategy is non-polynomial because it takes non-polynomial time to enumerate all cycles before assigning weights to nodes.

Hewett et al. used a *TDG* as a dependency model which was created from *UML* class diagrams. In [10], they used a fast algorithm to find a (optimal) test order with minimal generic stubs. In [9], they improved their previous algorithm by adding an additional heuristic information. Two papers all used *GBAs* to break cycles and their time complexity is O(n^2).

III. Minimizing the Overall Stub Complexity

Briand et al. [4] used an *ORD* as a dependency model which was created from *UML* class diagrams and had four types of dependency relationships: inheritance, aggregation, association and usage. They proposed a coupling measurement technique to estimate stub complexity based on inter-class coupling information and used a *GA* to break cycles. They disallowed to remove inheritance edges and composition edges to break cycles.

Abdurazik et al. [1] used a *WORD* as a dependency model which was created from source code and had nine

types of dependency relationships: inheritance, implementation, composition, aggregation, association, dependency, etc. They provided a coupling measurement technique to estimate stub complexity using more fine-grained information and presented three different algorithms to break cycles. Each of them used a *GBA* to break cycles, and preferred to select and remove an edge (node) with the highest cycle-weight ratio (*CWR*). Their coupling measurement technique only simply assigned fixed values to inheritance edges and composition edges. The time complexity of their algorithms is non-polynomial because their ideas are similar to *Triskell*'s proposed by Hanh et al.

Borner et al. [3] used an *ORD* as a dependency model which was created from source code and had three kinds of dependency relationships: inheritance, association and dependency. They believed that test focus should be considered when performing integration testing. They used a simulated annealing algorithm and a genetic algorithm to find a (optimal) test order that considered not only the simulation effort but also the test focus.

Our previous work [17] used an extended *WORD* (*EWORD*) as a dependency model which was created from source code and had six types of dependency relationships: inheritance, implementation, composition, aggregation, association and usage. We proposed a coupling measurement technique to estimate stub complexity for all types of edges and used a random iterative algorithm (*RIA*) to break cycles. Our *RIA* algorithm used some properties of minimal feedback arc set and the idea of simulated annealing, which made it more effective.

Cabral et al. [6] used an *ORD* as a dependency model which was created from source code and had four kinds of dependency relationships: inheritance, composition, association and dependency. They used a multi-objective ant colony algorithm (*MOCA*) to generate a set of *Pareto* optimal solutions that achieved a balance between attribute complexity and method complexity.

IV. Analysis And Evaluation

Table I is a summary table, where the time complexity of all *SBAs* is not provided because their time complexity is related to specific implementation information. From this table, We can obtain some analysis results as follows.

• Published year: Three papers are published from 1995 to 2000, six papers are published from 2001 to 2005 and eight papers are published from 2006 to 2010, which indicates that more and more papers give attention to *CITO* problem.

• Objective: Though only five papers try to minimize the overall stub complexity, four of them are published from 2009 to 2010, which indicates that finding a (optimal) test order with minimal overall stub complexity is current hot topic. The reason is that minimizing the overall stub complexity is more reasonable than minimizing the number of stubs.

• Model: Seventeen papers are listed. Ten of them create their dependency models from source code and six of them are published from 2006 to 2010, which indicates that *CITO* problem is given more attention in reverse engineering research field. The reason is that source code can provide more fine-grained information.

• Algorithm type: Though five papers use search-based algorithms to break cycles, three of them are published in 2009 and 2010, which indicates that based-search algorithms have more utilization potentiality than based-graph algorithms. The reason is that based-search algorithms can escape from a local optimal solution and can be used to perform multi-objective optimization.

• Time complexity: Two papers are published in 2008 and 2009 whose time complexity is O(n^2), which indicates that designing a fast algorithm to break cycle is given more attention in recent years. The reason is that some software systems have a large number of cycles to be broken.

• Algorithm constraint condition: From 2006 to 2010, seven papers allow to remove inheritance edges and composition edges to break cycles and only one paper does not, which indicates that it is acceptable to remove inheritance edges and composition edges to break cycles in recent years.

Some challenging problems encountered are identified and explained as follows.

• The models proposed for representing inter-class dependencies lack precision. An *ORD* and a *TDG* can represent polymorphism dependency relationships, but applying class hierarchy structure to construct these dependency relationships is too simply, because some dynamic dependency edges may be not exist.

• The techniques proposed for measuring inter-class coupling information lack precision. Different stubs may need different test effort to be constructed, so it is more reasonable to find a (optimal) test order with minimal overall stub complexity than minimal number of stubs. The number of accessed attributes and the number of called methods are usually used as inter-class coupling information to calculate stub complexity, but it is not sufficient to use these information to calculate stub complexity.

• The algorithms proposed for breaking cycles lack effectiveness and efficiency. For a large-scale application case, it is very difficult to design an effective and efficient algorithm to break cycles. Graph-based algorithms are usually very fast but they have no chance to escape from a local optimal solution. On the contrary, search-based algorithms are usually very slow and require to adjust a lot of parameters to improve their performance, but they have chances to escape from a local optimal solution.

As: association; De: dependency; Po: polymorphism; Ow: owenElement.
GBA: graph-based algorithm; SA: simulated annealing algorithm; GA: genetic algorithm;
RIA: random iterative algorithm; ACO: ant colony optimization algorithm.
Constraint represents whether or not inheritance and composition edges are allowed to be removed to break cycles.

V. Conclusions

In this paper, we first review some related work based on their objectives and then provide some analysis and evaluation. By analysis, it is found to be a good strategy for automatic integration test order generation to construct a more precise dependency model from source code, to calculate stub complexity using a more precise coupling measure technique, and to design an effective and efficient algorithm for breaking cycles.

***Abstract*—Software testing process has a high cost when compared to the other stages of software development. Automation of software testing through reuse of software artifacts (e.g. models) is a good alternative for mitigating these costs and making the process much more efficient and efficacious. Model-Based Testing (MBT) is a technique to automatic generation of testing artifacts based on software models. For software development, the most spread modeling language in either the industrial or academic environments is UML. In such environments, it is desirable to reuse UML models also for MBT, avoiding re-building a different model exclusively for testing automation. These are the main reasons that make these semi-formal models an alternative to implementing MBT. Even though there are a lot of testing tools available commercially, to the best of our knowledge, none of them fully uses MBT. Therefore, this paper describes a case study showing how to implement the MBT process to automate test scripts generation and execution in a real-world, context. Furthermore, our solution is generated automatically by a Software Product Line (SPL).** [1]

***Keywords* - Model-Based Testing; Software Product Line; Performance Testing.**

I. Introduction

Currently, a great number of people and companies use computer programs to automate their activities, delegating to systems the execution of complex tasks. This widespread use of computer systems has also increased the number of residual software or hardware faults that generate failures to users [1] [2]. Therefore, it is important that during the development of a system, different techniques are applied to guarantee that the system provides a service that can be trusted. The ability to deliver a service that can justifiably be trusted is known as dependability [1]. The main attributes that integrate the dependability are reliability, availability, security, confidentiality, integrity and maintainability. According to the taxonomy presented in [1], system dependability can be achieved by four techniques: 1) Fault Prevention - *prevent the occurrence or introduction of faults*; 2) Fault Tolerance - *avoid service failures in the presence of faults*; 3) Fault Removal - *reduce the number and severity of faults*, and; 4) Fault Forecasting - *to estimate the present number, the future incidence, and the likely consequences of faults*. Several works that provide system dependability through fault tolerance, fault prevention and fault forecasting are present in the literature [3] [4] [5].

Although all techniques are used to achieve software dependability, the most used technique in all areas of software development in industry is fault removal, through software testing. Software testing is a process that focus on finding program failures[2] during runtime [6], or that has activities to validate the requirements of a program, determining if the expected results are met [7]. Performance is a key component of reliability and availability; therefore, performance testing is a major activity in system fault removal. However, due to the systems evolution and their amount of features, systems are becoming so complex that testing them is a difficult task. Therefore, it is necessary to implement a testing process to mitigate testing execution on the final product. This process should aim to reduce the costs impact, improving the quality of the software product [2].

One of the techniques that improves the software testing process is Model-Based Testing (MBT) [8]. This technique consists in the generation of test cases and/or test scripts based on the application model. Besides, it also includes the specification of the features that will be tested [9].

In previous work [10] [11], we have used MBT to build testing tools for security and functional testing. These tools were derived products from a Software Product Line [12] called PL*e*T*s* [11]. The work presented in this paper expands our previous work to apply MBT in the generation of a new product to execute performance testing. This new product generates test scripts for a commercial tool called LoadRunner [13]. Basically, we include stereotypes in the system UML models to express performance information that will be used during the execution of test scripts.

This paper is organized as follows. Section II presents a short description of MBT, SPL and the PL*e*T*s* architecture. In Section III we show how we have used stereotypes to include information on the UML models and a brief description of the LoadRunner tool. In Section IV we apply our strategy to an actual case study that uses the LoadRunner tool to execute performance testing. This case study is a tool used in a major

[1]Study developed by the Research Group of the PDTI 001/2011, financed by Dell Computers of Brazil Ltd. with resources of Law 8.248/91.

[2]We use fault, error, and failure definition from [1].

IT company. Finally, Section V summarizes the contributions of our work.

II. Background

Software modeling is an important technique that is used in software development because it allows to capture and to share knowledge about a system. During the development process, information about the system is described in many different documents. To include this information, through, for example, UML stereotypes, enriches the specification documents. This increases the quality of the specification and the use of models developed as the system evolves [14]. Thus, this information is used to model the incremental creation of new artifacts, or even allows the automation of other processes to improve the quality of different developed artifacts. This section describes two approaches to automate software artifacts development based on features that are included in the system model: Model-Based Testing and Software Product Line.

A. Model-Based Testing

Usually, system behavior and requirements are described using a formal or semi-formal model, allowing team members to share and to use these models during the life-cycle of the software development. In spite of that, test engineers are still producing test cases or test scripts in an informal way based on a mental representation that they create. A better alternative would be to derive test artifacts from the system models [15]. This strategy is commonly known as Model-Based Testing (MBT) [8]. MBT is based on the idea of the automation of test case/scripts generation. Albeit, the use of existing models can increase productivity during the process of software testing [14].

The cost of software testing is related to the number of interactions and test cases that are executed during the development process. As it is one of the most costly and expensive phases of software development [6], MBT is a good approach to mitigate this problem by automating the process of generating test cases or scripts [16].

Several works on MBT have been produced in the past years. A systematic review is presented in [17] to evaluate quantitatively and qualitatively some features of MBT. In this study, 78 articles were evaluated and the following items were reviewed: type of model (formal or semi-formal) used for test generation; test types in which the approach can be applied to; level of automation; support tools; criteria for test coverage, etc. The study presents test domains (system, integration, unit/component, regression) in which each of the works were applied to. The survey identifies that most of the works use MBT in system testing domain (66%). System testing includes Performance testing, which is the focus of our work.

Some of the works mentioned in [17] use the same MBT process, for example [8] [18]. This process requires specific activities in addition to the usual activities of software testing. This will require that the test engineers adjust their testing process, and invest in the use and training of new tools. The main activities that define the MBT process are (see

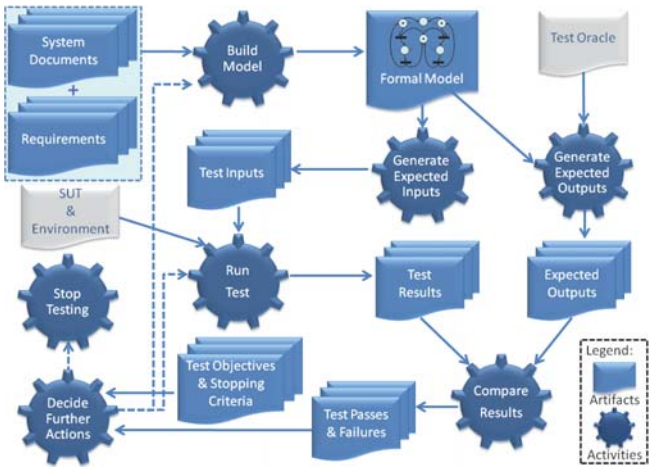

Fig. 1. Activities for MBT [8]

Figure 1) [8]: *Build Model*, *Generate Expected Inputs*, *Generate Expected Outputs*, *Run Tests*, *Compare Results*, *Decide Further Actions* and *Stop Testing*. 1) *Build Model*: constructs a model based on the specification of system requirements. This step defines the choice of the model, according to the application being developed; 2) *Generate Expected Inputs*: uses the developed model to generate test inputs (test cases, test scripts, application input); 3) *Generate Expected Outputs*: generates some mechanism that determines whether the results of a test execution are correct or not. This mechanism is the test oracle and it is used to determine the correctness of the output; 4) *Run Tests*: executes test scripts and stores the processing results of each test case. This execution can be performed in the system under test (SUT) and/or system's environment; 5) *Compare Results*: compares the test results with expected outputs (test oracle), generating reports to alert the test team about failures; 6) *Decide Further Actions*: based on the results, it is possible to estimate the software quality. Depending on the quality achieved, it is possible to stop testing (quality achieved), to modify the model to include further information to generate new inputs/outputs, to modify the system under test (to remove remaining faults), or to run more tests; 7) *Stop Testing*: concludes the system testing. The activities from MBT process can bring several new advantages to the test team [8], for example: shorter schedules, lower cost, and better quality.

A good possibility to reduce the problems mentioned at the beginning of the previous paragraph would be to have a single tool that would cover all the phases of the MBT process, i.e. a tool in which it would be possible to describe the system model, that would generate test cases/scripts, that would execute the test scripts and also compare the results. Even better if the test team could have a tool that could generate the testing tool for each different application or different type of test the test team wants to execute over the same application. Furthermore, it is desirable that the test team reuse implemented artifacts (e.g.: models, software components, scripts). Thus, in this context, it becomes interesting

to design a set of MBT tools based on a Software Product Line (SPL). A SPL ensures the variability, reusability of test artifacts, thus decreasing costs and time to market. Several evidence of the benefits of the use of SPL, in different areas, can be found in [19] [20]. The next section introduces the concept of SPL.

B. Software Product Line

A Software Product Line (SPL) seeks to exploit the commonalities among systems from a given domain, and at the same time to manage the variability among them [12]. According to [21], SPL engineering has three main concepts: core assets development, product development, and management. The core assets are the main part of an SPL, and its components aim to represent, in a clear way, the common and variable aspects of the future products. Thus, following the SPL concepts, new products variants can be quickly created based on a common architecture, models, software components, etc. Because of that, SPL allows for rapid entry of a product on the market as well as makes it easier for mass customization of products of a company. Companies are finding that the practice of building sets of related systems from common assets can, in fact, produce quantitative improvements in product quality and consumer satisfaction, efficiently meeting the current demand for mass customization.

However, given the large number of products that can be present in a product line (PL), it is necessary to control the variability and commonalities among them. The variability management is used to control the variables aspects present in the products of the PL.

Feature Models is an important concept to modeling variability. Originally, Feature Modeling was developed as part of Feature-Oriented Domain Analysis (FODA) [22]. However, nowadays it is applied in many areas such as embedded systems [23] or networks protocols [24].

When Feature Models are applied to represent variability, they are analyzed and categorized as common, optional or alternative [25]. *Common features* represent features that must be present in every product of the SPL. There are also called mandatory, necessary, or kernel features. *Optional features* represent features that are supported by some products in the SPL, and; the *alternative features* represent features that are mutually exclusive, i.e. only one of the features can be provided in each product of the SPL (see Figure 2).

C. PLeTs Tool

The PL*e*T*s* tool [11] aims to automate the generation, execution and results collection of MBT process. The tool is able to manage the whole MBT process and is based on the concepts of SPL. Its goal is not only the reuse of artifacts to make it easier and faster to develop a new tool of the family, but also to improve the creation, run and gathering of test results. It was developed with the intent to be used by software engineers, developers and test engineers, assisting the process of defining and executing test cases and test scripts. Figure 2 shows the current PL*e*T*s* Feature Model that represents some of the features that could be present in a software variant. The first level of the model has four main features:

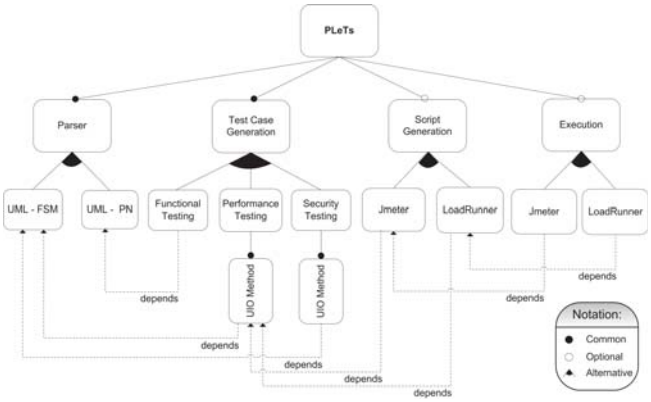

Fig. 2. Feature Model for PL*e*T*s* Tool [11]

1) *Parser*: represents the *Build Model* step in the MBT main activities (see Section II-A). It is a mandatory feature and has two child features: UML - FSM and UML - PN. Each one of these parsers is used to extract the information from the UML models to generate a formal model (Finite State Machine (FSM) or Petri Nets (PN)); 2) *Test Case Generation*: represents part of the *Generate Expected Inputs* step in the MBT main activities. It is a mandatory feature and has three child features: Functional Testing, Performance Testing and Security Testing (one of them should be selected in each software variant). Both Performance Testing and Security Testing have a mandatory child feature: UIO Method [26]; 3) *Script Generation*: represents another part of the *Generate Expected Inputs* step in the MBT main activities. It is an optional feature, because, for example, for security testing there could be no tool to execute the generated test cases. This feature has two child features: Jmeter [27] and LoadRunner [13]; 4) *Execution*: represent the *Run Tests and Compare Results* step in the MBT main activities. This feature also has two child features: Jmeter and LoadRunner.

It is important to highlight that there are dependencies between some features (see the dotted lines in Figure 2). For example, if some software variant selects the feature *Execution* and the child feature *LoadRunner*, it must select the feature *Script Generation* and the child feature *LoadRunner*, because the tool is not able to execute the tests without a test script.

Another important point is that the Feature Model can be extended to support new testing techniques or tools, adding new child features to the main four features. For example, if someone wants to add new features to work with the SilkPerformer tool [28], he should include new child features for the *Script Generation* and *Execution* main features.

To develop the tool in a way to represent the feature model flexibility, the PL*e*T*s* architecture is based on plug-ins that allows extensibility and flexibility. Based on that, the tool allows to select, in runtime, each plug-in (represented by a feature) that is necessary to perform a MBT activity and to automatically generate/execute the test scripts.

III. UML Models for Performance Testing

In previous works [10] [11], we described some components of PLeTs developed for security and functional testing. Here we apply our approach in a different application domain, reusing, or expanding, previous components automatically through SPL.

In our approach, the starting point for test script generation is the construction of an UML model activity diagram with performance stereotypes[3], represented in an XMI file. This XMI file is parsed and converted into a formal model, e.g. Finite State Machine (FSM). Then, performing the UIO Method [26], the sequences of activities that have to be executed are obtained. These sequences could be transformed in a description that is equivalent to test cases in natural language. This approach was used in our previous works, i.e. all these features have already been developed. To expand our work, we propose here a set of new features to support the generation of a product that can perform performance testing for the LoadRunner tool [13].

As mentioned above, we use stereotypes, which are the way we describe performance information necessary to generate our test cases and test scripts. We include stereotypes in two UML diagrams: use case and activity. Our approach uses four stereotypes from our previous works and a new one that was missing. The five performance stereotypes are the following: 1) <<PApopulation>>: this stereotype has two tags: the first one represents the number of users that are running the application, while the second one represents the host where the application is executed (defined in all actors of the use cases diagram); 2) <<PAprob>>: defines the probability of execution for each existing activity; 3) <<PAtime>>: expected time to perform a given use case; 4) <<PAthinkTime>>: denotes the time between the moment the activity becomes available to the user and the moment the user decides to execute it, for example, the time for filling a form before its submission; 5) <<PAparameters>>: defines the tags for the input data that will be provided to the application when running the test scripts (this is a new stereotype that our previous works did not include).

A. LoadRunner

HP LoadRunner [13] is a product to analyze the behavior and the performance of systems. This tool can emulate hundreds, or thousands, of users, known as Virtual Users (VUsers), simultaneously.

In the LoadRunner architecture the main configuration part that has to be changed for each application that is tested is stored in the script folder. Basically, our PLeTs plug-in generates a new *script* file, that are scripts written in C language. The test description, which includes application transactions and parameters, is included in that file. Our PLeTs plug-in also generates the configuration scenarios, which are included in *scenarios* file. This file contains performance counters that will be used in the reports that are generated by the LoadRunner.

[3]We use UML 2.0 SPT (Schedulability, Performance and Time) Profile [29] [30].

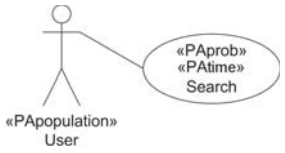

Fig. 3. Skill Management Use Case Diagram

Another important LoadRunner feature is a library with predefined functions. Each set of functions that are included in this library have a specific task in each of the testing protocols that LoadRunner implements. For example, functions starting with `web` are used to represent HTTP requests, while the ones starting with `lr` are general and can be used in all protocols. Some of the existing functions, which will be used in the work described in this paper, are: 1) lr_think_time: determines the idle time between user interactions and the system; 2) web_submit_data: submits web form data without a previous operation context; 3) web_url: is responsible for accessing a URL via a web browser; 4) web_image: represents a click on an image on a page (tag HTML <IMG>); 5) web_link: represents a click on a text link on a page (tag HTML <A href=...> e </A>); 6) web_submit_form: submits web form data but considering the context of the previous operation.

Based on these functions, it is possible to simulate the test scenarios in order to verify the performance behavior of a given application. Moreover, the concepts discussed in this section (tool architecture, script features and functionalities interpreted by LoadRunner), were important to implement the automatic scripts generation based on information extracted from the UML model.

IV. Case Study: Skills Management Tool

In this section, we apply our strategy and the PLeTs tool to an application that manage skills, certifications and experience of employees of a given organization. This tool is called Skills and was developed in collaboration between a research group of our institution and an IT company. Skills was developed in the Java programming language, using the MySQL database for data persistence and Tomcat as web application server.

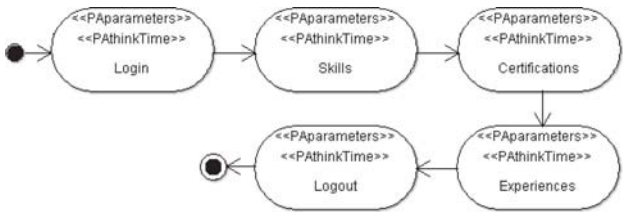

Fig. 4. Skill Management Activity Diagram

One example of our use of UML with stereotypes is the "Search" case. Figure 3 shows part of the user interaction behavior with the application. Furthermore, the necessary steps

to implement this case study are detailed in the activity diagram shown in Figure 4. This diagram represents five sequential activities, starting with "Login" to access the system, "Skills" to consult the user's abilities, "Certifications" to view the technical certification assigned to the user; "Experiences" a list the user's professional experience; and "Logout" to exit the system.

Once all the UML diagrams (e.g. see Figures 3 and 4) have been constructed, we use PLeTs to generate the test scripts for the Skill Management Application. The scripts were generated to run on LoadRunner, but we could have changed the plug-in that generates scripts and apply the same set of test using a different testing tool, for example the IBM Rational Performance Tester [31]. Figure 5 shows an extract from the script that was generated. This extract shows the actions of a given user, for example the think time through function `lr_think_time(10)` and the submission of data filled in the step "Login" (from the activity diagram - see Figure 4) through function `web_submit_form`.

```
Action()
{
web_url("Search",
"URL=http://192.168.1.26/skillsApp/mainIE.jsp",
"Resource=0",
"RecContentType=text/html",
"Referer=",
"Mode=HTML",
LAST);

lr_think_time(10);
web_submit_form("Loging.jsp",
ITEMDATA,
"Name=username", "Value=admin", ENDITEM,
"Name=password", "Value=123456", ENDITEM,
LAST);
```

Fig. 5. Script Generated for LoadRunner

As described in Section III, we can include five stereotypes in our UML diagrams, with one or more tags. As can be seen in Figure 3, the "Search" use case diagram has three of those stereotypes, and they are generated with the following values:

- $PApopulation$
  - $TDpath$ = http://192.168.1.26/skillsApp/mainIE.jsp
  - $TDpopulation$ = 30
- $PAprob$
  - $TDprob$ = 1.0
- $PAtime$
  - $TDtime$ = 300

The other stereotypes, in this case study, are included in the activity diagram as shown in Figure 4. For example, the "Login" activity has the following values:

- $PAthinkTime$
  - $TDthinkTime$ = 00:00:10
- $PAparameters$
  - $TDaction$ = login.jsp
  - $TDparameters$ = username@@admin
  - $TDparameters$ = password@@123456

Notice that the `TDparameters` tag is the concatenation of two pieces of information: name and value, separated by the delimiter @@. This information could be generated automatically for different scenarios that the test engineer wants to test.

All tags are extracted from the UML diagram and processed by the PLeTs plug-in that generates scripts for LoadRunner. Although all necessary information is included in the UML diagrams, LoadRunner also needs a description for the test scenarios. The configuration of the test scenarios is included in the *scenarios* file. The PLeTs plug-in uses a template to automatically generate the *scenarios* file for LoadRunner. This template has some markings that are replace by the tags from the UML diagrams. For example, tag `<<Vusers>>` represents the number of virtual users that will be simulated during the test.

Besides the `<<Vusers>>` marking, the template file for scenarios has other markings that are used when generating test scripts: 1) `<<Path>>`: contains the application host address; 2) `<<Result_file>>`: specifies the results file name; 3) `<<HostGenerator>>`: defines the server that generates the load; 4) `<<TestChief>>`: contains the paths for the script tests that will be run for the scenario; 5) `<<GroupChief>>`: stores information on each VUsers group that will be simulated by the test script; 6) `<<GroupInfo>>`: defines the performance counters that will be used during the test.

Once the test script generation is completed, PLeTs calls the LoadRunner tool passing as a parameter the test script and scenario produced. In the test we have performed, we used the LoadRunner standard performance counters that are already set in the default user interface. We could have redefined the screens and counters we wanted to verify, but for the Skill Management application this was not necessary.

V. Conclusion

The use of formal models is a good way for modeling the behavior and structure of a system. This allows for a precise understanding of the system behaviour by software developers or test engineers and, therefore, allows for a better reuse of the system components as the system evolves.

Although automatization of software testing is desirable, test engineers usually perform testing manually using, of course, a set of tools. Capture-replay tools, for example, are widely used, but they require a full, running build of the application in order to create the test scripts for the first time, thus delaying script development; moreover, they require the tester to execute (manually!) all the script al least once. Besides, test engineers have to build a mental model of the whole testing process or strategy. As shown in this paper, MBT can help test engineers to build a formal model for their testing process as well. It is important to mention that despite all the advantages of using MBT described in this paper, MBT requires a professional with skills in programming languages, software testing and modeling, and also with theoretical background

on mathematics, automata theory, graph theory and formal languages [8].

Furthermore, the use of MBT could require a significant investment if not supported by a set of tools to plan, monitor and produce test artifacts. This paper has shown how we have applied MBT to an application without having to start the whole process from scratch, hence helping test engineers that do not have the above mentioned skills or background. Our approach is based on an SPL tool that generates testing tools based on MBT. In some previous works we had already applied our strategy to different testing domains and we were able to reuse some already developed testing artifacts in the work presented here. This has reduced our costs to test an actual application that is used in an IT company.

Another important contribution of this paper is the development of a tool to allow the use of MBT in commercial tools, such as the LoadRunner. Currently there are none, to the best of our knowledge, commercial tool that uses MBT. The LoadRunner plug-in developed for the PL*e*T*s* tool shows that the use of MBT is viable in industry. Besides, the team of the IT company can now use the same plug-in for different applications they want to test.

Despite the advantages of the implementation of the new plug-in presented here, some improvements in this new plug-in could be adopted, for example, in the current plug-in implementation several data that are needed for the generation of the LoadRunner scripts are inserted in the model stereotypes (See Section IV). A simple modification could be the insertion, in the `TDparameters` tag, of a name of a file, or even a database, that would contain these data. The plug-in, then, would generate scripts based on the data stored in that file, or database. These improvements will allow us to use parts of the plug-in for different commercial tools and to further explore our strategy.

ACKNOWLEDGMENT

We also thank CNPq/Brazil, CAPES/Brazil and INCT-SEC for the support in the development of this work. We also thank the reviewers for their comments, which helped to improve our paper.

***Abstract* — Despite the fact that people frequently see software development as a commodity, decision-making processes in Information Technology (IT) projects usually require great effort in solving several types of conflicts. The main tool to solve such conflicts is negotiation, which requires strategies and personal skills. Preparation step is the cornerstone to lead successful deals, but one of the major issues faced by negotiators, especially beginners, is to find out when they are emotionally prepared. Regarding behavioral aspects, there are particularities in IT people's conduction, once they are more reasoning than other professionals. Thus, this work aims at presenting a research about how IT professionals face IT project's negotiations. The research was managed in Brazilian professionals and evaluated IT people's performance through psychological tests, behavioral simulations and negotiation games to set negotiator skills profile. In addition, some case studies and simulation results are presented. This exploration is important as a way to show possible characteristics of style and dominant skills used by IT people during software development deals. This study works as a fundamental starting point to realize the requirements to develop specific negotiation support systems to IT context.**

Keywords - Negotiation, Behavioral Simulations, Psychological Tests, Negotiation Support Systems

I. INTRODUCTION

In order to realize which strategy you should keep during negotiations, it might be helpful to identify some counterparty characteristics. In theoretical and practical researches, a set of specific types have been formed according to a number of characteristics. This work considers four types of negotiator's behavior: i) Logically Reasoning people, ii) Creative people, iii) Communicative people, and iv) Organized people.

A. Logically Reasoning people

There are some key features that a logically reasoning negotiator should possess [1]: a) set the rules of negotiation; b) develop an agenda; c) argue logically; d) adapt the position to meet changing situation; e) be likely to see the process as being more important that content or outcome.

Though the logic behavior of a negotiator may seem easy to be deal with there is a problem which can deter the resolution of negotiations and mislead the opponents. Logical reasoning implies that it is peculiar for the person who is using it, i.e. for one negotiator it may seem obvious to react in a particular way while for his counterpart his behavior is odd or incomprehensible [2]. In the framework of his researches, the author highlights a problem that appears when a logically operating negotiator confusing his opponent with "reasons" that do not address to his logic, which is a situation referred as "argument dilution". Usually, while confirming a viewpoint, people tend to use the strongest arguments in the beginning and the weakest ones are the last to be enumerated. But the listener deliberately marks the last arguments and bases his further opinion upon them. In order to avoid misleading the negotiation to an unsuccessful result, a logical reasoning negotiator should single out only a couple of reasons that give sense and approve his position.

B. Creative people

Another negotiation style should be applied while negotiating with creative people. This type has been given a close examination to by Michael Spangle and Myra Warren Isenhart [3]. They define creative thinkers as those who percept the given information in a unique way and look at the problems from various angles. These people are distinguished from other negotiators by their ability to arrange conventional solutions into more beneficial negotiation`s outcomes. DeBono [4] introduces a concept of "lateral thinking". Those who keep to this principle when managing negotiations tend to open new facets of the situations hidden to others. According to [4] lateral thinking can be expressed in the following actions: a) Looking again at things that are taken for granted (re-examining assumptions); b) Reducing division and polarization on issues, which are natural tendencies of the mind; c)Engaging in deliberate generation of ideas; d) repackaging information in different ways.

Authors compare the problem solving process executed by creative negotiators with completing the "blank spaces" with the missing parts. He argues that being creative negotiators cannot focus on already approved solutions, hence they start being inventive [3].

C. Communicative people

When negotiating, we confront people who are communicative and more reserved counterparts. Communicative people are prone to starting conversations first, responding with eagerness and interest. When it comes to negotiations it is not always easy to say which behavior is more beneficial. According to [5] every person must react in coherence with his personal peculiarities. For instance, if a person is reserved by nature he can turn it to an instrument of his negotiating strategy. As he listens more than speaks he gets more information, therefore he can make more solid decisions. Otherwise, if you are a talkative negotiator and your opponent turns to be the same, when you start asking him questions he will feel more at ease, the atmosphere will become less tense

and your chances of coming to an agreement (mutually beneficial) will increase.

The author adds up that disclosing information has also too sides. It can hurt you or your negotiating partner. Or it can reveal some information about you that will show your interests from the other side and the other negotiator will be able to count with it [5].

D. Organized people

One may assume that the most efficient (and probably easy) negotiations are held with organized (or disciplined) people. This estimation holds true for a variety of reasons. First of all it is important to clarify the terms "disciplined" and "organized". Ambler [6] gives an insight to discipline and shows that this type of people: i) is capable of completing the tasks they have started; ii) possesses unique skill sets; iii) is able to bear ordeals and face "brutal facts"; iv) is willing to adhere to the organization`s systems for getting work done.

If we look at the definition of the word "organized" in a business dictionary we can get the following explanation: "State of being efficient or methodical. For example, the employee was highly organized and knew immediately where to find the general ledger."

E. Other considerations

It is generally known that emotions convey information about the individual who by any way expresses them. The process of the transmission can be denominated as intrapersonal and interpersonal effects on the individuals [7][8]. Intrapersonal effect is the one which is directed exactly on the person who experiences the emotions which are later transforming his behavior during negotiations. Interpersonal effect incites one negotiator who interacts with the second one to react differently due to the conduct of the first. The emotions are given much attention to, since they are used as an indicator of the preferences and priorities of an individual.

It is interesting to compare the theories of the behavior`s impact on the negotiations. Let us regard the first one conducted by Lerner [9] and the second by Pietroni [10]. The first, as it has already been described earlier, presented the negative outcomes for a negotiator that are induced by his (her) bad mood. Here, a person can face a problem of being confused by his (her) inner state and is willing to opt for the delay of the negotiations.

On the other hand, Pietroni argues that a negotiator undergoing emotional difficulties (such as being angry with something) wins from this state of affairs since his opponent tends to concede him in this case.

The two contrary viewpoints show two possible outcomes of a negotiation and leave field for more exploration and research. Often, dealing with the field of investigation we face all kinds of research methods by which we can identify the peculiarities of their originators.

For this purpose, this work will speak about the investigating methods showed above and will try to understand the profile of IT professionals through the prism of logical reasoning, creative, communicative and organization aspects. The article aims at presenting analyses about Brazilian IT negotiator's profile and dominant skills. The follow sections show studies and results about how IT professionals face negotiations. The evaluations were carried out during the last 4 years and a group of specialists were select for the experiments depicted in this work.

II. IT PROFESSIONALS IN BRAZIL

In 2008 there were more than 80 thousand IT regular professionals working specifically in IT companies in Brazil, as show in Table 1. Considering other companies (not only IT corporations), this number grows to 285 thousand people [11].

TABLE I. IT REGULAR PROFESSIONALS WORKING IN IT COMPANIES [11]

Occupancy	IT Companies	All Companies
IT Director	160	1.138
IT Manager	1.730	10.118
Computer Engineer	622	1.103
System Analyst	37.435	81.836
Software Development Technician	11.616	26.588
Network and DB Administrators	2.073	6.017
Computer Operators and Monitors	12.285	44.621
Network Operators	357	5.417
Data Transmission Operators	10.134	72.329
Telecommunication Staff	4.051	35.777
Total	**80.463**	**284.944**

The group of IT Brazilian Industry concerns people who work in followed activities: Hardware consulting, Software development and maintenance, Software development consulting, Data processing, Data base, on line distribution and electronic contents, Maintenance of IT equipments, among other IT activities.

On the other hand, there are people who work not only in IT Brazilian Industry but also in others [11]. This background reveals the relevance of IT area in Brazilian Industry.

Therefore, this work analyses how these professionals behave as negotiators. The deal, in this case, may occur in several circumstances in software development projects, such as in sales prospecting, purchase of services, changing requirements, resources allocation and other conditions.

III. EXPERIMENTS AND RESULTS

One goal of the current work is to verify if information technology professional, especially in the software development area, has dominant skills and specific behaviors styles in their negotiations.

Notably, Brazil is a huge country, with the fifth largest territory of the world and about 184 million people, according to the final report from the IBGE population accounts, made in 2007 in 5,435 municipalities [13]. In the Information Technology subject, Softex points out that in 2008, about 285.000 professionals worked in the Brazilian industry, whether or not for computer companies. This reports shows the expectative for 2009 were 340.000 IT people [11]. This work used this value to base the experiments.

From these data, some criteria that reflect the limitations and boundaries of this research were used. The confidence level, the margin of error and the population frequency were allowable for the desired ends.

- Target audience: 340.000
- Desired confidence level: 95%
- Estimated margin of error: 15%
- Estimated populational frequency: 50%
- Sample size: 43

In order to find out the sample size, Cochran studies [14] and the table available on the work of [15], whole presented in Figure 1. , were used.

PARAMETERS	
P(pop)	Hypothesized true proportion for population
N	Fixed population size
n(f)	Sample size for finite population
n(i)	Sample size for infinite population
Error	Desired margin of error or precision
C.L.	Desired confidence level
Test	One- or two-sided test
Z(tab)	Statistical parameter used to test significance
S.E.	Standard error

User Defined (Enter Your Information in These Cells)
Calculated by Program (These Cells are Locked)
Additional Definitions Found in Embedded Notes (i.e., cell with red triangles)

One-Sided Test: "Greater than Test"	One-Sided Test: "Less than Test"	Two-Sided Test:
H_0: P ≤ P0	H_0: P ≥ P0	H_0: P = P0
H_A: P > P0	H_A: P < P0	H_A: P ≠ P0

	P(pop)	N	Error (%)	C.L. (%)	Test	Z(tab)	S.E.
Enter Data:	0,50	340.000	15,0%	95%	2	1,96	0,001

MINIMUM NUMBER OF SAMPLES REQUIRED	
n(f) Finite Population	n(i) Infinite Population

Figure 1. Sampling calculation used in this research (based on [15])

This work uses questionnaires found in [12][16] and some interesting results have been achieved. The questionnaire was applied to 74 professionals aiming to verify the types of 3.prevailing skills. 53 people were from IT area and 21 were from other areas.

Although outnumbered, the individuals classified as non-IT were kept as a benchmark. Thus, some analysis could be observed, as shown in Figure 2, which suggests that IT professionals are concentrated in the Logical Reasoning profile.

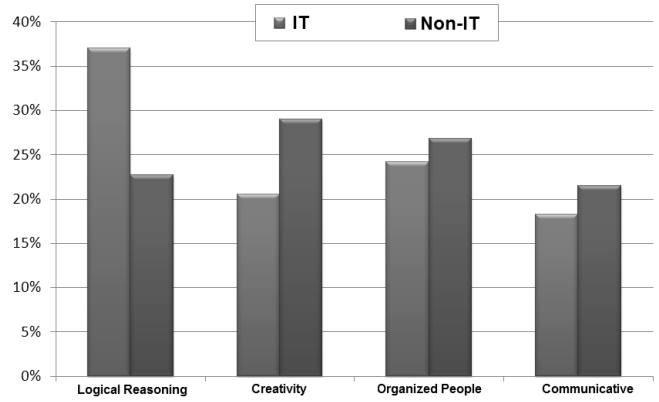

Figure 2. Profile types comparative

The arrangement presented in Figure 2 and Figure 3 suggests, generally, some characteristics of IT professionals that can be remarkable during negotiations, such as:

- Easily identify problems and rationally deal with them;
- Work with facts instead of aspirations;
- Remain prepared to justify the done deal, since they are comfortable at explaining their position in a logical and rational;
- Seem to be inefficient to handle multiple creative solutions;
- They have difficulty coping with emotions;
- They can take too long to close the deal on behalf of an attempt to find a unique and rational solution.

Figure 3 shows that the Intellectual and Technical / Organizational profiles are dominant in the interviewed IT professionals. This layout reflects the instinct to seek solutions through methodical and well-defined processes. Besides, the Figure 3 indicates that the individual IT has the greatest difficulties in dealing with interpersonal and creative aspects and is also slightly less inclined to routine, since it does not involve major innovations and challenges.

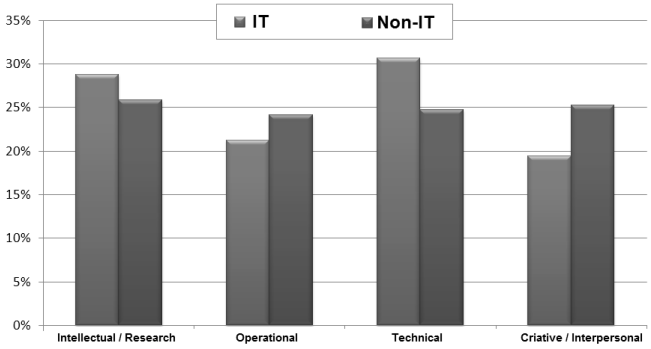

Figure 3. Prevailing aptitudes

Figure 4 and 5 respectively show the profiles and dominant aptitudes of IT professionals, referred as Technical and the ones, known as Management. The technical individuals do not lead any person, while the managers have leadership role.

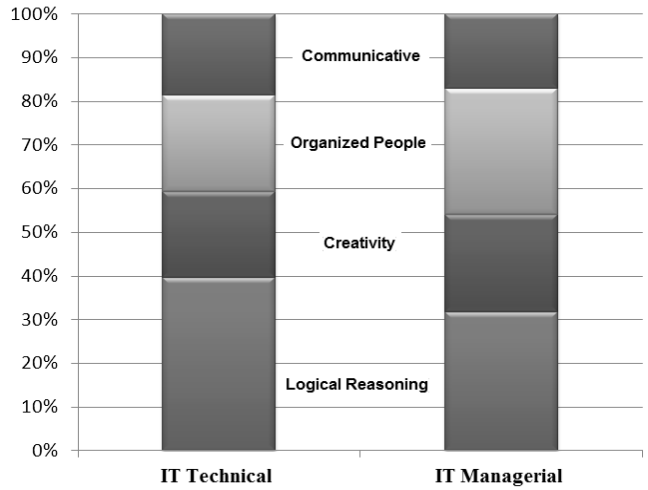

Figure 4. Profiles: IT professional

Figure 4 shows that the professional IT technician tends to be more logical and analytical while management has a more balanced structure, highlighting the organization as dominant aptitude.

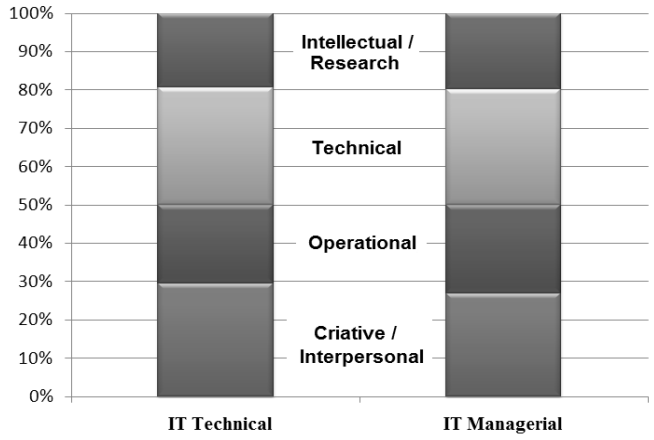

Figure 5. Prevailing aptitudes: IT professional

In the skills assessment, the results did not show discrepancies between the technical and managerial profiles, as illustrated in Figure 5.

From this research, some aspects (methods and tools) were developed or customized to deal with the points of better understanding and the possible difficulties faced by professionals at the time of negotiation:

- The setup method should consider that the individual will be rational in their assessment and will have difficulties to transcribe large volumes of information.
- Models that comprise sequential steps may have synergy with the methodical professional profile.
- Because it is a more synesthetic profile, the preparation tool must provide mechanisms that indicate that the provided data was really processed and instead of just be stored, for example, if the tool request textual data, it is important to generate graphs or tabulated mining mechanisms text indicating the major concerns (words or phrases, for example) in the current negotiation.
- Also from the synesthetic profile perspective, teaching methodologies that rely on computers can benefit IT professional negotiation skills learning. In this case, as it is a learning environment, a negotiation games approach can be associated with a context that involves settlement options and multiple outcomes in order to supply the lack of creativity intrinsic to the professional.
- About the difficulty of handling interpersonal work, the tool must contain mechanisms to assemble a relationship tree, so that the IT negotiator always remember the others involved, even when they are not at the negotiating table.

CONCLUSIONS

We addressed that a great difficulty during negotiations is to distinguish if the negotiator is well prepared or not. This work provides an analysis of how to understand a negotiators' psychological profile, their tendencies during conflict resolution and attempts to show their experience in the involved negotiation context.

Experiments were carried out through questionnaires and psychological tests that respondents could not realize they were being analyzed. This approach was important to guarantee impartiality during the answers.

The results depict the relevance of behavioral studies, especially considering how difficult is to analyze tendencies during negotiations among IT professionals. The rate of use of this mechanism is growing as well as the interest of new IT professionals and also students.

Abstract— **Power engineers who are striving to improve real-time attribute of power grid applications are ill equipped with software engineering methods and tools that allow them to rigorously evaluate their designs, taken into account data communication, geographic locations, and high performance computing capacity. This paper presents a technical approach to designing a testbed for embedding real-time monitoring and computation functionalities into the power grid. The approach focuses on integrating the parallel computational models with the data management infrastructure for near-real time state estimation. We study and summarize various forces and requirements that drive the design decisions in the distributed systems architecture. Given the continental scale of the power grid, it is important for the testbed to be extensible and scalable within a complex topology of physical entities, controlled by an overlaid network of power utilities and regulatory balancing authorities. This paper outlines the technical steps, and software toolkits to develop this testbed.**

Keywords-distributed architecture, power grid, real-time, testbed

I. INTRODUCTION

The power grid is a continental scale distributed generation and distribution system with a complex topology of physical entities, controlled by an overlaid network of power utilities and regulatory balancing authorities. For example, the eastern interconnection has approximately a dozen reliability coordinators and over a hundred balancing authorities. Each reliability coordinator and balancing authority has its own control center that uses a state estimator to maintain situation awareness of their internal system; the state estimator at the reliability coordinator is often a hierarchical state estimator that covers several balancing authorities.

To improve the reliability of the power grid, near real-time situational awareness is recognized as one key enabling functionality for better planning and reliable grid operations. Underpinning this vision, emerging and future deployments of high speed sensors such as PMUs (Phasor Measurement Units) give direct access to the current state of the grid at various points within the power grid. Synchronized phasor measurements are commonly referred to as *synchrophasors*. PMUs produce real-time synchrophasor data that capture the dynamic characteristics of the power system, and hence facilitate time-critical control. PMUs typically generate measurements 30 samples/second with precise time synchronization. This is in comparison with traditional Supervisory Control And Data Acquisition (SCADA) measurements, which generate a sample every five seconds or longer and are not time synchronized.

PMUs are becoming increasingly attractive in various power system applications such as system monitoring, protection, control, and stability assessment. The number of PMUs connected to the power system is expected to increase by 3-5 orders of magnitude by 2020. Inevitably, the substantial growth of these high quality sensors in the near future creates the need for new models such as dynamic state estimation to enable real-time predictions[1]. It is envisioned the time to solution of such models needs to be radically reduced to the 10 milliseconds to 1 second range, compared to current delay of 2-4 minutes to obtain results. In addition, the growth of model size is expected to be 2 orders of magnitude in the next 10 years.

Consequently, the solution is envisaged that High Performance Computing (HPC) capabilities accommodate the computing demand of these models at the regional scale [4,5]; and state estimation results are communicated at the wider continental scale. Connecting HPC-enabled distributed power models across regional locations becomes a systems architecture design challenge, involving many intricate factors

- Transmission latencies for data from sensors to distant monitoring applications;
- Requirements from applications for hard-real delivery of monitoring data in order to provide highly accurate situational awareness;
- Tolerance of applications for delayed or missing data;
- The hierarchical nature of data collection functions and associated monitoring applications such as state estimation.

At the regional scale, evaluating the performance of running power models on the local computing center is vital to meet the required time constraints. At the continental scale, the geographical location of various computing centers impacts the communication delays of the status exchanged between regional computing centers [9]. As a result, it is essential to design a distributed systems architecture well equipped with a rigorous evaluation method and software toolkit to collect empirical evidence for a design option.

In this paper, we propose technical approaches to designing a testbed for exploring HPC-enabled power models in

distributed systems architecture. In section II, the testbed design is motivated by the requirements and issues arising from the large scale and distributed nature of the power grid. The testbed approach is presented in section III, followed by the conclusion.

II. System Requirements and architecture challenges

At the infrastructure level, one mission of North American SynchroPhasor Initiative (NASPI) is to create robust, widely available and secured data management infrastructure, called *NASPInet* [2]. NASPInet explored a tiered architecture for distributed continental scale network. This conceptual architecture outlines the guidance at the network level, connecting sensors, monitoring entities, and power grid applications through NASPInet phasor gateways and data bus middleware. However, it still remains an open research question - what is the optimal architecture design to leverage the data management infrastructure at the programming level.

To address this issue, we envision the solution is threefold. First, power models in parallel have practical needs for connecting to the data management infrastructure[1]. These models usually implement the algorithms using specific parallel computing programming models such as MPI (Message Passing Interface), hence their communication with the infrastructure is more complicated than device-based equipments such as sensors in the power grid, which have limited computing tasks and mostly communicate data directly through network protocols. For an instance of the distributed state estimation, communication across the local MPI boundary is necessary to exchange power grid monitoring data or analysis results.

The interface between MPI code and the infrastructure not only needs mechanisms wrapping the middleware APIs, but also software utilities pre-processing and post-processing accessed data. For example, the monitoring data from remote regions of the power grid represent bus line status in addition to the local regional bus line model. These data need to be assembled into one bus line model according to an overall network topology. Since data may arrive at different time, they need to be buffered first and then partitioned to the processors for parallel computing.

Second, the effectiveness of the parallel power models includes near real-time requirements solving the models and the accuracy of the state estimation. The evaluation of a model must take into accounts the communication delays and failures. In fact, power grid engineers are ill equipped with simulation tools that allow them to construct representative distributed architecture scenario and do what-if analysis. Although network simulators are available, they are mostly used to analyze the end-to-end data flow between entities [8] rather than being integrated with the top level applications.

The simulation of the distributed architecture entails customizing the network simulators in a way that allows power engineers to configure the network topology by assigning values to networking parameters for each bus line within the communication scope. In addition, sampling data need to be collected according to the network topology configured. In reality, these sampling data should be obtained using the interface through the infrastructure. For the testing purpose, sampling data are synthetically generated and sent to the parallel power models through the interface.

Third, applying the parallel computational model to improve the real-time feature of the power models is an active research topic. The power grid algorithms and tools are typically run on personal computers and at most, moderate-sized clusters. As we envision the size, complexity, and interconnectedness of the power grid are dramatically growing, forecasting the vulnerabilities of the future grid using these outdated capabilities hinders the ability to predict, react to and/or mitigate failures such as the 2003 blackout on the East Coast in the US.

New development of the power models underpinned by HPC capability or re-engineering the existing ones are emerging. The ability to estimating the end performance at the design level can provide early feedback to improve the model as well as reduce the costs of faulty deployment. Predicting performance at the design level entails a systematic performance analysis method and tools to collect profile data.

Overall, we define the testbed in this paper that encompasses the simulation toolkit for running experiments and predicting performance of the power models in distributed systems architecture. By experiments we mean exploring scenarios of deploying the HPC centers at different geographic locations, observing the data communication effects on power model performance, and partitioning the network topology to do what-if analysis.

III. The technical approach

The testbed is designed to explore the distributed systems architecture depicted in Figure 1. In this architecture, a site (such as site A) accommodates the computing center deployed at a local balancing authority that controls the system. Such a computing center is equipped with parallel computing software and hardware. A site also encapsulates the computing center of a regional reliability coordinator (such as site B) that oversees reliable operation of the systems. A reliability coordinator connects to multiple sites of balancing authorities or other reliability coordinators, exchanges lower level state estimation results, and performs hierarchical state estimation. We envision both the balancing authority and reliability coordinator employ high performance computing centers to run power models such as state estimation.

The sensor reading data from transition substations are sent via SCADA systems within each site. With PMU data available from several Phasor Data Concentrators (PDC)s deployed within the site, PMU data can be combined with SCADA data to improve the accuracy of state estimation.

[1] Later in this paper, we refer data management infrastructure as infrastructure for short.

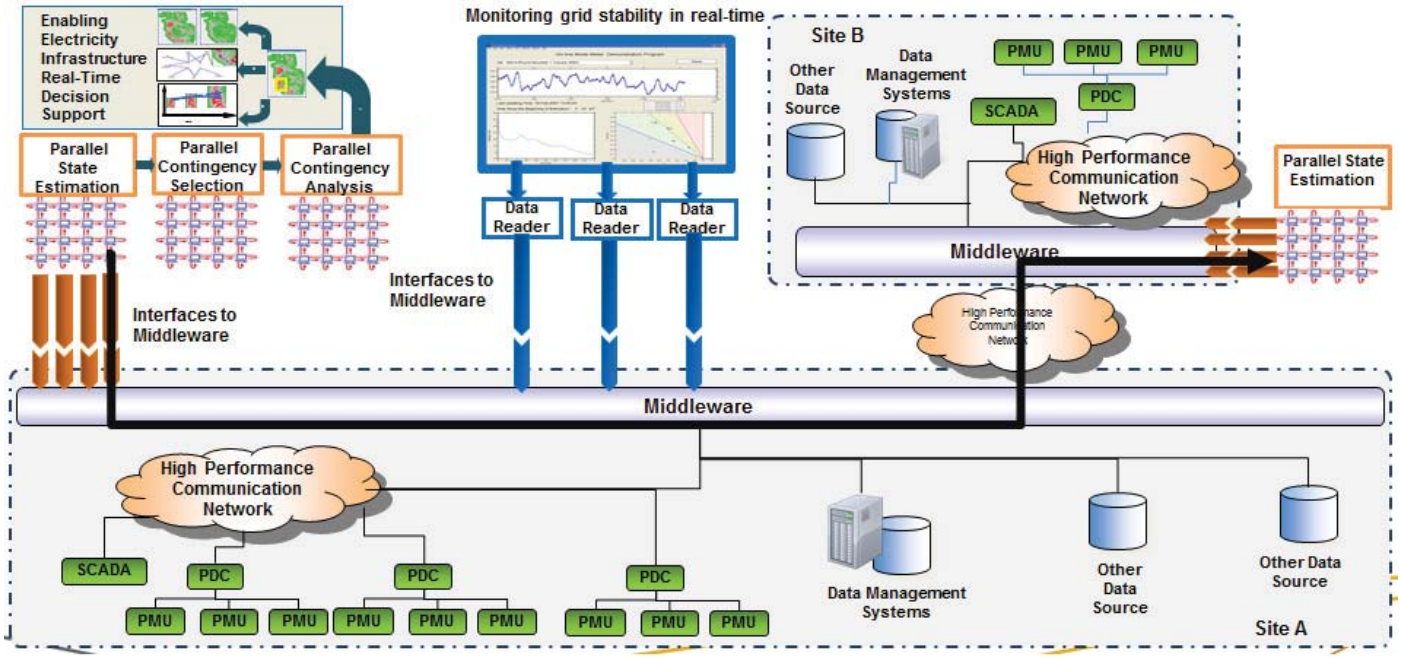

Figure 1: A distributed systems architecture for real-time power grid system

The data communication across sites is through dedicated middleware that can handle high throughput and large amount of sensor reading data in the power grid. In this work, we assume the middleware provides APIs and supports the IEEE standard protocols of disseminating power grid data. On each site, historical sensor reading data from the local region are stored in its data management system. The middleware is also responsible for retrieving the datasets of interest to the power grid applications.

Given the middleware and data management infrastructure in Figure 1, the testbed is devised in three steps as follows.

A. *Step one*

An interface layer is developed to wrap the communication between the MPI processor and the outside as shown in Figure 1. Using MPI, the parallel power model usually has a master processor to fetch the data for computing, partition the data and dispatch a piece of data to a number of worker processors running the computing tasks in parallel. Hence only the master node needs to explicitly invoke the interface as a client to the remote site. We refer the master node as the communicator node.

The interface layer devises key components of data processor and data buffer at the client side. The data processor resolves the location of data demanded (either from the local region or from remote sites) from a centralized data registration service. The data processor then uses the location information to connect to the corresponding server and fetch the data through the middleware. Depending on the protocol that the middleware supports, the data processor needs to extract the required fields of data (such as bus voltage, phase angle) and assemble them as inputs to the parallel power models. To illustrate the assembly of the data from disparate sites, the IEEE 118 bus system is grouped into three areas as the experiment devised in [3]. Each area can be considered as a separate site in the architecture of Figure 1 that delivers the SCADA and PMU data along the bus lines involved. Consequently data retrieved from individual areas need to be assembled into a single bus model before they are input to the state estimation model.

B. *Step two*

The interface layer is ported to a network simulation tool as shown in Figure 2. The network simulation tool is configured to estimate the delay incurred by data communication from remote sites.

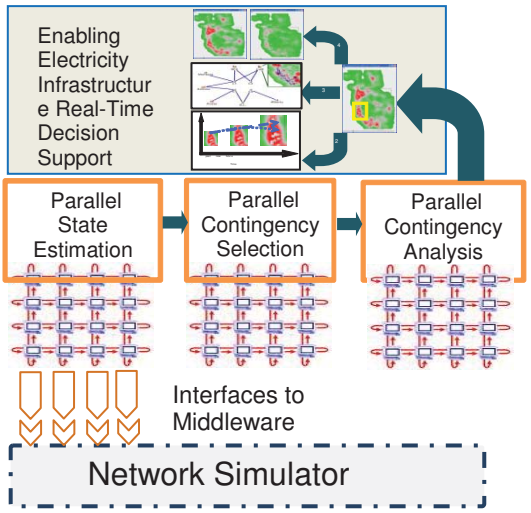

Figure 2 Simulating data communication delays

Since individual site in the architecture represents the power grid utility centers and balancing authorities, the network simulation needs to have a precise network topology reflecting the real topology of physical entities. The goal of the distributed systems architecture design is to embed HPC-enabled power grid models at the optimal site, given the geographic locations of the physical entities. Using the network simulator has obvious benefit in the testbed. The network simulator allows flexible designation of the HPC sites, and estimates the effects through simulation.

C. *Step three*

The ultimate goal of the testbed is to predict the performance of new parallel models and effects of any modifications made to existing models. Without complete source code of the model, predicting the performance at the design level entails a systematic approach. Our previous work [6] develops a benchmark based performance predication method for Java enterprise applications. The core of this method is applied to the testbed as shown in Figure 5. Benchmarks are deployed to observe the performance characteristics. They are useful vehicle to obtain performance profile by empirical measurements. The performance profile is then used to calibrate a performance model characterizing the parallel models. Performance modeling of parallel applications is well established research [7]. Existing modeling techniques can be applied to develop the model.

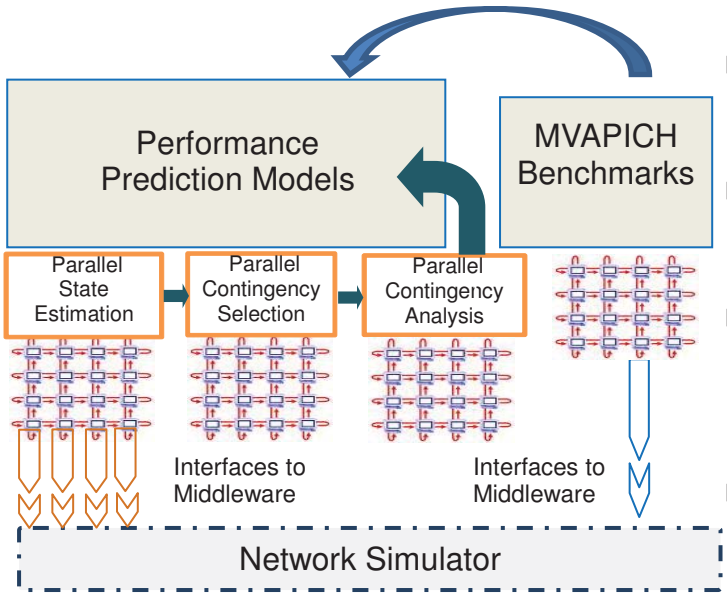

Figure 3 Performance prediction using the testbed

The testbed packs the interface layer, the customized network simulation toolkit, the benchmark suite, and the performance analysis model in a single environment. The testbed aims to facilitate engineers who design future HPC power grid models to evaluate their design, given the infrastructure capacity, networking condition, and geographic location.

I. CONCLUSION

The evolution of the power grid advocates HPC capabilities for improving the power models and delivering near real-time operations in power systems. Computing centers equipped with HPC software and hardware need to be designated in the overlaid network of physical entities. This raises architecture challenge to integrate the HPC applications with the data management infrastructure and the networking environment. Power engineers are in need of software engineering tools that facilitate them to evaluate their parallel power models in distributed systems architecture. From our research experience, we prioritize the requirements and discuss the challenges to address them. We propose a testbed design to make the integration between HPC applications and the infrastructure more transparent to the power engineers. The ultimate goal of the testbed is a useful tool for engineers to estimate the performance of their models under certain conditions of data communication. Our future work aims to validate the testbed design with hieratical state estimation and dynamic analysis of power systems.

***Abstract* – The formation of human resources in Software Engineering (SE), as well as in other areas of Computer Science (CS), depends on the education research. It is possible to identify some efforts performed by SE community. However, they represent isolated and localized initiatives, reducing their diffusion and use in large scale in global and regional scenarios. This work presents a strategy to support the educational research in SE focused on empirical research. The goal is to contribute to a body of knowledge in SE education thought a learning objects and experience reports repository.**

Keywords – Software Engineering Education;Learning Objects; Experience Reports; Empirical Software Engineering; Reuse.

I. INTRODUCTION

The teaching and learning process in Software Engineering (SE) has been discussed in the last years [14] to reflect the current demand for complex and large systems of systems and software-intensive systems. Usually, professors teach SE concepts through theoretical courses, contemplating practical activities in a small and short time project. Thus, the new software engineers meet a scenario where learned techniques and methods are not applicable, and they use *ad hoc* practices based on their experiences, focusing on coding. This can negatively impact the establishment of engineering principles and good practices in software development processes. The university should not take all the responsibility (since it is not a company) but need to prepare the students for real challenges in SE industry [15].

Motivated by this fact, some efforts consisted in developing reference documents such as SWEBoK [7], SE2004 [1] and CSDP [10], as well as the establishment of many undergraduate and graduate programs around the world. However, all these efforts tend to dissipate when treated as a set of isolated strategies, contributing to a divergent and localized scenario in SE education, no evidence-based and no focused on use of the best educational resources [9]. So, it is important to identify mechanisms that allow the organization of this knowledge, exposing it to the SE community.

In order to contribute to SE education, the empirical paradigm involves the collection and analysis of data and evidences that can be used to characterize, evaluate and show relations among technologies, practices, and experiences on SE teaching and learning processes. Therefore, empirical results can compose a body of knowledge over time [5], providing a base to accepted and well-formed theories about SE education. These theories can be materialized by a learning objects and experience reports repository, where researchers and professors can communicate, act as producers and consumers of educational resources, and also drive SE education to a more mature field of Computer Science (CS).

In this sense, this paper aims to present EduSE Research Strategy, an approach to explore empirical studies as a mean to support large scale SE education. From cooperatively developing a scientific investigation protocol with SE community in four phases, a unified body of knowledge can be organized, taking into account SE global aspects and regional peculiarities (i.e., problems, solutions and challenges in education in SE areas). Also, this process allows the existence of a dynamic and evidence-based repository of SE learning objects and experience reports in its fifth phase. The paper follows this structure: Section II discusses the concepts of learning objects and experience reports, contextualizing SE education; Section III presents EduSE Research Strategy, its phases and infrastructure; and Section IV points out final considerations and future work.

II. BACKGROUND

A. Learning Objects and Software Engineering Education

A learning object is the smallest independent structural experience that contains an *objective*, a *learning activity* and *assessment*. It represents a set of reusable and self-contained digital resources with an educational objective structured by three internal components: *contents*, *learning activities* and *contextual elements* [25]. A learning object must have an external information structure (metadata) that facilitates its storage, search and retrieval.

For the Learning Technology Standards Committee (LTSC) of the Institute of Electrical and Electronics Engineers (IEEE), a learning object is any digital or non-digital entity that can be used in the technological support to learning, education or training, e.g., texts, images, graphs, tables, presentations, diagrams, videos, games or any digital educational material, used by the professors assisting students in teaching a subject [11]. In its essence, a learning object is reusable.

Some types of information may be included in a learning object and its metadata [11]: general course descriptive data, life cycle, instructional content, glossary of terms, quizzes and

assessments, rights, relations to other courses, and educational level. Some works consider a process model for learning object development, such as ADDIE [17]. Besides, the creation of the learning object standards makes the definition of important characteristics possible, such as reuse, durability, and accessibility, highlighted in standards (e.g., SCORM [2]).

In SE education, the use of learning objects aims at minimizing the mentioned problems since it provides mechanisms to facilitate the teaching and learning processes, beyond promoting relations between concepts, practices and results in SE. Some learning environments are developed to assist the SE learning process and simulate many real situations related to software development that stimulates and motivates students. This kind of learning objects can be games, scenes, graphs, and others. Some games used in SE learning considering *Project Management* (e.g., *The Incredible Manager* [8]) and *Requirements Engineering* (e.g., *Guess what we want* [3]) areas.

B. *Experience Reports and Software Engineering Education*

An important element in CS educational techniques is the *experience report*, i.e., the exposition of a tradeoff between educational proposition and realization made by professors, which evidences success and failure strategies and tactics in teaching and learning processes over time [9]. This element represents a channel among professors and researchers to treat educational issues and communicate new solutions among them. In this sense, the efforts to generate an experience report database use empirical techniques [5]. The empirical studies allow theories to be formulated, tested, and validated, evolving an experience report to a status of evidence (or not), i.e., evidences are generated from characterizing, assessing, predicting, controlling, and improving products, processes, and theories. Thus, experiences in education can explore these studies towards the continuous improvement.

The execution of educational research is supported by studies which aim to discover something unknown or test something known. They can be classified into **primary** and **secondary studies**. Primary studies are directed by hypotheses to be verified or inferred. These studies are conducted when it is necessary to characterize a particular learning object in use within a specific context (e.g., game, educational technique or software). The result analysis of a primary study can be quantitative, semi-quantitative or qualitative, and it can represent (or is associated to) an experience report. Three types can be identified [26]: (i) *case study* is executed to observe a behavior or phenomenon shown by an entity within a limited time; (ii) *quasi-experiment* is executed once a greater control of the situation is needed, aiming at manipulating one or more variables and control the value of others; and (iii) *survey* is executed to collect information from a sample of the population through a set of questions.

Although primary studies characterize a specified learning object, they are not sufficient [26]. Thus, secondary studies aim to integrate results from several correlated primary studies. Secondary studies are useful in revealing evidences and constructing bodies of knowledge that can be mapped to real and everyday educational experiences. These studies happen through *systematic reviews* and *meta-analysis* [6]: the first one is a methodology focused on a literature search protocol; and the other one is a study applied after a systematic review to statistically treat the quantitative data from analyzed papers.

Initiatives of empirical studies plan and execution in SE education can be found in the literature, some of them reporting experiences of using different and interesting strategies to have the students' attention. Papers of two conferences, Brazilian Forum on SE Education (FEES) and International Conference on Software Engineering Education & Training (CSEET) were examined, identifying some educational discussions, such as (i) SE as an undergraduate course and SE in CS courses, (ii) teaching areas of knowledge from SWEBoK, (iii) interdisciplinarity, and (iv) status of SE in university and industry. This analysis is presented in FIGURE I.

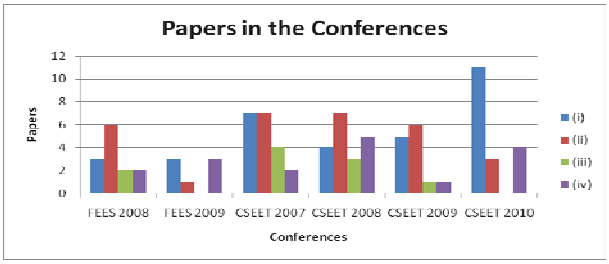

FIGURE I. Educational aspects identified on papers

III. EDUSE RESEARCH STRATEGY

Based on Shull *et al.* [22] and Spínola *et al.* [23] proposals, EduSE Project was started in order to generate a collaborative and large scale research strategy to support SE education, called EduSE Research Strategy [19]. It proposes secondary (i.e., systematic review) and primary (i.e., survey) studies to establish, base and integrate SE education researches in a *collaborative* (i.e., among different SE researchers), *distributed* (i.e., among different institutions) and *specialized* (i.e., dividing experts by SE areas work groups, such as requirements, design, test, reuse etc.) way. Hence, two communities are highlighted as direct EduSE Research Strategy stakeholders: *researchers* (who research in SE and wish to improve the education of their SE areas) and *professors* (who teach SE classes).

Using the GQM (Goal/Question/Metric) approach [5], the project goal *is* to analyze SE teaching and learning processes *for the purpose of* characterizing *with respect to* identifying problems, solutions and challenges, beyond regional peculiarities from the SE researchers' *point of view*, *in the context of* SE and CS courses. In this sense, the research question could be established as: *What are the main problems, existent solutions and pointed challenges in SE teaching and learning process related to dimension <SE area>?*.

From the research question, four phases were developed to compose EduSE Research Strategy's kernel (FIGURE II.) by deriving work focused on the technology definition research strategy proposals mentioned above. These phases are connected and refined by activities and tasks: (1) *Ad hoc Literature Review Phase* aims at identifying basic concepts about SE education, and allowing the definition of a systematic review protocol for supporting each SE area work group; (2)

Systematic Review Phase aims at elaborating and executing the systematic review protocol in each SE area work group – based on the results extracted from papers analysis, the work group decides if the study needs to be refined, or if the set of mapped knowledge should be evaluated through a survey; (3) *Survey Phase* aims at planning and executing studies to evaluate the knowledge acquired in the previous phase, considering SE professors community perspective in regional scenarios; and (4) *Body of Knowledge Phase* aims at joining all knowledge obtained from the last three phases in order to organize a SE education body of knowledge (i.e., studies reports; tracking among researches questions and problems, solutions, challenges and regional peculiarities; search, retrieval and communication mechanisms to find and improve teaching practices and SE techniques etc.). Thus, this phase requires a *repository* to share information related to SE education.

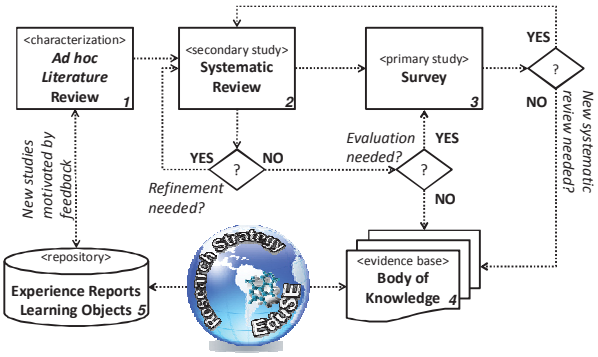

FIGURE II. EduSE Research Strategy Phases

When the set of research questions mentioned before are treated through the empirical paradigm, a body of knowledge can support well-formed theories in this field and directly impact the process of transferring research products to software industry, since SE researchers and professors can interfere in SE human resources formation. It means that SE courses and classes should be treated as laboratories that use leaning objects and are based on experience reports to explore regional SE industry issues, using and improving SE tools, techniques, and processes, as well as disseminating SE good practices. All stakeholders win: *regional and global software industry* hires well-formed software engineers, and *universities and research centers* have a chance to evaluate their SE scientific researches through educational researches on their SE areas using the empirical paradigm in different scenarios and subjects.

The results of preliminary survey with professors discussed in [21] provided knowledge for two research activities in EduSE Project: the first one is the definition of the *EduSE Research Strategy fifth phase*, and the last one is the modeling of a *web environment architecture* to support EduSE Research Strategy. Initially, the *Management of Learning Objects and Experience Reports Phase* aims to support the learning objects and experience reports development and life cycle, as shown in FIGURE III. So, a mechanism integrated to the repository should allow search, retrieval, storage, documentation, and publishing of the mentioned educational resources.

Aiming to validate their researches through *in vivo* primary studies, SE researchers create and publish educational resources as reusable components, each of them composed by a *learning object*, a *manual* (instructions), and an *XML scientific protocol* which will generate a questionnaire with data of interest to be collected when a resource is used *in vivo*. On the other hand, aiming to improve their classes and save time, SE professors freely search and retrieve these educational resources, and download them after agreeing with feedback terms. That is, after using and collecting required data in classes, SE professors should provide feedback, fulfilling a form with the questionnaire prepared by the resource producer. Hence, SE researchers can aggregate and summarize data, extracting information about their educational resources and, consequently, improving educational resources and related SE research products. Also, they can publish papers related to their researches based on real cases, creating a positive cycle.

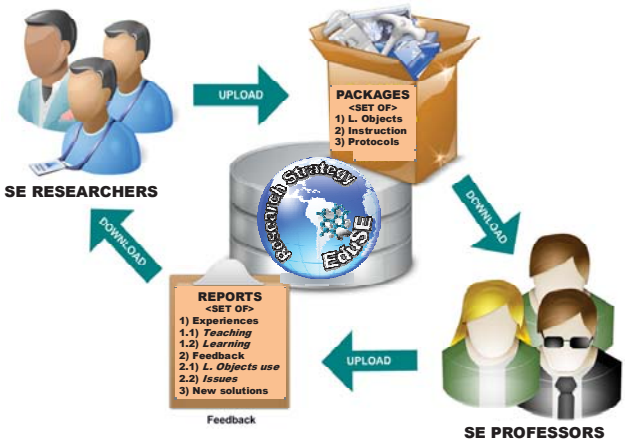

FIGURE III. Management of Learning Objects and Experience Reports

In order to share teaching and learning experiences as well as learning objects evaluations, SE professors can report opinions and describe situations, particularities, scenarios, and contexts faced during SE classes in any SE area or course. This information is also a reusable component and should be stored and classified to be searched and retrieved. SE researchers can access them to develop or evolve learning objects as solutions. In this sense, it is important to track learning objects and experience reports to problems, solutions, challenges, and regional peculiarities previously identified in EduSE Research Strategy phases 2-3 that compose the SE body of knowledge.

Based on the five phases, a web environment architecture to support EduSE Research Strategy was developed and a infrastructure is under development, the *EduSE Portal*, as shown in FIGURE IV. EduSE Portal is a JEE web information system to Computer Supported Cooperative Work developed on the JBoss Seam framework [4]. It combines communication, collaboration, cooperation, and coordination mechanisms to empirical studies processes, activities and tasks aiming to semi automatize EduSE Research Strategy phases 1-4. Currently, EduES Project is focusing in integrating EduSE Portal and the components and services library *Brechó-EcoSys* [20]. This step aims at generating a SE education ecosystem[1] for learning

[1] *Software Ecosystem* consists of a set of businesses functioning as a unit and interacting with a shared market for software and services, together with the relationships among them, frequently underpinned by a common technological

objects and experience reports development and management, based on software reuse processes [12].

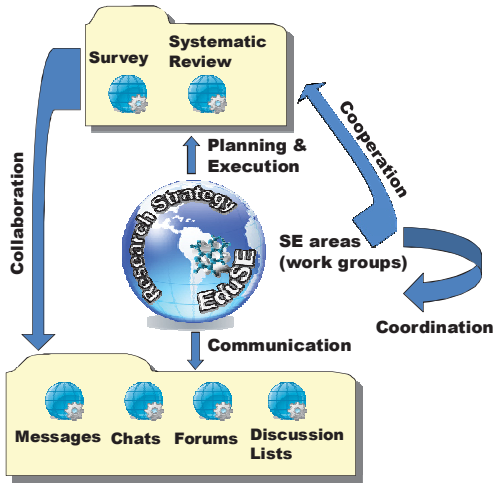

FIGURE IV. EduSE Portal's Architecture

IV. CONCLUSION

Since SE teaching and learning processes consist in an important concern for the next years, this paper presented EduSE Research Strategy, an approach to explore empirical studies as a mean to support large scale SE education. Related work consists of (i) SAKAI [18]: a tool to create an environment to Computer-Supported Collaborative Learning, (ii) Moodle [16]: an open source tool to Learning Management Systems, and (iii) SWEnet [24]: guided by SWEBoK and IEEE, this network community presents a framework to categorize knowledge areas in SE. In any case, the empirical paradigm basis is missing, when compared to EduSE Strategy Approach and EduSE Portal, as presented in Section III. SAKAI and Moodle are used in local or situated scenarios (course/faculty), and SWEnet presents no scientific protocol or methodology to expose and evaluate educational resources, i.e., leaning objects and experience reports. In this way, EduSE Approach aims to generate a business model to support continuous improvement in SE education, linking and motivating the involved stakeholders.

Future work consists of: (i) planning and executing a case study to verify EduSE Portal mechanisms to support EduSE Research Strategy phases 1-3; (ii) creating a framework for developing and managing learning objects and experience reports based on software reuse processes; (iii) finishing the infrastructure to support EduSE Research Strategy phases 4-5 and integration to Brechó-EcoSys. Thus, the researchers hope to contribute, improve and evolve SE education through the empirical paradigm and generate an educational ecosystem.

Structuring Software Engineering Case Studies to Cover Multiple Perspectives

Emil Börjesson and Robert Feldt
Software Engineering and Technology
Chalmers University
Gothenburg, Sweden
Emil.Borjesson@Chalmers.se

***Abstract*—Case studies are used in software engineering (SE) research for detailed study of phenomena in their real-world context. There are guidelines listing important factors to consider when designing case studies, but there is a lack of advice on how to structure the collected information and ensure its breadth. Without considering multiple perspectives, such as business and organization, there is a risk that too few perspectives are covered.**

The objective of this paper is to develop a framework to give structure and ensure breadth of a SE case study.

For an analysis of the verification and validation practices of a Swedish software company we developed an analytical framework based on two dimensions. The matrix spanned by the dimensions (perspective and time) helped structure data collection and connect different findings. A six-step process was defined to adapt and execute the framework at the company and we exemplify its use and describe its perceived advantages and disadvantages.

The framework simplified the analysis and gave a broader understanding of the studied practices but there is a trade-off with the depth of the results, making the framework more suitable for explorative, open-ended studies.

***Index Terms*—Case Study, Multi-perspective, Framework, Empirical**

Version 1, May 5, 2011.

I. Introduction

The case study is an observational research method used in many different fields of research due to its flexibility and its ability to investigate a phenomenon in its context [1]. Case studies are also applicable when there is no clear distinction between the phenomena and its context. This is particularly true in empirical software engineering research where there are many factors that impact the phenomenon, such as the type and organization of the company, the development processes used etc. To understand a contemporary phenomenon we also need to understand its history and how the different factors have evolved over time.

Existing advice for empirical research in software engineering focus on experiments and systematic reviews while guidelines for case studies was only recently published by Runeson and Höst [1]. There, a high quality case study is defined as a study that produces valid information of academic or industrial significance, either generic or practitioner oriented [1]. A key criteria for achieving this is that the data is collected in a planned and consistent manner and that conclusions are based on a clear chain of evidence. This can be a challenge in practice since case studies are typically flexible research designs with multiple sources of evidence; it is not clear-cut how to find the right balance between a flexible research design that allows multiple factors and causes to be taken into account while providing enough structure and support for planning and analysis.

Software engineering is different from computer science in that it takes more perspectives than only the technical into account. For example the personality or motivation of the engineers [2], [3] can affect the quality of their work and organizational and career considerations can affect important activities such as effort estimation [4], [5]. In general, the characteristics not only of the people but of the organization, business and processes used in software development are all important.

In recent empirical research in industry we were faced with designing a case study to describe and understand the verification and validation practices at a Swedish company developing safety-critical software systems. From initial talks at the company we understood that the practices could not be studied in isolation; they were heavily tied to the whole context of the company as well as how they had evolved over time. To structure our data collection and understanding we based our case study on an analytical matrix combining these two main aspects. On one dimension we wanted to cover at least the main perspectives of the BAPO framework with its four aspects [6]: Business, Architecture (technical aspects), Processes and Organization. The other dimension was time detailed in three steps as Past, Current and Future. Together this created a matrix of 12 different sub areas to be considered during the case study. We also defined a general six-step process to design, collect and analyze the findings of the study and adapted it to the company. This paper describes this analytical framework, called the BAPO/PCF framework for software engineering case studies, covering both the matrix and the process to adapt and use it. We exemplify and evaluate the framework based on our application of it at the studied company. In particular this paper addresses the following research questions:

1) What are the perceived advantages of a multi-perspective approach to conducting a case study?

2) What are the perceived disadvantages of a multi-perspective approach to conducting a case study?
3) How does the multi-perspective structure of the design affect research validity?

The definition of a research design is in this paper a methodology used to conduct a research project, such as a case study, an experiment, a longitudinal research project, etc. A research method is defined as a way of eliciting information within a research project; hence a research design can include the use of one or several research methods.

To help the reader differentiate between what was done in the state of practice analysis and what are general case study practices in the paper, we refer to the latter as the 'case study' and the former as either 'company study' or 'study at the company'.

The paper is divided as follows, section II will present the research context in which the research design was developed and executed. Section III will present how the framework was developed and executed. In Section IV the advantages and disadvantages of the design will be discussed, and finally some conclusions will be presented in Section V.

II. Research Context and the studied Company

The project, for which the research design was developed, was a state-of-practice analysis of a small company, less than 50 employees, which develop safety critical software applications. The state-of-practice analysis constituted the first part of a larger project, with the goal of improving the company's verification and validation practices. The analysis was conducted in order to understand the company's needs, regarding the company's processes, organization, etc, to narrow the scope of the process improvement effort.

The company conducts software development in bespoke projects to single customers, but the end applications are developed from a set of core products. These products are maintained according to market demand, making the company's business strategy a mix of bespoke and market driven engineering. Because of the nature of the software the company is developing, the company's business is governed by different quality standards and frameworks. These standards affect the development, but primarily the company's verification and validation practices. Standards and frameworks are also imposed on the company by the company's customers, who have different needs in their own domains. These demands require the company to be flexible in their development, which has resulted in the adoption of iterative as well as an agile software development based on Scrum [7]. The architectural granularity of the company's systems is on a sub-system level, hence coarse grained, but efforts are made to increase the granularity by refactoring the systems with reusable components based on services, so called service oriented architectures (SOA). The decision to change the system architectures was taken internally at the company but driven by external business factors related to a large European project that will change much of the company's market domain. The migration from sub-systems to SOA has required the company to acquire both new knowledge as well as new practices. Organizational changes have also been made, including changing the responsibilities of different roles and how communication is handled internally at the company. The company study was conducted over approximately 6 months, during which 7 structured interviews, 2 surveys, 1 structured observation, and a considerable amount of hours were spent on document analysis and watercooler discussion.

III. The BAPO/PCF Framework

The term research process is in this paper defined as the six-step methodology that was used to develop the case study design used at the company as well as the execution of the design. Figure 1 presents the process steps and how they incrementally relate to one another.

Get Knowledge about the Domain. Very little was known about the company when the project started and therefore the first step of the process was to gain a deeper understanding about the company and the company context. This information was acquired through a combination of interviews with people at the company and through literature review of internal documentation as well as documentation about the company's domain. The context in which the company operates was important to understand the goals and needs of the company, in order to align the improvement effort with these goals, such as process changes or introduction of new tools, etc. The initial interviews also served as a way of finding new sources by using snowballing, sources that could be used later during the company study. Snowballing is conducted by asking questions at the end of interviews and looking at document references to locate further artefacts to study [8]. The majority of the domain documentation that was studied was market quality standards and frameworks. Development and quality standards were important to study because the results of the company study would be used as a base for a larger project that focused on the company's verification and validation (V&V) practices, hence changes done to the V&V practices would, other than to comply with company needs, also have to comply with such standards. Domain specific documentation is often hard for someone from outside the domain to understand, so therefore all interpretations and question marks related to the analyzed domain documentation had to be verified with people at the company.

The collected data from step 1 showed that a broader view would be required to capture the state-of-practice at the company in its context. To meet this requirement and structure the research a multi-perspective framework was developed based around an analytical matrix with two dimensions. The first dimension was chosen to represent the perspectives of the company that would be analyzed, defined as company Business, Software Architectures, Processes and Organization (BAPO). These perspectives were chosen because they are used within academic and industrial frameworks such as the Family evaluation framework, which is used to evaluate Software Product Lines [6]. The second dimension of the matrix was chosen to represent time, defined as the Past, Current and

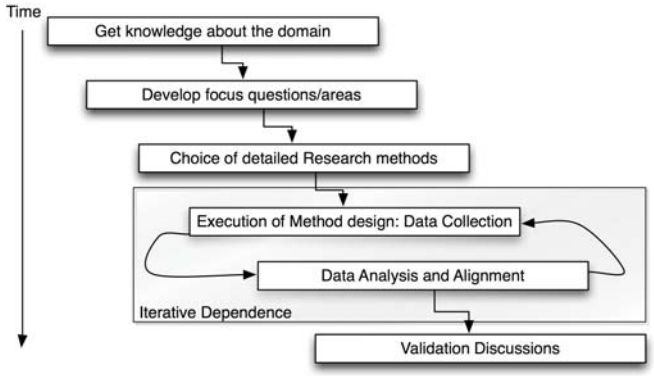

Fig. 1. Research process

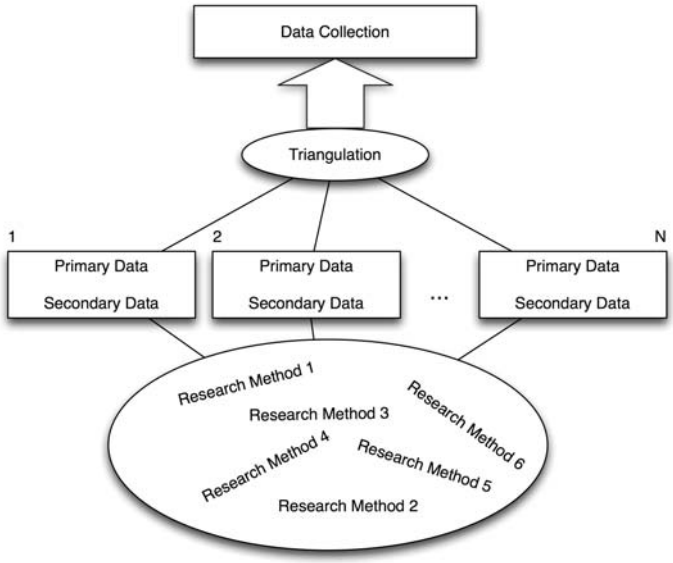

Fig. 2. General triangulation method

Future (PCF), since a chronological dimension of the elicited information was perceived to enable deeper and more precise conclusions to be drawn from the research findings. Hence the matrix starts with past Business, moving on to current business and so on, until finally reaching future organization. The BAPO/PCF framework was also chosen because it was perceived to be a good fit in this particular study, which might not be the case in the context of another company.

Develop focus Questions/Areas. The second step of the process was to use the information that was gathered in the first step, combined with the BAPO/PCF framework, to narrow down the focus of the company study by developing concrete research questions. The research questions were split up among the 12 sub areas/cells of the analytical matrix, which gave an initial understanding of where within the company to elicit information to answer the research questions. For instance it gave a coarse-grained view of which roles within the company that should be interviewed and what documentation to analyze. Information about existing company roles and documentation was provided by the first step of the process. The research questions were split among the 12 matrix cells based on the researchers own opinion on where they fit best, with the company context taken into consideration. For instance questions regarding the company's agile development processes were mostly constricted to the process row of the matrix, only sorted in time, whilst questions about the organization were split up between business, processes and organization in this case. The reason for the spread of organizational questions came from the need to understand how the organization had been affected by the other company aspects, for instance how the introduction of agile processes had affected the organization, or what affect business changes had resulted in, how roles had changed, etc. Some questions could not be confined to just one cell, such questions were mostly of higher level, but they helped to find logical connections between cells within the matrix. The options in these cases were to add the question in several of the cells, or to redefine them to make each of the questions unique and only fit in a specific cell.

Choice of Detailed Research Methods. The third step of the process was to choose what research methods that would be used in the company study. Primarily qualitative methods were chosen, such as interviews, visual inspection, structured observation and water-cooler discussions. Water-cooler discussions are conducted during coffee and lunch-breaks and make use of the fact that most information sharing within development companies are conducted during breaks [9]. This allows the researcher to get qualitative data that was current and truthful, but since the information often included the persons own opinions the information had to be verified to remove bias. Surveys were also used to provide quantitative results that would give depth to the research results. The surveys were deductive, hence based on previously elicited information, to verify the collected results and therefore conducted later in the company study. Different research methods are more appropriate to use depending on what sources are available, and therefore it is good to have a set of methods to choose from [1]. Creating a plan of what methods to use in what cells is suitable, but it should be considered a guideline that can be changed depending on the conditions of the study rather than a strict plan.

Data collection and Data analysis and Alignment. The first three steps of the process constitute the development of the design, whilst the following three steps of the process discuss how to execute the design. The fourth and fifth steps are defined as data collection and data analysis and alignment, and were executed incrementally, meaning that collected data was continuously analysed and aligned with previously collected information within the BAPO/PCF matrix, before new information was elicited and analyzed. Such analysis and alignment became essential since the data collection governed how the research would proceed, meaning that the collected information was used to evaluate if a certain research question had been answered or not. If the question had been answered

the research could move on to a new cell, otherwise further time was spent to find more information.

Case studies require flexibility to be able to respond to different events that may occur during the course of the study, such as for instance sudden research opportunities. For instance during the company study an opportunity arose to do observation of the company's system testing practices that would not arise again during the course of the planned study period. Because events, such as opportunities, have to be considered the research has to be flexible and can not follow a strict research plan. The BAPO/PCF framework does however support such flexibility, since the research questions connected to the BAPO/PCF matrix cells can be answered out of order, which allows the researcher to jump between cells and work with the question that is the most urgent at the moment. The progress of the research can also be measured through what research questions within the matrix have been answered. Each cell that gets filled with information, and its research question answered, constitutes a measurable part of the study progress, and once all questions in all cells have been answered the study is complete. The time spent with a certain matrix cell can either be planned according to a fixed time budget, or in a more ad hoc manner where the collected results drive the time spent working with a cell as well as the order which the matrix cells are traversed. There are academic papers that state that research using the BAPO perspectives should start with the business aspect because this has the largest impact on the company, followed by software architectures that has the second largest impact and so on until the organizational aspect has finally been analyzed [6]. No evidence could be found to support this claim during the company study, which used an approach where intermediate results decided what cell to jump to next in the study. The study at the company did not follow the matrix row by row, but instead company processes were first investigated, followed by software architectures, followed by company business and finally company organization. The BAPO/PCF matrix traversal was not chosen at random, it was chosen based on information that became available in the initial part of the forth process step and proved throughout the study to be valuable asset to keep the research focused. Even though several deviations were made from the research plan, because opportunities arose, it proved to be valuable to have a plan to fall back on, which is also supported by Runeson and Höst that state that a plan is crucial for a case study to succeed [1].

To strengthen the analysis of the collected information, in the company study, cause-effect chains (CEC) were combined with the BAPO/PCF matrix. These event chains link the research results together to provide a broader contextual view and also help to find the causes behind a result. Two different types of CEC's were used during the company study, where the first type focuses on one path through the matrix, the simplest being from a certain perspective's past to the same perspective's current or from the current to the future, hence a chronological view of to the result. The first type of a CEC can also span between different company perspectives

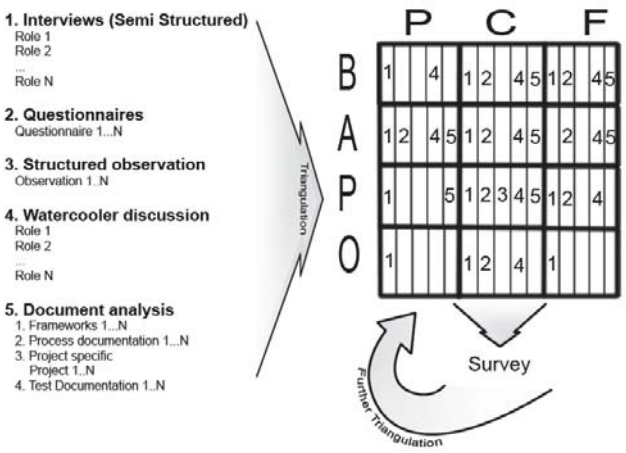

Fig. 3. Research design triangulation

to provide a cross-perspective view, but always form a single path through the BAPO/PCF matrix that shows how an event in one perspective in time has affected another perspective in time and so on. The second CEC type differs from the first type in the sense that it starts in one matrix cell and spans out to several cells both in time and between perspectives, which shows the broader impact an event has had within the company. In the company study the CEC's were developed post-elicitation of the research information by using inspection to find the internal connections between the results, which made it possible to draw clearer conclusions, develop predictions about the future of each company perspective, and also raise the result validity. Predictions for the future perspective of the matrix were developed using induction, with qualitative research data as input, based on the concept that if a specific action A in context B has outcome C in the past, which is repeated in the current in the same context B with result C, it would be likely that the same pattern would reoccur also in the future. A visual representation of the CEC's was also developed that uses the research results, described in bullet-point lists in the matrix cells, which are connected by drawing arrows from the origin matrix cell to the cell(s) that have been impacted by the event in the origin cell. It should be noted that a CEC can never find a connection between the current to the past, or from the future to the current, but if there seems to be a connection backwards in time it might be possible to create another CEC that was previously overlooked. An example of how to visualize the second type of a CEC is presented in Figure 4, which shows how the introduction of unit-testing impacted the studied company in a larger context, which could have been overlooked if the scope of the research design had been narrower. The general reasoning behind CEC's has also been visualized in Figure 5.

The BAPO/PCF matrix can also be used as a tool to visualize the research result quality. Several techniques were used to ensure data validity during the company study, but the primary technique was triangulation [1], [10], which states

that in order for information to be valid it must be verified by at least three sources. These sources can be either artefacts or roles, for instance documentation, different roles at the company, etc, or results gathered by using several research methods, such as interviews, literature review, etc. The matrix can be used to show how triangulation was performed during a study by visualizing which sources were used to answer what research question within the BAPO/PCF matrix. This provides a graphical overview of the data validity that is easy to understand, also by non-researchers like for instance the managers of the company under study. The general triangulation technique is presented in Figure 2, and the visualization of what sources that were used for triangulation, in the company study, is presented in Figure 3. Another technique that was used to ensure data validity during this step of the process, in the company study, was to send transcripts of interviews, preliminary documentation analysis reports, etc, to different roles within the studied company for validation. This technique provides the researcher with fast feedback if the elicited information has been correctly interpreted or not, which is valuable in cases where the information includes contextual jargon unknown to the researcher.

Validation Discussion. The final step of the process was to validate the research results with the studied company. This was partially done in step four and five since those steps deal with information validation through the means of company review, but those reviews were on a information level, whilst the final validation was on a conclusion level to ensure that the conclusions drawn from the research information were reasonable and correct. The final validation can be done in different ways, like for instance writing a report that the company can review, or the results can be presented orally. In the company study the results were presented orally during a power-point presentation where the analytical matrix was once more used. All significant results from the study were broken down into bullet-points in the matrix cells and added to a power-point slide. The graphical representation of the results gave the audience a clear overview of the results, which could afterwards be discussed further in more detail. Errors or discrepancies in the results were finally analyzed further and rewritten in a final study report.

IV. Discussion

The perceived advantages of applying the BAPO/PCF framework for case studies are related to the structure and the broadness of the multi-perspective view of the framework. By applying the multi-perspective approach to a case study it becomes possible to collect results specific to the different perspectives of the company, as well as in time. This provides a contextual structure that makes it clear where and how to acquire information to answer the research questions, but also how to find information that can link the results together. For instance by pointing out a role within the studied company that has knowledge about several perspectives, the information gained from this knowledge can be used to draw cross-perspective conclusions about the cause of a particular

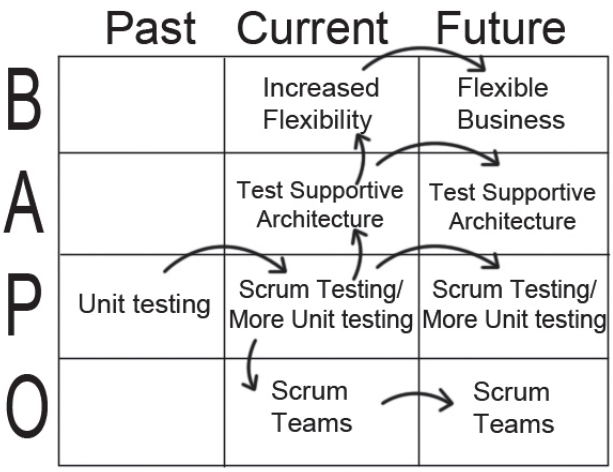

Fig. 4. Cause-effect chain example

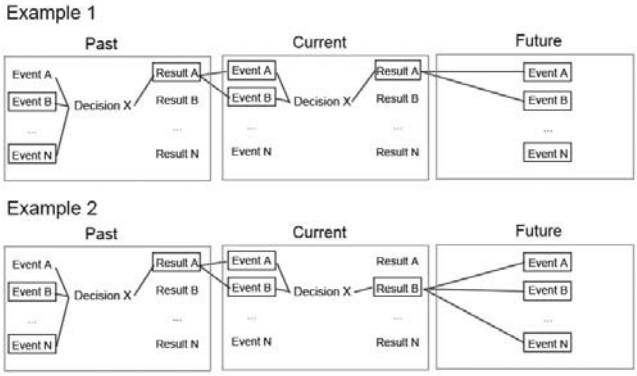

Fig. 5. General Cause-effect chain structure

result. By looking at the entire matrix, including these cross-perspective results, longer chains of cause and effect can also be drawn that provides a deeper as well as broader undestanding of results and of the company. Internal validity is also improved with this approach since as described by Wohlin et al. 2000 [11], a factor that is investigated because of its effects on another factor may itself be affected by a third factor, and if the third factor is overlooked there may be a threat to internal validity. Hence the BAPO/PCF framework improves the internal validity by giving the researcher the means of finding these connections between different factors that could have otherwise been overlooked with a narrower scope. It is however important to recognize that this framework, like other case studies, does not solve the issue regarding to what extent a factor within a given perspective affects another factor in another given perspective. A change within a company is seldom localized to a certain perspective of the company but rather has ripple effects to several different perspectives. An example from the company study is how changes to a company's business goals resulted in the introduction of new processes, new architectural development methods as well as

organizational change.

Other advantages that are side effects of the BAPO/PCF framework's structure include support for project planning, visualization of the validation through triangulation, as well as to visualize the research results. The framework supports research plans that are flexible and allow events, such as research opportunities, to be taken advantage of as they arise during the study. Visualization of the triangulation provides an overview of the validation effort and also makes it easy for non-researchers to see how the results have been validated, for instance making it easier to trust results and conclusions that are previously unknown to the studied company. Result visualization has similar advantages in terms of providing an overview of the collected results, and help to find connections between the collected information.

As for general case studies this design does not limit what research methods that are applicable for acquiring information, but unlike many other case study designs that rely on purely qualitative methods for data elicitation and analysis, this design allows longitudinal design concepts to be used as well, which are quantitative. This is made possible by the chronological axis of the matrix that links the past to the future and therefore allows quantitative metrics to be developed. An example of such a metric could be organizational change over time, i.e. the company's growth rate. Such information can also be used deductively to draw more plausible predictions about the future, for instance how the growth of the company will continue or decrease.

The design does provide context to the research results but by broadening the research it becomes necessary to sacrifice information depth in projects with fixed budgets. Hence one of the BAPO/PCF framwork's greatest strengths is also its primary weakness. There is a trade-off that must be made when using the framework, which states that in order to gain information depth in one perspective, information depth will have to be sacrificed in another perspective. The consequences of this trade-off has not been investigated in this study, and since the design has only been used during one empirical case this subject is still open to speculation. The broadness of the design does however make it more suitable for research with open ended questions where very little or nothing is known about the phenomenon under study, rather than research with narrow research questions of a more deductive nature.

The results and conclusions that were developed during the company study proved to have high validity, however since the design has only been used in one study it is uncertain if the same results would be achieved in another study. The design is flexible in many ways, including the core concept of the analytical matrix, but once again, since only the BAPO/PCF configuration has been tested nothing can be said about another configuration even though it can be speculated that another configuration could be more beneficial in another company context.

V. Conclusions

This paper introduced the BAPO/PCF framework for structuring case studies in software engineering and ensuring they cover multiple perspectives. The framework was evaluated in a case study of verification and validation practices in a Swedish software company.

The combination of the BAPO (Business, Architecture/technical, Process and Organization) and PCF (Past, Current and Future) dimensions resulted in 12 sub areas to consider in designing and executing the case study. The matrix allowed the research questions to be connected to the research effort, as well as providing the researcher with tools for result visualization, project planning and result validation. The structure also allowed an analysis of cause-effect chains across perspectives and in time providing a broader understanding and increased validity. Most importantly the framework helped uncover issues and connections the company themselves were not aware off.

The largest perceived disadvantage is that the approach can become too broad and therefore require considerable effort to cover all 12 sub areas. This can be addressed by sacrificing depth of analysis within less prioritized sub areas but this needs further research.

In summary, a flexible yet powerful case study research design can be created by adding structure through the use of an analytical matrix and a simple process to adapt it to the context being studied. The analytical matrix used, based on BAPO and PCF, can be of general value for such software engineering research.

***Abstract*—The importance of usability engineering in software development is acknowledged by an increasing number of software organizations. This paper reports from a survey of the practical impact of usability engineering in software development organizations. The survey was conducted in Southern Italy, replicating one conducted in Northern Denmark three years earlier. The results show that the number of organizations conducting some form of usability activities is nearly the same, but there are important differences in the understanding of usability. The key advantages emphasized by the respondents are product quality, user satisfaction and competitiveness in both surveys. The main problems emphasized are developer mindset, resource demands and customer participation.**

Usability engineering; software development; survey.

I. INTRODUCTION AND BACKGROUND

It is now widely acknowledged that usability engineering is a key area in software development. Since the beginning of '90 (see [1]), various methods for usability engineering have been developed and assessed; an overview is in [2]. There is also a considerable amount of research of the relevance of these methods in software development practice. Evaluating software systems for usability has been documented to be economically beneficial in terms of increased sales [3], increased user productivity [4], reduced training costs [5], and decreased needs for user support [6].

Many software organizations devote a substantial and increasing amount of resources on determining the right functionality of their products. Yet there are numerous examples of systems that fail despite having the right functionality, simply because the prospective users cannot use the system for its intended purpose [7]. A problematic or incomprehensible user interface is a typical source of such problems. Usability is a measure of the extent to which prospective users are able to apply a system in their activities [8]. A low level of usability means that users cannot work out how to use a system, no matter how elaborate its functionality is [1].

Despite the fact that documented benefits of usability engineering exist and software developers state that usability is even more important than functionality [9], the literature provides studies that show software development organizations have limited or no usability engineering activities. Thus, it seems as if the benefits have little impact on software development practice. This has been shown not only in studies performed in the '90 (e.g. [10]), but also in more recent ones. While many authors have discussed the benefits and challenges of usability engineering in general, fewer have studied specific software development organizations in order to understand the reasons of the limited impact of usability engineering in practice. A case study of software organizations identified obstacles to increased deployment of usability engineering methods [11]. Another study found that usability is interpreted differently by different actors, depending on their formal roles, and they often experience more focus on efficiency and economy [12]. In a study of the way usability evaluations are conducted in practice, a significant gap between this practice and the literature was identified [13].

In [14], a survey has been conducted in order to identify possible obstacles that prevent organizations to actually take usability into account in their software development practices. The study involved 39 software development organizations, located in a region of Denmark. It consisted of a questionnaire survey, whose aim was to determine whether software development organizations were evaluating the usability of their software and to identify key obstacles.

A limitation of the study performed in Denmark (we refer to it as "DK-Study" in the remaining of the paper), as the authors clearly said, is that it was conducted in a limited geographical area in Northern Europe. This motivated us to replicate the study in a completely different area, namely a region in Southern Italy (we refer to it as "Ita-Study").

The paper has the following organization Section II describes design and execution of the Ita-Study, while Section III reports its results. Section IV discusses and compares results of Ita-Study and DK-Study. Section V provides conclusions and indicates future work.

II. ITA-STUDY: DESIGN AND EXECUTION

The study described in this paper replicates the one in [14] by involving organizations located in the Apulia region in Southern Italy. It aims at investigating the current usability engineering practices in software development organizations.

A. Method

As first step in the study, we conducted an online questionnaire survey using the same questionnaire of the DK-Study. Special care has been devoted to avoid any influence of the results of the DK-Study in analysis of the collected data and in results interpretation. Then, a comparison with the results of the DK-Study has been performed.

B. Participants

In order to be consistent with the DK-Study, we considered organizations with the following characteristics: a) they develop software with a graphical user interface, (e.g. web applications, mobile applications); b) they develop for customers or for internal use; c) they are located in the Apulia region in Southern Italy (University of Bari is in this region); d) they employ more than a single person.

In order to find the organizations, we used search engines on the Web, our own knowledge of organizations, and we looked at the list of organizations of the DAISY-net consortium (www.daisy-net.com), which brings together ICT (Information and Communication Technology) companies in the Apulia region. The considered organizations have their headquarter located in Apulia, even if most of them work in the whole Italy. The product types of most organizations are distributed between web sites, Internet banking, data warehouse, mobile applications, and business management software.

C. Data collection

Data from the selected organizations have been collected through an online questionnaire. The questionnaire used in the DK-Study, which was written in Danish, was translated to English by its authors. Then, the Italian researchers translated it to Italian; finally, a Danish native speaker, who has lived and worked in Italy for 20 years, checked the Italian version with the original Danish questionnaire. The questionnaire, available at "http://tinyurl.com/questaziende", contains open and closed questions, aiming at acquiring information about: 1) the organizations (number of employees, product types, platforms, development method); 2) their understanding of the term "usability evaluation"; 3) organization's use, experiences with and opinions about usability evaluation.

For each selected organization, we identified a contact person, who was called by phone to explain the purpose of the study and to invite her/his organization to participate in it. The contact person indicated the more appropriate person in the organization who could participate in our study.

All the forty-six contacted organizations agreed to fill in the online questionnaire. An email containing the link to the questionnaire was sent a few days later. twenty-seven filled in the questionnaire in few days; the remaining nineteen have been solicited again. Ten organizations did not respond. At the end, we got thirty-six questionnaires.

D. Data analysis

The collected data have been analyzed by three Italian HCI researchers. In order to avoid influences from the DK-Study, they had no knowledge of that study. However, they have been asked to adopt the same methodology. For the closed questions they have made a quantitative analysis. For the open questions they have followed the grounded theory approach: they have individually analyzed the data from each of the open questions and have put codes on sentences. Then, the code for each sentence has been discussed among the three of them, and a single code has been agreed upon. They have individually assigned codes to categories. Again, the individually assignment of codes to categories has been agreed upon in a joint session. This process has resulted in a list of categories and codes, which has been used to get a condensed overview of the results from the questionnaire.

III. ITA-STUDY: RESULTS

This section reports the results obtained by the questionnaire.

A. Understanding of "usability evaluation"

The main important questions the survey addresses are whether the organizations perform usability evaluations and what possible problems and/or advantages they find. Preliminary to this, it is necessary to understand what the respondents actually mean by usability evaluation. Thus a first significant question was "describe what you understand by the concept *usability evaluation*".

The thirty-six answers have been coded in five categories: Evaluation of usability, User involvement, Usability definition, Accessibility test, Do not know. As shown in Figure 1, thirteen respondents have provided an acceptable explanation of usability evaluation. For example, one said: "Usability evaluation is a process to verify that a software product has the following features: short learning time, fast task execution, low error rate, easy to remember commands, high user satisfaction". Another said that usability evaluation "is a set of measures obtained from activities performed to evaluate effectiveness, efficiency, ease of use, etc., of the products that the company produces and/or uses". Five respondents explicitly referred to usability evaluation as a test or a process involving end users (User involvement category); an example is the following answer: "Usability evaluation is a field test, which involves end users who are the target of the system, as well as the customer". We consider this category different from the previous one since we want to highlight the fact that these respondents are not using other usability evaluation methods that do not involve end users, e.g. inspections and analytical methods. Fifteen respondents provided a more or less acceptable definition of usability, thus indicating that they are aware of what usability is, but not of how actually to evaluate it. One organization put more emphasis on accessibility than usability; this can be explained by considering that accessibility of software for public institutions is forced in Italy by a specific

law of year 2003, called "Stanca Law", after the politician (Stanca) who proposed it. Finally, two respondents explicitly said that they do not know what usability evaluation is ("Do not know" category).

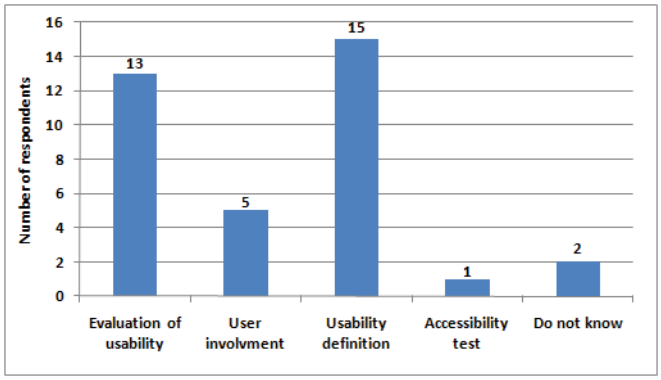

Figure 1. Respondents' understanding of "usability evaluation".

B. *Deployment of usability evaluation*

In order to avoid misinterpretations that would compromise the possibility to compare the answers of all respondents in the following questions, the following two definitions of usability evaluation were provided: 1) the analysis of the user interface to identify interaction problems through methods performed by usability experts, with the possible involvement of users chosen from the system's target group; 2) the use of methods to check if the system (and any other possible user guidance) is: easy to learn, easy to remember, effective to use, satisfactory to use and to understand".

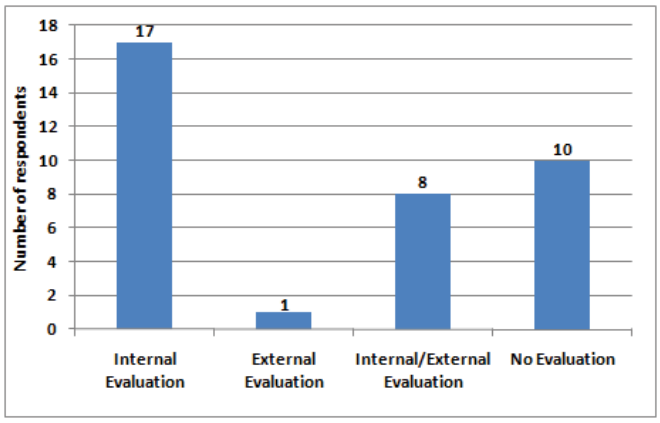

Figure 2. Type of usability evaluation performed by the respondent organizations.

With reference to these definitions, it was asked if the organization performs usability evaluations. Twenty-six respondents out of thirty-six said that their organization performs usability evaluation. As reported in Figure 2, seventeen respondents say that their organization performs usability evaluations internally (i.e. with its own personnel), one performs external evaluations (i.e. performed by external consultants), eight organizations perform both internal and external evaluations. Finally, ten organizations do not execute any usability evaluation, even if four of them say that software developers are asked to take into account usability principles in their work.

C. *Problems in usability evaluation*

The twenty-six respondents who said that their organization performs usability evaluations have been asked to report the problems they encountered in introducing and performing usability evaluations in their software life cycle. Answers to this open question have been classified in the following categories, as reported in Figure 3: No suitable methods, Resource demands, User availability, Developer mindset, No problems, Do not know. Some respondents indicated more than one problem.

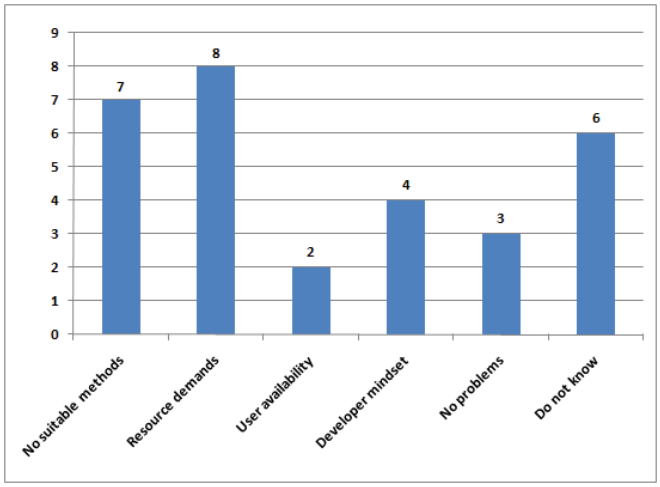

Figure 3. Problems in usability evaluations, as reported in the questionnaires.

No suitable methods. Seven respondents indicated the lack of suitable methods for usability evaluation as one of the main problems. One answer was "Lack of agile methodologies for the evaluation". Another said: "There is no standard for usability evaluation. Each customer has his own specific reality with problems of different types, and this prevents to identify standard methods and metrics which are applicable".

Resource demands. Eight respondents said another main obstacle to performing usability evaluations is that they require a lot of resources in terms of cost, time, and involved people. More specifically, one clearly said: "There are many problems of time and resource demands"; another said: "There is a conflict between time required by evaluations and the need of resource optimization that the organization has". Other answers addressed the cost for designing and performing usability evaluations, and the problems to allocate time and personnel to the evaluations.

User availability. As shown in Figure 1, some respondents think that usability evaluation necessarily involves users. Thus, it is not surprising that a problem in carrying out usability evaluation is user availability. Indeed, it is well known that it is not easy to involve users in the evaluations. This is one of the main reasons why methods that are not user-based, e.g. analytical methods and inspections, are often employed in usability evaluations. It is worth mentioning the following answer: "… it is difficult to get the time and resources

necessary to perform usability tests from the customer". It remarks another well known misunderstanding of people working in industry, who often refer to customers and not to real end users. Interesting is the answer of another respondent, who highlights the difficulty, as well as the importance, of involving real users, since "… user testing in a lab often does not provide reliable results".

Developer mindset. This category refers to problems due to the fact that some professional developers still have their main interest on functionality and efficiency of the code, i.e. on qualities of a software system which are of great interest for developers but have no impact on end users. The HCI researchers who analyzed the questionnaire answers proposed different names for this category. At the end we decided to call this category Developer mindset for analogy to the DK-Study. One respondent clearly said that it is difficult to consider usability among the software quality they address in their development process. He also mentioned that they do not allocate specific budget for usability evaluation: we considered this a resource demand problem. It is worth remarking that another respondent explicitly said that "usability evaluation is considered sometimes a waste of time".

No problems. Three respondents have explicitly answered that they did not find any problem. We cannot say whether this means lack of motivation in filling the questionnaire or they actually did not remember any problem.

Do not know. In this category we have grouped six respondents: four have explicitly said that they do not know about problems (one of them said that he is not the person in the company directly involved in performing evaluations); the other two did not say anything explicit about problems.

D. *Advantages of usability evaluation*

Next question for the respondents who said that their organization performs usability evaluations asked to report the advantages they got in performing usability evaluations. Answers to this open question have been classified in the following categories, as reported in Figure 4: Quality improvement, User satisfaction, Competitiveness, Resource saving, No advantages, Do not know. Some respondents indicated more than one advantage.

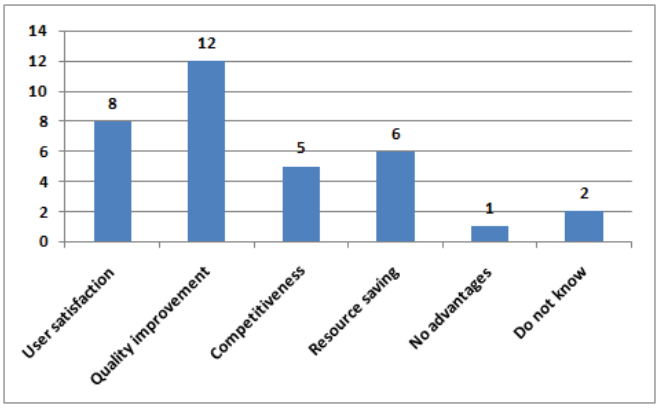

Figure 4. Advantages of usability evaluation, as reported in the questionnaires.

Quality improvement. Most answers pointed out that an advantage of usability evaluation is quality improvement of the developed products. These are some answers: "We can offer a better product to the end user"; "For sure, the product becomes closer to users' needs and expectations"; "The final product is more complete"; "[with usability evaluation] user interfaces keep improving, balancing user requirements and application complexity". A more articulated answer is: "We can increase the involvement of the end user and customer in the development process. It is a cost, since requirements are often completely modified after a usability evaluation. However, the quality of the final product improves, since the customer is active in the development process and that will produce software that is really useful and usable". As we can see, this respondent actually believes that usability evaluation will greatly improve software quality; the consideration about the cost is mainly due to the fact that, as it is well known, when usability evaluation is performed too late in the product life cycle, often it shows many problems deriving from not adequate requirements analysis, and, at this point, redesign would have a high cost.

User satisfaction. Eight respondents explicitly indicated user satisfaction as another advantage of usability evaluation. One said: "Greater satisfaction of final users, especially of regular users". This shows that the organization cares about customer fidelity and is aware that usability evaluation may help in better satisfying its customers. Other respondents indicated that usability evaluation helps ensuring that the final product better meets user needs and foster product acceptability and involvement of final users.

Competitiveness. Five respondents addressed an important objective of organizations, namely competitiveness on the market. In their opinion, usability evaluation helps increasing organization competitiveness as well as customers' appreciation. Moreover, one respondent explicitly mentioned sales increase as an advantage. Another said: "We can improve our business performances". Other mentioned advantages are: "Software will be used by many more users"; "To ttract new customers and improve relationships with current ones".

Resource saving. Despite the fact that resource demand was considered a problem by some respondents (see Section IV C), six answers report resource saving as advantages of usability evaluation. Those people pointed out that performing usability evaluation at right time in the product life-cycle actually reduces overall costs. One respondent said: "The risk to allocate resources for developing products that will have problems in their use is reduced". Another said: "Development costs decrease, thus saving time and money". Other two respondents pointed out cost saving during maintenance and evolution phase after product release, reducing the need of revisions.

No advantages. One respondent explicitly answered that usability evaluations do not give any advantage. Again, it is impossible to say if he does not see any advantage or if he did not pay enough attention to the questionnaire.

Do not know. Two respondents explicitly said that they do not know about advantages since they are not directly involved in performing evaluations.

E. *Organizations not performing usability evaluation*

Six of the ten organizations that do not carry out usability evaluations have a number of employees ranging from 60 to 200, three have about 50 employees and the last one is a small company with four employees. The structure of the questionnaire was such that, when the respondent answered that his/her organization does not perform usability evaluation, four more questions were presented, the first one was an open question asking to explain the motivations for not performing usability evaluation. One respondent addressed a resource demand problem: "I think that there are not economic and temporal margins to do this type of evaluation". Several respondents reported problems that can be considered in the Developer mindset category. For example, one said: "… our current development process does not include usability evaluation and we do not have expertise for performing them". Another said: "Our company does not have personnel allocated to these activities. I do not know why". A third one mentioned: "Lack of adequate culture". Another respondent provided a more articulated answer: "… many of our products are customizations of existing systems already on the market; in such cases, our approach is to align them to the logic of use of the existing product". This answer shows a clear misunderstanding of the concept of usability and of the need of usability evaluation.

One respondent also focused on the future when saying: "Currently our need [of usability evaluation] is still in its infancy. It's very likely that in the near future metrics and measurements to assess usability during the development of a product will be available". Another respondent said: "Even if in our company there is not a team allocated to usability evaluation, people developing software and performing requirement analysis have to take into account usability principles in their work".

The final three questions for a person who said that his/her organization does not perform usability evaluation were closed questions. The first one asked: "Has it been considered to introduce usability evaluation in your organization, possibly by demanding it from external consultants?". Of the total of ten respondents, three answered Yes, two answered No, and five said Do not know. The second closed question asked: "If the problems that prevent your organization from performing usability evaluations could be minimized, would your organization be eager to perform usability evaluation?". Four respondents said Yes, six said Do not know. Finally, the third question was: "Do you think that the products of your organization could improve with usability evaluation?". Eight respondents said Yes, two said Do not know.

IV. DISCUSSION AND COMPARISON WITH DK-STUDY

Looking at the first important question in the submitted questionnaire, namely the understanding of the term "usability evaluation", only two respondents said that they do not know its meaning, and one emphasized accessibility evaluation rather than usability evaluation. All the other thirty-three respondents either provided answers that refer to methods to evaluate usability or gave a correct definition of usability (fifteen respondents) without mentioning methods to evaluate it. The answers provided to the same question in the DK-Study, which has been performed in 2007, show that thirteen respondents actually addressed functionality tests instead of usability evaluation. This indicates that organizations are actually becoming more aware of what usability really is (our study has been conducted during November-December 2010), but either they are still reluctant to evaluate it in the software life cycle or they do not have a clear understanding of how to evaluate it.

The percentage of organizations that perform usability evaluation was also almost the same between the two studies. In the DK-Study thirty-nine organizations were considered: twenty-nine (74%) said that they perform usability evaluation, ten (26%) said that they do not; in Ita-Study, twenty-six (72%) do, ten (28%) do not.

By carefully looking at the other answers provided in the Ita-Study by the twenty-six organizations who said they do usability evaluation, we did not find any indication of problems due to the used evaluation methods: none mentioned difficulties when performing a specific method, when gathering information during tests, etc. This makes us question how carefully usability evaluation is performed by such organizations. Moreover, the answers to the open question about the background of the persons performing usability evaluation indicated that they have the Italian equivalent of Master degrees in Computer Science or in Computer Engineering. In most cases, such persons, especially if they do not belong to younger generations, have very limited knowledge about human factors (HCI courses only recently have been introduced in such curricula).

The results from the DK-Study revealed that the organizations not performing usability evaluations are aware that they would improve their products, but the obstacles are greater than the expected advantages. When the ten organizations in the Ita-Study that do not perform usability evaluation, were asked if they are considering to introduce usability evaluation, only three said Yes. This pushes usability researchers and practitioners to deeply consider how to change this situation, devoting more attention on how to transfer academic work into practical value for industry. It is responsibility of academics to translate scientific articles, which formally describe evaluation methods, into something that makes sense for companies and it is ready to be applied.

Comparing the problems in introducing and performing usability evaluation, only some category of problems were common to both studies, namely Resource demand and Developer mindset. In the DK-Study, the most frequently mentioned obstacle was "Developer mindset", i.e. many developers have their minds set more on programming aspects, technical challenges and functionality of the product than its usability. The second highest obstacle was the felt "Resource demand" of usability evaluation. Another mentioned obstacle was "Customer participation", which refers to the difficulties to get customers to participate in usability engineering activities. Overall, it emerged that many software organizations lacked practical knowledge about the way usability engineering activities should be conducted. The fact that in the DK-Study there are twelve problems in the category Developer mindset, while in the Ita-Study there are seven, is a further indication

that, as time goes by, software developers are changing their mind, becoming more aware of what usability is and of the importance of usability evaluation.

The DK-Study identified two further categories of problems, called Test participants and Customer participation; the first one refers to the difficulties in finding and motivating users to participate in usability tests; the second one refers to the difficulties to convince customers of the value of usability evaluations and getting them to participate actively in a project. In the Ita-Study, none mentioned the importance of involving customers in the project. Two respondents mentioned the difficulties in finding users to be involved in usability tests. Thus the category User involvement in the Ita-Study is equivalent to the category Test participants in the DK-Study. The last category in the DK-Study is Conducting test, which refers to problems regarding the way tests are conducted. None of the respondents mentioned similar problems in the Ita-Study; instead, another category in this latter study is No suitable methods, since the lack of methods suitable to be used in industry was indicated as a problem by seven respondents.

Considering advantages in conducting usability evaluations, in the Ita-Study "Quality improvements" was mentioned most frequently, followed by "User satisfaction". The DK-Study revealed an almost identical tendency with respect to categories and their ordering. In that study "System improvements" was mentioned by sixteen respondents followed by ten mentioning "Customer satisfaction"; five named "Marketing value", i.e. the equivalent of Competitiveness. However, the category "Resource saving" found in the Ita-Study was not found in the DK-Study.

V. CONCLUSION

This paper reports from a survey of the practical impact of usability engineering in software development organizations. The survey was conducted in Southern Italy during November-December 2010. It replicated a survey conducted in Northern Denmark three years earlier. The results show differences in the understanding of usability, where the concept is better understood by the Italian respondents. This shows that, as time goes by, software developers are becoming more aware of what usability is and of the importance of usability evaluation. The amount of organizations conducting some form of usability activities is nearly the same. The key advantages emphasized by the respondents are product quality, user satisfaction and competitiveness in both surveys. The problems emphasized differed more, with more practical problems emphasized in the DK-Study.

We are planning to complement these studies with more in-depth understanding of the advantages and problems of usability engineering as they are perceived by the individual organizations. Moreover, it would be worth focusing on software developers who are motivated to increase the usability of the products they develop. The key question to be addressed is why developers who are clearly motivated do not increase the adoption of usability engineering methods in their development processes. Once more data will be collected, it should be useful to analyze the correlation between organization characteristics (size, sector, process in use, activities performed etc.) and the adoption of usability engineering methods. Finally, the use of ethnographic methods could provide another means to get an in-depth understanding of the socio-technological realities surrounding everyday software development practice [15], thus providing other hints on how to overcome obstacles to a wider account for usability engineering.

ACKNOWLEDGMENT

The research reported in this paper has been partially supported by: 1) EU COST Action IC 0904 TWINTIDE (Towards the Integration of Transectorial IT Design and Evaluation); 2) DIPIS (DIstributed Production as Innovative System) Project sponsored by Apulia Region; and 3) WPU (Web Portal Usability) financed by the Danish Research Councils (grant number 2106-04-0022).

Abstract— **As competition for market space continues to increase worldwide and the information technology (IT) budget of many organizations these days comprises hundreds of projects running concurrently across different business functions, decision making units and geographical locations, selecting IT projects for investment has become a challenge in itself, not to mention the need to maximize the benefits yielded by these projects. This paper presents an optimization model, based upon balanced scorecard and minimum marketable feature modules, that makes it easier for management to maximize the financial benefits yielded by a portfolio of IT projects at the same time that ensures the strategic fit and reduces both the risk and the need for capital investment. Furthermore, the application of the model is exemplified with the help of a real world inspired example. Besides, the potential benefits to business are also analyzed.**

Keywords- IT Portfolio Management, Economics of Software Engineering, Balanced Scorecard, IT Investment Analysis, Minimum Marketable Features and Strategic Fit.

I. INTRODUCTION

From a versatile programmable apparatus that makes processes to run faster and yield more reliable results, information technology (IT) grew into a transformation enabling tool capable of improving business performance and, in many cases, providing competitive advantages [1, 2]. Not surprisingly, IT became a central piece in the business strategy of organizations of different types, sizes and culture [3, 4].

Moreover, as competition for market space increased, IT became one of the main sources of capital investment across many lines of business. As a consequence, the portfolio of IT projects of any middle or large sized organization comprises hundreds of projects running simultaneously across a variety of lines of business, business functions, decision making units, geographies and having a diverse number of aspects to be considered about their customer, such as: occupation, gender, age and socio-economic status. Therefore, selecting the projects that are to be part of an organization's portfolio is frequently a challenge in itself [5].

In addition, each organization has its own strategy defined by many differently-thinking stakeholders and, if it wants to remain competitive in the long run, these projects are better to be aligned with this intended business strategy, so that all the available resources are consistently applied to achieve what is indeed relevant to business [6].

However, managers of any IT-related project that requires capital investment are expected to provide proper returns and are exposed to risk, let alone a large number of projects grouped into a portfolio. As such, IT-portfolio management should be treated with the same due diligent rigor as any other capital investment, in which stakeholders are often interested in keeping risk exposure under control, at the same time that the return on investment is maximized [7].

Despite the relatively extensive literature on IT portfolio management, little has been said on how to maximize the financial benefits of an IT portfolio while ensuring the strategic fit [8, 9].

This article goes towards filling this gap by presenting an optimization model that enable managers to maximize the financial benefits yielded by a portfolio of IT projects, at the same time they reduce risk, curtail the need for investment capital, and ensure the strategic fit. The use of the model, which is based upon balanced scorecard and minimum marketable feature modules, is exemplified with the help of a real world inspired example. Also, the potential benefits yielded by the optimization model to business are analyzed.

The remainder of this paper is organized as follows. Section 2 contains the conceptual framework the paper is based upon. Section 3 discusses how the benefits of a portfolio of IT projects can be maximized while ensuring its strategic fit. Section 4 exemplifies the application of the model using a real world inspired example. Finally, Section 5 presents the conclusions of this paper.

II. CONCEPTUAL FRAMEWORK

A. Minimum Marketable Features Modules

According to [10], the buying process of any products and services by consumers has four main components:

- There is a perceived need that urges to be satisfied;
- There is at least one product or service in the market that is believed to satisfy that need;
- Consumers have enough buying power to pay for the product or service; and
- Consumers are willing to pay what they have being asked for.

While many simple products and services have a reduced and relatively rigid set of features for which consumers are willing to pay, software most often has a large collection of such features that may be easily grouped into different sets [11].

According to [12-14], minimum marketable features (MMFs) are self-contained software units comprising features that have an intrinsic market value. These units create value to business in one or several of the following areas:

- Competitive differentiation - it allows the creation of service or products that are different from anything else being offered in the market;
- Revenue generation - it provides an extra value by offering the same quality as other products in the market for a better price;
- Cost savings - it saves money by making business processes cheaper to run;
- Brand projection - it promotes certain characteristics that make the service or product more attractive to customers; and
- Enhance loyalty - it influences customers to buy more, more often, or both.

Moreover, the total value brought to an organization by a software project consists of several interdependent MMFs, each one with its own development cost, precedence restrictions, financial and non-financial benefits.

Although an MMF is a self-contained software unit, it is often the case that it can only be delivered after other project parts have been completed. These parts may be either other MMFs or the architectural infrastructure, i.e. the set of basic features that offer no direct value to customers and, as a result, for which they are not willing to pay, but that are required by the MMFs [14].

The architectural elements, or AEs for short, can also be decomposed into self-contained deliverables, enabling the underlying architecture to be delivered ``on demand'', further reducing the initial investment of a project [13].

Fig. 1 presents the precedence graph of a software project consisting of a set of MMFs and AEs. Note that A, B, C, D are module building activities and that an arrow going from A to B, i.e. A → B, indicates that the work on module A has to be

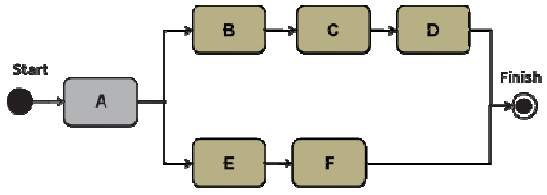

Fig. 1. The precedence graph of a set of MMFs and AEs.

completed before the work on module B can start.

No software provides revenues forever. After some time, market forces will inevitably make any software obsolete and promote the need to replace it by a more up-to-date and financially attractive alternative. The time elapsed between the beginning of a software development effort and its replacement is often referred to as *software lifetime* or, alternatively, as the *software window of opportunity*.

Table 1 shows the investment required by each module introduced in Fig. 1, together with its respective flow of net returns, considering a window of opportunity of ten periods. In this case both the investment required for the development effort and the flow of returns are accessed in thousands of US dollars.

TABLE I. REQUIRED INVESTMENT AND NET RETURNS YIELDED BY A SET OF AES AND MMFS (US$ 1.000).

Period	Software Modules					
	A	***B***	***C***	***D***	***E***	***F***
1	-80	-50	-40	-20	-50	-60
2	0	45	60	35	50	30
3	0	45	60	35	50	30
4	0	45	60	35	50	30
5	0	45	60	35	50	30
6	0	45	60	35	50	30
7	0	45	60	35	50	30
8	0	45	60	35	50	30
9	0	45	60	35	50	30
10	0	45	60	35	50	30

For instance, while ***B*** requires an initial investment of US$ 50K, it generates a net revenue of US$ 45K per period for a total of ten periods, once completed. Module ***F***, on the other hand, requires a higher investment of US$ 60K and generates a net revenue of US$ 30K per period.

Module ***A*** is the only one that yields no return, despite requiring the largest initial investment among all modules and, therefore, is an AE. As the remaining modules do provide some return on the investment required to their development, they are considered to be MMFs.

Because it is improper to perform mathematical operations on monetary values without taking into account an interest rate, in order to compare the business value of different MMFs and AEs, one has to resort to their discounted cash-flow [15]. Table 2 shows the sum of the discounted cash-flow of each module introduced in Fig. 1, considering an internal rate of return of 2% per period.

TABLE II. DISCOUNTED CASH-FLOW CONSIDERING THE PERIOD IN WHICH THEIR RESPECTIVE DEVELOPMENT STARTS (US$ 1.000).

Period	Software Modules					
	A	***B***	***C***	***D***	***E***	***F***
1	-78	311	441	260	351	181
2	-77	269	384	227	304	154
3	-75	227	328	195	258	126
4	-74	187	274	163	213	100
5	-72	147	220	131	168	74
6	-71	108	167	101	125	48
7	-70	69	116	70	82	23
8	-68	32	65	41	40	-1
9	-67	-5	16	12	-1	-26
10	-66	-41	-33	-16	-41	-49

Such a sum is the net present value (NPV) of all cash flow elements of a module considering that its development starts at period n ∈ [1..10]. For instance, according to the information

presented in Table 2, if ***B*** is developed in the first period, it yields an NPV of US$ 311K, i.e.

$$NPV(B,1) = -50 + \frac{45}{\left(1+\frac{2}{100}\right)^1} + \frac{45}{\left(1+\frac{2}{100}\right)^2} + \cdots + \frac{45}{\left(1+\frac{2}{100}\right)^9} = 311 \quad (1)$$

If ***B*** is developed in the second period, it yields an NPV of US$ 269K, in the third, US$ 227K and so on and so forth.

Obviously, not all modules can be developed in the first period. The precedence graph presented in Fig. 1 indicates that only ***A*** can be developed at that time. Because in this example each module requires exactly one period to be developed, ***C*** cannot be developed until the third period. Furthermore, each particular implementation order yields its own return on investment. For instance, sequence ***ADBCEF*** yields an NPV of US$ 866K, i.e.

$$NPV(ADBCEF) = NPV(A,1) + NPV(D,2) + \cdots + NPV(F,6) = 866 \quad (2)$$

while sequence ***ABDCEF*** yields US$ 875K.

Although MMF identification and ordering is an area that would benefit from further investigation, [12] shows that Function-Class Decomposition can be successfully applied to identify MMFs and AEs in a software project [16]. Moreover, both [13] and [17] provide the necessary means to find the implementation sequence that maximizes business value.

According to [18] the advantages of dividing a software project into MMFs are numerous:

- Large and complex systems can be developed from a relatively smaller investment,
- Return on investment in software development is maximized, together with return on investment in IT related areas and projects,
- Demand for shorter investment periods and payback time are addressed,
- Favor faster time-to-market of software and also of products that depends upon software development,
- Bring financial discipline into the software development, and
- Position software development process as a value creation activity in which business analysis is an integral part of it.

B. Balanced Scorecard

Although it is generally accepted that one cannot manage what one cannot measure, even in this day and age decision makers rarely consider measurement as an essential part of their strategy [19]. As an example, it is not unusual that managers introduce an innovative technology in their working environment with the intention of bursting performance and, without second thoughts, keep using the same short-term financial measures they have been using for years [20].

In the same way that there is no single medicine that can successfully tackle all illnesses, there is no single indicator that can properly report all business scenarios and activities. Therefore, when facing a new reality, one has always to question not only what measures provide better support for decision making, but also whether the old ones continue to be relevant [21].

Moreover, despite the best intentions that high management may have in making their strategy easy to understand and divulge among employees, goals such as "becoming the preferred supplier of our customers", "providing the best products to the market" and "being widely recognized as a top quality organization", which are so common in organizations' missions and strategic visions, do not translate easily into financial measures, not to mention terms that provide clear guidance to the efforts that are required at the operational level to have a strategy successfully implemented [22].

Therefore, if one wants that all the resources at the disposal of an organization are properly applied to achieve its strategic goals, one has to look beyond the classic financial measures for a more flexible set of indicators [20, 23].

Balanced scorecard, or BSC for short, is a strategic planning model and management methodology due to Kaplan and Norton [24]. It provides a multidimensional framework in which high level management can translate strategic goals into a coherent set of performance indicators that are easily understood by both middle management and operational personnel [25].

Since it has been firstly introduced in the early 1990s, the BSC has evolved from a performance measurement tool, designed to reveal and tackle the problematic areas within an organization [26], to a framework for implementing strategies and determining the strategic fit of an organization's human, information and organization capital [27].

The BSC model advocates that any business strategy should be translated into four distinct but related sets of performance indicators, i.e.

- *Financial* - reflecting how an organization is seen by their shareholders, both as a short-term and a long-term investment;
- *Customer* - describing how an organization is perceived by their customers, regarding their products, services, relationships and value-added;
- *Internal process* - revealing which aspects of business processes must improve and excel in order to satisfy shareholders and customers; and
- *Innovation and learning perspective* - showing how an organization can continue to evolve and create value.

A practical example of how a simplified version of a balanced scorecard might look like is presented in Fig. 2. Note that in a BSC table each perspective usually contains several

goals, whose achievements are signaled by one or more performance indicators (PIs) reaching pre-determined values by a deadline.

Perspective	Goals	Performance Indicator		
		Id	Description	Target (next 30 months)
Financial	Increase revenue	pi_1	Annual revenue	US$ 50 million
	Increase net margin	pi_2	Annual net margin	25%
Customer	Increase customer satisfaction with projects	pi_3	Quarterly survey mean satisfaction index	5 in a 1 to 7 scale
	Increase the percentageof retained customers	pi_4	Annual percentage of retained customers	20%
Internal Processes	Increase function points (FPs) delivered by employees	pi_5	Monthly average number of FPs delivered by employees	at least 20 points
	Decrease the number of nonproductive hours	pi_6	Monthly average percentage of nonproductive hours	15%
Innovation & Learning	Increase employees' technical skills	pi_7	Annual average number of training hours attended by employee	at least 80 hours
		pi_8	Percentage of certified project managers among employees	at least 20%
	Increase employees' job motivation	pi_9	Biannual survey mean motivation index	5 in a 1 to 7 scale

Fig. 2. A simplified version of an organization's balanced scorecard.

It is central to BSC's effectiveness that a causal relationship is established among the four set of PIs, or four perspectives, as they are most often referred to. Using the causal relationship perceived among perspectives, one is able to connect all of the non-financial measures ("drivers of the performance") to the financial measures ("final outcome"), showing the links by which specific improvements in the drivers are expected to lead to desired outcomes [28, 29].

In a well conceived BSC, the PIs in the learning and growth perspective are the drivers of the PIs of the internal processes and possibly some of the PIs of the remaining perspectives. Besides, the PIs of the internal processes perspective are expected to be the drivers of the PIs of the customer perspective and possibly some of the PIs of the financial perspective. Finally, the PIs of the customer perspective are intended to be the drivers of the financial PIs [30]. Fig. 3 summarizes these ideas.

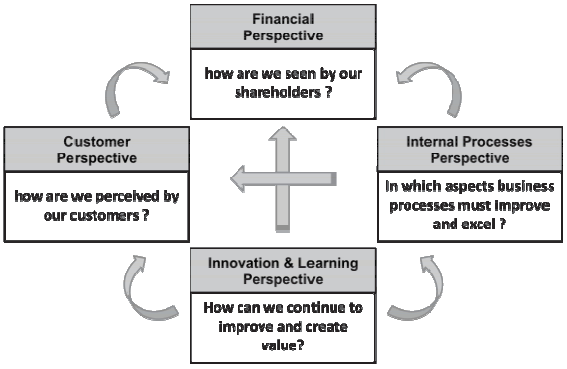

Fig. 3. A software organization balanced scorecard.

In the BSC model, this causal relationship among perspectives is expressed in a strategy map, which is a framework for linking intangible assets to shareholder value [21, 31]. Fig. 4 shows the strategy map that served as the basis for the construction of the BSC presented in Fig. 2.

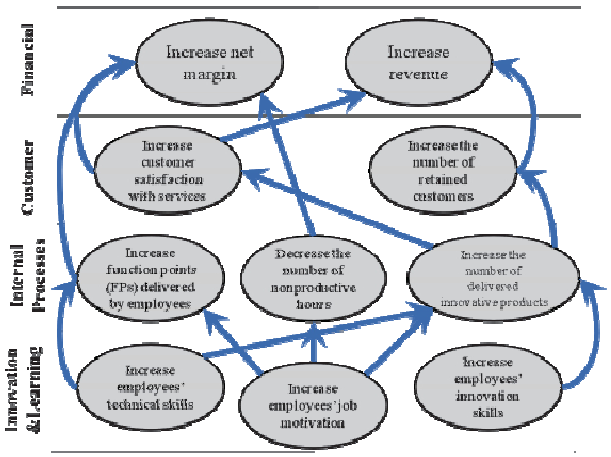

Fig. 4. The causal relationship among the four perspectives.

In a well conceived strategy map, the financial perspective is expected to describe tangible outcomes of a strategy in terms that are of interest to investors and shareholders, while the remaining perspectives define intangible value creation propositions that intends to generate those outcomes [20].

According to [20, 23, 30], when using the BSC model one should adhere to the following steps:

1. Revise the organization's mission and strategic vision;
2. Translate the strategic vision into a set of goals considering the financial, customer, internal processes, and innovation and learning perspectives;
3. Use a strategy map to identify the causal relationship that should exist among the goals in the four perspectives;
4. Determine the appropriate performance indicators to monitor each goal; and
5. Determine attainable but challenging target values for each performance indicator and a deadline for those targets to be reached.

Both the strategy map and the balanced score card should be revised on a regular basis as changes in market conditions may very well require adjustments in an organization's strategy, and consequently in its BSC model [32].

III. Maximizing the Appropriation of Financial Benefits

It is important to keep in mind that it is very unlikely that the target values in a BSC can be reached without further capital investment. Most often several interdependent projects have to be properly undertaken until those values can be matched, each one with its own capital requirement [33].

Once completed, each project either makes a direct contribution towards helping one or more PIs to reach their targeted values or enables other projects to make such a contribution. Anyway, when due, these contributions can be achieved at once or, most often, incrementally in the course of time. Besides, it is important to consider that all projects connected to a BSC may provide financial returns, even when related to non-financial perspectives.

Therefore, because for-profit organizations are business arrangements set up to provide return on investment to shareholders, when managing a portfolio of BSC related projects, one is interested in maximizing their financial return, while contributing as planned to reach stated goals by a pre-established deadline.

Among all the different kinds of projects that can be connected to a BSC, the IT based ones share the common property of being potentially factored out in MMFs and AEs. As a result, besides increasing return on investment, and shortening both the payback time and the time to market, these MMFs may also contribute to PIs so as their intended values can be reached.

A. Formalizing the Ideas

Since the portfolio $\boldsymbol{P}$ of projects connected to a BSC is usually composed of both IT and non-IT projects, it is helpful to define a function $\boldsymbol{f}$ that takes every project $\boldsymbol{p_i}$ in $\boldsymbol{P}$ to its corresponding set of MMFs and AEs.

If $\boldsymbol{p_i} \in \boldsymbol{P}$ is a non-IT project, than $\boldsymbol{f}$ takes $\boldsymbol{p_i}$ to an indivisible one and only MMF or AE, depending on whether $\boldsymbol{p_i}$ yields or not some financial return on the investment required for its development over the BSC *window of opportunity*.

In formal terms, a precedence graph like the one presented in Fig. 1 is a mathematical structure $\boldsymbol{G = (V, E)}$ composed of two sets, i.e.

- The set of vertices $\boldsymbol{V} = \{ v_1, v_2, \ldots, v_n \}$; and
- The set of edges $\boldsymbol{E} = \{ (v_i, v_j) \mid v_i, v_j \in V \}$.

Note that if $(v_i, v_j) \in \boldsymbol{E}$ than there is a dependency relation between vi e vj, such that if s and d are functions that respectively return the startingpoint and the duration of the development of a module,

$$(v_i, v_j) \in E \Rightarrow s(v_j) \geq s(v_i) + d(v_i);$$

A valid sequence $\boldsymbol{S} = v_j \cap v_k \cap \ldots \cap v_l$ is an ordered set of MMFs and AEs satisfyingthe following restrictions

- Every module in the sequence derives from the portfolio of projects connected to the BSC, i.e.

$$\forall \text{vi} \in \boldsymbol{S} \Rightarrow v_i \in p_k, \text{ onde } \{p_k \in \boldsymbol{P} \mid 1 \leq k \leq \#(\boldsymbol{P})\}$$

- Every module belonging to the sequence is listed exactly once, i.e.

$$v_i, v_j \in \boldsymbol{S} \text{ and } v_i = v_j \Rightarrow \text{i} = \text{j};$$

- The precedence relations between the modules listed in $\boldsymbol{S}$ must uphold at all times, i.e.

$$\forall \{v_i, v_j\} \in \boldsymbol{S} \text{ and } (v_i, v_j) \in \boldsymbol{E} \Rightarrow s(v_j) \geq s(v_i) + d(v_i);$$

- At any given time the total number of teams available to work on the development of the modules, i.e. *nteams*, cannot be exceeded, i.e.

$$\forall t_i \in \boldsymbol{T}, \#(\{v_k \in \boldsymbol{S} \mid s(v_k) = t_i\}) \leq nteams, \text{ where } \boldsymbol{T} \text{ is the BSC } window\ of\ opportunity;$$

- The development effort must start at period one, i.e.

$$\exists\, v_k \in \boldsymbol{S}, s(v_k) = t_0$$

Let $\boldsymbol{PI}$ be the BSC set of performance indicators. Also, let *current* and *target* be functions that return respectively the current and intended value for each $pi_i \in \boldsymbol{PI}$. Moreover, let *makespan* be a function that return the time necessary to implement all $v_i \in \boldsymbol{S}$. In these circumstances, one is interest in finding a valid sequence $\boldsymbol{S}$ that maximizes:

$$NPV(S) = \sum_{k=1}^{\#S} NPV\left(S(k), s\left(S(k)\right)\right) \quad (3)$$

where $\#\boldsymbol{S}$ and $S(k)$ are functions that return, respectively, the number of elements in $\boldsymbol{S}$ and the element in the k^{th} position, provided that the planned contribution of all project in $\boldsymbol{P}$ to reach the targeted values of performance indicators are fully realized within the BSC *window of opportunity*, i.e.

$$\forall pi_i \in \boldsymbol{PI}, current(pi_i) \geq \text{target}(pi_i) \text{ and } makespan(\boldsymbol{S}) \leq \boldsymbol{T} \quad (3)$$

IV. An Example

According to Benjamin Franklin (1706--1790), the American statesman, "a good example is the best sermon". Hence, the model presented in this paper is introduced with the help of a real-world inspired example.

A. Context Information

Consider a large mobile telecommunication carrier such as AT\&T, VERIZON, TELEFONICA and many others, which have millions of subscribers and provide different kinds of value-added services. For the purpose of this paper this organization is called World Mobile Telecom Corporation[1] or WMTC for short.

Technology advances in mobile telecommunications have brought significant changes in the services provided by mobile carriers around the world, creating opportunities and risks to which business must respond. As a result, WMTC and its competitors are fiercely struggling for any strategic advantages that would enable them to gain market-share and ultimately surpass each other.

[1]The data used to obtain the results presented in this paper is closely related to real data provided by one of the largest Latin America's mobile network operator. Because it reflects the current portfolio of on-going IT projects, the authors have been kindly requested no to disclose its name.

Moreover, a growing number of customers conscious of their bargaining power has been demanding for better products and services for reduced prices, so the need for innovation and differentiation is increasing rapidly.

Therefore, if WMTC wants to advance its position as a major player in the mobile telecommunication business, it must select the right business strategy, making the best possible use of its human and financial resources.

WMTC's mission statement tells that the company wants to be recognized as "a highly trustable organization that provides valuable mobile telecommunication services to its customers". In its strategic vision WMTC declares that "the value that the organization creates to its customers stems from innovative products and services that excite the imagination of mobile telecommunication users, fulfilling their needs and desires".

After analyzing the forces acting upon the markets in which it does business (consumer's behavior, competition, uprising technology, interest rates, etc.) and considering its own strengths and weaknesses, WMTC decided to encode its business strategy in the strategy map introduced in Fig. 4. A simplified version of the corresponding balanced scorecard is presented in Fig. 2.

To reach its goals, among other actions, WMTC has decided to invest in the development of five innovative IT-based value-added services, i.e.

- *Goods & Services Purchase (GSP)* – which allows subscribers to use their mobiles as a credit cards to pay for goods and services in associated stores;
- *Mobile Entertainment Pass (MEP)* – which lets subscribers to search for movies, plays and shows, browse their synopsis and buy tickets directly from their mobile phones;
- *Global Navigator (GN)* – which enables subscribers to determine where they are, where others belonging to the same group of related people are, and to draw routes between any two points in a map;
- *Universal Translator (UT)* – which makes it possible for subscribers to communicate in a number of foreign languages using their mobile keyboard, microphone and speakers; and
- *Voice of the Customer (VoC)* – which let customers to compete for prizes by timely reporting on their buying experience, information that is crucial to perfecting the services of customer-oriented organizations.

B. Identifying MMFs and AEs

To take advantage of Denne and Cleland-Huang's ideas on minimum marketable features [13], the projects within the WMTC portfolio have being decomposed into AEs and MMFs using Function-class Decomposition [16], so that they can be incrementally delivered as "mini-projects". Tables 3, 4, 5, 6 e 7 introduce the AEs and MMFs identified by the WMTC's Project Management Office (PMO).

TABLE III. GOODS & SERVICES PURCHASE'S MMFS AND AES.

Id	Type	Name	Description
GSP_1	AE	Service Subscription	Allows customers to subscribe to and unsubscribe
GSP_2	AE	Credit Analisys	Figures the likelihood of a customer paying a debt
GSP_3	AE	M-Payment	Lets customers pay for goods and services they want to buy
GSP_4	AE	Refund	Allows customers to be refunded when returning goods and services they bought
GSP_5	MMF	Shopping	Entitles customers to shop for goods and services in associates stores

TABLE IV. MOBILE ENTERTAINMENT PASS' MMFS AND AES.

Id	Type	Name	Description
EP_1	AE	Service Subscription	Allows customers to subscribe to and unsubscribe
EP_2	AE	Credit Analisys	Figures the likelihood of a customer paying a debt
EP_3	MMF	Search movie	Allows customers to search for movies, plays and shows based on multiple criteria such as: title, cast, genre, district, etc
EP_4	MMF	Browse synopsis	Make it possible for customer to browse the synopses of movies, plays and shows
EP_5	MMF	Buy ticket	Allows customers to choose which specific seat they would like to purchase, charges the ticket value to the customer's account and provides a queue avoiding electronic ticket via SMS
EP_6	AE	Capture location	identifies the current geographical location of a customer
EP_7	MMF	Browse nearby places	Provides information on all theaters and showrooms in the vicinity of the current customer location

TABLE V. GLOBAL NAVIGATOR'S MMFS AND AES.

Id	Type	Name	Description
GN_1	AE	Service Subscription	Allows customers to subscribe to and unsubscribe
GN_2	AE	Credit Analisys	Figures the likelihood of a customer paying a debt
GN_3	MMF	Where am I?	Allows customers to know their geographic location
GN_4	MMF	Navigator	Lets customers select the best route between two points
GN_5	AE	Group Membership	Allows customers to create a group, apply for membership of existing groups and cancel an existing memberships
GN_6	MMF	Find my friends	Reveals the whereabouts of people belonging to the same group of acquaints

TABLE VI. UNIVERSAL TRANSLATOR'S MMFS AND AES.

Id	Type	Name	Description
UT_1	AE	Service Subscription	Allows customers to subscribe to and unsubscribe
UT_2	AE	Credit Analisys	Figures the likelihood of a customer paying a debt
UT_3	MMF	Basic language set	Lets customers to communicate in a reduced set of commonly used languages: English, French, Spanish and Portuguese
UT_4	MMF	Extended set	Provides an extended set of languages

TABLE VII. VOICE OF THE CUSTOMER'S MMFS AND AES.

Id	Type	Name	Description
VoC_1	AE	Service Subscription	Allows customers to subscribe to and unsubscribe
VoC_2	AE	Credit Analisys	Figures the likelihood of a customer paying a debt
VoC_3	MMF	VoC	Allows subscribers to freely express their opinion about ser- vices and products they have purchased
VoC_4	AE	Membership information	Enables customers to check upon the membership points they have earned and prizes they can win
VoC_5	MMF	Prize redemption	Lets customers exchange their membership points by the prizes of their choice

C. Establishing the precedence between MMFs and AEs

One of the main benefits of organizing MMFs and AEs in a portfolio is the possibility of more easily identifying common software units [34]. By factoring out such units one may reduce the portfolio's need for capital investment, increase profit and speed up time-to-market, at the same time that increases quality [35].

Analyzing the portfolio, the PMO identified the "Service Subscription" and the "Credit Analysis" as units that are common to two or more projects. From now on, these units are referred to as $\boldsymbol{CSU_1}$ and $\boldsymbol{CSU_2}$, respectively. Fig. 5 introduces the WMTC's portfolio precedence.

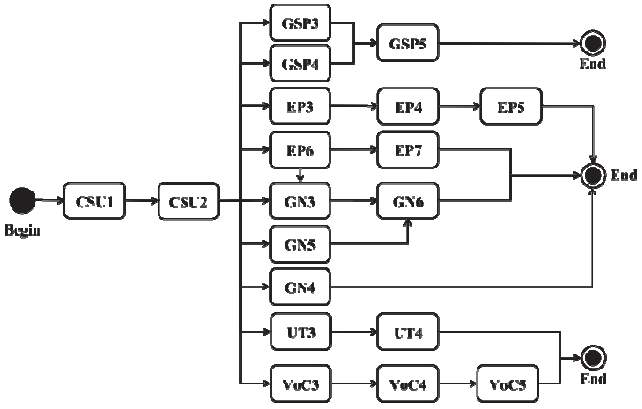

Fig. 5. WMTC's portfolio precedence graph.

D. Estimating the contribution of each MMFs and AEs

Once the AEs and MMFs have been identified and arranged into a precedence graph, their corresponding cost and revenues have to be estimated. Table 8 shows the estimates regarding the sum of the discounted cash-flow of every MMF and AE in the WMTC portfolio, considering a discount rate of 1\% per period.

To produce these estimates the WMTC PMO used average values drawn from a databank of similar projects. See [36, 37] for a discussion on alternative ways of making these estimates.

TABLE VIII. NPV OF THE AE AND MMF IN THE WMTC PORTFOLIO (US$ 1,000).

Module	Software Modules				
	1	2	3	4	5
CSU_1	-35	-34	-34	-34	-26
CSU_2	-80	-79	-78	-78	-59
GSP_3	-50	-49	-49	-48	-37
GSP_4	-18	-18	-17	-17	-13
GSP_5	1,141	1,115	1,089	1,064	-11
EP_3	713	699	685	670	-25
…	…	…	…	…	…
VoC_5	616	607	593	580	-15

E. Selecting the best implementation sequence

Because the number of MMFs and AEs is high, the number of possible implementation sequences is considerable. Even with the help of the precedence graphs introduced in Fig. 5, which has the effect of reducing the number of possible sequences of MMFs and AEs, the problem is still too computer consuming to be tackled by brute force. Hence, the WMTC appealed to the branch and bound algorithm for MMF sequencing developed by [17].

Although branch and bound algorithms may perform as poorly as their brute force counterparts in the worst case scenario, in many circumstances it can provide the optimum solution in a polynomial time [38]. Table 9 presents the results obtained by the algorithms according to the number of software development teams used by WMTC.

TABLE IX. PROJECT PERFORMANCE INDICATORS ACCORDING TO THE NUMBER OF DEVELOPED TEAMS.

# of Dev. Teams	NPV (US$ 1K)	Makespan (Periods)	PI Reaching Planned Value	Capital Invest. (US$ 1K)
1	7,313	19	70%	210
2	8,216	11	100%	258
3	8,444	8	100%	381
4	8,467	7	100%	385
5	8,559	7	100%	439
6	8,559	7	100%	439

It is important to note that if just one development team is used, not all performance indicators in the WMTC balanced score card will reach their intended target value, within the BSC window of opportunity.

On the other hand, there is a certain point from which increasing the number of development teams leads to neither a higher NPV nor a shorter total makespan. For example, using five or six development team leads to exactly the same NPV and total makespan.

Moreover, employing more development teams than necessary just adds to the complexity of managing the development of the portfolio without yielding any foreseeable benefits. According to [39], the more complex a project is, the more difficult it is to keep it on track.

As a result, the decision of the number of development teams to use resides on the amount of capital investment. The more capital investment is made available, the shorter the total makespan and the higher the total NPV.

As competition in the telecommunication market brought down the margins in almost all of the products and services, WMTC was able to allocated only US$ 300K for the portfolio. Hence, the logical choice according to the information displayed in Table 9 is to use only 2 development teams.

V. Conclusion

The Kaplan and Norton's balanced scorecard provides valuable insights regarding an organization strategy, assembling all their strategic goals and performance indicators. Therefore, undertaking the projects that will provide the highest NPV while achieving one or more of the performance indicators targeted values, within the BSC window of opportunity, is a must to any for-profit organization.

To accomplish such a goal, this paper introduces an optimization model based upon Kaplan and Norton's balanced scorecard and Denne and Clelang-Huang's minimum marketable features. The model allows organizations to maximize the return on investments of their portfolio while ensuring its strategic fit.

Abstract— **We built Smart Home applications for the Cognitively Impaired population. We have chosen to work with an existing framework, OSGi, which allows us to develop specific applications more quickly. We use a combination of traditional testing and formal verification to insure these applications will cause no harm to the cognitively impaired users of our systems. This paper will focus on our results to date of using model checking to verify OSGi applications. We have created a formal model parallel to OSGi, which can be reused as a modeling framework to plug in and check OSGi applications. The trick has been to vary and combine different features of OSGi (i.e., abstract away the details that are not relevant to the particular property we wish to verify, but include the details when they are relevant), since a feature tends to involve code scattering in multiple classes. We have found that aspect-oriented programming, using AspectJ, is a potential solution. Using aspects, we have been able to prune large portions of OSGi in a controllable manner. One obstacle to this approach is that AspectJ will introduce native code so that an AspectJ program can't be checked by Java PathFinder (JPF). We report our efforts to date to resolve this problem and enable model checking AspectJ programs in general.**

Keywords- Model Checking; Java PathFinder; AspectJ; Framework; OSGi

I. INTRODUCTION

Our group has actively participated in the design and development of Smart Home applications [1][2]. We have chosen to work on the OSGi platform [3], which offers us standardized ways to manage the software lifecycle and more quickly develop applications across platforms. We are also advocates of formal methods, and have relied on model checking to uncover bugs in real systems [4][5]. We use a combination of traditional testing and formal verification to insure that the OSGi-based applications we build will cause no harm to the cognitively impaired users of our systems. As the OSGi framework and its applications are both developed in Java, we chose the model checker Java Pathfinder (JPF) [6][7], which directly checks Java bytecode.

In the process of checking OSGi applications, we soon found ourselves in a dilemma. On the one hand, OSGi applications are based on the OSGi framework; hence, it seems natural to build a formal model paralleling the OSGi framework and reuse the modeling framework to check OSGi applications. On the other hand, this approach is complicated by the very nature of model checking. A major obstacle to formal modeling is state space explosion, where the interleaving of processes leads to an exponential increase of system states that is beyond the capacity of a typical computer. This restriction requires a formal model being reduced to its bare essentials before the verification step. However, since OSGi applications may use different features of OSGi, it is nearly impossible to come up with a modeling framework that has just enough details for all OSGi applications. We will need some way to vary features of a modeling framework to check various applications.

The Object-Oriented nature of Java has offered some help for customizing the modeling framework. For example, one can override slots and hooks to specialize the modeling framework. However, there are some crosscutting concerns that may not naturally fit in this paradigm. For example, when we are interested only in the stale references problem [3][11], we don't need permission check in the framework and may remove all related fields and statements to save the state space. On the other hand, when we want to assure that no malicious application spoils the OSGi framework, we have to add back the missing fields and statements to enable permission check. Changing a feature is often a tedious task that involves modifications in multiple files, and it will be even worse when we have to come up with a specific combination of different features.

In our experience, such crosscutting concerns have prevented us from effective reuse of formal models and incurred much overhead in model maintenance. In view of these difficulties, we have found that aspect-oriented programming (AOP), using AspectJ [9][10] for Java, is a potential solution. Using AspectJ, we have been able to prune large portions of the OSGi code-base that are not relevant and vary features in a modular way. We report our findings in this paper.

The rest of the paper is organized as follows. We briefly explain the model checker Java Pathfinder in section II, and the application domain, OSGi applications, in section III; in section IV we use real examples of OSGi applications, to show that we can vary features of a formal model with AspectJ in a modular way; in section V, we show a necessary step, the construction of a specialized JPF, to enable verifying AspectJ programs in

general. We summarize the contributions and the future work in section VI.

II. JAVA PATHFINDER

Java PathFinder is an explicit model checker that directly checks Java bytecode. It has a specialized virtual machine, which takes on the role of a model checking engine like state cache, query, comparison, and restoration. Through a well-defined component architecture, JPF allows one to customize the search procedure. For example, it has a Model Java Interface (MJI) to intercept Java method calls, which may be used to resolve native methods (by executing native methods outside the JVM, but store interesting results in the JVM) and reduce state space (by excluding state information in the transition from the JVM). The extension schemes in JPF also allow expert users to experiment with novel search heuristics and state representations, which can be conveniently reused through the well-defined component interface.

There are several restrictions on JPF. First, it is not able to check platform-specific native methods like I/O methods, since the execution information is not available to the JVM. Second, due to state space explosion, it typically deals with Java programs with no more than 10k lines-of-code [7]. Therefore, before using JPF to check a real system, one would have to (a) resolve Java native methods with pure Java implementations or the MJI, and (b) apply various reduction techniques to construct a model with only the bare essentials for the actual system. In addition, one may also need to specify the interactions with the environments (e.g., user inputs) in a closed form. This is general to model checking since model checkers can only handle finite systems for a complete verification. In JPF this process can often be combined with the step to resolve native methods.

III. THE OSGI FRAMEWORK

For the purpose of explanation, we briefly introduce the application domain, i.e., the OSGi framework and OSGi applications [3]. The OSGi specification articulates a generic component structure for Java modularization. The unit for modularization is a bundle, which is a jar file typically composed of a manifest file, Java classes, native library and other resources. An OSGi framework has a base framework to fulfill the core functionality of the OSGi specification, e.g., manage the lifecycle of bundles. In particular, when starting a bundle, the base framework instantiates a bundle activator designated in the manifest file and invokes a callback function BundleActivator.start (i.e., a bundle activator is a Java class that implements org.osgi.framework.BundleActivator). When stopping a bundle, the framework invokes another callback function BundleActivator.stop. These callback functions are the main places to extend functionalities in a module. Each bundle runs in a separate JVM environment to avoid interferences between bundles; bundles communicate with each other through events delivered by the framework and services managed by the framework. A service is the unit to dynamically import/export functionality by a bundle. The OSGi framework maintains a mapping to associate service names to service references: a bundle (or more exactly, a bundle activator) can register a service by adding a mapping in the table, and use a service by first looking up a service in the mapping table.

A common pitfall in OSGi applications is the stale references problem. It happens when a service used by a consumer bundle has actually been unregistered by the producer bundle. This problem is acknowledged in the OSGi specification, and an auxiliary class, ServiceTracker, has been created to track valid services. We will uncover violations belonging to this category in our case studies. An interested reader can refer to [3] [11] for more information about the stale reference problem and some of its treatment at the application level.

There exist several reference implementations for the OSGi specification. Knopflerfish is a leading implementation and has been certified to be OSGi compliant [5]. It is composed of a base framework to fulfill the OSGi specification, mandatory bundles for basic functionality like input/output and optional bundles for extended functionality like logging. We base our case studies on the Knopflerfish framework. An interested reader can refer to [3][8] for a full explanation of OSGi and the Knopflerfish framework.

IV. ADVICE VERIFICAITON VIA ASPECTJ

We have built a formal model paralleling the OSGi specification, to ease modeling OSGi applications [10]. In this section, we point out some crosscutting concerns in the formal model, and show that we are able to modularize such concerns with AspectJ and conveniently specialize the base model with various features.

A. Add Modeling Code to Check Correctness

For the purpose of testing and model checking, we often add additional code to record system status and check the status in appropriate places. Such code is not part of the base model (not even part of the implementation code) and should be added only when we model check relevant properties.

Consider the example in Figure 1. It is the formal model one would reasonably derive with to check the stale references problem: the statements in *italic font* are the extra code solely added for verification purpose. It mandates that all services extend a BasicService (line 5), which has a boolean field valid to indicate whether a service is currently available. Upon the invocation of a service, the service will check whether it is currently available to other bundles (line 7). From the point of the framework, the field valid is set to true (line 14-19, line 24-29) when a service is registered successfully (line 13, line 23), and set to false (line 37-40) when a service is removed from the registration table in the framework (line 36). The code, solely for the purpose of model checking (all lines in italic font), spans multiple places of several Java files (e.g., ServiceRegistrationImpl.java, BundleContextImpl.java and all service implementation files), which is cumbersome to vary and interact with other model checking features.

```
1. public class BasicService {
2.   public volatile boolean valid = false;
3.   public ReentrantLock service_lock=new ReentrantLock();
4. }
5. class DictionaryImpl extends BasicService implements
DictionaryService {
6.   public boolean checkWord(String word) {
7.     assert(valid);
8.     ...// do the actual work
9.   }
10.}
11.public class BundleContextImpl {
12.  public ServiceRegistration registerService(String[]
clazzes, Object service, Dictionary properties) {
13.    ServiceRegistration sr=...// do the actual work
14.    if (sr!=null) {
15.      if (service instanceof BasicService) {
16.        BasicService ds = (BasicService)service;
17.        ds.valid=true;
18.      }
19.    }
20.    return sr;
21.  }
22.  public ServiceRegistration registerService(String clazz,
Object service, Dictionary properties) {
23.    ServiceRegistration sr=...// do the actual work
24.    if (sr!=null) {
25.      if (service instanceof BasicService) {
26.        BasicService ds = (BasicService)service;
27.        ds.valid=true;
28.      }
29.    }
30.    return sr;
31.  }
32.}
33.public class ServiceRegistrationImpl {
34.  Object service;
35.  private void unregister_removeService() {
36.    ...//remove the service
37.    if (service!=null && service instanceof BasicService) {
38.      BasicService ds = (BasicService)service;
39.      ds.valid=false;
40.    }
41.  }
42. }
```

Figure 1. Adding model checking code w/o AspectJ

The crosscutting concerns in Figure 1 can be conveniently modularized in a single aspect. As shown in Figure 2, the rule that all services shall additionally extend BasicService is specified by the declare parents phrase (line 1). The rule that the field BasicService.valid shall be set to true when a service is registered is realized by the pointcut that matches the completion of a successful registration (line 18-21) and the advice (line 22-25). The rule that the field valid shall be set to false when a service is unregistered is realized by the pointcut that matches the completion of the unregistration (line 11-13) and the advice (line 14-17). The rule that the service's validity shall be checked upon the invocation to its functions is realized by a pointcut that matches the access of a service's functions (line 2-4), and an advice that does the assertion (line 5-9). Whether to perform the verification of the stale references problem can be easily specified as inclusion or exclusion of the aspect while compilation.

```
1. declare parents: (DictionaryImpl) extends BasicService;
2. pointcut ServiceFunction(Object service) :
3.   execution(* checkWord(..)) && this(service)
4.   && this(DictionaryService);
5. before(Object service): ServiceFunction(service) {
6.   if (service instanceof BasicService) {
7.     BasicService bs = (BasicService) service;
8.     assert (bs != null && bs.valid);
9.   }
10.}
11.pointcut ServiceUnregister(ServiceRegistrationImpl sr):
12.  execution(* unregister_service(..)) &&
13.  this(ServiceRegistrationImpl) && this(sr);
14.after(ServiceRegistrationImpl sr) : ServiceUnregister(sr) {
15.  if (sr.service != null && sr.service instanceof BasicService)
16.    ((BasicService) sr.service).valid = false;
17.}
18.pointcut ServiceRegister(BundleContextImpl bc, Object
 service):
19.  this(bc) && this(BundleContextImpl) &&
20.  args(service) && if (service!=null) &&
21.  execution(ServiceRegistration registerService(.., Object,
 Dictionary));
22.after(BundleContextImpl bc, Object service)
 returning(ServiceRegistration sr):ServiceRegister(bc,
 service){
23.  if (sr != null && service instanceof BasicService)
24.    ((BasicService) service).valid = true;
25.}
```

Figure 2. Modularizing model checking code with AspectJ

B. *Vary Security Feature*

In addition to specifying correctness properties, we can also leverage AOP to conveniently choose a specific combination of features to check. As mentioned, we shall remove all non-mandatory fields and statements from the base model, and only add them back when they implement a specific feature relevant to the particular property to be verified. This methodology is critical to crack the state explosion problem and shall be enforced when possible.

However, we often find that adding back a feature involves adding fields and statements in multiple places of various files, and they are often different from their counterparts in the application code due to the result of abstraction. Enforcing such unfamiliar programming logic across multiple files is a daunting task when we have to check combinations of different features.

Consider the formal model in Figure 3. The statements in *italic font* enforce permission check for OSGi operations. A permission handler is created in Framework (line 5) and referred in Listeners and Services. The framework checks the permission when a bundle adds itself as a SynchronousBundleListener, to avoid a silly bundle blocking the whole framework (line 14-17). Similarly, the framework also checks the permission for registering a service to avoid a malicious bundle to preempt other valid services (line 31). These statements (in *italic font*) are not in the base model and are only needed when checking properties related to privileged operations. They scatter in more than ten places of three files (only a fragment of them are shown in Figure3), which is

tedious and error-prone for frequent addition and removal of features in model checking.

```
1. public class Framework {
2.   PermissionOps perm;
3.   public Framework(Object m) throws Exception {
4.     ...// Do other initialization
5.     perm=new SecurePermissionOps();
6.   }
7. }
8. public class Listeners implements {
9.   PermissionOps secure;
10.  Listeners(PermissionOps perm) {
11.    secure = perm;
12.  }
13.  void addBundleListener(Bundle bundle, BundleListener
listener) {
14.    if (listener instanceof SynchronousBundleListener) {
15.      secure.checkListenerAdminPerm(bundle);
16.      ...// do the actual work to add listeners
17.    } else ... // do the actual work to add listeners
18.  }
19.}
20.class Services {
21.  private PermissionOps secure;
22.  Services(PermissionOps perm) {
23.    secure = perm;
24.  }
25.  ServiceRegistration register(BundleImpl bundle, String[]
classes, Object service, Dictionary properties) {
26.    ...
27.    for (int i = 0; i < classes.length; i++) {
28.      String cls = classes[i];
29.      if (cls == null)
30.        throw new IllegalArgumentException("...");
31.      secure.checkRegisterServicePerm(cls);
32.      ... // do actual registering...
33.    }
34.  }
35.}
```

Figure 3. A formal model to check permission voilation in OSGi

```
1. static PermissionOps Framework.perm=new
SecurePermissionOps();
2. pointcut BL (Bundle bundle, BundleListener bl):
3.   execution(* addBundleListener(Bundle, BundleListener))
4.   && args(bundle) && args(bl);
5. before(Bundle bundle, BundleListener bl) : BL (bundle, bl)
{
6.   if (bl instanceof SynchronousBundleListener) {
7.     Framework.perm.checkListenerAdminPerm(bundle);
8.   }
9. }
10.pointcut ServiceRegistration(String classes[]):
11. execution(ServiceRegistration
register(..))&&args(classes);
12.before(String[] classes): ServiceRegistration(classes) {
13.  for (int i=0; i<classes.length; i++) {
14.    Framework.perm.checkRegisterServicePerm(classes[i]);
15.  }
16.}
```

Figure 4. The security model advised with AspectJ

We can modularize the inclusion of security in a single aspect. As shown in Figure 4, we use an intertype declaration to add back the permission handler (line 1). The invocation of permission check when adding a SynchronousBundleListener is matched by a pointcut (line 2-4), and advised before it is actually added (line 5-9). The invocation of permission check when registering a service is matched by a pointcut (line 10-11), and advised before it is actually registered (line 12-16). Compared with the needed modifications across multiple places of three files, adding permission check with AspectJ is modularized in a single aspect and much easier to change.

C. Change the Granularity of Atomicity

Despite the existence of partial order reduction, program slicing and other techniques to save the state space, we often need to manually enforce atomicity in various places of a model. On the one hand, manually enforcing atomicity may significantly reduce the search space, so that errors may be uncovered much faster and with less memory - in many cases it is also the only way to complete the verification run before running out of resource (e.g., memory and time). On the other hand, we may want to change the atomic code block when we are exploring potential solutions to a concurrency error.

```
1.public class ConsumerActivator implements
BundleActivator{
2.  public void start(BundleContext context) throws
Exception{
3.   ...
4.   DictionaryService service=...//look up service in
framework
5.   if (service!=null && service instanceof BasicService) {
6.      BasicService bs = (BasicService)service;
7.      bs.service_lock.lock();
8.      if (service.valid)
9.        service.checkWord(...);
10.     bs.service_lock.unlock();
11.   }
12. }
13.}
14.public ServiceRegistrationImpl {
15.  Object service;
16.  public void unregister() {
17.    ...
18.    if (service instanceof BasicService) {
19.      BasicService bs = (BasicService)service;
20.      bs.service_lock.lock();
21.      bundle.framework.listeners.serviceChanged(new
ServiceEvent(ServiceEvent.UNREGISTERING, reference));
22.      bs.service_lock.unlock();
23.    }
24.  }
25.}
```

Figure 5. Varying atomicity to explore counter examples

For these reasons, we would like to have a mechanism to conveniently vary the granularity of atomicity. However, the conventional approach to do this is fairly involved. For example, Figure 5 shows a potential solution to avoid the stale references by enforcing atomicity when invoking a service (line 5-12) and unregistering a service (line 18-23). We have to entangle the code (that changes atomicity) with other statements in the two files, and similar code will have to spread in each service declaration file if we want to enforce such atomicity for them.

```
1. pointcut atom_check(DictionaryService ds):
2.   target(ds) && execution(boolean checkWord(..))
3.   && if (ds instanceof BasicService)
4.   && !cflow(adviceexecution());
5. void around(DictionaryService ds) : atom_check(ds) {
6.   if (ds instanceof BasicService) {
7.     BasicService bs = (BasicService)ds;
8.     bs.service_lock.lock();
9.     proceed(ds);
10.    bs.service_lock.unlock();
11.  } else proceed(ds);
12.}
13.pointcut atom_unregister(ServiceRegistrationImpl sri):
14.  execution(void unregister(..)) && target(sri)
15.  && !cflow(adviceexecution());
16.void around(ServiceRegistrationImpl sri) :
atom_unregister(sri) {
17.  if (sri.service instanceof BasicService) {
18.    BasicService bs = (BasicService) (sri.service);
19.    bs.service_lock.lock();
20.    proceed(sri);
21.    bs.service_lock.unlock();
22.  } else proceed(sri);
23.}
```

Figure 6. Advising atomic blocks with AspectJ

The daunting task of enforcing atomicity across multiple files can be modularized by aspects. For example, we can intercept the execution of a non-atomic block with an around clause, and enforce atomic execution of the block with a shared, exclusive lock. As shown in Figure 6, we use an around pointcut to intercept the intended atomic block (line 1-4), and enforce atomicity for the action sequence (checking the service validity and using the service) in line 5-12. Similarly, the around pointcut in line 13-15 intercepts the intended atomic block, and the advice in line 16-23 enforces the desired atomicity. By this way, we can enforce arbitrary atomicity without scattering code here and there, which will ease feature management at the model level and improve the efficiency in exploring candidate solutions. In our experience, we do find a verified solution for the stale references problem in this approach.

V. MODEL CHECKING ASPECTJ PROGRAMS

In section IV, we have shown that formal models have crosscutting concerns that may be elegantly modularized via AspectJ assistance. However, such superiority of aspects is not practically useful if the Java bytecode woven by AspectJ can't be checked by JPF. In particular, we are concerned whether AspectJ will introduce extra native code to a pure Java model. This question is also significant for applications developed with AspectJ but now to be checked by JPF.

A simple AspectJ program like Figure 7 shows our fears are well founded. This program merely gets the signature of a joint point and involves no I/O from the surface. After we compile the program with the AspectJ compiler and check it with JPF, JPF reports the error as shown in Figure 8. Since all statements irrelevant to AspectJ are written in pure Java, the symptom shows that AspectJ introduces native code to a pure Java program. In this example, it occurs when the woven bytecode calls the native code in the AspectJ runtime library. A closer look at Figure 8 reveals that the NullPointerException is thrown when System.getProperty(String, String) is called (line 3). This is natural since it is a system-level function, which gets the environmental information outside the scope of the Java virtual machine.

```
1. public class Framework {
2.   public static void main(String[] args) {
3.     Framework fw = new Framework();
4.   }
5. }
6. aspect FrameworkConstructor {
7.   pointcut FrameworkConstructor(Framework f) :
8.     execution(Framework.new(..))
9.     && !cflow(adviceexecution()) && this(f);
10.  after(Framework f): FrameworkConstructor(f) {
11.    Signature sig = thisJoinPoint.getSignature();
12.  }
13.}
```

Figure 7. A simple AspectJ program that fails JPF

```

```

Figure 8. Error message from JPF

We can use the MJI scheme in JPF to resolve native methods in the AspectJ runtime library, or customize the runtime library with a pure Java implementation. It is beyond the scope of this paper to fully describe the details to resolve native code in the AspectJ runtime library. As an example, we briefly explain the procedure to resolve native methods invoked by the program in Figure 7.

Defining a peer function in MJI is similar to calling a native method in Java Native Interface (JNI). A MJI method for System.getProperty(String, String) is shown in Figure 9. The function signature has name mangling so that it allows proper association in case of function overloading. The particular implementation in Figure 9 allows reading system properties outside the closed JVM.

After this peer method is installed, JPF will intercept the call to System.getProperty(String, String) by matching the function name. Thereafter, the host JVM executes the peer method to get the environment information (line 8), and stores

the result in a special area. JPF fetches the result from this special area as if it is read from the environment.

```
1. public static int getProperty__Ljava_lang_String_2Ljava
_lang_String_2__Ljava_lang_String_2 (MJIEnv env, int
clsObjRef, int keyRef, int defRef) {
2.   int r = MJIEnv.NULL;
3.   if (keyRef != MJIEnv.NULL) {
4.     String k = env.getStringObject(keyRef);
5.     String defaultString = env.getStringObject(defRef);
6.     if (k==null)
7.       return MJIEnv.NULL;
8.     String v = System.getProperty(k);
9.     if (v != null)
10.      r = env.newString(v);
11.    else if (defaultString!=null) {
12.      r = env.newString(defaultString);
13.  }
14.  return r;
15.}
```

Figure 9. Peer method for System.getProperty(String, String)

As a result to date, we have created a MJI abstraction library and customized the AspectJ runtime library, to help resolve native methods introduced by AspectJ. We also created a test suite that includes all sample programs (excluding those that have native code in the Java program) from [9][10]. In our testing, all native code introduced by the AspectJ keywords has been successfully resolved, and we are currently investigating the whole runtime library (~180K) of AspectJ.

VI. SUMMARY

When we use model checking to verify real-world Smart Home applications, we have found a strong need to vary features of a formal model and customize the verification procedure. This is required as part of the efforts to conquer the state space explosion problem, by removing irrelevant details. However, varying features for a formal model tends to result in modifications scattering in multiple Java files, and it is even worse when we vary the combination of different features to study feature interactions. With examples, we have shown that these crosscutting concerns can be modularized with aspects, and can thus be easily enabled and disabled. We also point out that AspectJ may introduce native code to a pure Java program, and show an example that we can leverage the MJI scheme to solve it. We are currently building a MJI abstraction library, which will benefit not only our paradigm to advise model construction with AspectJ, but also AspectJ applications in general that have been developed without the awareness of model checking. In general, if we deem a model checker as an explorer for counter examples, the overall methodology enables easy exploration of solution space with very different features and goals.

We are also investigating the performance overhead introduced by AspectJ and looking for ways to minimize such impact. This occurs because additional state variables are introduced, e.g., aspect initialization. In our current experience, the state space increase of a complex model is relatively small and doesn't appear to be a show stopper. This problem can be further mitigated with search heuristics, e.g., one can enforce atomicity for aspect initialization. This brings up an interesting distinction between model checking AspectJ programs and using AOP techniques to ease model checking Java programs.

***Abstract*—Ubiquitous computing provides a dynamic access to different functionalities of networkable electronic devices. Whereas basic services have limited use, predefined complex services cannot encompass every end-user's needs nor be adapted to a set of services that are dynamically discovered in an open environment. Alternatively, users need to be provided with means to express their requirements, choosing precisely which services to compose into a scenario of their own. In service-oriented computing, some systems propose mechanisms to develop tailored components that provide composite services; however they are not adapted to end-users, have limited composition capabilities and/or do not consider several characteristics of ubiquitous environments (such as multiple users and devices).**

This paper presents a novel user-centric system called SaS for mobile personal devices. SaS provides end-users with an easy access to services and a simple GUI to combine them into complex scenarios. A new architectural description language is used to specifically support scenario creation by service composition. Scenario may be shared among users and devices. SaS offers scenario execution control for example to start and stop it but also to query the current state of a scenario. In addition, SaS proposes some mechanisms to maintain scenario availability in case of service/device unavailability. SaS is currently implemented in a proof-of-concept prototype on top of OSGi.

Keywords*—*Ubiquitous computing, service-oriented computing, user-centric system, service composition, scenario creation.

I. INTRODUCTION

With the rise of ubiquitous computing [1], [2], we are surrounded by electronic devices (such as smart phones or TVs) that propose a huge amount of services through public or private networks. According to the OASIS organization, *"a service is a mechanism to enable access to one or more capabilities"* [3]. In service-oriented computing (SOC) [4], and specially in home automation [5], [6], [7], efforts have been made to facilitate the use of these electronic devices through their services. As shown in Figure 1, the more complex user requirements can only be satisfied by compositions of multiple services provided by multiple devices. Different service composition means have been studied and proposed [8], [9], [10], [11]. However, they are not designed for end-users without technical knowledge.

Enabling end-users to describe their own *scenarios* is a first improvement and a step towards ambient intelligence [12]. In addition, users should easily manage the created scenarios and have access to them from several control devices (PDA, mobile phone or laptop). Moreover, ubiquitous environments imply that several users might be eager to share scenarios. Scenarios should therefore be exported in the environment to be shared and reused.

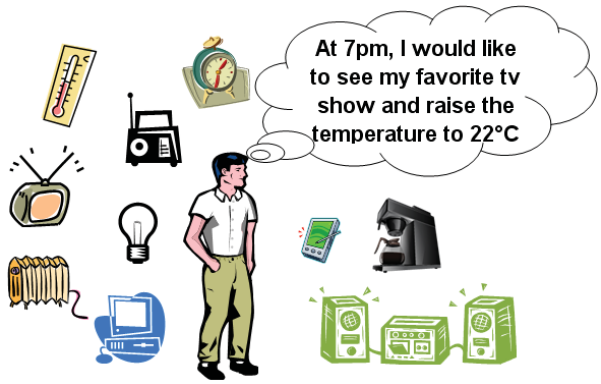

Figure 1. User's main issue

In this paper, we propose the SaS (Scenarios as Services) system specifically designed for end-users to describe, use and share *scenarios* in a high level manner. SaS comprises a new architecture description language (ADL) [13], [14], [15] dedicated to user scenario creation. SaS also integrates a graphical user interface (GUI) based on this ADL. This GUI presents a classified and filtered view of the services available from a set of widely spread devices and provides tools to easily *compose* selected services. SaS integrates scenarios as *regular services*. This enables easy scenario execution control, scenario sharing among users and hierarchical composition of scenarios. The SaS system has been prototyped. Its current implementation is on top of OSGi [16].

The remainder of this paper is structured as follows. Section II introduces the context of this work, presents the requirements for open and distributed environments and discusses the state of the art. Section III presents the first part of our proposition: scenario creation. Section IV is dedicated to scenario execution control and sharing. Section V presents the architecture of the prototype implementation. Finally, section VI evaluates our proposition, concludes and draws some perspectives to this work.

II. User-Centric Systems in Ubiquitous Environments

This section first describes the terminology of ubiquitous environments and especially that of user-centric systems. It then presents the requirements that are mandatory for that kind of systems. It finally compares some of the main state of the art approaches regarding these requirements.

A. Terminology

Ubiquitous systems involve multiple *users* and multiple *devices* that each provide a set of *services*. A device is an electronic object (such as a clock). Devices publish services (such as `Time`). Each service provides one or more *operations* (such as `getTime` or `setTime`). They are called "capabilities" in the SOA norm [3] by the OASIS consortium. End-users use these operations as an access to functionalities of devices.

Devices can interoperate but the overall goal that the system has to achieve always comes from users. Users can be simple consumers or technical experts that command devices, their needs can always be considered as *scenarios* which are combinations of operations. However, we choose to name this combination a *service composition* because services are not stand-alone elements and to stick to the terminology used in SOC.

A SaS system is deployed on a mobile personal device. The system and the device on which it is deployed together define a SaS *platform*. A SaS platform participate in one or more networks which constitute the platform's environment. The global environment is the union of all the environment of its constituting SaS platforms.

B. Requirements for user-centric systems

User needs always constitute a scenario. User-centric system must therefore enable *scenario creation*. As seen in Figure 1, user scenarios are not always simple service aggregations but can imply conditions, control statements and logical operators. Users should thus be able to *compose services* according to their needs. Most of the users are not technical experts. Scenario creation should therefore be *user-friendly* and adapted to devices. Ubiquitous environments imply multiple users and devices. So, created scenarios should be available into the environment and *shared* among users. Users must be able to easily start and stop created scenarios and check scenario status and execution advancement. Thus, the system should control the *scenario life-cycle*. Moreover, already created scenarios should be easily modified and *recomposed* into other ones. In addition, devices that provide services and/or scenarios can disappear. The system must therefore *maintain* scenario execution and availability in case of device disappearance.

C. State of the art

With the requirements established previously, we can analyze some of the main systems that provide a solution for ubiquitous environments and enable end-users to create scenarios.

- **SLCA** [17] provides developers with the capability to compose web services. A composite service contains proxy components attached to involved web services. SLCA enables hierarchical service composition. In addition, it is an event-based system which adapts to environment changes. In case of service unavailability the composite service replaces it if an appropriate service is found. If not, the composite service removes the proxy component attached to this service.
- **MASML** [6] is a multi-agent system for home automation. Scenarios are defined with an XML syntax and consist of a sequence of service operation invocations. MASML XML documents can embed ECMA scripts [18] to add logic elements. A mobile agent is in charge of scenario execution. It is moving to each appropriate device with the scenario description file to execute it. This enables scenario advancement tracking but not parallel execution.
- **SODAPOP** [19] proposes an innovative approach based on the same observation than us: user needs are scenarios. What is important is the goal to achieve. The main hypothesis is that each service contains informations about its initial conditions and its effects. SODAPOP automatically classifies new services with these informations. Then, it can combine some of them to reach the user's goal.
- **SASHAA** [20], [21] is one of our previous work, focused on ubiquitous systems for home automation. It enables end-users to create scenarios with Event - Conditions - Action rules through an appropriate GUI. It is an adaptive system which creates a new component for each new device.

Table I compares these systems with respect to the requirements that we identified in II-B. Symbol $\surd$ means that the requirements is fulfilled, - signifies that it is partially accomplished and X represents an absence of solution.

Systems	Scenario Creation	Advanced Service Composition	User friendliness	Scenario sharing	Scenario Lifecycle	Hierarchical Composition	Scenario Maintenance
SASHAA	$\surd$	-	$\surd$	X	-	X	$\surd$
SLCA	$\surd$	$\surd$	X	X	X	$\surd$	-
MASML	$\surd$	$\surd$	X	X	-	X	$\surd$
SODAPOP	$\surd$	X	-	X	X	X	X

Table I
SYSTEM COMPARISON WITH OUR REQUIREMENTS

Except for SAASHA, we can notice in Figure I that all these works propose programming tools for developers. They are not directed to end-users. In addition, scenario sharing is never took into consideration. For scenario life-cycle control, SASHAA only enables to start and stop scenarios whereas MASML just allows users to check scenario advancement. Because of this, we decided to propose a new system which best meets all the expectations of user-centric systems for ubiquitous environments.

III. The SaS System: Scenario Creation

A. Overview of SaS

The purpose of SaS which stands for *Scenarios As Services* is threefold:

1) help end-users create scenarios by service composition,
2) monitor scenario execution on a given platform,
3) export scenarios into the environment for future use or sharing.

To do so, several steps are necessary that define a user-centric cycle, as illustrated by Figure 2:

0. The system (placed into a user device) discovers the services available in its neighboring environment.
1. SaS classifies service operations depending on their providers (devices) and services. It then displays them.
2. Users can compose several available services to create a scenario. This is possible through a dynamically adaptive graphical user interface based on our ADL.
3. The created scenario is translated into a descriptor file. It therefore becomes easily transmissible and can be shared with other platforms and users.
4. Next, SaS analyzes the scenario descriptor. It extracts information about the different services involved and how they are composed.
5. The system creates a composite with the involved services and a generated *manager*. This manager handles the services according to the previously made user choices.

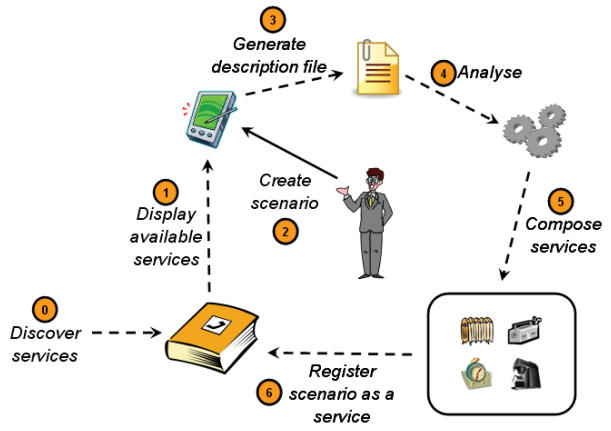

Figure 2. Overview of the proposed SaS scenario creation and reuse cycle

6. Finally, the manager, which is in the composite, registers the scenario as a new service into the environment. It becomes accessible from other devices and shared among end-users. Moreover, it can be composed into a new scenario.

B. Scenario creation

This section describes scenario creation, which is the main part of our system. It consists in three steps: service selection, scenario construction by service composition and scenario export. As described in Section III-A, the first functionality of the SaS system is service discovery. Some protocols already exist that do so (*e.g.* UPnP [22], SLP [23], Jini [24]) along with different extra functionalities. To be as interoperable as possible, our SaS system does not prescribe the use of a particular discovery protocol. Once the available services are discovered, they can be listed and ordered by SaS to enable service selection.

1) Service Selection: Every service proposes one or more operations (for example, the *light* service might offer two operations: `getValue` and `setValue`). To define a scenario, users always select operations, but the name of the service and the identity of the provider device do not always matter. For example, to print a document a person generally chooses his favorite printer, accesses the specified service and selects the appropriate operation. Alternatively, if he needs to know what time it is, he directly selects the `getTime` operation, no matter which clock or service provides it.

Service selection in SaS sticks to this requirement. SaS proposes three filtered views to select available operations: by device type (*e.g.* the list of available printers), by service name (*e.g.* the *printService* service) or directly by operation name (*e.g.* the `print` operation). If users select a device, services provided by this device are then proposed to choose from. If users select a service, operations that compose this service are then proposed to choose from. Moreover, distinct devices can propose services with the same name, sometimes with additional operations. SaS groups these services together and displays all the available operations collectively.

2) Service Composition: SaS enables service composition thanks to an ADL and its GUI. Depending on user choices, created scenarios can be then exported into the environment.

a) Presentation of the ADL: In order to help end-users create scenarios that correspond to their needs, we propose a new ADL. It is simple and tailored to scenario creation. Compared to other programming languages for service composition (like BPEL [25]) which are imperative and designed for executable process, our ADL is a high level language, declarative and destined to end-users. With this ADL, one can declare both services and scenarios.

- Service declaration
  We define a service by a device (its provider), a name and an operation list. This list cannot be empty. Operations have a return type (which can be *void*) and can have typed parameters. We represent only the main elements of the grammar in Listing 1.

```
<service> ::= service <device> <service_name> <op_list>

<op_list> ::= ( <operation> ; )*

<operation> ::= operation <operation_name> (
   [<parameter_list>] ) : <return_type>

<parameter_list> ::= <parameter_type> (,<parameter_type>)*

<return_type>::= <type>
<parameter_type> ::= <type>
```

Listing 1. Service declaration with the Backus–Naur Form (BNF)

- Scenario declaration
  By definition, a scenario has a name and an action list. An action can be:
  - **an operation invocation**: a service operation is invoked, with its parameter values. Users can directly enter parameter values or invoke another service operation to create the desired value (operation composition). SaS checks if parameter types conform to the service definition.
  - **an alternative (*if - else*)**: conditions compare the result of two service operations or the result of a service operation and a value chosen by the user.
  - **a repetition loop**: enables `while` loops iterations while a condition remains satisfied. Alternatively, it is possible to precise how many `times` a series of actions should be invoked.

Listing 2 describes the main elements of a scenario declaration using the BNF notation.

```
<scenario> ::= scenario <scenario_name> <action_list>

<action_list> ::= { <action> + }
<action> ::= <op_invocation> ; | <alternative> | <repeat>

<op_invocation> ::= [<device>] <service_name>.
  <operation_name>([<parameter_list>])
<parameter_list> ::= (<op_invocation>|<parameter_value>)
                  (, (<op_invocation>|<parameter_value>))*

<alternative> ::= if <cplx_cond><action_list> [<else_clause>]
<else_clause> ::= (else <action_list> )*
<cplx_cond> ::= (<condition> (<log_operator><condition>)*)
<condition> ::= <op_invocation> <comp_operator>
                (<op_invocation> | <compare_to_value>)
<repeat> ::= (while <cplx_cond> | <repeat_value> times)
             <action_list>

<log_operator> ::= and|or|not
<comp_operator> ::= < | <= | > | >= | ==
```

Listing 2. Grammar of the scenario declaration using the BNF notation

b) The graphical user interface: This ADL syntax is simple and declarative as we can see in the example on the right of Figure 3. Nevertheless, SaS proposes a more user-friendly option to create scenarios through a graphical representation of the ADL. Users therefore do not manipulate the ADL anymore but compose service operations with basic instructions (based on the *operators* of our ADL): `if`, `else`, `while`, `times`, `and`, `or`, `not`, $<$, $>$, $\leq$, $\geq$, $==$. For parameters entries, users can select an operation result or choose fixed values and apply an arithmetic operation (such as $+$, $-$, $*$, $/$).

Once the scenario is defined, users can choose to export it into the environment. They also have to specify if the scenario can be redeployed into another SaS platform. Thanks to a transformation process, the scenario is then automatically transcribed into our ADL. Figure 3 (right) shows the scenario transcription with a simplified version of the GUI (left).

3) Composite service creation: After the scenario is created, SaS analyzes its description file to create a composite that manages

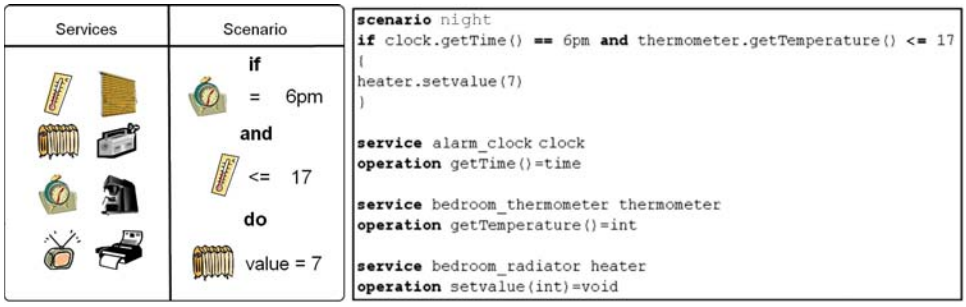

Figure 3. Scenario Transcription: from our ADL

its deployment. This composite includes references to the services chosen in the scenario and a *Scenario Manager*. The manager has two roles: manage the different services and export the scenario as a new service in the system according to users preferences.

Depending on user choices, services instantiated inside the composite are specific to a device or come from any of its available providers[1]. In this last case, if the service provider disappears, SaS dynamically recomposes the composite that implements the scenario to integrate another implementation of the same service (if available). Figure 4 illustrates composite services with an example. The scenario is simple and placed in a home automation environment: at 6pm, close the main door and set the thermostat at 7. There are three services: only one is defined from a specific device (the main door). Others are instantiated from any devices that provide these services.

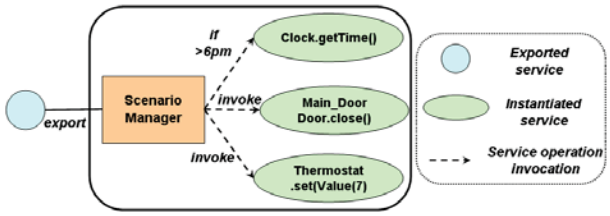

Figure 4. A Composite Service

IV. Scenario execution control and sharing

Once scenarios are created, they can be shared among users. In addition, scenarios are easily manageable and should stay available into the environment in case of service or device unavailability.

A. Scenario sharing

As seen in subsection III-B3 the Scenario Manager registers the scenario as a new service. The scenario can then be used as a service and, as such, composed into a new coarser grained scenario (scenario hierarchical composition). This service has four operations: `start`, `stop`, `getScenarioState` and `getDescriptor`. It does not describe the functioning of the scenario: it hides services and their interactions inside the composite. This guarantees encapsulation. Reflexion is nonetheless provided (composites are not black boxes but gray boxes) thanks to a service operation: `getDescriptor`. This operation provides access to the scenario descriptor file. Users can directly read this file or obtain a visual transcription of the scenario on his GUI.

Figure 5 illustrates scenario sharing. The user of the SaS platform named A creates and exports a scenario. This scenario is registered as a new service. It is then discovered by platforms B and C. The user of platform B recomposes this scenario into a new one, whereas the user of platform C just gets an overview of the scenario on its GUI.

[1]An optimized selection scheme is a perspective.

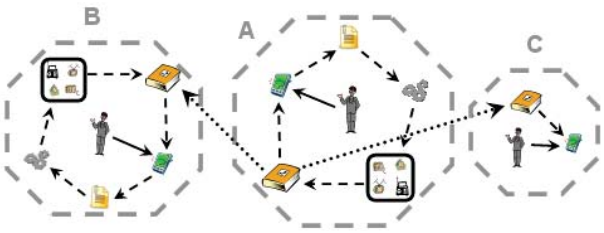

Figure 5. Overview of SaS scenario sharing

B. Scenario execution control

We define scenarios as service compositions. We can see a scenario as an active entity, which evolves, changes from one state to another. Moreover, the execution contains several steps which can fail or succeed. For example, users that discover a scenario might want to know if this scenario is currently in execution. If so, it is important to check which steps have been executed, which succeeded and what are the next steps. This is why, SaS manages scenarios' life-cycles and enables to check scenario execution status.

1) Scenario life-cycle: Scenarios are dynamic. They can be executed, stopped, have a missing service... The state diagram of Figure 6 illustrates the different states of scenario life-cycle which are:

- **Installed,** the scenario has been deployed and registered (and so discovered) as a new service. SaS automatically checks if the different involved services are present.
- **Ready to launch,** all involved services are available. If a service disappears, the scenario goes to the previous state.
- **Running,** the scenario has been launched and is currently executed. The scenario could finish and come back to the previous state or be interrupted.
- **Stopped,** the scenario has been stopped by a user or a service inside the scenario disappeared. The scenario is paused waiting to be restarted or to be executable again by the appearance of an appropriate service.

Figure 6. State diagram of scenario life-cycle

2) Scenario running state advancement: Users must know which scenario operations are running and which have already been executed. This is why, SaS registers scenario execution progress. To do so, SaS considers the *Running* state of the scenario life-cycle as

a succession of stages: the operation invocations. These stages are evaluated depending on their types:

- **Functions**, if an operation is invoked to obtain a result, SaS logs this operation as done when we obtain the result. If an error occurs, SaS continues to execute the scenario if possible (*i.e.* if the operation result is not needed) and displays a warning to the user.
- **Procedures**, if the operation does not return a result, SaS logs it as *executed* when the operation is invoked.

In addition, SaS logs the execution times of the different scenario steps. Users can see when the scenario began and how long every operation took. So, SaS enables users to check the current scenario position and control its correct advancement. Users can get these informations thanks to the `getScenarioState` operation.

C. Scenario availability

With scenario export as new services, users can have access to the same scenario on several devices, however, they might want access to it even if the original provider is off. This is why, scenario access should be maintained if the original provider disappears.

To do so, SaS enables scenario redeployment on other platforms. This is possible because SaS differentiates scenarios from available services. When a scenario appears, every SaS platform downloads the scenario description. Thus, users can directly have an overview of the scenario definition and platforms can redeploy the scenario if the original scenario provider disappears.

V. System Design and Implementation

This section describes the design and implementation of the SaS prototype. It is an ongoing work implemented in Java over OSGi [16], [26] with iPOJO [27]. OSGi is a popular SOC framework that is widely adopted by industry for developers to create *bundles* (Java components). iPOJO is based on OSGi and follows the Service-Oriented Component Model [28]. The main idea is that a component should only contain business logic as in EJB 3.0 [29] (*EJB entities*); SOC mechanisms should seamlessly be handled by the component container as container-managed cross-cutting services.

A. Model

As shown in Figure 7, four components compose SaS. Each of them is packaged as an OSGi bundle because it is safer and easier to update.

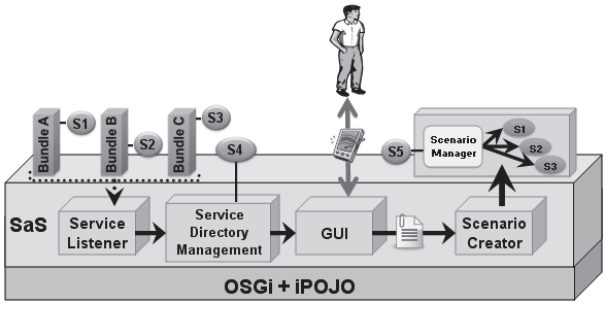

Figure 7. The SaS prototype implemented over OSGi and iPOJO

- **Service Listener**. This bundle obtains, orders and dynamically updates the list of available services from the OSGi context.
- **Service Directory Management (SDM)**. It is the intermediate between the *Service Listener* and the GUI responsible of managing (adding, removing) services and scenarios in the *Service Directory*.
- **GUI**. The GUI is platform and operating system specific (PDA, mobile phone, Android, iOS,...). It provides a graphical representation of our ADL which provides users with the capability to see the available services and compose them.
- **Scenario Creator**. It creates scenario bundles which are composed of the selected services and a scenario manager. This latter manages services inside the composite and exports the scenario as a service.

B. Insights into the SaS prototype

This subsection presents the implementation of the main functionalities of the SaS system.

The latest version (4.2) of OSGI now supports distribution (RFC 119 [26]). So, for service discovery, SaS uses the API of distributed OSGi which can be implemented by many discovery protocols. Then, the *Service Listener* retrieves the list of available services from the directory provided by the OSGi framework and sends it to the *SDM*. This latter orders and classifies the service list. The GUI[2] displays available devices, services and operations. It filters the displayed services (*resp.* operations) if a specific device (*resp.* service) is selected. A user creates a scenario through the GUI which stores it in an XML-based description file. This description becomes easily transmissible and promptly interpretable and analyzable since XML is a standard as an exchange format. Using this description, the *Scenario Creator* of SaS automatically (i) generates a scenario manager which (ii) exports and manages the scenario. Finally, the scenario (iii) is redeployed on other SaS platforms according to user preferences. The remainder of this section describes more deeply this three important steps.

1) Scenario Manager generation: Starting from the XML-based description of a scenario, SaS generates a Java class that represents the manager of this scenario (*Scenario Manager*). To do so, the first step consists to parse the XML description file using a *SAX* parser [30]. SAX translates XML elements into a sequence of Java instructions. Then, SaS generates a *Scenario Manager* class with the Javassist [31] library that enables dynamic byte code edition such as creating classes or modifying existing classes. The *Scenario Manager* is generated as a class that implements the *ScenarioManagerInterface* interface. This interface declares four public methods including a `start` method which is automatically filled in the *Scenario Manager* class with the Java instructions resulting from the SAX parsing.

2) Scenario export and execution control: SaS uses the iPOJO API [32] to dynamically create an OSGi composite bundle that packs together the generated *Scenario Manager* and the involved services. This composite bundle is then installed and started into the OSGi platform. Finally, the *Scenario Manager* registers a new service inside the OSGi directory, specifying its capability to execute four public methods (`start, stop, getScenarioState` and `getDescriptor`).

For scenario execution control, the *Scenario Manager* creates a log file every time the `start` service operation is invoked with the invoker platform *id* and the current time. Then, the *Scenario Manager* logs in this file every service invocation success (or failure) with time. With this log file, SaS knows at every moment if the scenario is currently in execution, when it began, who launched it and which steps are already executed. These informations are available through the service operation `getScenarioState`.

3) Scenario automatic deployment: As seen in V-B1, all scenarios implement the same Java interface (*ScenarioManagerInterface*). So, SaS can easily recognize them. Thus, when a scenario is discovered as a new service, the *Service Directory Management* automatically gets the scenario description file thanks to the `getDescriptor` operation provided by the service. The scenario is not deployed again but SaS keeps the XML description file. *SDM* sends the scenario description to the GUI. If the original provider disappears, another SaS platform may redeploy the scenario if its directory contains all the involved services.

[2]which is still under development.

VI. Evaluation and Conclusion

With the SaS system, we propose a newly user-centric system that meets the expectations of ubiquitous environments. First, we provide *scenario creation* by service composition. Users can create *complex scenarios* that correspond to their needs thanks to an appropriate ADL. This ADL is simple, user-oriented and proposes an alternative graphical view to be *accessible for everyone*. SaS exports scenarios as new services into its environment, thus, users can easily *share* their scenarios. Moreover, SaS manages *scenario life-cycle*: it enables users to start and stop scenarios, check scenarios status and scenario execution advancement. Moreover, users can get an overview of a scenario specification (scenario introspection capability) thanks to a descriptor file and *reuse a scenario* as a service being part of a new encapsulating scenario composition (scenario hierarchical composition). SaS also tries to *maintain scenario availability*. Locally, if a service involved into a scenario disappears, SaS tries to replace it into the composite. Globally, when a SaS platform disappears, scenarios exported by this platform are redeployed on other ones to remain available. In conclusion, the SaS system presented in this paper satisfies all the requirements defined is section II-B. A prototype of SaS in Java over OSGi and iPOJO is currently under development.

We have three major perspectives. First, we want to evaluate SaS to show its simplicity for non technical end-users by comparing it with existing tools such as Yahoo Pipes [33], Automator [34] and Scratch [35]. Such tools provide non-technical end-users of the capability to graphically develop small applications by composing elements. Then, we plan to define some recovery strategies to anticipate service loss such as *caching* and *hoarding*. Finally, we want to improve scenario distribution and propagate scenarios into the network.

***Abstract*—As embedded systems become more widespread in industry it is important to investigate new ways of maintaining these systems that are less time consuming and conform to the industry standards for quality assurance. One of the key software components in many embedded systems is the controller logic whose responsibility is the coordination of sensors, actuators, user interfaces and machine interfaces. Making changes to the controller logic without having to recompile the entire system can offer major benefits to the development process.**

This paper introduces a lightweight scripting language for embedded systems, SC-xScript, and the environment that supports the compilation and interpretation of Sc-xScript programs. Using Sc-xScript, application engineers can rapidly and safely test changes to the control logic, customize a product for different customers or applications, and add extra functionality to applications, all without requiring a new release of the underlying embedded software product. The strength of SC-xScript is its small size, simplicity and portability making it suitable for embedded systems. SC-xScript combines procedural constructs with matrix driven data structures.

I. Introduction

An important aspect of developing and maintaining control systems for advanced processing equipment is making changes to the controller logic, to allow for enhancing the controller performance and adapting to changes in the system design or functional specifications. The controller logic is often part of a larger embedded software application that is responsible for integrating sensors, actuators, user interfaces and machine interfaces, and implementing the required functionality. Making changes to these embedded applications is often time consuming due to the quality assurance procedures commonly used in industry. Those procedures frequently involve several people at multiple departments, such as application engineering and software engineering, and require rigorous inspection and testing. By incorporating scripting into the embedded control logic application with a carefully restricted scope and strong error checking, application engineers can rapidly and safely test changes to the control logic, customize a product for different customers or applications, and add extra functionality to applications, all without requiring a new release of the underlying embedded software product.

For these and other reasons, embedded scripting is gaining popularity in the design of software systems and applications. In the programming paradigm of embedded scripting, an interpreter is embedded into a binary application program. The application can execute script code through the embedded interpreter. Many interpreters are available for embedded scripting: Tcl/Tk [1], Python [2], Ch [3], and Lua [4], among others. However, none of the available solutions satisfy the requirements of the different embedded platforms one encounters in the field. In many cases it is not allowed to make system calls in task code, and the code must meet real-time execution requirements, and has limited memory available.

The above restrictions have led to the development of SC-xScript, a lightweight embedded script language for embedded systems that combines a simple procedural syntax with matrix driven data structures. SC-xScript is statically typed, uses parametric polymorphism for functions, and the implementation runs by interpreting bytecode generated by its compiler. It has automatic memory management of a single contiguous heap where bytecode, data and temporary variables are stored. SC-xScript can process matrix expressions, and it currently only supports two dimensional matrices. SC-xScript is small and simple, suitable for embedded systems. For porting purposes, it is implemented in ANSI C, and does not use system calls such as `malloc()` and `printf()`.

SC-xScript has the following properties:

1) Declares local variables explicitly with their size and type while input and output arguments of functions are only named to provide parametric polymorphism. Meanwhile a static type system is maintained by checking each input argument and output argument of functions against each function invocation for type safety.
2) Provides a scripting language supporting linear algebra operations. Inconsistencies or constructs that are hard to parse are avoided.
3) Uses pass-by-reference or pass-by-value only and does not support pointer types.
4) Script compilation happens at initialization.
5) Allows compile-time verification of suitable matrix dimensions for each operation, including the operations related to input and output arguments of functions against each function invocation.
6) Allows compile-time verification of the required heap size; recursive functions are not allowed.
7) Allows the running of multiple scripts in one program.

Scripts are compiled at embedded system initialization and then executed at each interval (the scripts typically run periodically at a fixed interval). Before each execution call the input variables are set from the calling program and after the call the output variables are read by the calling program. The input and output variables are agreed upon for each embedded application, and often include sensor readings, parameters, flags, reference signals, and actuator commands.

The rest of the paper is organized as follows. In Section II, we discuss the syntax of the language SC-xScript. In Section III, we present the overall design of our implementation. In Section IV, we present our static type system including parametric polymorphism. In Section V, we discuss the related works. In Section VI, we conclude the paper.

II. Syntax of the Script Language

Script languages are distinct from the core code of the application, which is usually written in a different language. Script languages are interpreted from source code, while the applications they control are traditionally compiled to native machine code. SC-xScript, as introduced in this paper, is a simple script language inspired by the Matlab [5] and GNU Octave [6] languages with influences from C, which can be easily embedded into C/C++ applications with the help of an interpreter for the script language.

The complete grammar of SC-xScript is presented in the Appendix. The language consists of three parts: variable declaration, function definition and statements, in which the function definition part is optional (Line 1 of the Appendix). The first part of the language is used to declare variables, in which each variable is a matrix whose elements are of type integer or double (Lines 2-10 of the Appendix). The second part of the language is optional, and is used for function definitions. As Lines 12-15 of the Appendix show, both input arguments and output arguments are only a variable name (identifier) without any type information. It offers the flexibility of writing a single function that handles different types of arguments. The third part of the language contains the statements, in which each statement could be an `assignment` statement, `if` statement, `iterative` statement or `jump` statement. For `assignment` statements (Lines 20-22 of the Appendix), it could be either assigning the value of an arithmetic expression to a variable or an element of a variable, or assigning the return value of a function call to return variables. The `if` statement, `jump` statement and `iterative` statements (including `while` loop and `for` loop) are similar to the C language (Lines 23-29 of the Appendix).

III. Overall System Design

Figure III shows the subsystems and the relationships between the subsystems. The `ScriptAPI` contains the functions that invoke the `Compiler` and the `Interpreter` subsystems. The `Compiler` and `Interpreter` use the `HeapManager` during the compilation and interpretation of the script to manage the allocated heap. The heap is a chunk of memory allocated to the SC-xScript Runtime

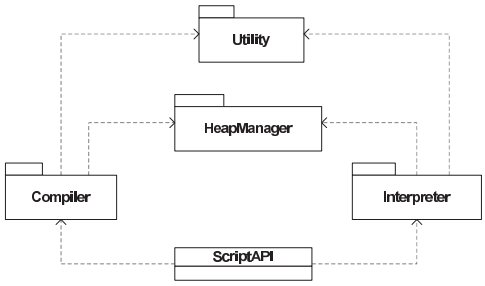

Figure 1. The Architecture of Implementation

System when it is invoked. The `HeapManager` maintains the heap and provides the functions required to allocate memory within the heap for the objects in the `Compiler` and the `Interpreter`. The `Interpreter` does not contain any subsystems and its main purpose is to execute the bytecodes generated by the `Compiler`. The `Utility` contains several components used by the `Compiler` and the `Interpreter`.

A. Heap Management

This section explains how we organize the heap. The heap manager maintains the heap and provides the functions required to allocate memory for the objects in the Compiler and the Interpreter. The structure of the heap is shown in Table I. The first row of the table shows the size in bytes for those sections that are restricted in size. The second row shows the names assigned to the different sections on the heap.

There are several registers reserved in the beginning of heap as below.

1) PC, the program counter for the next bytecode to execute;
2) SP, the logical address of the beginning of Stack section;
3) DP, the logical address of the beginning of Data section;
4) ST, the logical address of the beginning of Symbol Table section;
5) RS, the result code;
6) MR, the message reference.

The starting offset in the heap for Instructions is placed at the end of registers. For the Data, Symbol Table Data, Stack and Temp sections, the starting offset in the heap is predefined as a ratio. All addresses used by the Instruction and Data sections are logical addresses, not physical addresses, which makes it easy to move sections in case one section is full while there is still space in other sections.

B. Bytecode Design

The compiler uses no intermediate representation; it emits bytecodes for the interpreter "on the fly" as it parses a script. The bytecodes are not using the traditional stack based implementation. Traditional stack based implementations for bytecodes usually have most values stored on the stack, while only a limited number of registers are used for instruction execution, and the instructions usually are referring to their operands implicitly. In SC-xScript most bytecodes use a three-address format, as depicted in Figure 2, and refer to their

Table I
LAYOUT OF HEAP (B REPRESENTS BYTES.)

PC	SP	DP	ST	RS	MR	Instructions	Data	Symbol Table	Stack	Temp

Figure 2. Bytecode format

operands explicitly. In this way, excessive copying of values is avoided during pushing and popping to/from the stack, which is expensive for matrix manipulation, and reduces the total number of generated bytecodes. SC-xScript also uses part of the stack to store activation records of functions. Ierusalimschy et al. [4] use a similar mechanism called register based virtual machine, and state that the overhead brought by code size and decoding for register based virtual machine is ameliorated by several factors.

As for code size overhead, the bytecodes in a register based virtual machine have to specify their operands, three operands in our case, so it typically results in larger bytecodes than a stack based virtual machine. However, register based virtual machines usually generate less bytecodes than the stack based virtual machine, so there is not much difference in the total size. As for the decoding overhead, register based virtual machines have to decode their operands from the bytecodes, while stack based virtual machines typically use bytecodes with implicit operands. However, stack based virtual machines also spend some time manipulating implicit operands, and bytecodes in stack based virtual machines frequently need multi-byte operands, which make it impossible to fetch the operand at once because of the alignment. Davis et al. [7] argue in defense of register-based virtual machines and provide hard data on the improvement of Java bytecode. Winterbottom and Pike [8] also defend register based virtual machines based on their suitability for on-the-fly compilation.

IV. TYPE SYSTEM

SC-xScript has only two types: `INTEGER` matrix and `DOUBLE` matrix, and maintains a static type system. Each variable is declared explicitly with its size and type, except input and output parameters of functions. The input and output parameters of functions are only named without specifying their size and type, thus making SC-xScript more expressive. In other words, the functions and their input and output parameters are generic to handle values identically without depending on their type, providing abstraction within the script. In each statement of a function, the input and output parameters are checked for type safety against each function invocation, thus maintaining full static type safety. Therefore, SC-xScript has a static type system, and uses parametric polymorphism for functions. The script in SC-xScript is to be used as a whole by external programs, and functions cannot be accessed by external programs.

A. Storage of Type Information

For SC-xScript, types are attached to values rather than to variables. Each value stored in either the Data or Temp section has a 32-bit header to store the type information. The dimension of each matrix is specified in the script. A single integer is represented in an `INTEGER` matrix with one row and one column, and a single double is represented in a `DOUBLE` matrix with one row and one column. By using a matrix to represent each data item, all data operations become matrix operations. This greatly simplifies the data manipulation making SC-xScript small and fast. Besides `INTEGER` matrix and `DOUBLE` matrix as user defined types, SC-xScript has one internal type: `REF`, which is not to be declared by the script, it is for internal usage only. Each parameter of a function in SC-xScript, including input parameters and return values, is only represented by an `ID` without specifying the type information. Therefore, the type of parameters could be different in each function invocation, depending on the data passed by the function invocation. `REF` is introduced as a reference to a matrix to allow function supporting matrix with different dimensions as input or output.

Representation of values in the heap is shown in Table II. The first row shows the number of bits allocated to each field. The second, third, and fourth rows contain the type information for the data in the matrix. Our implementation of SC-xScript uses 3 bits to indicate whether the matrix is a `INTEGER` matrix, `DOUBLE` matrix or a `REF/NREF` matrix. In the future, we can also use these 3 bits to indicate `INTEGER` scalar and `DOUBLE` scalar to improve performance. One bit is reserved for type checking purpose to indicate whether there is data following the header, because the matrix header is required during type checking to store the numbers of rows and columns, but additional space is not necessary to be allocated for the matrix values. Our implementation of SC-xScript uses 14 bits to store the number of rows, supporting up to 16383 rows. It also uses 14 bits to store the number of columns, supporting up to 16383 columns. Because the matrix values are stored right after the matrix header, it is not necessary to use any bits to store the offset of matrix values. For the `REF` matrix, we use 28 bits to store the address of the destination matrix, which is the offset in the data section of the heap. Hence our implementation of SC-xScript supports a data section of up to 256MB, which should be sufficient for the intended applications.

To define the structure shown in Table II in a compact manner in ANSI-C, if using a tagged union as shown in Program 1, proper memory alignment will result in each matrix header needing 64 bits instead of 32 bits, which consumes unnecessary space on the heap.

To store the matrix header as compactly as possible, SC-

Table II
LAYOUT OF SC_MATRIX IN THE HEAP.

3bits	1bit	14bits	14bits	0bit
INT	tc	Number of Rows	Number of Columns	Data Offset
DOUBLE	tc	Number of Rows	Number of Columns	Data Offset
REF	tc	Offset of target SC_Matrix		
NREF	tc	Offset of target SC_Matrix		

Program 1 Data Structure of Matrix using tagged union

```
1  typedef struct
2  {
3    unsigned rows:14;
4    unsigned cols:14;
5  }Data;
6  typedef struct {
7    unsigned type: 3;
8    unsigned tc: 1;
9    union{
10     Data d;
11     unsigned ref;
12   } u:28;
13 }SC_Matrix;
```

xScript uses 14 bits for `rows` and 14 bits for `cols` to represent each matrix header while introducing two functions to read or write the offset of reference in those two 14-bits. `MatrixRefRead` reads the offset of reference based on calculation from `rows` and `cols`, and `MatrixRefWrite` writes the offset of reference back to `rows` and `cols`.

B. Type checking for Functions

The statements in functions demand a special strategy for type checking, because each function can be called multiple times with different types of variables. Each statement in a function should be checked against each function invocation, because the parameters of a function are just variable IDs without any type information specified; the type information is specified at each function invocation. For example, suppose there is one function defined as `function a=mult(b, c)`, followed by two invocations of the function, as shown in Program 2, are legal because the statement `a=b*c` is legal for each function invocation.

The script shown in Program 3 is illegal, because in the second function invocation `A2=mult(B2,C2)`, the statement

Program 2 Legal script for multiple times of calling a function

```
1  int A1[2,3], B1[2,4],C1[4,3];
2  int A2[8,9], B2[8,15],C2[15,9];
3  function a = mult(b, c)
4  {
5    a=b*c;
6  }
7  A1=mult(B1,C1);
8  A2=mult(B2,C2);
```

Program 3 Illegal script with multiple function calls

```
1
2  int A1[2,3], B1[2,4],C1[4,3];
3  int A2[8,9], B2[8,15],C2[15,20];
4  function a = mult(b, c)
5  {
6    a=b*c;
7  }
8  A1=mult(B1,C1);
9  A2=mult(B2,C2);
```

in function `a=b*c` is illegal, as `a` is a matrix with 8 rows and 9 columns, while `b*c` returns a matrix with 8 rows and 20 columns.

SC-xScript does not check the function definition itself, since there is no type information attached to the parameters. Instead, it checks each function invocation. For each function invocation, the parameters have a known and fixed type, which is stored with the parameters. Taking Program 3 as an example, `each of a`, `b` and `c` is a `REF`, so when the type checking algorithm arrives at the statement `A2=mult(B2,C2)`, it points `a` to `A2`, `b` to `B2` and `c` to `C2`. Section IV-A explains how a `REF` variable points to another variable.

C. Code Generation for Functions

It seems straightforward to generate bytecodes for a function call: just jump to the beginning of the desired function. However, it is required to take the function return into consideration. In SC-xScript, there is no recursion, but it allows a function to be called multiple times, and it allows a function to call another function. Therefore, it is required to know where to return for each function invocation. For example, a function `f1` calls a function `f2`, the function `f2` calls a function `f3`, so when the function `f3` is about to return, there should be a place to store the return address of functions `f1`, `f2` and `f3`. SC-xScript implements this by introducing a small stack section in the heap to store the return addresses.

When calling a function, the generated bytecodes push a return address onto the stack, and then jump to the beginning of the desired function. When returning from a function, the generated bytecode pops an item from the stack as the return address, and jumps to the return address.

In the bytecodes for function definition, both input and output parameters are represented by a variable of type `REF`. At each function invocation it must be determined where the `REF` variable must point to.

To summarize, when calling a function the generated bytecodes must take the following steps.

1) Bind the given address of parameters to each `REF` variable. Taking Program 2 as an example, bind `a` to `A2`, bind `b` to `B2` and bind `c` to `C2`.
2) Push the return address onto the stack.
3) Jump to the beginning of the desired function.
4) Execute the statements in the function.
5) Pop one item from the stack as the return address.
6) Jump to the return address.

Table III
BYTECODES GENERATED FOR PROGRAM 2

OpCode	Operand 1	Operand 2	Operand 3	Description
MUL	1464	1456	1460	d=b*c
MOV	1452	1464	0	a=d
RJMP	0	0	0	Function Return
EXE	0	0	0	Mark the beginning of script
REFWR	1452	16	0	REFWR a, A1
REFWR	1456	44	0	REFWR b, B1
REFWR	1460	80	0	REFWR c, C1
FJMP	0	8	0	Call function at 0 with return address 8
REFWR	1452	132	0	REFWR a, A2
REFWR	1456	424	0	REFWR b, B2
REFWR	1460	908	0	REFWR c, C2
FJMP	0	12	0	Call function at 0 with return address 12
END	0	0	0	Mark the end of script

There is additional REF variable required for the temporary variable in function definition. Taking Program 2 as an example, a=b∗c leads to two bytecodes using a temporary d as follows.

$$d = b * c$$
$$a = d$$

Each function definition has only one corresponding copy of bytecodes, and each function invocation jumps to the same beginning address of the function. Therefore, the bytecodes for each function definition cannot include information on how much memory is required for the temporary variable d, since it is unable to determine the size of b∗c until the function invocation. Consequently, the compiler cannot figure out the space requirement of the temporary variables for the function, and must manage the temporary variables dynamically. The management of REF variables is explained in section IV-D.

D. Interpreter Design for Functions

Each function definition has only one corresponding copy of bytecodes, and each statement calling a function jumps to the same beginning address of the function, so the generated function bytecodes have to take care of the different types of parameters. For example, in Program 2, a=b∗c leads to two bytecodes using a temporary d as follows.

$$d = b * c$$
$$a = d$$

As mentioned before, each parameter does not have a fixed type, and depends on the specific function invocation. SC-xScript uses the REF type for the temporary variables as well as the parameters. However, the strategy to handle with REF type for the temporary variables is different than the one to handle the REF type for the parameters. Regarding the REF type for the parameters, the statement calling function can simply bind it to a logical address, so for the statements in the function definition the interpreter only needs to resolve REF variables to get the real values. However, in case of the REF type for the temporary variables, the interpreter needs to determine the size of the temporary variable dynamically and allocate the memory in the TEMP section of the heap. In the above example, b and c are INT or DOUBLE variables or REF variables, which could be resolved to INT or DOUBLE variables. Therefore, the size of d can be determined during the interpretation of the bytecodes, and the interpreter can allocate memory in the TEMP section of the heap for d, and bind d to the logical address of newly allocated memory.

Table IV
DATA SECTION FOR PROGRAM 2 - PHASE 0

Variable	Address	Type	Address of Destination Matrix
a	1452	REF	0
b	1456	REF	0
c	1460	REF	0
d	1464	REF	0

Since there are two different strategies to deal with the REF variables, SC-xScript has to figure out which strategy to take for a REF variable. Table III gives the example bytecodes for Program 2, Table IV gives the data layout of function variables in data section when the interpreter starts executing bytecodes, and Table V gives the data layout of function variables when the interpreter enters the first function call. When the interpreter executes the bytecode in function definition MUL 1464 1456 1460, it can resolve 1456 and 1460 to a destination matrix, while it cannot resolve 1464 since 1464 is pointing to 0, which actually means it is waiting for memory to be allocated. So for operand 1, which is 1464, the interpreter first needs to allocate memory in the TEMP section of the heap, according to the operation code and the size of matrices referred by operand 2 and operand 3. For example, the matrices referred by operand 2 and operand 3 are of size [2,4] and [4,3] accordingly, then the interpreter needs to allocate memory for operand 1, which is a REF type, with a matrix of size [2,3], because it is a matrix multiplication.

Table VI gives the data layout of function variables after the execution of the first function call, in which the temporary variable d is referring to the destination matrix at 4 in the TEMP section of the heap. The issue is then: when the interpreter executes the second function call, for the bytecode MUL 1464 1456 1460, the first operand 1464 is referring

Table V
DATA SECTION FOR PROGRAM 2 - PHASE 1

Variable	Address	Type	Address of Destination Matrix
a	1452	REF	16
b	1456	REF	44
c	1460	REF	80
d	1464	REF	0

Table VI
DATA SECTION FOR PROGRAM 2 - PHASE 2

Variable	Address	Type	Address of Destination Matrix
a	1452	REF	16
b	1456	REF	44
c	1460	REF	80
d	1464	REF	4

to 4, which is a matrix with size [2,3]. However, for this function call, it requires a matrix with size [8,9]. Then how the interpreter could be able to distinguish these specific `REF` variables from other `REF` variables for memory allocation? To resolve this, SC-xScript introduces an additional type, `NREF`, to provide temporary variables generated by the compiler for functions. This way, when the bytecode is going to write to a temporary variable marked as `NREF` type, it can always allocate memory for that.

V. RELATED WORK

A number of languages have been designed for replacing application-specific scripting languages by being embeddable in application programs. The application programmer (working in C or another system language) includes "hooks" where the scripting language can control the application. These languages serve the same purpose as application-specific extension languages but with the advantage of allowing some transfer of skills from application to application. JavaScript began as, and primarily still is, a language for scripting inside web browsers; however, the standardization of the language as ECMAScript has made it popular as a general purpose embeddable language. In particular, the Mozilla implementation SpiderMonkey is embedded in several environments such as the Yahoo! Widget Engine. Other applications embedding ECMAScript implementations include the Adobe products Adobe Flash (ActionScript) and Adobe Acrobat (for scripting PDF files).

Lua [9] is a lightweight, reflective, imperative and functional programming language, designed as an embedded scripting language. It is not interpreted directly from the textual Lua file, but is compiled into bytecode, which is then run on the Lua virtual machine. The difference of our work with Lua is that, in our work SC-xScript, everything is a matrix, that makes it easy for matrix operations. In Lua, Tables are the most important data structure. Our work offers a way for embedded system to easily use scripts for scientific computation.

Regarding scientific computation, two categories of general scientific software can be identified as 1) computer algebra systems that perform extensively symbolic mathematical evaluations such as Maple [10] and Mathematica [11] and 2) matrix computation systems that are designed for numerical computations and are well suited for engineering applications such as the Matlab [5] that dominates at the commercial market and the open source "clones" Scilab [12] and Octave [6]. Chonacky and Winch [13] offers an excellent comparative review of three well-established commercial products. The open source jLab [14] environment extends the potential of Java for scientific computing. It provides a Matlab/Scilab like scripting language that is executed by an interpreter implemented in the Java language. The scripting language supports the basic programming constructs with Matlab like matrix manipulation operators.

The control engineering design and analysis problems have grown increasingly complex with both technological breakthroughs and theoretical advances over the last few decades. A number of software packages have been developed to bridge the gap between modern control theory and the software/hardware implementation. The existing well-known interpretive software packages, such as MATLAB Control System Toolbox [15], MATRIXx [16], and Mathematica's Control System Professional [17] are commercially available for the purpose of computer-aided control system design, that offer scientific computation toolboxs to solve the complex design and analysis problems in the host, while our work is to deploy the scientific computation capability in the target embedded devices.

VI. CONCLUSIONS

In this paper we present SC-xScript, a lightweight script language for embedded systems, which combines simple procedure construct syntax with matrix driven data structures. It is statically typed, and the implementation runs by interpreting bytecodes generated by its compiler, has automatic memory management of a single contiguous heap where bytecode, data and temporary variables are stored. Its strength is in processing matrix expressions, and matrix is the only data structuring mechanism. It is small and simple, suitable for embedded systems. It is implemented in about 40,000 lines of code.

We attach the type information into the values instead of variables, so that when executing the generated bytecodes the interpreter does not have to do symbol table lookups to check the type information for operands, which saves time for each bytecode execution. As the matrix is the only data structuring mechanism and SC-xScript is statically typed, attaching the type information into the values by adding a matrix header make it simple to view the data section of the heap for debugging purpose.

We introduce a `REF` type to allow function definition to support different parameters, which is important for some functions as they may have to handle with all kinds of matrix size. Otherwise, the script user would need to identify the matrix size for each parameter to make the type fixed, and design functions with the same functionality for different size of a matrix.

We carefully designed the heap management to support both compiling and execution based on the same fixed heap, managing the space for bytecodes, data, stack and temporary

data. As the heap size is fixed, it may be possible that there is not enough space for the data section while there is still space left in the temporary section. SC-xScript solves this by supporting the movement of memory sections, which is simplified by using logical addresses.

By supporting matrix data and matrix expressions, while keeping small and simple, SC-xScript is suitable for embedded systems that require an embedded scripting language for scientific computation.

SC-xScript is portable to be embedded into any C/C++ programs, as it is implemented in ANSI C.

Further work may include optimizing the generated byte-codes to save space in the heap and improve the execution efficiency.

Context-aware Services for Multiple-Users

Abstract

This paper presents a framework for providing context-aware services in public spaces, e.g., museums. The framework is unique among other existing context-aware systems in implementing services as mobile agents and supporting groups of users in addition to single users. It maintains a location model as containment relationships between digital representations, called virtual counterparts, corresponding to people, terminals, or spaces, according to their locations in the real world. When a visitor moves between exhibits in a museum, it dynamically deploys his/her service provider agents at the computers close to the exhibits via virtual counterparts. When two visitors stand in front of an exhibit, service-provider agents are mutually executed or configured according to the member of the visitors. To demonstrate the utility and effectiveness of the system, we constructed location/user-aware visitor-guide services and experimented with them for two weeks in a public museum.

1 Introduction

Many of the early applications of pervasive computing have focused on interaction between individual users and their environments [1, 2]. They have paid little attention to environments that might effectively sense and respond to groups of co-located people. However, much of our time is spent in shared physical spaces, e.g., offices, factories, schools, and public spaces, so it is important to consider how an environment might effectively sense and respond to groups of co-located people as well as individual people.

When there are multiple users in a space, context-aware services should be customized to according to the combination of people in current places in addition to the people themselves. For example, when a married couple stands in front of digital signage, advertising content displayed on the signage should be specific to neither mens' nor women' items. When a visitor stands in front of an exhibit in a museum, where another visitor is already standing, annotation services provided from a terminal close to the exhibit may be provided to the existing visitor, and then the new visitor sequentially, or customized to the two visitors.

This paper presents a framework for providing context-aware services to not only individual people but also groups of co-located people in specified spaces. Since such services tend to depend on the co-location of people, the framework maintains a location model for the real world.

2 Background

This section describes basic ideas behind the framework presented in this paper.

2.1 Example Scenario

Suppose a context-aware visitor-guide system is in a museum. Most visitors to museums lack sufficient knowledge about exhibits in the museum and they need supplementalary annotations on these. However, as their knowledge and experiences are varied, they may become puzzled (or bored) if the annotations provided to them are beyond (or beneath) their knowledge or interest. User-aware annotation services about exhibits are required. For example, when a user stands in front of an exhibit, an annotation service about the exhibit is provided in his/her personal form on a stationary terminal close to the exhibit. However, there are multiple users in a public space. Suppose a visitor arrives in front of an exhibit, where another visitor is standing and receiving an annotation service from on a terminal there. We have several approaches to solving this. 1) After the annotation service for the existing visitor has finished, an annotation service for the new visitor is provided. 2) The annotation service for the existing visitor is shared by and customized to the existing and new visitors. In fact, we constructed and provided such a context-aware visitor-guide system to several museums [3]. This problem was serious during rush hours at the museums.

2.2 Design Principles

To provide services according to groups of co-located people, we need to model the locations of the people and the terminals that provide the services. This framework maintains a symbolic location model about their locations to select and customize services. It maintains the locations of people, physical entities, and places in the real world as structural relationship between programmable entities, called *virtual counterpart* objects, corresponding to them.

It uses the spatial co-location of physical entities as a primary attribute for selecting communication partners. Communication partners, including terminals, should also be selected according to their co-locations. Co-locations between people and terminals are modeled as a spatial relationship between the virtual counterparts corresponding to the people and the terminals. The framework allows us to explicitly define the condition that activate and configure services provided to the groups of people in the same space. The condition is defined as a combination of relationships between slots in a counterpart. As seen in 1, each slot has one input port and one or more output ports to receive or issue events. The output ports can be classified into the following types.

- *Arriving* port: when a slot receives a counterpart, it issues an event to another counterpart from the port.
- *Staying* port: when a slot holds a counterpart, it periodically issues events to another counterpart from the port.
- *Left* port: when a slot sends a counterpart, it issues an event to another counterpart from the port.

The framework enables us to define a one-to-one connection from each of the output ports of a slot to be explicitly connected to the input port of another slot contained in the same counterpart. Also, we introduce many-to-one connections, in the sense they have multiple input ports and one output port.

- *And* connections: when it receives events from all its input ports, it issues an event to its output port.
- *Or* connections: when it receives events from at least one of its input ports, it issues an event to its output port.

Context-aware communication between counterparts are defined as a graph notation consisting of connections between ports.

We discuss differences between the framework presented in this paper and our previous frameworks. We earlier constructed a location model for pervasive computing environments [3]. Like the framework presented in this paper,

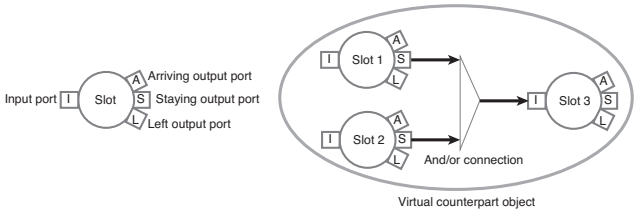

Figure 1. Slot and connection

the model represented spatial relationships between physical entities (and places) as containment relationships between their programmable counterpart objects and deployed counterpart objects at computers according to the positions of their target objects or places. We previously presented a context-aware museum guide system [4]. Our previous model and systems provided no support to location-aware communications and group-aware communications, unlike the framework presented in this paper.

3 Design and Implementation

Our framework consists of four subsystems: 1) context-aware directory servers, called CDSs, 2) virtual counterpart management systems, 3) agent runtime systems, and 4) service provider agents. The first is responsible for reflecting changes in the real world and the location of users when services are deployed at appropriate computers. Our system can consist of multiple CDSs, which are individually connected to other servers in a peer-to-peer manner. Each CDS only maintains up-to-date information on partial contextual information instead of on tags in the whole space. The second manages a structure of virtual counterparts according to up-to-date information on the state of the real world, such as the locations of people, places, and things.

The third is running on stationary computers, which are located at specified spots close to exhibits in a museum and are equipped with user-interface devices, e.g., display screens and loudspeakers. It is responsible for executing and migrating service-provider agents, like existing runtime systems for mobile agents [4]. The fourth is an autonomous entity that defines application-specific services for visitors. It is implemented as one or more mobile agents. Virtual counterparts are used as forwarders in the sense that they migrate mobile agents from one terminal to the next. The framework deploys and executes mobile agents at computers near the positions of the users instead of at remote servers. As a result, mobile agent-based content can directly interact with users, where RPC-based approaches, which other existing approaches are often based on, must have network latency between computers and remote servers. Mobile agents can help to conserve these limited resources, since each agent only needs to be present at the computer while the computer needs the content provided by that agent.

3.1 Location-sensing systems

The framework itself is independent of any location-sensing system. The management system has interfaces for monitoring its underlying location-sensing systems. Tracking systems can be classified into two types: proximity and lateration. The first approach detects the presence of objects within known areas or close to known points, and the second estimates the positions of objects from multiple measurements of the distance between known points. The CDSs support the two types, but they map geometric information measured by the latter sensing systems to specified areas, called *spots*, where the exhibits and the computers that play the annotations are located. This is because most context-aware services in public spaces should be provided within specified spaces rather than at specified geometric points. Each CDS has its own local database to maintain the locations of visitors and their agents. When a CDS detect the presence/absence of people, physical entities, or computers, it tries to discover virtual counterparts corresponding to them by sending other CDSs and runtime systems for virtual counterparts through UDP multicast communications.

3.2 Virtual counterpart management

The framework itself is independent of programming languages, but the current implementation uses Java (J2SE version 1.5 or later versions) as an implementation language to define the framework itself and virtual counterparts.

The framework manages a location model as an acyclic-tree structure of virtual counterparts, where each virtual counterpart can be defined as a self-contained computing entity without any description of a counterpart hierarchy. The management system provides a container for the counterpart corresponding to a virtual counterpart. The container technology developed by Enterprise Java Beans provides interfaces for components and enables them to transparently adapt to runtime services, e.g., it manages transactions. That is, this framework provides each agent corresponding to a counterpart with a wrapper, called a *tree container*. Each container includes its target agent, its attributes, and containment relationships between itself and its parent container and between itself and its child containers. As a result, a hierarchy of containers is maintained in the form of a tree structure, which has the component tree nodes of containers.

3.3 Virtual counterpart

Each virtual counterpart is defined as a mobile agent and a whole or part hierarchy of counterparts is maintained as a acyclic-tree structure of virtual counterparts. The framework provides agent runtime system(s) on computer(s). The system is responsible for managing and exchanging virtual counterparts and controls messages or counterparts with runtime systems running on different computers (if the framework is maintained in one or more computers). The runtime system was designed for this framework, but is similar to other existing Java-based mobile agent systems.

Each agent can have one or more activities implemented using the Java thread library. The system can control all the components in its container hierarchy, under the protection of Java's security manager. Furthermore, the system maintains the life cycle of the agents: initialization, execution, suspension, and termination. When the life cycle state of an agent changes, the system issues certain events to the agent and its descendent agents.

Counterpart migration within a container hierarchy occurs merely as a transformation of the tree structure of the container hierarchy. When one counterpart is moved to another in the same computer, a sub-tree, whose root corresponds to its container and branches, including counterparts, is migrated to the container that maintains the destination. When a counterpart can be deployed in another subtree maintained on another computer, the system marshals the state of the counterpart, e.g., instance variables and the counterpart embedded within its container sub-tree, into a bit-stream and transmits their serialized state program code through TCP sessions by using the underlying mobile agent runtime system.

3.4 Context-aware communication

Each service should be activated through connections between slots for target people or physical entities and the slot that contains it. Each of slots in a virtual counterpart has its attribute and can hold at most one virtual counterpart that can satisfy the attribute. Although the attributed can be explicitly defined, the current implementation supports built-in attributes corresponding to users, unknown visitors, administrators, terminals, and services. Each slot also has more output ports and one input port to receive events. The former ports issue events at certain changes in the structure of counterparts and the latter port forwards receiving events to the counterpart contained in its port's. Each connection are maintained as event queues between its source slots and its destination slots. Connections are defined in LISP-like expressions and then evaluate them by using a LISP-based interpreter.

3.5 Service-provider object

Virtual counterparts corresponding to terminals deploy service-provider objects at the terminals. Each service-provider object is automatically deployed at and maintains per-user preferences on a user and record his/her behavior,

e.g., exhibits that they have looked at. The service-provider object can also define user-personalized services adapted to the user and access location-dependent services provided at its current computer. Each service-provider object is spatially bound to, at most, one user. When a user gets closer to an exhibit, our system detects his/her migration by using location-sensing systems and then instructs the user's counterpart objects to migrate to a computer close to the exhibit. Mobile agent help to conserve limited resources, because each service-provider object only needs to be present at the computer for the duration the computer needs the services provided by that service-provider object. The framework is open to define connections as long as they are subclasses of the classes for built-in connections.

4 Experience

We constructed and carried out an experiment at the Museum of Nature and Human Activities in Hyogo, Japan, using the proposed system. We did the experiment over two weeks. Each day, more than 60 individuals or groups took part. The experimental environment provided several spots in front of exhibits, which were specimens of stuffed animals, e.g., a bear, deer, racoon dog, and wild boar in an exhibition room of the museum. Each spot could provide animation-based annotative content about the animal, e.g., their ethology, footprints, feeding, habitats, and features, close to its location and had a terminal and Spider's active RFID reader with a coverage range that almost corresponded to the space.

The experimental system provides each visitor or group of visitors with colored pendants including RFID tags. The counterpart is spatially attached to a pendant assigned to each visitor. These pendants are colored, e.g., green, orange, or blue. Each spot has three kinds of slots. The first can contain counterparts for visitors, the second can contain counterparts for terminals that can execute services, the third can contain counterparts for museum staffs. These slots have connections as shown in Figure 2.

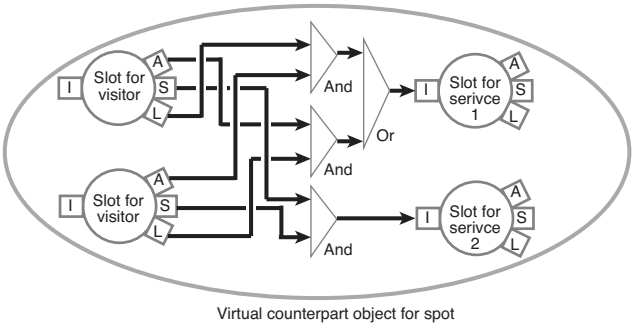

Figure 2. Connections between slots for museum guide.

For example, suppose that a visitor enters a spot with the specimen of a racoon dog and a terminal is located in the spot. His/her virtual counterpart is migrated to the slots for visitors' counterpart and service-provider objects are contained in the slots for terminals. A service-provider object is activated according to the connection for slot for service 1 in Figure 2. When another visitor enters the spot, his virtual counterpart is migrated to the slot for visitors in the counterpart corresponding to the spot. The connection executes a service for newly arriving visitors after executing services for existing visitors. The connection for slot for services in Figure 2 is to block executing services when specified conditions are satisfied even when some visitors have arrived.

5 Conclusion

We designed and implemented a framework for providing context-aware services in public spaces, e.g., museums. It supported groups of users in addition to single users and implemented application-specific services as mobile agents to deploy the services at terminals. It maintained a location model as containment relationships between digital representations, called virtual counterparts, corresponding to people, terminals, or spaces, according to their locations in the real world. When a visitor moved between exhibits in a museum, it dynamically deployed his/her service provider agents at computers close to the exhibits via virtual counterparts. When two visitors stood in front of an exhibit, service-provider agents were mutually executed or configured according to the member of visitors. To demonstrate the utility and effectiveness of the system, we constructed location/user-aware visitor-guide services and experimented with them for two weeks in a public museum.

Abstract—**Enterprise Service Bus (ESB) is responsible for publishing and discovery of services in a global distributed delivery system. Context-aware systems offer entirely new opportunities for application developers and for end users by gathering context data and adapting systems' behavior accordingly. In this paper, we propose a Context Aware ESB (CA-ESB) that will publish and discover services based on location context. The main modules of the framework consist of Context Provider (senses location context), Context Aware Logic Module (decides which regional service to be selected based on location context) and Service Choreographer (choreographs selected services). We propose a graphical model named Context Aware Graph (CA-Graph) that will help us to dynamically choreograph the services. These modules along with other modules of SOA reference architecture will help the ESB to sense the location of users, to select the required services and dynamically choreograph those services. We define a set of metrics based on CA-graph and analyze the performance of CA-ESB. An algorithm is proposed that will dynamically choreograph the selected services based on location context. The results of the case study of an Insurance System are used to illustrate our approach.**

Keywords— Cloud Computing, Context-aware, Enterprise Service Bus, SOA based global delivery model, dynamic service choreography, CA-Graph

I. INTRODUCTION

Distributed Delivery Model[11] is a bi-directional sequence of activities consisting of requirements specification, analysis, design, development, integration, testing, and maintenance. These activities may not always be performed in a linear fashion, as there may be some overlap between and across certain processes. The distributed delivery model has gained immense importance as these days software is developed in a distributed manner with a common core component and various regional components interfacing with it.

Service-orientation requires loose coupling of services with operating systems, and other technologies that underlie applications. SOA separates functions into distinct units known as services, which developers make accessible over a network in order to allow users to combine and reuse them in the production of applications. These services and their corresponding consumers communicate with each other by passing data in a well-defined, shared format, or by coordinating an activity between two or more services.

In the distributed delivery model the services can be divided into core services and regional services. The core services will remain same for all applications and regional services will vary from one application to another application. The regional services interface with the global services to serve the overall business function requirements at each location. In this paper, we propose a Context Aware ESB (CA-ESB) that will publish and discover services based on location context. This type of ESB framework is very relevant for region specific global development scenario. A new graphical model named Context Aware Graph (Ca-Graph) is proposed that models the services/processes and their interconnections for all the locations. Discovery of services becomes much simpler using CA-ESB as the CA-Graph proposed here unveils the service choreography for each location dynamically. Analysis of CA-Graph using a metrics proposed in this paper clearly illustrates the performance of CA-ESB vis-à-vis a traditional ESB.

II. RELATED WORK

Areas related to SOA have become prominent research domains. Here we discuss about some of the relevant research works in the field of Enterprise service bus (ESB).

A dependable ESB framework that enables automated recovery from component failures is proposed in [1]. The authors in [2] propose an ESB framework to enable the content-based intelligent routing path construction and message routing. [3] presents computation-independent models (CIMs) and platform independent models (PIMs) for service oriented architectures.

Existing ESB-based system have difficulties to manage complex

events of real-world applications very well. A complex event-processing model based on the relational algebra is proposed in [4], and then it proposes a complex event processing oriented enterprise service bus. [5] presents Omnipresent, which is a service-oriented architecture for

context-aware applications that may be accessed from either mobile devices or Web browsers, and it is based on Web services page layout.

In [8], a design of a Dynamic Composition Handler on Enterprise Service Bus (ESB) is presented which analyze different types of service compositions to clarify what dynamic composition really holds in SOC.

In [9], service composition and discovery are not treated separately. Here a matching algorithm is developed that combines several services which are not known and need to be discovered. In [10], the flexible architecture of the discovery engine Glue2 is proposed which comes with a powerful set of discovery components (for functional matching, non-functional matching, data fetching, etc.) that can be executed in different order as required by specific execution workflows.

In our previous work in [7] a graph named D-SG is proposed to model design models in distributed environment. The sequence diagrams are interleaved such that the business process at a location spans several sequence diagrams modeling the common and regional use cases. This is modeled graphically using Distributed Scenario Graph (D-SG). Our work in this paper closely relates to this graph model.

In the domain of context aware software architectures, the current work proposes to encompass the design of a context aware ESB that will enable publishing and discovery of services based on location context of the users. Our approach is to incorporate context awareness to ESB unlike other existing work. Incorporating context awareness to ESB will enable the developer to control the algorithms related to context awareness centrally in the ESB(which act as a middleware) where as in the existing works in Context Aware SOA the context awareness is achieved through end devices. This kind of ESB framework will be of immense importance in global software development scenario where services can be region specific of the users.

III. SCOPE OF WORK

In this work, Context Aware Graph (Ca-Graph) is proposed that models the services/processes and their interconnections for all the locations. In this framework, the traditional ESB with the help of CA-graph and location information functions in such a manner that it gets the essence of CA-ESB that performs dynamic service choreography. An Algorithm is proposed which will perform the dynamic choreography of services based on location context. Some metrics are also proposed to analyse the performance of this CA-ESB framework.

In this work we have used some terms to describe our work. Before the description of our proposed work, we will define those terminology that are frequently used throughout this paper for better understanding of our work.

- Service Vs Process

The term *Process* is used when we describe a specific task in the Analysis Phase of SOA software development. Different processes are arranged together (choreographed) to render a specific functionality. *Service*s on the other hand are loosely coupled entities spread over a distributed system. Once the processes are choreographed for a particular application, they will be mapped with the loosely coupled services. So, processes are tightly coupled logical entities and services are loosely coupled physical entities. In this work , we will use *process* in parallel with *service* Once the processes are choreographed , the same process will be mapped with the services and that service will be either constructed or discovered in ESB.

- Regional Processes Vs Common Processes

In a global development scenario, the s/w development is done for requirements that cross regional boundaries. In an application, there will be multiple region specific processes for the same functionality. For example, GUI interface will be different for different location (language specific). Also, different regions have different business policies leading to multiple processes of the same function.

IV. PROPOSED CA-ESB FRAMEWORK

The CA-ESB (Context Aware Enterprise Service Bus) framework is shown in Figure 1.

The modules of CA-ESB are:

A. Service Consumer

They are the users of the application. In our context aware scenario, they are spread over multiple regions. Their request will be served based on the location context provided by the Context Provider.

B. Context Provider

Context Provider will provide location context of the users. The enterprise service bus will be provided with location context of the users. Based on this location context, the regional services will be chosen by the ESB. The location context can be the URL or IP address of the users. The output of this module (URL or IP address) will be forwarded to Context Aware Logic Module (CAL) for selecting region specific services.

C. Context Aware Logic Module (CAL)

Using the context data (i.e. The IP address or URL) of the user, this module will choose region specific services that are different for different users. Different regions have different business policies, different GUIs etc. So, the services will be different for different users of different location. This module will store the information regarding region specific services and select those services based on the location context of particular user. These selected

services will be used for choreography by the next module.

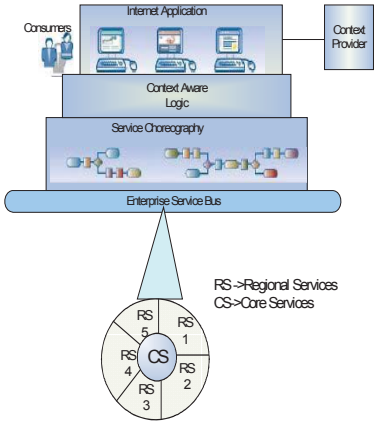

Figure 1: The CA-ESB Framework

D. *Service Choreographer*

This module choreographs the services chosen by CAL dynamically at run time. Services are regional services as well as core services. Dynamic choreography is required as the regional services are different for different applications (or users).

The fifth module is the traditional enterprise service buses that will work along with the other four modules give the flavor of CA-ESB

V. DYNAMIC SERVICE CHREOGRAPHY AND EFFICIENCY OF CA-ESB

The Context aware logic (CAL) module of the CA-ESB framework stores the region specific process/ services information and selects services accordingly when location information is acquired and sent by the context provider. To model the process/service information in CAL module, we propose a Context Aware Graph and calculate the efficiency of CA-ESB compared to traditional ESB using the proposed graph. CA-Graph is used to model the processes of an application and their interconnections for different locations of users.

A. *CA-Graph: Graphical representation of processes*

We propose a graph called Context Aware Graph (CA-Graph) that will help us to categorize the processes of the application according to the location of the users. The processes represent the business processes of the SOA reference Architecture [6].

The processes will be mapped with the services in the service choreography module. The CA-Graph = (V, E) is a graph comprising of nodes/vertices and directed edges. The vertices represent processes and edges are drawn to connect the vertices based on the interconnection of the processes. Different graph construct for CA-graph is tabulated in table I.

TABLE 1: CA-GRAPH CONSTRUCTS

Grap_ Constr_ID.	Graph Construct	Meaning
1	1.L1	Naming syntax for regional process means Process 1 for location 1
2	2.C	Naming syntax for common processes which means process 2 for all location
3		Flow of events(or processes)
4		Process ‘a’
5		Exclusive-OR flow which mean from process ‘a’ the flow will move to either ‘b’ or ‘c’ depending on some condition
6		Parallel flow which means from event(process)’b’ and ‘c’ will occur in parallel after ‘a’

The key points of the graph are:

- Regional processes are labelled as <process name>. < location name > Eg. 1. L1, 2.L2 etc where L1, L2.etc stands for different location.
- Common processes will have extension C.
- Solid Arrow is used for flow of events
- Circle indicates events/ process.

B. *CA-ESB and CA-graph*

The process information in a tabular form will be stored in the Context Aware Logic (CAL) part of our proposed CA-ESB framework. This process represents a collective main process that consists of sub processes. This tabular information is named as Process Table .The Process Table has the following fields

- **Sub process name:** The name of sub processes that constitutes the main process.
- **Pre process:** This is the set of probable processes preceding the process.
- **Post process** This is the set of probable processes succeeding the process.
- **Type of Process:** This field indicates whether the processes are regional (R) or common (C).
- **Process Flow Type**: This field indicates the flow of the process with its post process (es). This can be normal flow (N), parallel flow (P) or exclusive-OR flow (E)
- **Total Processes:** This field consists of list of all possible location based processes for a particular sub process.

Table III in appendix represents a process table for the case study of insurance system that is explained in Section VI.

When the context provider provides the information regarding the location, the CAL module chooses the processes for that particular location from the process table along with common processes. These processes will be mapped with the services.
The next section briefly discusses the process of dynamic choreography.

C. *DYNAMIC SERVICE CHOREOGRAPHY*

The service choreographer does the dynamic choreography of services with the selected processes at runtime based on the process connections as modelled in CA-Graph.
As an example, if the context provider senses the location as location1 (L1), it will send the information to the CAL module. CAL module has the information regarding which sub processes are required for location L1 and Service Choreographer will do dynamic service choreography at runtime with the selected processes (or services). Once the services required for a particular location are determined, the ESB will publish only those services in the registry. This will reduce the time associated with the discovery of services.
The following algorithm will identify services based on location context from the process table and identify the scenario path composed of services in a particular order.
Algorithm:
a) Input: Location context as LocationName
b) Data Structure to be used:

- Graph construct schema table (TABLE I)
  Schema: GraphID, GrConstruct)
- Process table (TABLE III of appendix)
  Schema: ProcessId, ProcesssName, PreProcess, PostProcess, ProcessType, ProcessID, ProcessFlowType
- ProcessFlow
  Schema: Source, Destination

c) Steps to be followed:

1 .L: = GetLocationInput;
ProcessIDLoc is used to store instantaneous ProcessId locally
2. Set ProcessIDLoc: = 1;
3. LOOP
   T = GetTuple from Process Table
   where (ProcessId = ProcessIDLoc);
4. If (ProcessFlowType = 'N') then
   ProcessFlow = (Select GrConstruct when GraphId = 3 from Graph construct table)
5. Else If (ProcessFlowType = 'E') then
   ProcessFlow = (Select GrConstruct when GraphId = 5 from Graph construct table)
6. Else If (ProcessFlowType = 'P') then
   ProcessFlow = (Select GrConstruct when GraphId = 6 from Graph construct table)
7. Set ProcessFlow. Source: = T. ProcessId and
   ProcessFlow. Destination = T. PostProcess
8. If T.ProcessType == 'C'
   Then ProcessIDLoc = T. PostProcess
9. Else If T.ProcessType == 'R' then
   T = GetTuple from Process table
   where (LocationName = L AND
   ProcessID=ProcessIDLoc)
   Set
   ProcessIDLoc: = ProcessID. LocationName;
   Else continue;

END LOOP
d) Output:
Choreographed process based on the particular location context (As Figure 3)

D. *Performance Analysis*

In this section, we calculate the complexity metrics and search metrics for the CA-ESB The notations used to evaluate different performance metrics of CA-ESB is given in table II.

TABLE II: Notations

Notation	Meaning
C_{mx}	Complexity metrics of CA-Graph for traditional ESB
$C_{mx(}$(CA)	Complexity metrics of CA-Graph for CA-ESB
T_{mx}	Search metrics of CA-Graph for traditional ESB
$T_{mx(}$(CA)	Search metrics of CA-Graph for CA-ESB

- Complexity Metrics

Here we will calculate the complexity metrics for the CA-ESB. This metrics will give the measure of no. of processes and interconnections giving us an idea of the complexity of the application.
If we suppose a Global development scenario that consists of
No. of common processes=m
No. of regional processes for a particular main process=n
No of location = L
Total no. of regional process
= (No of location) x (No. of regional processes for a particular main process)
= n*L
So, total no. of processes
= (No. of common processes) x (No. of regional processes)
= m + n*L
In a CA-Graph, the processes (common as well as regional) are represented as the vertices of a graph and the communication between processes are represented as the edges of the graph.
Total no. of vertices of the CA-graph = m + n*L
Then, the maximum complexity of the graph (when all the m+n*L processes communicate with all other processes)
C_{mx}= (m + n*L) (m + n*L – 1) ---------- (1)

When CA-ESB using Context Aware Logic discovers the services, only the services pertaining to a particular location along with common services become visible in the CA-ESB for discovery. As a result the graph effectively reduces to Subgraph for a particular region having m+n processes.

The maximum complexity of the graph (when all the m+n processes communicate with all other processes)

C_{mx} (CA) = (m + n) (m + n –1) ---------- (2)

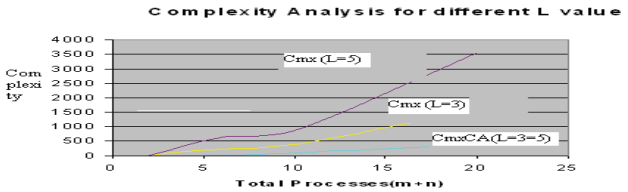

Figure 2: Comparison of CA-ESB vis-à-vis traditional ESB

Based on equations (1) and (2) we chose different values of L=1, 3 and 5 and plotted the C_{mx} and C_{mx} (CA) values corresponding to normal ESB and CA-ESB respectively. As evident from the graph in figure 2 that the C_{mx} (CA) values are lower than the C_{mx} values indication that the use of CA-ESB significantly reduces complexity.

- Search Metrics

We use a metrics to mathematically compare the time complexity involved in searching and discovering services in a CA-ESB as against a normal ESB

If CA-ESB is not used, all the processes/services will be visible, the total vertices (processes/ services) to be discovered is

T_{mx} = m + n*L---------- (3)

When CA-ESB is used, the total vertices (processes/ services) to be discovered only pertains to a particular location,

T_{mx} (CA) = m + n---------- (4)

So, Search complexity without using CA-ESB

T_{mx} = O (n*L)

Search Complexity when CA-ESB is used

T_{mx} (CA) = O (n)

From (3) and (4), the time complexity of searching of services in the ESB is reduced by L times if the CA-ESB is used.

VI. CASE STUDY

We consider an application for an Insurance company who plans to start its business operations in several countries across the globe. The application consists of different processes, which are being used by different users located in different places. Some processes are common which are being used by all users who are accessing the application irrespective of where they are located. While some processes are specific to a country. Let us consider that the application consist the following main processes

- Policy Creation
- Policy Maintenance
- Policy Claim
- Policy Termination

The flow of events (or sub processes) of the first processes "Policy Creation" is given in a tabular form as Table III of appendix. The processes are categorized as common processes (marked as 'C') and regional processes (marked as 'R'). Here, the processes are considered for two locations namely L1 and L2.

The main process ("Policy Creation") consists of 10 sub processes that are labelled according to the rule defined in section V.A. CA-Graph is generated for process "Policy Creation" as in Figure 3.

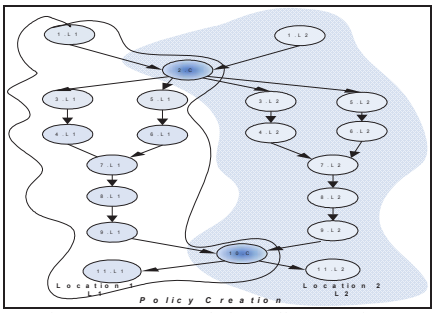

Figure 3: CA –Graph for Policy Creation

Details are given below

- It consists of 2 common processes i.e. m=2
- It consists of 9 regional processes i.e. n = 9
- The common processes are 2.C and 10.C labelled in the graph as vertices.
- The regional processes are (1.L1, 1.L2), (3.L1, 3.L2)…….(9.L1, 9.L2) and (11.L1, 11.L2)
- CA-graph is generated for location L1 and L2, where common processes are shared by both the locations.
- There is an Exclusive-OR flow from process 2 to the process 3 or 5
- The complexity metrics for the graph (m = 2, n=9 and L =2)
- Total processes = m + nL = 2 + 9x2 = 20
  C_{mx} = (m+nL) x (m+nL -1)
  = 20x19 = 380,
- Using CA-ESB,
  Total processes = m + n = 2 + 9 = 11
  C_{mx} (CA) = (m+n) x (m+n -1)
  = 11x10
  = 110 (Using equation (1) and (2))
- The search metrics for the graph (m=2, n =9 and L =2)
  T_{mx} = 20 and T_{mx} (CA) = 11
  (Using equation (3) and (4))

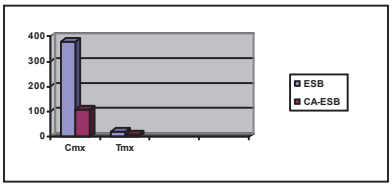

Figure 4: Performance metrics comparison for *Policy Creation*

Figure 4 shows a performance metrics chart that depicts the fact that the performance of CA-ESB is improved both in terms of complexity metrics(C_{mx}) and search metrics(T_{mx}) as compare to traditional ESB for the process *Policy Creation* which is distributed in two location(L=2). With the increase of the value of L, we will get more increase in performance of CA-ESB as compare to a traditional ESB.

VII. CONCLUSION

Presently, global delivery model is gaining significance where applications are being developed in an integrated manner for different users spread over geographically different locations forming a cloud. The core processes remain same, with several region specific processes catering to different because of variations of languages, currency, business policies, etc. In SOA architecture, ESB is responsible for publishing and discovery of all services. We propose a new variation of ESB named Context Aware ESB (CA-ESB) that will be very useful for publishing and discovery of services in a global development scenario. CA-ESB is able to sense location context, selectively discover relevant services for a region and finally dynamically choreograph them with the core services such that the whole application behaves uniquely for each different location context. We demonstrate using an algorithm and a set of metrics that the efficiency of a global software development scenario improves to a significant extent by using CA-ESB. This framework attempts to provide solution for the problem of efficient dynamic coordination of geographically distributed services.

Abstract - This work describes a new web system to aid project management that was created to correct the principal deficiencies identified in systems having a common purpose which are at present available, as well as to follow the guidelines that are proposed in the Project Management Body of Knowledge (PMBoK) and the quality characteristics described in the ISO/IEC 9126 norm. As from the adopted methodology, the system was structured to attend the real necessities of project managers and also to contribute towards obtaining quality results from the projects. The validation of the proposed solution was done with the collaboration of professionals that used the functions available in it for a period of 15 days. Results attested to the quality and adequacy of the developed system.

Keywords - project management; web-based tool; software quality

I. INTRODUCTION

Tough competition existing since the beginning of commercial activities, allied to changes provoked by technological advances, market integration and globalization have increasingly required more efforts from enterprises to find solutions which will guarantee their survival and growth [1]. Due to this, project management has become more important and an indispensible resource to increase competitive potential since it details tools and techniques that enables the organizations to increase their capacity to stimulate internal communication, plan activities, estimate and monitor time and costs, as well as to guarantee the quality of the jobs done, all of which contribute to objectives being successfully fulfilled [2, 3].

In conceptual terms, a project can be understood as being a unique process consisting of a group of coordinated and controlled activities having dates for starting and finishing, to create a product, service or exclusive result, which will satisfy customers [4, 5]. Managing projects involve complexity and celerity to make decisions. Due to this, different systems to aid project management have been developed to supply relevant information to managers in a fast, safe, and consistent manner.

Nevertheless, such systems as are available on the market have a restricted scope of the indispensable managing aspects contemplated by Project Management Body of Knowledge (PMBoK) [5], one of the most reputed guides to project managing. In this context, the objective of this paper is to present a web System to Aid Project Managing (SAPM), and to show that this system is a new solution capable of correcting deficiencies identified in systems that have the same purpose and are available in the market, follow the proposed guidelines in the PMBoK [5] and the software quality characteristics described in the ISO/IEC 9126 [6], besides complying with general requirements from project coordinators and managers from small and medium sized enterprises.

The rest of this paper is organized as follows: Section II shows a general panorama about the tools to aid project management available in the market; Section III shows the methodology adopted to develop the work; Section IV shows the principal results that were obtained; lastly, Section V shows final considerations and future works.

II. SYSTEMS TO AID PROJECT MANAGEMENT

Currently, various software systems are available on the market to supply relevant informations to project managers in a fast, safe and consistent manner [7, 8, 9]. Nevertheless, these systems are functionally restricted in relation to the real project management necessities as described in the PMBoK. For example, the system described in Ref. [7] only aids risks management area, thus making it necessary to use other tools to manage the rest of the areas. A similar situation occurs in other systems described in Ref. [8] and [9] which supply automated aid for specific contexts.

With a view to presenting an overall panorama of the scope of the software systems that aid project managing, Ref. [10] shows a comparative analysis between four desktop systems and five web systems, which were assessed as to their alignment with the PMBoK guidelines and the ISO/IEC 9126 software quality norm. The authors verified that the assessed systems had similar functions, but did not supply aid for all of the project management necessities since they all prioritize some areas in detriment to others. As to the quality criteria of the analyzed software, important limitations were noted. Therefore, it can be concluded that, although various

This research was partially supported by The State of São Paulo Research Foundation under projects number 2008/07094-2 and 2010/13478-8.

computational systems have been developed, it can be seen that there is a lack of a wider scope of resources capable of offering an effective environment for activities related to project management. Moreover, it is notorious that existing systems do not have, even indirectly, a resource that instinctively guides the user without him realizing that he is obeying the guidelines stipulated in the PMBoK.

In this scenario, there is a need to develop a new system to aid project management activities based on a quality criteria that will cover real present market necessities.

III. METHODS

The methodological process was divided into three stages:

Analyses and Projects – At this stage, the identification of requirements to be considered by the SAPM was first done. Having the requirements, architecture in layers was structured for the system, improving the organization of the information, as well as supporting incremental development of the system and to guarantee its modularity, mantainability and extensionability [1, 11, 12, 13].

In a recent work, Ref. [10] presents detailed results of this stage, with a specification of identified requirements and an illustration and description of the developed software architecture (see Appendix A).

Implementation – At this stage, an initial version of the system was constructed which reflected the contemplated requirements of the defined software architecture. The construction of the system only used free resources to guarantee an easy access to implemented resources: PHP, JavaScript and HTML languages; MySQL database management system; Apache web server.

Validation – At this stage, the system was assessed by professionals involved in project management activities, which sought to refine or confirm requirements identified initially as well as enhance the established architectural design [14, 15]. The validation was done between August and November, 2010, when the system was personally presented to nineteen project managers from fourteen Brazilian enterprises from different sectors: education, administration, consultancy, civil engineering and information technology. At the end of each presentation, the assessors received a form to grade the scope and adequacy of the system using a scale of 0 to 10 points. Moreover, there was an open space on the form so that the assessors could indicate the strong and weak points of the system. The filled in form was returned via email after the assessors had remote experienced the system for 15 days.

IV. RESULTS

The results which were obtained from the implementation and validation stages are detailed below.

A. Implementation

The objective of this stage was to obtain a usable satisfactory web system for later validation by acting project managing professionals.

The system considers the functions shown in Table I, which are organized according to the nine knowledge areas as defined in the PMBoK guide: integration, scope, time, costs, quality, human resources, communication, risks and procurements. Besides that, two complementary functions that are not directly related to any of the areas, but which were considered essential to managing activities, were incorporated to the proposed solution.

Figure 1 (a) shows the SAPM project's portfolio, from which an identified user can select an existing project to edit or register a new project. Figure 1(b) shows the screen which is exhibited by the system after a project from the portfolio has been selected, evidencing the alignment of the SAPM's principal menu to the PMBok guide, as it has the options organized according to the guide's knowledge areas, thus contributing towards the agile execution of managing activities based on solid concepts.

Besides registering and organizing information, the SAPM is capable of generating and presenting different types of diagrams and graphic indicators which aid decision making processes for project coordinators and managers. Figure 2 shows one of the diagrams generated by the system, Gantt chart, which was configured to exhibit, in different colors, activities having different status, to facilitate the understanding of the general panorama of the project. Figure 3 shows graphic indicators that refer to human resources performance in previous projects which aids coordinators and managers with their process of selecting people to make up the project teams.

B. Validation

The SAPM validation stage allowed refining the previously identified functional requirements, as well as the architecture of the project, leading the system to be adequate for the identified present necessities in the Brazilian market. Ratifying this market demand, during the validation there was a strong interest in acquiring the system with some assessors showing interest in continuing to use the SAPM in their actual projects.

The main evaluated topics in the questionaire utilized in validation were: usability - the degree of ease to access and use system resources; interface quality – the users' apreciation of the system's interface; graph quality – the appearance and representativity of the data; reports quality – the degree of users satisfaction with the type of report information generated by the system; operational efficiency – referring to degree of operational stability.

The histograms in Figure 4 reveal that the general result of the evaluation of the system by the participants was satisfactory. The vast majority of the assessments were in the range of 8 to 10 points. The left asymmetry of the data

TABLE I. FUNCTIONS CONTEMPLATED BY THE SAPM

Knowledge areas	
1. Integration	**6. Human resources**
1.1 Manage project documents	6.1 List project team members
1.2 Register events during project execution	6.2 Control personnel availability and prevent conflicting allocations
1.3 Register learnt lessons	6.3 Register and present team member performance graphs
2. Scope	**7. Communications**
2.1 Define the scope of the project	7.1 Enable online meetings between those involved in the project
2.2 Create a Work Breakdown Structure (WBS)	7.2 Production and distribution of custom made reports and warnings
2.3 Create the WBS dictionary	
3. Time	**8. Risks**
3.1 Include activities	8.1 Management risks
3.1.1 Identify activities	8.1.1 Identify risks related to the project
3.1.2 Estimate starting and ending dates of the activities	8.1.2 Estimate risk impacts
3.1.3 Allow definition of parent-activities (made up of other activities)	8.1.3 Estimate the probability of risks happening
3.2 Register activity progress updates	8.1.4 Identify events related to the probability of an increase of risks
3.3 Register finished activities	8.1.5 Monitor the probability of an increase of risks
3.4 Warn project delays	8.1.6 Create alerts about the occurrence of risks
3.5 Generate Gantt and activity network diagrams	8.1.7 Identify mitigation and contingency plans for each risk
	8.1.8 Prioritize risks based on the probability of them happening and the impact
4. Costs	**9. Procurements**
4.1 Produce cost estimates by activity	9.1 List suppliers
4.2 Create project budgets	9.2 Plan purchases
4.3 Generate project budget graphs	9.3 Register and present supplier delivery performances
5. Quality	**Remaining requirements**
5.1 Register management quality plan	Links with other software systems
5.2 Register audits to be done	Existence of access levels
5.3 Produce audit reports

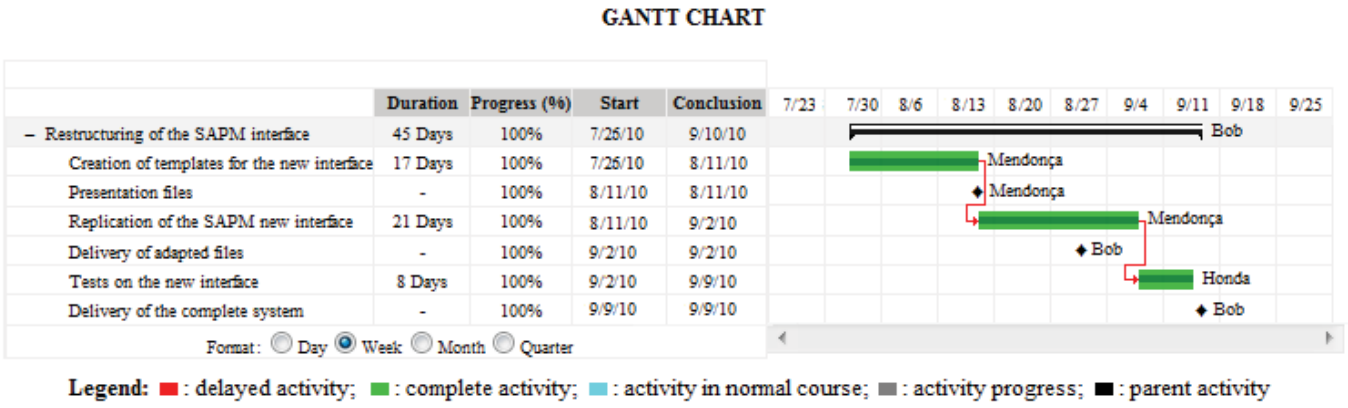

Figure 2. Gantt chart.

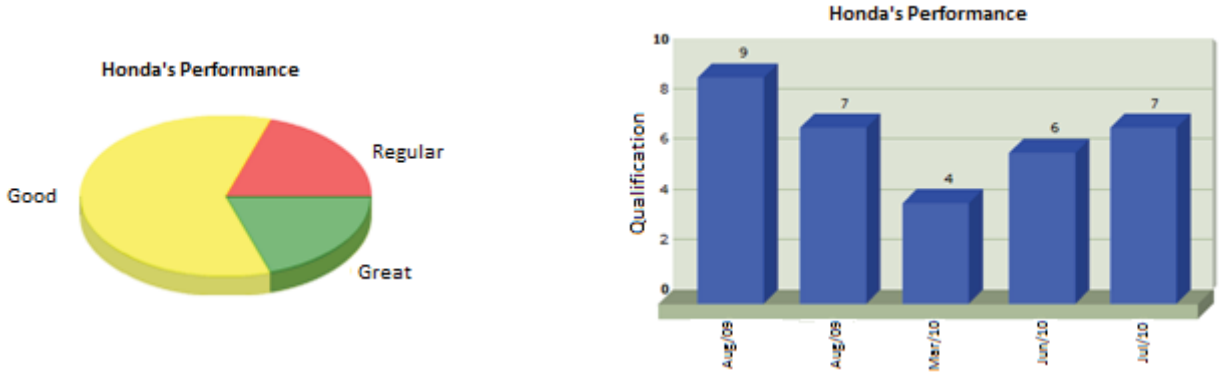

Figure 3. Human resources performance graphs.

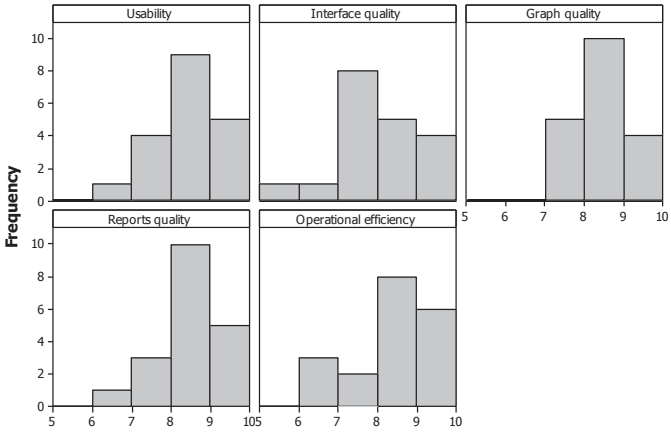

Figure 4. SAPM general assessment result.

distribution and the absence of points below 5 reinforce the high degree of satisfaction felt by the SAPM assessors.

The principal system differentials pointed out by the assessors in relation to existing options were: learnt lessons recorder; storing and organizing project documents; automatic generation of the Work Breakdown Structure (WBS); automatic detection of project activity delays; quality of generated graphs; agenda and record of auditing quality results; control of human resources and project materials availability; availability of environments for online meetings; automatic risks priority; creation of a historical of suppliers and human resources performances.

Besides mentioned differentials, the participants also contributed with some suggestions for future system improvements, among which are: create a correspondence between the chronogram and the WBS; consider holidays and vacations in the estimates; include resources that will allow estimating costs based on statistical analysis; generate graphs and diagrams to aid quality managing, such as the Pareto and Ishikawa diagrams; make available individual calendars for human resources; create mechanisms to aid quantitative risk analyses.

As a fundamental part of the methodological context, the validation exceptionally contributed towards the refinement of functional requirements for Brazilian enterprises, leading to the inclusion of new functions to the system to better serve today's necessities of small and medium sized enterprises.

To highlight SAPM's wider scope than those of other web systems on the market that have the same purpose, Table II shows an adaption of the comparative analysis presented in Ref. [10], considering only the five web systems and the SAPM. To attribute qualifications, disc representation indicating the frequency of each analyzed topic in each system was favored: greater the frequency, the larger the portion in black. This comparative analysis sought to highlight the wider scope of the SAPM as to its alignment to the PMBoK and the

quality criteria of the ISO/IEC 9126.

V. FINAL CONSIDERATIONS AND FUTURES WORKS

This paper presented the SAPM which had its relevancy attested by market professionals who are involved with management projects in small and medium sized Brazilian enterprises. According to validation results, it may be concluded that the SAPM, due to the conceptual referential used in its realization, can increase efficiency and efficacy in the conduction of projects.

As it was projected to incorporate the guidelines proposed in the PMBoK plus the software quality characteristics described in ISO/IEC 9126, as well as to value the satisfaction of clients who are, mostly, well versed in the present scenario of web systems to aid project management, it was possible to make the SAPM capable of fulfilling the necessities of project managers and coordinators from said aforementioned enterprises in their daily activities.

Despite the limitations identified during the validation, was highlighted the contribution of the proposed system to improve the quality of project results.

Future works will seek to cover such limitations and iteratively widen this system, following the exploring evolutionary model [1, 11], which will lead the more refined and complete versions of the system.

***Abstract*—Software effort estimation research has been ongoing for almost 40 years. Over the years, several classes of effort estimation techniques have been introduced. Some of these techniques include model-based, expertise-based, learning-oriented, regression-based, and dynamics-based effort estimations. However, none of these techniques is best for all situations. In this study, we propose a composite technique to estimate the development efforts in a recent enterprise software development project. This paper shows how we specify and document software requirements and how we use these requirements in a novel effort estimation approach. The proposed approach is particularly effective for agile development projects.**

Keywords- Effort estimation; use case points (UCP); IFPUG; function point; cost estimation; business process management

I. INTRODUCTION

The ability to estimate a software project cost and development effort accurately is still an elusive goal, even though software engineers have been working on effort estimation models for decades. Research on software effort estimation started in the 1960s and is still a very active research area [1].

Software project managers try to control the project duration and the budget by estimating the effort and the cost at several stages of software development, such as system analysis and requirement analysis. At each stage, managers update the project plans depending on the estimation results. Furthermore, estimation can be used to approve or reject a project proposal [1]. Several purposes of effort estimation techniques are shown as follows [2]:

- Budgeting
- Tradeoff and risk analysis
- Project planning and control
- Software improvement investment analysis.

We use cost estimation and effort estimation terms interchangeably throughout the paper. Cost estimation research is not only limited to the estimation of total project cost but also to the estimation of effort necessary to perform a software process assessment and to become ISO-9001 certified for software organizations [1]. Therefore, we can state that cost estimation research has a wide application area for software engineering.

Several research findings showed that the cost and effort overruns are still beyond acceptable levels. For example, the Standish Group's Chaos Report [3] showed that an average cost overrun for software projects is around 89%. Another example, Molkken and Jorgensen [4] reported that effort overruns are lower (30-40%) than the effort overruns reported by consultancy companies (89%). However, this overrun percentage (30-40%) still drastically affects the project duration and cost. Also, they stated that expert judgment-based estimation is the most frequently used approach, because there is no empirical evidence that formal approaches are better than the expert-based techniques. There exist several significant models and techniques in literature for estimation. A good categorization for these techniques is shown as follows [2]:

- Model-based techniques
  - COCOMO
  - SEER-SEM
- Expertise-based techniques
  - Delphi technique
  - Work Breakdown Structure (WBS)
- Learning-oriented techniques
  - Case studies
  - Neural networks
- Dynamics-based techniques
  - Dynamics-based
  - System dynamics approach
- Regression-based techniques
  - Ordinary Least Squares method
  - Robust regression
- Composite techniques

Authors in Reference [2] reported that no method should be preferred over all others and discussed that a better approach may be to use several techniques. In a recent project aimed at developing a Portal, Document Management System and Business Process Management (BPM) software for Turkish Energy Markets Regulation Authority, we used a composite effort estimation technique to estimate the development effort, because different work packages had different types of modeling requirements in the agile development context. Our project had three work packages that are shown as follows:

1. *Document Management System:* This software is developed based on an open source content management system known as Alfresco.
2. *Portal Server:* This software is developed by utilizing and customizing an open source portal server known as Liferay.
3. *Business Process Management:* This software is developed with an open source business process management engine known as jBPM.

All of the software packages will work on a Linux distribution called Pardus that was developed by The Scientific and Technological Research Council of Turkey (TUBITAK). During the requirement analysis phase, we created use case diagrams and use case elaboration tables for the requirements related to Work Package 1 and Work Package 2.

In the analysis phase of the software development cycle, we spent three months identifying the business processes for Work Package 3. We used simple flowcharts to represent the workflows for each business process. In turn, this helped us to better communicate with the customer. In addition, we used sketch diagrams for graphical user interfaces (GUI) for each business process. We discussed each diagram with the customer in iterative meetings. The customer was very satisfied during the requirement analysis phase because they could easily share their ideas during the preparation of workflows and user interfaces in the analysis meetings.

For Work Package 1 and 2, we used use case modeling for the requirement analysis. Thus, we chose the Use Case Points (UCP) effort estimation approach to do cost estimation for these work packages. For Work Package 3, we used the Function Point Analysis technique (IFPUG), since we had to communicate with the customer through sketch diagrams and flow charts for each business processes. Therefore, our effort estimation approach is a composite form of UCP and IFPUG technique. In turn, this enabled a suitable software estimation effort for agile software development methodology.

In this paper, we explain how we specified and documented software requirements in this project. We show how we used these requirements in our composite project effort estimation approach. The rest of the paper is organized as follows. Section 2 presents related work and Section 3 explains our methodology for the requirement analysis. Section 4 presents our effort estimation approach and Section 5 explains our conclusions and plans for future work.

II. BACKGROUND

In this section, we explain the UCP and IPFUG methods that we utilized to estimate development efforts for our enterprise software development project. In addition, we discuss previous research conducted on composite effort estimation techniques. In [5], three stages of cost estimation are suggested for the traditional software development projects: Macro estimation (feasibility phase), detailed estimation (requirement analysis phase), and enhanced estimation (design phase). In this paper, our approach falls into detailed estimation, which takes place in the requirement analysis phase.

A. Use Case Points

Gustav Karner of Objectory developed the Use Case Points (UCP) estimation technique as his PhD thesis at the University of Linköping in 1993. Karner used several small projects while developing this technique and therefore, in-depth research that may be applied to many projects will improve the applicability of this approach. This technique is used when an object-oriented programming paradigm is chosen for implementation. Anda reported that UCP is better than expert estimation [6]. Due to space limitations, we omit the steps to calculate the development efforts.

B. IFPUG Method

Function Point (FP) measures the functionality of software systems. It was first proposed by Allan Albrecht of IBM in 1979. Function Point Analysis (FPA) evolved into the IFPUG method in 1990. The FPA is maintained by the International Function Point User Group. IFPUG is more suitable for data intensive applications but not appropriate for real-time and embedded systems. The number of inputs, outputs, enquiries, external internal files, and internal logical files in a program are taken into account to calculate the FP value. Therefore, we need to draft some graphical user interfaces for the program. Due to space limitations, we omit the details of this method.

C. Composite Techniques

Composite techniques combine two or more effort estimation methods [2]. Some researchers [7, 8, and 9] reported that the combination of effort estimation techniques and expert judgment improves the performance of estimates [10]. The Cost Estimation Benchmarking Risk Analysis (COBRA) [7] combined algorithmic and experiential approaches. According to a recent systematic review that investigated 204 papers, only 5 papers used a combination of different methods [11]. Our effort estimation methodology is different than these studies, since we used two parametric estimation models separately for each work package. Our study shows that two or more estimation techniques can be used in a single project successfully if the modeling requirements for each work package are different.

In the following sections, we give several examples to show how we documented the software requirements and combined them to estimate the total development effort. While the UCP technique was very useful for work package 1 and 2, IFPUG helped us to calculate the Business Process Management

(BPM) work package's effort. We did not prepare use cases for the BPM work package. Instead of use case modeling, we drew flowcharts and graphical user interfaces for business processes. In addition, all of the requirements were documented textually.

III. REQUIREMENT ANALYSIS

Requirements related to the work package 1 and 2 were documented by using a use case template. This template has the following sections: *Use case name, use case number, author, last modified by, creation date, last modification date, actors, summary, preconditions, post conditions, normal flow, alternative paths, notes, included use cases*. Each use case had a unique number for the traceability matrix. While 12 use cases were created for work package 1, 35 use cases were described for work package 2. However, use cases in work package 2 were much simpler than the use cases in work package 1 because they could be easily implemented by customizing the open source portal software. Use case modeling is a well-known modeling technique, and therefore we omit the details.

We preferred simple flowcharts instead of use case diagrams to document the business processes in work package 3. The customer could easily participate in the process modeling efforts because flowcharts are very simple to understand and adapt. In addition, we created sketch graphical user interfaces (GUI) for each business process. While Appendix A of the Software Requirement Specification (SRS) document includes business processes, Appendix B consists of sketch GUIs. Sketch diagrams helped our customer to visualize what the final product would look like.

Three types of business processes were identified: *Operational Processes (core business processes), Supporting Processes, and Strategic Management Processes*. 289 business processes were defined for this project. Appendix A includes 636 pages of documentation. Each requirement was documented textually by referencing the relevant diagram shown in Appendix A and user interface shown in Appendix B. A simple textual requirement for work package 3 is shown as follows:

> 3.1 *Business Process Management (BPM) software shall automate the business process BP-1 shown in Appendix A with the user interface UI-1 shown in Appendix B.*

During the requirement analysis phase, we prepared user interface prototypes; in later stages of the project, we are planning to use functional prototypes to get early feedback from the customer. Van Lamsweerde [12] emphasizes the advantages of prototyping:

> *"Prototyping as an elicitation vehicle has a built-in advantage: experimenting with some concrete flavor of what the system might look like helps us understand the implications of some requirements, clarify others, turn inadequate requirements into adequate ones, and elicit requirements that are hidden in the stakeholder's mind."*

He also expresses the limitations of prototyping and states that prototyping restricts itself to a few non-functional requirements, such as usability requirements. However, requirements such as performance, cost, interoperability, reliability and real-time constraints are ignored [12]. While there are several limitations to prototyping, prototypes are successfully used in software engineering to help the client understand some of the software features, and therefore we are using prototyping during our software development life cycle.

IV. EFFORT ESTIMATION

We applied the UCP technique to estimate the effort needed to complete for work package 1 and 2. To simplify the calculation process, we preferred the Enterprise Architect (EA) software design tool because it includes an easy-to-use UCP calculation module. Estimated values for work package 1 (Document Management System) are shown in Table I. According to these values, we need 2600 hours (or 325 days) to complete this work package. Because three developers worked on this project, we estimated that it will take 5,5 months to complete this software.

After this effort estimation was completed in June 2010, we saw that we would be able to finish this work package by the end of year 2010, in keeping with the initial plans. Estimated values for work package 2 are shown in Table II. We estimated that we need 4060 hours (or 507,5 days) to complete this work package. We will use four developers on this work package, and therefore estimated that we need 6.5 months to complete this document management system software. This estimation also showed that we will be able to finish the project on time, as we estimated at the beginning of the project proposal.

We assumed that each Use Case Point (UCP) is implemented by spending 20 hours. For the work package 3, we used the IFPUG technique because we did not prepare use cases. First of all, we calculated the Function Point (FP) value using the IFPUG technique. Later, we estimated lines of code (LOC) by using gearing factor information. The Quantitative Software Management (QSM) Company provides gearing factor information for many programming languages [13]. Because this is a Java Project, we chose value 55 for *LOC / FP* factor. A value of 55 shows that we should multiply value FP by value 55 to estimate the LOC. After LOC is estimated, we used COCOMO (Constructive Cost Model) to estimate the development effort. We have four developers in this work package.

Our effort estimation based on Basic COCOMO model showed that we need 24 persons * months to complete this work package, and therefore we need six months. The software project's complexity was chosen as semi-detached in the Basic COCOMO model. As we have seen in this effort estimation study, sometimes it may be more effective to use more than one technique in effort estimation and no one technique is best for all cases. We are planning to make an enhanced estimation after our design phase has been completed.

TABLE I. EFFORT VALUES FOR WORK PACKAGE 1

Element	Value
Estimation Date	03.06.2010
Number of Use Cases	12
Unadjusted Use Case Points (UUCP)	148.00
Technical Complexity Factor (TCF)	1.17
Environmental Complexity Factor (ECF)	0.75
Use Case Points (UUCP * TCF * ECF) = UCP	130.00
Hour per UCP (HRS)	20.00
Total Duration (HRS * UCP)	2600.00
Total Cost	78000.00

TABLE II. EFFORT VALUES FOR WORK PACKAGE 2

Element	Value
Estimation Date	03.06.2010
Number of Use Cases	33
Unadjusted Use Case Points (UUCP)	231.00
Technical Complexity Factor (TCF)	1.17
Environmental Complexity Factor (ECF)	0.75
Use Case Points (UUCP * TCF * ECF) = UCP	203.00
Hour per UCP (HRS)	20.00
Total Duration (HRS * UCP)	4060.00
Total Cost	121800.00

V. CONCLUSION AND FUTURE WORKS

This paper presented a case study of using Karner's Use Case Points (UCP) and a traditional Function Point Analysis (IFPUG) to estimate the development effort for a Turkish IT project. UCP is used for two work packages, and IFPUG is used for a third work package. We applied different estimation methods for two work packages in this project because each of them has different modeling needs. Although UCP and IFPUG seem to be competing techniques, we successfully integrated them in this enterprise software development project.

In addition, we explained how we documented software requirement specifications in project documents and effectively used these specifications in our approach. The documentation approach used in this study can be useful for IT companies that develop business process management software.

Effort estimation results are consistent with the initial predictions based on expert judgment that we've made during the project proposal. After design phase has been completed, we are planning to check the effort estimation results again. The main benefit of this approach is that we could put together use case points and function points into one effort estimation model. This approach can be used in agile development projects in an effective manner.

For future work, we are planning to apply both estimation methods to the same work package and compare the results with the actual effort observed when the work packages were implemented. In addition, we will compare the proposed approach with state-of-the-art estimation methods that were mentioned in the introduction.

Abstract - Risks are unavoidable in systems engineering projects due to emerging changes during the lifetime of projects. Changes in activities and peoples' roles are usually not free from conflicts, which in some cases if not dealt adequately, increase the project failure risks and could bring the whole project to a standstill. Herein, we present a method that examines the impact of change to project's duration which constitutes one of the most critical risks in project management. The method proposed utilizes two main criteria namely, the degree of dependency among activities and actors, and the temporal costs associated with the change. The proposed methodology is realised in Event Calculus (EC) and elaborated with an example.

Keywords: Event Calculus, Project Risk Managment, Conflict Impact Analysis.

I. INTRODUCTION

Despite sophisticated tool support for project management, projects still continue to suffer by budget overruns and a failure to meet user requirements. Various approaches have been proposed as solutions. An example is the capability maturity model integration (CMMI) [6] that defines layers of control to help ensure quality and efficient procedures that yield an improved project development process. In particular, CMMI's change control, limits project's scope creep, while, the management review, enables intermediate quality checks on the system. These have shown to be effective in improving project performance. One indicator of project quality is process flexibility, that allows rapid and cost-effective modifications of new needs [7]. However, achieving a high level of project flexibility has often been slow, inflexible, and time-consuming, even with the aid of sophisticated tools and methodologies, which oppose the goal of efficient production. Therefore, it is necessary to examine higher levels of project development flexibility by evaluating risks while still meeting budgetary and temporal restrictions. These include, role management and requirements change during a typical system development life cycle (SDLC). Requirements change analysis is translated into change impact analysis that investigates the effect of change to dependent requirements, activities and people involved. However, in most of the times changes to requirements or roles during the SDLC are not free from conflicts. If these are not resolved they could lead to inconsistencies in the process that could result in product failure. Conflict analysis falls under the change management process that is composed of three conceptual phases, namely: dependencies specification, traceability methods, conflict analysis and resolution. The method proposed herein, demonstrates the application of EC to identify conflicts in project given specifications of project's schedule, tasks and modifications. Resolving conflicts is of critical importance since they can bring a project to a standstill. The proposed method can monitor the task completion of each team member, and check if the project schedule falls within agreed time limits. Changes to requirements are also considered to assess the extra time introduced.

A. Problem Definition

Project risk management encompasses knowledge, techniques, and tools necessary to manage the risks that emerge during projects' life cycle. It is a methodological approach to minimizing uncertainty that could jeopardize achieving agreed output upon specified time frame with defined resources. An important phase during project risk management is the definition of activities. These may be related to each other via dependencies, i.e., action A_i must be implemented before A_j is completed. Given these interdependencies, risks emerge with the introduction of change to project plan that could lead to conflicts. The potential of conflicts in systems engineering projects is usually high due to the involvement of individuals from different backgrounds, specializations and locations, working together to achieve complex tasks. The objective of risk management is to provide the system designers/managers with early detection of risky situations as these are manifested by conflicts. Output from this process aids system designers in adopting appropriate countermeasures to resolve or at least mitigate emergent risks.

B. Contribution

During the development of a project, it is critical that some tasks are completed at specific times. However, actions or inactions from project members could cause critical delays. Hence, this could lead to failure to complete critical tasks that lay on the critical path. Therefore, changes in initial team structure or project specification could cause extensive overheads to the project's schedule due to conflicts. These changes could create risks of the following types: critical requirements, people and estimation risks.

Herein, we propose a Project Risk Management tool that evaluates the effect of project changes and in essence provides valuable feedback regarding the project's estimation risk. During project execution, activities of each member are recorded in the tool that detects possible conflicts that emerge due to changes in team structure. The tool resolves conflicts by suggesting appropriate modifications in the project implementation plan to improve the likelihood for guarantying success. The tool is realized using EC. In particular, using appropriate event specifications and axioms, the tool identifies conflicts upon changes to project properties. Information that is used during the analysis includes: events relating to functional project requirements, temporal specification of project characteristics i.e. start, end date of the project, roles, capabilities and actions of project members and modifications to project specifications. Inference rules are used to identify

conflicts caused by changes or actions that do not adhere to the project plan. Conflicts resolutions are provided when feasible.

C. Related Work

Work by Giorgini et al [5] describes a conflict detection method, composed of three phases namely: modeling, extensional description and verification. During the modeling phase the designer draws the extensional requirements models where every node and edge corresponds to a fact in the formal framework. Then, the reasoning system completes the extensional description of the system using rules and verifies its consistency using constraints. If any inconsistency is detected by the reasoning system, the designer revises the requirements model to avoid or at least mitigate detected conflicts and repeats the formal analysis step. This method uses the Datalog solver which is based on Boolean algebra to detect conflicts. In contrast to this approach the methods described herein is not indented to work solidly on requirements analysis, but also during project implementation where changes are more expensive to be realized and alterations to project schedule more important. EC was also utilized in [5] for policy and specification and analysis. The proposed method transforms policy and system behavior into formal notation which is based on EC. Work by [8] and [4] also use EC as a specialised first-order logic for formalising policy specification and accordingly identify conflicts and propose resolutions in network and systems management. Chomicki [9], similarly use constraints which are policies that prevent a specified action from being performed in a given situation.

II. BACKGROUND

A. Event Calculus

EC allows specification of system behaviour using notations, such as, state charts, which can then be automatically translated into a logic program representation. EC supports deductive, inductive and abductive reasoning. Abductive reasoning proof for EC can be used to detect the existence of potential conflicts in partial specifications and generate explanations for the conditions under which such conflicts may arise [4]. EC is a "logical language" from which actions and their effects can be represented using predicates. Therefore, in system engineering projects, actions that took place at particular time using certain resources to produce specific output, can be defined, explained and proved using EC. Consider the following example: Maria was hired as an account in a company on May 11 2001, Maria was promoted to head accountant on May 11 2002, Maria left her position on 23 April 2004. Based on these statements we can make the following assumptions:

A) Maria was an accountant after May 11 2001.

B) Maria ended his accountancy post on May 11 2002,

C) Maria was a chief accountant from May 11 2002 until 23 April 2004.

If the events however were mentioned in the following manner: "Maria is hired as an accountant in a company on May 11 2001, Maria left the company as a chief accountant on 23 April 2004" then the assumptions cannot hold; There is a timing gap between the ranking of the person, therefore the promotion cannot be assumed, as other events could have happened such as maternity leave. Solution to this problem is divided into two phases: the theorem problem solving, which uses theorems that have been proven in order to give the solution and the problem specification and execution part, which uses logic to infere solutions. In logic programming the implications are treated as a base for goal reduction procedures.

B. Logic Programming & Prolog

Logic programming uses mathematical propositions expressed in computational terms. Prolog is a logic-based programming language developed by Alain Colmerauer, that use the following constructs: an *atom* that describes a general-purpose meaning, a number which can be floating or integer, a variable denoted by a string consisting of letters, finally, compound terms composed of "factor" which is an atom and the arguments. Prolog works by making *deductions* and *derivations* from facts and rules stored in a *database*. The essence of Prolog programming is writing crisp, compact rules. The deductions and derivations, instigated by user-entered queries, are products of Prolog's built-in inference mechanism called *backtracking* which is part of abductive reasoning.

III. METHODOLOGY

The Project Risk management tool is built in EC terms using events and rules. Events related to project implementation, such as the beginning date of the project, actions of members and changes to project specifications are specified using EC constructs. Inference rules are used to backtrack the queries to identify conflicts caused by changes in project plan or actions that do not satisfy project constraints. Conflict resolutions strategies are presented when feasible.

A. Describing Events and Relationships with EC

Consider the following scenario: Two teams are working on systems engineering project involving the development of a car simulation project, which includes both hardware and software implementation. The project requires parallel development of both software and hardware. This procedure has the advantage of allowing various parts of the project to be progressed simultaneously. Testing can be done after completion of each phase. Team one consist of Martha, Tim, and Thomas. Martha has similar expertise acquired from similar training with Tim and can replace him if necessary. Tim is responsible for the gas system, Martha for the pipeline system and Thomas for the steering system. Give these descriptions, the following events hold:

- E1 is an event at which Tim is trained for the gas system. E1 has time 10 March 2004.
- E2 is an event at which Martha is trained for the pipeline system. E2 has time 5 March 2004.

Events are recorded in a database. Note that updates of the database are additive; events are added in the database and no deletions are allowed. In order to delete an event that expresses a relationship, a new statement needs to be set that ends the relationship. Temporal events are treated without any particular order, hence, older events can be added after adding recent events. The chronological order of the events can be expressed

using the <, >, = symbols. For instance, if an event E1 occurred before an event E2 then it can be described as E1<E2. Events can also have duration, a starting point and an ending point.

1) Representation

Given the systems engineering example, an event concerning the ranking of a person in the project, is expressed in EC as follows:

X has rank Y for a period E, provided that X has done something at a period that is equal to E.

This means that after an event happened, variable X has rank Y for a period E, which is actually equal to the time following E. In this example let's assume that Tim started working on the project on the 21st of April 2004. Therefore E1 is an event with timing: 21 of April 2004, at which X has rank Y (Tim is working on project) for the period after E, that is after the 21st of April. The events E1, E2 are in the past and their time period will finish when the person is assigned on a different rank. Events are expressed in EC using the following form: (*i*) Time (Event, Time), to express that event Event happened at time Time. (*ii*) Trained(Martha, pipeline system), to express the person Person was trained for activity A and (*iii*) Rank (Person, Time, trained A), to express that the person Person at time Time has been trained for activity A. So, for example, events E1, E2 can be expressed as follows: Trained(Tim, gas system). The *Hold* predicate is used in order to express the time periods of the relationships. The *Holds(p)* predicate states that a relationship associated with P holds for a time period p. Likewise the statement,

Rank(Tim, working on gas before (E2))

can now be written as

Holds(before (E2 rank (Tim working on gas))

which means that "Tim holds the rank of working on gas for a time period which is before E2, or in other words which last before E2 starts."

Additionally, the following predicates state:

- Initiates: represent the start of an event.
- Terminates: represent the termination of an event.
- Broken: represent identical or incompatible relationships.

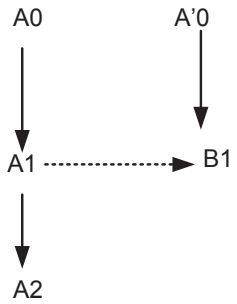
Therefore, Holds(before(e u)) IF Terminates(e u), implies that "An event E holds before time period u, if the event E is terminated at time period u".

IV. Example Application of EC in a Systems Engineering project

Application of the approach is demonstrated with an example from the systems engineering domain. In particular, we elaborate on the approach through an example drawn from the development of a vehicle subsystem. The process commences with the population of the database with the temporal project activities relating to the functional system requirements and their dependencies. Next, a second database of *actors specializations* is created. Finally, the "*event planner*" database is specified that holds the tasks of each actors as scheduled by the project plan. New events can be added in the database during project execution and while monitoring the project's progress. During project execution changes can be instantiated and subsequently evaluated using queries relating to activities or roles in the project schedule. The tool provides the user with the impact and feasibility of each change.

A. Project Specification

Consider the following model of a project specification depicting *activities* A0, A1, A'0, B1 and their dependencies. The diagram is read as follows: Activity A2 should be implemented before A1 and activity A1 should be implemented before A0, and B1 should be implemented before A'0. The dashed line means that Activity A1 can be replaced by activity B1.



B. Actors

Participants in the project, called *actors* are involved in the development of the project by undertaking activities, provided they are trained prior to engaging with the activity. Therefore, the training of actors P1 and P2 could be set as follows:

- Actor P1 is trained for the implementation of A0, A1, A'0, B1 and A2.
- Actor P2 is trained for the implementation of A0, A1, A'0 and B1.

C. Events

The following events E0-E3, that took place during the development of the project are recorded in the database:

- E0 is the event that defines the project start date. Date is 10 Feb 2010.
- E1 is the event stating that actor P1 completes activity A0. Date is 11 Feb 2010.
- E2 is the event stating that actor P1 completes activity A1. Date is 16 Feb 2010.
- E3 is the event stating that actor P1 leaves from project for 4 days. Date is Feb 21 2010.

Training of each actor is recorded in the database in the following manner:

- Rank(P1,(before E0),trained A0)) ^ Rank(P1,(before E0),trained A1)) ^Rank(P1,(before E0),trained A'0)) ^ Rank(P1,(before E0),trained B1)) ^ Rank(P1,(before E0),trained A2)).

which is translated to:

"P1 will be trained for activities, A0,A'0,A1,B1,A2 at time period before E0".

Also, we record:

- Rank(P2,(before E0),trained A0)) ^ Rank(P2,(before E0),trained A1)) ^
- Rank(P2,(before E0),trained A'0)) ^ Rank(P2,(before E0),trained B1)) .

which is translated to:

"P2 will be trained for activities, A0,A'0,A1,B1 at time period before E0".

D. Conflicts Identifications and Resolution

After recording all events related to the project, we can make queries concerning the temporal feasibility of the project. In particular, we can make queries of the following form:

- Rank_of (P,Y,T): to get the rank of actor P at time T. The system will report the actions Y performed at that date.

Moreover, to find the rank of actor P, on the 16th of Feb 2011 we make the following query: "Rank_of((P1,Y,(16 Feb 2010))".The system will search the database for the rank of actor P1 and will return the actions Y based on which the rank of P1 on the specified date is satisfied. Hence the output would be: "implements activity A0". When a project manager is interested to change an activity in the project plan, the following query could be used to get the dependencies of an action A:

- Activities_of(A, Y)

Similarly, in order to inquire about the training of actor P, on activity Y, for time T we can use the following statement:

- Rank(P,T,trained Y):.

Therefore, to check whether a change in activity A'0 and B1 is free from conflicts, the following queries are made:

- Rank(P1,(before E0),trained A'0)),
- Rank(P1,(before E0),trained B1))

In this case the system responds with a "TRUE" clause which stipulates that we can safely assume the change of P1 without any conflict.

E. Examples of Queries

1) Example1

At time period E0, if there is a request for a change in activities A1 to B1, then this will result in no conflict: This however is the best case scenario since the project has just began and none of the activities have been implemented. In this case , the following predicate holds:

Holds (before E0 (P1 implements A0)) FALSE

Which means that the predicate "actor P1 has implemented activity A0 before event E0" does not hold.

2) Example 2

Similarly, if there is request for a change to project activities, on the 21st of Feb, E4, then this will result in a conflict, since no actor would be available to take over the change. Hence,

- Initiates (after E3 and before E4(P1 implements A0)) FALSE
- Initiates (after E3 and before E4(P2 implements A0)) FALSE

To resolve this conflict: Actor P2 can replace actor P1 and implement the required parts. A conflict however, may occur, when the activity A2 needs to be implemented at a time prior to actor's P1 completion of training :Rank(P2,(before E0),trained A2)) FALSE. This means that "Actor P2 is NOT trained for activity A2".

V. CONCLUSIONS AND FUTURE WORK

The work presented herein addresses an important problem in project risk management, namely, the analysis of conflicts and their resolution. The method described elaborates on the pressing need for timely delivery of projects within agreed time limits. The complexity and uncertainty of modern systems however makes this a challenging task. The statistics of project failures alone highlights the complexity of the problem. The method described provides the mechanism for an effective mitigation of project overrun risk that emerge with changes in project requirements, activities and roles using EC. This enables automated inference of project's state given instantiations of events that define changes to schedule, requirements or structure of the project plan Preliminary results from this work are encouraging. However, the full extent of the method will be realized with its thorough validation. On the same vein, project cost is also another burden to project managers that effectively could bring projects to standstill if not managed adequately.

***Abstract*—The influence of software team dynamics on well-organized software development knowledge process could prevent software development organizations from suffering from the knowledge atrophy problem. To explore this, we have studied several team dynamics factors that influence the Knowledge Management Processes (KMP) in Very Small Entities (VSEs) [1]. A survey was conducted in a variety of VSEs and through statistical and qualitative content analysis for the research data, results indicate that small teams, informal team process and structure have an important influence on the level of team dynamics in the software development process**

Keywords-component; software process, knowledge

I. INTRODUCTION *(HEADING 1)*

Software development is a complex activity and depends strongly on human commitment for its implementation. Furthermore since software development projects involve knowledge intensive exchanges and collaborations, the influence of team dynamics on the organization of software development knowledge could assist software companies to become more innovative and efficient. Hence KMP is more effective in an organization if the development teams have a good team culture with ability to share knowledge, collaborative relationship and personal responsible in creating and sharing knowledge [2]. In addition KMP is also reshaped by the attitudes and behaviour of team in order to ensure that both personal and organizational knowledge are always available [3]. The issues of limited resources; especially in cost and people almost always become an issue and can have an impact on the KMP in VSEs [4]. Therefore it is our belief that better understanding the influence of team dynamics in software projects could assist small companies to mitigate VSEs KMP against the knowledge atrophy problem.

II. BACKGROUND

A. Very Small Entities (VSEs)

The definition of "*Small*" and "*Very Small*" companies is challengingly ambiguous, as there is no commonly accepted definition of the terms. In Europe, for instance, 85% of the Information Technology (IT) sector's companies have 1-10 employees. In the context of indigenous Irish software firms 1.9% (10 companies), out of a total of 630 employed more than 100 people whilst 61% of the total employed 10 or fewer, with the average size of indigenous Irish software firms being about 16 employees [5]. The term "*Very Small Entity*" (VSE) had been defined by the ISO/IEC JTC1/SC7 Working Group 24 "*an entity (enterprise, organization, department or project) having up to 25 people*" [6]. Furthermore the issues of limited resources in VSEs always become a constraint in producing a competitive product in today's dynamic software business. [7] states that micro enterprise including VSEs whose have limited resources, particularly in financial and human resources, are practicing unique processes in managing their business. These unique characteristics have influenced VSEs in their business style and companies' process infrastructures compare to large companies' [7]. In addition due to the small number of peoples involved company's activities, most of the management processes are performed through an informal way and less documented.

B. Teams and Knowledge Management

According to [8] software development is a combination of two basic processes; social process and technological process. [9] argues that software production is more effected by social process rather than technological process. People are not only claimed as the greatest asset in a software organization [10] but also critical to software development success [11]. Software is always developed in a group rather on the individual basis [8] and the basis of every software project is a team [11]. [12] argue that the dynamic performance software project which involved many processes is always depends on team especially in quality of communication within team and between teams. They added that the communication can be applied in many ways not only in verbal but also in term of documentation form such as version control, guidelines, reports and many more. Moreover the communication also has a related impact with the team proximity [7]. They add that the increase distance from one team to another could effected the team dynamics in which it will interrupt team communication, coordination, mutual support, effort and cohesion [13]. Therefore in order to be success in KMP, organization must have a solid support from the software development and management team. The development and management team must be able to work together, share the knowledge and able to communication one another effectively. This is because the essence of software development is good relationship, effective communication and

high esteem of teamwork among software development and management team.

C. Teams dynamics

Team dynamics effect how team reacts, behaves or performs and the effects of team dynamics are often very complex [15]. There are various forces could influence team dynamics including nature of the task, the organizational context and team composition. In her dissertation [14] on dynamics of successful software team identified four characteristics of team dynamics; positive, negative, internal and external team dynamics. Positive team dynamics is the positive forces that can lead a team be a high performing successful team. [16] states the present of social relationship in a team could increase team productivity and could enhance social and interpersonal skill [17]. [18] argues that social interaction skill dimension can divide a team member to extrovert or introvert. Extroverts' team member is a people oriented, sociable person, who enjoys interaction with others. Meanwhile introvert person is a type of person who like to work alone and with less social interaction. Meanwhile, [19] believes that the positive mode of leadership (such as well focus directive, well plan and others) in software organization could enhance the positive team dynamics. Negative team dynamics is a negative force that could lead the decrease of team performance and preventing people from contributes with their full potential [14]. According to [10], from management point of view, in software development organization people are required three types of needs that have to be fulfilled and satisfied; social, self-esteem and self-realization needs. Social needs are related to social interaction and communication. The lack or ignorance of these needs will give a negative impact on the organization because people may feel unsecured, have low job satisfaction and decrease their motivation [20]. These will stop them from giving full commitment and cooperate in their work as a team member. Internal team dynamics are referring to the forces that exist within the team itself [14]. Team member also will not cooperate if they do not feel that that are a part of the team [21]. While internal social interaction between people could build team cohesion that will enhance team performance. [29]. External team dynamics are referring to the present of external forces that beyond the team control and could impact the team performance [14]. According to [23] the intrinsic and extrinsic factors in projects may motivate team. Intrinsic factors are the internal factors that consist in the task and team activity itself. Extrinsic factors are external factors that influence team from the outside such as reward and recognition, feedback from the organization and customer, team member pressure and the working environments. Moreover a better working environment also could enhance job satisfaction among team member [24].

III. Study Methodology

For this study we have developed and distributed a survey questionnaire to software VSEs (involved in software product development) in Dublin, Ireland. The survey questionnaires (which followed a GQM approach) were consisted of quantitative and qualitative questions. In order to get a quick replied, we regularly contacted the respondents via email and phone. Each received and completed questionnaire were compiled and analysis. The close-ended questionnaire were grouped according the issue and analyze using a statistical analysis. Meanwhile, on the open ended data, we analyze and categories the data according to the category that this study intends to understand. In summary we adopted the qualitative contents analysis approach in analyzing the open-ended answer [23]. At the end, we have merged the both analysis result in order to gain more understanding and validate the results. We have received a total of 70 filled questionnaires and have conducted 15 interviews for this study, In order to produce details analysis results, we have divided the survey respondents into 2 main group namely the Micro VSE (M) (1-9 employees) and Larger VSE (L) (10-25 employees) [1].

IV. Findings and Discussion

A. Teams dynamics and Structure

In this section, we explore the respondents' opinions on the companies' software development team status and study people working relationship and team environment in the companies.

TABLE I. Team Dynamics

Grp		Clear Roles	Appropriate Size	Diverse Skill Range
M	Mean	3.60	3.20	3.60
L	Mean	3.60	3.40	4.00
Avg	Mean	3.60	3.30	3.80

Table 1 indicates that the respondents' strongly agree that the development teams in their companies have a high level of team dynamics. The results shows that the team have a great working and social relationships, willing to share opinion and idea, having a good interpersonal skill and working closely each other. Further, other results (data not shown here due to lack of space) show that even though VSEs having a small team and a flat structure but staff are clear about their roles, they have enough manpower and skill to do all the development tasks. Meanwhile from the qualitative analysis, indicated that all respondents claimed that their development teams are efficient and effective. They claimed that their development team are having all important criteria such as high skills, motivated, dynamic, socialize and good teamwork, open communication, able to meet project deadline and budget, active in sharing and involved in strategic planning. These points are illustrated in the following extracts from interviews: "*They get on well as a social group and communicate regularly and openly. Also the projects we manage are normally 1 to 2 man projects and hence easily manage in an ad-hoc manner by two people that get on and communicate well." 2) "We practice clear communication and we are active in informal knowledge sharing. Beside that our environment is a family culture and, following specific strategic planning... We also actively use communication tools.*"

Beside that the result on employee turnover rate question has strengthen the above finding regarding team environment in the VSEs. The result in this question shows that the companies do not have any serious problem with the staff turnover. They claimed that the company environment, management and working styles and team relationships that

satisfied the employees have motivated people to stay longer in company. The following interview quotations which best explain the details of this situation: *"We handle many varying projects of different sizes and complexities and have a very loose/informal and friendly atmosphere. This means the work is challenging and rarely gets boring while it also being enjoyable here." "We have 14 employees. Last one who resigned in was 3 years ago. The reason people stay is we operate in relaxed and informal environment.".*

In overall team environment issue give an indicator that all the above parts or processes are much related and depended to the organization team environment, process and culture in the organization

B. Communication

The results from the analysis as shown in table 2 indicate that the companies are practicing regular informal meetings (e.g stand-up meeting, online meeting) and practicing informal formal communication in their business operations. However the results also show that organizations have clear communication process and channel. Moreover the results also indicated that that employee size has influence the formal communication process level in their VSEs daily business operations. This has been shown in comparison results between the L-VSEs and M –VSEs for this issue.

TABLE II. COMMUNICATION PROCESS

Grp	Staff Knowledge	Project Exp. & Lesson Learned	Experience Doc	Progress & Procedure
M	2.20	2.20	2.20	2.20
L	2.80	3.20	2.80	2.60
Avg	2.50	2.70	2.50	2.40

In relation to the communication process in VSEs, the analysis on the open-ended question indicated that 90% of respondents are agreed that in development projects they regularly receive feedback from the project stakeholders. However the result showed that this process been done either in face to face, informal discussion, online communication, informal internal feedback or 'on the job training' process. The interview extracts following illustrates how the process has happened: *"Online communication, informal feedback, internal discussion, and informal communication" "We sit in one office so I talk to them all the time"*

C. Learning and Sharing

All respondents' are agreed that their development team sharing and learning activities are active in the organization. This was shown from the research result which obtained more than 3.00 point in mean. This represents an indicator that in VSEs companies, they always utilize the knowledge and experience within the organization in performing their tasks. This analysis also found out that there are no big differences in term of company size in utilizing existing knowledge and experience in company.

Related to above data the open-ended question indicated that the learning and sharing activities in VSEs are being done either informal self-learning or informal knowledge sharing among the development team. This has shown how the employees enhance their skills which resulted in 90% of the respondents agreed that no formal training were given to the staff in enhancing their skills. The interview extracts below reflect the above points: *"Informally through ad-hoc conversations and some code review", "Ensuring that no single member of staff has any exclusive knowledge by using a mentoring/buddy system."*

D. Documentation Process

Our data indicates that the documentation process has been done in informal process. In details it showed that people's knowledge, experience and activities are not documented properly or have been done personally. This was showed on the total mean score which presents that all respondents do not practice a formal documentation process in their documentation activities. Our data also indicates that number of employees working in the companies give an influence to the documentation formality process in VSEs.

In relation, the qualitative answers have highlighted that only business procedure and technical issues are being documented properly and organized. This could be identified in question on documentation process where 50% of the respondents claimed they felt that they are regularly update their document regularly especially on a specific works and procedures. Moreover the analysis results also showed that small team size issue is an obstacle to VSEs from performs seriously documenting their activities as shown by below interview extracts: *"We documented it electronically, and having an equal decision on it". "We are too small to do proper documentation process"*

The result in this part of analysis demonstrates a pattern and indication that in VSEs documentations process are done in two ways; (1) the specific documentation process which is related to business and technical process and (2) informal documentation process which are inclined toward informal, personal and online documentation.

E. KM Process and Commitment

The questions on this part emphasize particularly on KM process and commitment in the software development projects. The results from the analysis as shown indicate that the respondents were agreed that the level of KM process and commitment in VSEs are very significant. This could be identified with the average mean score for each question is relatively high. Our data indicates that in principle respondents are agreed they are having a clear KM strategy and a good leadership in their organization is important in organization software development knowledge as reflected in the mean score results for these two questions. However our results indicate that activities related to KM within VSEs have not been performed properly. It is indicated in average total mean row that gained less than satisfied agreement level. Our data showed that the management is very supportive in the KMP and peoples in the organization are always communicate, share and having good relationship among them. This issue could be identified in open-ended answer related to which indicates KMP were done informally through sharing activities and informal documentation such as personal or impromptu process as the interview extracts below show: *"We are doing more on*

self-learning and sharing among us", "Regular sharing process, internal sharing and team work".

In addition to the above analysis, the analysis of the knowledge loss issue have indicate that the informal process environment in VSEs helps the companies to mitigate knowledge loss problems from happened. The analysis in this part showed 90% of the respondents claimed that they do not face knowledge loss problem in their company due to the informal process. These interview extracts illustrate this situation: *"Ensuring that no single member of staff has any exclusive knowledge by using a mentoring/buddy system.", "Not a problem since we are using the same technology and process in all our project…. We occasionally sharing and transferring knowledge among each other".*

V. CONCLUSION AND FUTURE WORK

The analysis has indicated that VSEs have a clear KMP in their organization. The results also show the knowledge atrophy problem is not a serious problem in VSEs. From the analysis we found that due to small team size which creates a flat work structure, direct and active communication, close relationship and open environment have created positive team dynamics environments in respondents' organization. These situations also have encouraged software development teams to share and create knowledge in organization. In addition the analysis in the first stage (qualitative) have indicated that management style in VSEs which is more informal and macro, and working style which more autonomous have helps to create team dynamics environments. This situation help VSEs enhance their KMP and mitigate several factors which lead to knowledge atrophy problems. This is shown from the analyses which have indicated that in VSEs knowledge sharing level is high; staff turnover rate is low, high levels of knowledge exploration, continuous guidance from the senior staff and active communication in exchanging idea or knowledge among staff. Meanwhile in second stage data analysis process indicates that 90% from our research respondents believed that informal process environment in their organization has helped the development team to become more dynamic and this situation has assisted them in KMP beside mitigated knowledge atrophy problem from happened. In addition, the second stage data analysis result also shows that 80% of respondents claimed that their software development activities are not affected by the knowledge atrophy problem. They claimed that by, having frequent guidance and mentoring activities, being active in knowledge sharing and proactive coaching could mitigate this problem from occurring.

Quick Acquisition of Topic-based Information/Knowledge from News Site Databases

Hao Han
National Institute of Informatics (NII), Japan
han@nii.ac.jp

***Abstract*—Web news is an important resource of information/knowledge. We can analyze news to observe the difference in various topics (e.g. economy, health, and culture) and trends in the past years. However, the collection of topic-based Web news is considered as a long-period process usually. In this paper, an effective and efficient Web-based knowledge acquisition approach is proposed to extract topic-based Web news full contents from the news site databases directly. This approach is applicable to the general news sites, and the experimental results show that it can extract the topic-based Web information/knowledge from news site databases automatically, quickly and accurately.**

***Index Terms*—Web-Based Tools, Knowledge Acquisition, News, Extraction, Database**

I. Introduction

Nowadays, fresh news contents on a variety of topics are being created and made available on the Web at breathtaking speed. We can analyze them to acquire the desired information/knowledge. For example, if we want to compare the monthly topics of each country in the past years from CNN, we need to collect the CNN news about each country and analyze these news contents to learn the desired information for personal use (*not anti-copyright republication*).

However, the process of the news pages collection consumes much time. Usually, the Web pages crawlers are used to collect the Web pages. They are executed at regular intervals, and the collection process has to last for a long period of time if we want to collect the news pages of long period. We do not think each one of the collected Web pages is usable because there are many non-news Web pages, such as the blog pages, advertisement pages and even similar pages with different URLs. Sometimes, we just want to collect the news with specific topics such as the news on ”soccer” or ”whaling”, and the other collected news are undesired. Furthermore, the news sites are crawled to find as many news pages as possible, but actually, it is difficult to acquire the old news pages because the latest news are shown prior to the old news. Besides, in a news page, there are advertisement, related stories and other undesired parts usually. In order to recognize and extract the parts of news contents from the news pages, the extraction patterns are generated based on the layout of news pages. Web page layout is the style of graphic design in which text or pictures are set out on a Web page. The different news sites use the different news pages layout, and each news site uses more than one layout usually. It is necessary to generate many news contents extraction patterns manually or automatically for each news site. It is a costly work. Moreover, the news sites update the layout of news pages irregularly. If the news sites update the layout of news pages, the corresponding analysis has to be done again. Therefore, it is not easy to extract news contents on the specific topics from news sites quickly, and the current methods of news pages collection and news contents extraction can not work efficiently.

In this paper, we propose an approach to extract the topic-based Web information/knowledge from news site databases quickly. Usually, the news sites provide site-side news search engines for the users. These engines are affiliated to the news sites and can access the news databases of news sites directly. We use these news search engines to search for the news by giving the keywords of specific topics, and extract the page URLs and titles of the matched news from the search result pages automatically. Then we use an efficient extraction algorithm to extract the full contents of the news without Web page layout analysis. We can designate the target news sites, publication dates/periods (e.g. last week, this month, from 2008 to 2010) and topics. A topic is a discrete piece of content that is about a subject, such as a series of countries, sports, companies and etc. Our approach is applicable to the general news sites and can extract a large number of news including the old ones published some years ago. *Our main purpose is to provide a practical and easy-to-use Web-based information/knowledge acquisition tool for news-oriented research*.

The organization of the rest of this paper is as follows. In Section 2 we give the motivation of our research and an overview of the related work. In Section 3, 4 and 5, we explain our topic-based Web information/knowledge extraction approach in detail. We test our approach and give an evaluation in Section 6. Finally, we conclude our approach and give the future work in Section 7.

II. Motivation and Related Work

In order to realize the analysis and comparison of Web news in many major topics, it is necessary to collect the news with specific topics from one or many designated news sites over a long period of time. Some related work has been done on Web news *collection* or *extraction*. For the news pages collection, the Web pages crawlers are often used. They are executed to collect the news pages from news sites and the collection process costs much time. Several collection approaches and systems have been proposed. More and more news sites distribute news by RSS. Generally, news sites classify the

news into different categories and publish them by RSS feeds. However, different news site uses different categories and RSS feeds just comprise the latest news. For example, CNN provides RSS feeds by fields such as science, sports, business and etc, while AllAfrica (allafrica.com) offers RSS feeds grouped by countries/regions. AllInOneNews (www.allinonenews.com) is a news search system based on automatic extraction of search results from search engines [9]. It passes each user query to the existing search engines of news sites, collects their search results for presentation to the user. However, the users of this system can not select the target news sites, and just collect the results from the first search result page. Google News (news.google.com) provides the news search service and distributes the news search results by RSS or Atom. If we use the default or advanced search of Google News, we can select the target news sites, but the publication date/period selection is weak. If we use the archive search, we can not select the target news sites. If we use the search result RSS feeds, only the results from the first search result page can be collected. These methods/systems can not satisfy the flexible and quick collection of news pages very well. Moreover, these methods can not realize the comprehensive analysis or comparison of news because they can not extract the full contents of each news. They can not easily answer the questions like ”which countries had an argument over whaling during the last years and whether the other countries were attracted to discuss it as the arguments went on”.

For the news contents extraction, a number of approaches have been proposed to analyze the layout of the news pages with the purpose of manual or semi-automatic example-based information extraction pattern learning, and to extract the news contents from the general news pages ultimately. Reis et al. gave a calculation of the edit distance between two given trees for the automatic Web news contents extraction [2]. Fukumoto et al. gave the focus on subject shift and presented a method for extracting key paragraphs from documents that discuss the same event [3]. It uses the results of event tracking which starts from a few sample documents and finds all subsequent documents. However, if a news site uses too many different layout in the news pages, the learning procedure costs too much time and the precision becomes low. Zheng et al. presented a news page as a visual block tree and derived a composite visual feature set by extracting a series of visual features, then generated the wrapper for a news site by machine learning [10]. However, it uses manually labeled data for training and the extraction result may be inaccurate if the training set is not large enough. Webstemmer [7] is a Web crawler that automatically extracts main text of a news site without having banners, advertisements and navigation links mixed up. It analyzes the layout of each page in a certain web site and figures out where the main text is located. All the analysis can be done automatically with little human intervention. However, this approach runs slowly at contents parsing and extraction, and sometimes news titles are missing. TSReC [6] provides a hybrid method for news contents extraction. It uses tag sequence and tree matching to detect the parts of news contents from a target news site. However, for these methods, if the news sites change the layout of news pages, the analysis of layout or tag sequence has to be done again. As the layout-independent extraction approaches, TidyRead (www.tidyread.com) and Readability (lab.arc90.com/experiments/readability) render Web pages with better readability as an-easy-to-read manner by extracting the context text and removing the cluttered materials. They run as plug-in or bookmarklet of Web browser. However, the extraction result is a part of Web page containing the HTML tags. It also contains some other non-news elements such as the related links. Wang et al. proposed a wrapper to realize the news extraction by using a very small number of training pages based on machine learning processes from news sites [8]. The algorithm is based on the calculation of the rectangle sizes and word numbers of news title and contents. However, these approaches still need to set the values of some parameters manually, and could not be proved to extract the news successfully or automatically if news sites update the page layouts. Full-Text RSS (echodittolabs.org/fulltextrss) only returns the news contents when the supplied RSS has a summary or description of some kind.

These news contents extraction methods are still not widely used, mostly because of the need for high human intervention or maintenance, and the low quality of the extraction results. Most of them have to analyze the news pages from a news site before they extract the news contents from this news site. If we select the different target news sites, topics and publication dates, the analysis of layout needs to be done again. It is costly and inefficient. Compared to these developed work, we use the news search engines affiliated to the news sites instead of the often used Web crawlers. We can get a large number of news from the news site databases, not only the latest news but also the old news. The target news sites, topics and publication dates are selective. Furthermore, we do not need to delete the non-news pages or other undesired news pages from the search results because all the news extracted from search result pages satisfy our designated topics. Meanwhile, we propose an algorithm special for the news contents extraction. It is applicable to the general news pages, and we do not need to analyze different kinds of news pages to generate the corresponding extraction patterns for each news site. The full contents of news are quickly extracted from the matched news pages for the further analysis.

III. Overview

Our approach is made up of two parts mainly as shown in Fig. 1: news pages collection and news full contents extraction. Firstly, we collect the topic-based news pages. We create a submitting emulator to emulate the submitting process of search engine of the target news site. We get the search keywords of a specific topic and send them to the emulator one by one, then extract news titles and URLs of news pages from the continuous search result pages. Secondly, we extract the news contents from the news pages. We propose an extraction

algorithm special for news pages, which can extract the news contents from a news page only by using the news title.

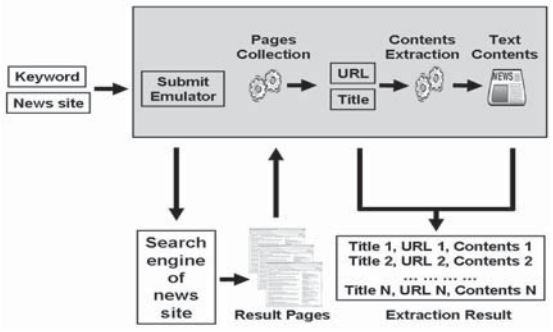

Fig. 1. Overview of our system

IV. News Pages Collection

We collect news pages from news site search engines. Although many Web sites, such as Amazon and YouTube, open their search engine services by Web service APIs, most of the news sites, such as CNN and BBC, do not provide Web services for their news search engines. We have to extract the partial information, such as news titles, news page URLs and publication dates, from the news search result pages. As shown in Fig. 2, we generate a submitting emulator for designated news site, and send the search keywords to the submitting emulator to receive the search result pages. Then, we analyze the search result page to extract the news titles and URLs.

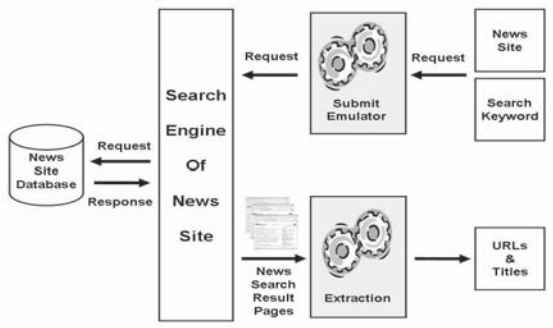

Fig. 2. Overview of news pages collection

A. Submitting Emulator

Usually, in a news Web site, there is a site-side search engine used to get the requests from users and return the search result pages. The users enter the query keywords into a form-input field by keyboard and click the submit button by mouse to send the query. For the request submitting, there are POST method and GET method, and some news Web sites use the encrypted codes or randomly generated codes. In order to get the search result pages from all kinds of news sites automatically, we use HtmlUnit (htmlunit.sourceforge.net) to emulate the submitting operation instead of URL templating mechanism.

We need to get the start Web page which comprises the form-input field and submit button of search engine. Usually, this start Web page is the top page of news site or a search result page of news site. Then we analyze the HTML document of this Web page to find the <form> nodes. If a form comprises *a text input field* and *a button next to this text input field*, and *the server-side form handler of this form is within this news site*, we think it is a possible form which includes the necessary form-input field and submit button. If we find more than one possible form in this Web page, we choose the first one as our final selection because the target form is at the top side of Web page usually.

We generate a submitting emulator and send the search keyword to it. Submitting emulator uses HtmlUnit to emulate the submitting process (input the search keyword into text field and click the button to complete the actual submit). Finally, we get the response page (search result page) from submitting emulator. All the processes of submitting emulator generation in our approach are completed *automatically* after the start Web page is given.

B. News Title and News Page URL Extraction

After we get the search result page, we need to extract the news titles and news page URLs. There are links to the advertisement pages, video pages, external non-news pages and other irrelevant information besides the page links to matched news. Fortunately, there are some similar features in the news search result pages of most news sites, which can be used to extract the news titles and links to the news pages.

- Each search result set contains the similar information at the similar position such as news page link, news title, headline and publication date.
- The news title is contained inside the news page link as text value.
- Matched news are listed in a column and spread over multi-pages.
- All the news search result pages from a news site search engine have the same Web page layout.

We extract all the link nodes from the HTML document of search result page, and find out the news page link nodes. Through our analysis of search result pages of many news sites, we find that the news page link node has some common features in its text and path (XPath expression). We calculate the possibility value of link node by the following steps. Usually, a larger possibility value represents the corresponding link node is more possible to be a news page link node.

1) We split the text value of link node into word list WL using whitespace as the delimiter, and get the length of WL as L_1 ($L_1 \geq 1$).
2) We calculate the occurrence time of search keyword in WL as L_2 ($L_2 \geq 0$).
3) We get the path of link node including the ID and class value. We calculate the occurrence time of "news" and "search" and "result" in path respectively. We count these three values up to get the sum value L_3 ($L_3 \geq 0$).
4) We calculate the possibility value of each link as P by using the following formula.

$$P = L_1 \times (L_2 + \alpha) \times (L_3 + \beta) \quad (1)$$

where, $\alpha = 0$ if $L_2 > 0$, and $\alpha = 1$ if $L_2 = 0$. Similarly, $\beta = 0$ if $L_3 > 0$, and $\beta = 1$ if $L_3 = 0$. We can not make certain that the search keyword must occur in the news title because the search range contains not only the news title but also the news contents, which is not visibile in the search result page. Also, the value of L_3 may be 0 in many news sites.We use α and β to avoid the possible occurrence of *P=0*. They work well and do not bring the negatives to the actual extraction in our experiments.

In some news search result pages, the link node with the largest possibility value is not a link node of the news page always (e.g. a link to contextual advertising or blog). Usually, the news page links are listed in the similar structures (XPath) and not mixed with other non-news links. We use the following steps to detect the news page link nodes range and find out a news page link node.

1) We count up the possibility value P_N of all the link nodes, and get the root mean square RP as a threshold.

$$RP = \sqrt{\frac{\sum P_N^2}{|N|}} \quad (2)$$

where, $|N|$ is the sum of link nodes.

2) For each Node N, we calculate P_N as follows.

$$P_N = \begin{cases} P_N & \text{(N is a link node)} \\ \sum_{n \in Child_N} P_n & (P_n > \text{RP}) \end{cases} \quad (3)$$

where, $Child_N$ is a set of child nodes of the node N. Fig. 3 shows an example of calculation of P.

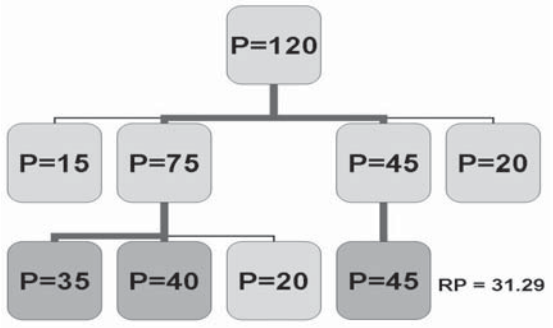

Fig. 3. Calculation of P

3) We select the child node whose value is the largest among the sibling nodes from root node to leaf nodes as shown in Fig. 4.

We think the final selected child node is the link node of a news page, and use the path of this node to extract the list of nodes with the similar paths (like WIKE [5]). Each node of list represents a news page link node, and the text value from each node is the news title.

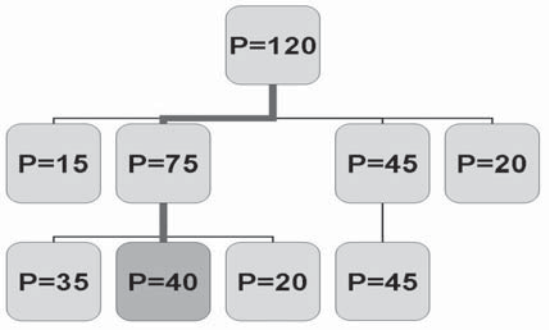

Fig. 4. Selection (largest P)

If the paths of these nodes show that these nodes are listed in a column, we think they are the final extraction results and represent the news page links because most news sites show the search results in a column, not in a row. Otherwise, we think the search result page does not comprise the matched news and shows the message like ”No Results Found” because the search engine does not find the corresponding news about the search keyword in news database.

The news search results are spread over multi-pages and we need to extract the page number links for our continuous query and extraction. The extraction of these links has to satisfy the following rules.

1) The text values of links are a series of numbers such as 1,2,3....
2) The *href* attribute values of links have the similar length.
3) The links are listed in a row.

We use the paths of news page link nodes to extract the news page link nodes directly from the second result page. If we search for the news for many search keywords continually in a news site, we use these paths to extract the news page links and page number links directly.

C. Publication Date Extraction

The publication date is necessary if we collect the news of a specific period. For example, we need to extract the news of baseball of the last 5 years if we want to find out which team was the annual focus of attention in the last 5 years.

Different news sites choose the different formats of date information such as ”March 7, 2011”, ”Mar. 7, 11” and ”2011-3-7”. Table I shows the most used format patterns of date information. We use these patterns to find the publication date in search results. Usually, a news site displays the publication date at the same position in a search result and uses a same pattern for all the publication dates in all search results. After we find a publication date in a search result, we can use the similar paths and same pattern to extract other news publication dates from search results easily.

V. News Full Contents Extraction

We extract the full contents of news from our collected news pages. The news pages from different news sites use the different page layout and news sites update their news page

TABLE I
PUBLICATION DATE FORMAT PATTERN

Pattern	Component	Format	Example
YY	Year	2-digit number	11
YYYY	Year	4-digit number	2011
MMM	Month	Text	Mar, March
MM	Month	Number	3, 03
DD	Day	Number	7, 07
Mark	Delimiter	Character	',' '-' '/' ' '

layout irregularly. We propose our news contents extraction algorithm, which is independent of the layout of news page and applicable to the general news pages. We detect the position of a news title in the news page and extract the body of news (paragraphs of news contents).

The first process detects position of a news title in the obtained news page. The news title is a piece of important information for the recognition of the news contents from the full text of news page. If we correctly locate the position of the title in a news page, the position of news contents text would be found easily because the contents text is a list of paragraphs closely preceded by the title usually. In addition, for a news, the contents describe the same topic of news title in detail, and the words constituting the title would occur in the news contents frequently usually.

The second process detects a part of the news body and extracts the whole body. Since body of a news is usually preceded by its title, the process tries to find the news body in some "contents ranges" at first, and, if it cannot find out the body in the range, it tries to find the body in a "reserve range". "Contents range" and "reserve range" are parts which might include the news body. We gave a detailed description of extraction algorithm in [4].

VI. EVALUATION

In this section, we give the experiments to test our algorithms and analyze the experimental results to evaluate our approach. We use the news sites listed in Table II as our test bed. These news sites are the popular on-line news publishers, including the global and domestic news sites.

A. Experiment 1

We selected the countries/regions and their leaders as our test topics. There are 242 countries/regions in the world and most of them have the leaders [1]. We used these country/region names and leader names as our search keywords. We collected the news page URLs and titles from the 10 (No.1-No.10, if the total number of pages is less than 10, we got them all) result pages of each keyword. As shown in Table II, *Page Collection* is the average execution time of extracting the news page URLs and titles from *one result page* (including the submitting emulation process), and *Contents Extraction* is the average execution time of extracting the news contents from *one news page*. The submitting emulation of two news sites (Washington Post and Xinhuanet) failed, and the corresponding *Contents Extraction* values are calculated by extracting news contents from manually collected/saved result pages. We selected 500 news page URLs randomly and checked them one by one manually, and found that 17 news pages could not be obtained (the server responded the message like "page not found").

TABLE II
LIST OF NEWS SITES AND EXECUTION TIME

Country/Region	News Site	Page Collection (second)	Contents Extraction (millisecond)
United States	CNN	14.3	6.02
	New York Times	4.6	0.63
	Washington Post	×	(*6.62*)
United Kingdom	BBC	3.6	3.19
Africa	All Africa	7.3	2.98
China	Xinhuanet	×	(*2.94*)
France	France 24	8.6	3.67
Japan	Mainichi Daily News	9.3	2.40
South Korea	Chosun Ilbo	6.6	0.52

B. Experiment 2 (precision $\simeq$ 97.0%)

We sent the keywords used in Experiment 1 to submitting emulator one by one, and extracted 96,095 news titles and page URLs of matched news (published from January 1, 2003 to December 31, 2007) from news database of CNN. Our computer (CPU: Intel Pentium M 1.30GHz, Memory: 1.0GB RAM, Network: 54.0Mbps Wireless) uses about 20 hours to complete this extraction process. We selected 200 news page URLs randomly and checked them one by one manually. The experiment results are listed in Table III. We found that 2 news pages could not be obtained as the reasons described in Experiment 1. Among the rest 198 news pages, the news article contents of 192 news pages are extracted correctly. In the 6 extraction failures, some parts of news article contents are not extracted.

TABLE III
EXTRACTION RESULT OF EXPERIMENT 2

Sum	Extracted	Success	Failure	Precision
200	198	192	6	96%

C. Experiment 3 (precision $\simeq$ 97.4%)

We have crawled and extracted more than 1.8 million news contents from 38 famous news sites [4] since 2007. We select 2500 news articles randomly and check them one by one manually. The experiment result is listed in Table IV.

TABLE IV
EXTRACTION RESULT OF EXPERIMENT 3

Sum	Success	Failure	Precision
2500	2434	66	97.4%

D. Analysis and Evaluation

We use the first and second experiments to test our submitting emulator and news page collection algorithm. It proves that our approach can extract the news titles and URLs of news pages of a long period from news site databases easily and

quickly. Our approach is applicable to the general news site search engines and does not need the methods like machine learning or extraction pattern matching, which cost much time when news sites change the layout of search result pages. However, some news sites use the external JavaScript files comprising the complicated JavaScript functions to realize the request submitting, or even the minor syntax errors occur in Web pages where the search keywords are inputted. Although the most of the current Web browsers, such as Firefox and Internet Explorer, can run smoothly on these Web pages, our submitting emulator still can not emulate this kind of submitting processes. We think it is a bug of HtmlUnit and wish the new version would solve this problem in the future. Furthermore, the emulation processes of some news sites run slowly. For example, the emulation of submitting search keyword to CNN news search engine costs about 10 seconds. Moreover, some old news pages are not obtained though their URLs and news titles are shown in news search result pages.

We use the second and third experiments to test our news full contents extraction algorithm. We use a large number of news to test our algorithm and the experimental results prove that our extraction algorithm is highly accurate over a long period of time. Although the news sites change the layout of news pages irregularly, our extraction method works well and the precision of extraction is over 97%. However, in some news pages, a paragraph, usually the outline of news, shows in different style compared to other paragraphs. This kind of paragraph looks like a non-news part such as an advertisement in text format, and is omitted in the extraction. Moreover, some news contents are too short to recognize from the news pages. For example, a news flash about baseball game result, which contains just a short paragraph of ten words, maybe can not be extracted correctly.

Compared with other developed extraction systems, our extraction approach has the following strong points.

1) Our extraction system is constructed easily, even for the users who know little about the information extraction technologies. The extraction processes run automatically, such as submitting emulator generation, news pages collection and news contents extraction. It needs little maintenance during the long period extraction. We do not need to analyze the layout of search result pages and news pages of news sites since our extraction algorithm is independent of the layout of Web pages. It does not need to reconfigure extraction even though the news sites change the layout of news pages.
2) Our extraction system supports the designation of news collection/extraction range, such as the target news site, news topic and publication date. By analysis of extracted news contents, we can compare the viewpoint of a topic among different news sites, see monthly/yearly variation of a topic, observe co-occurrence of one or two country names, and find other useful information/knowledge.
3) Our extraction system runs quickly because of simple and efficient algorithms. For the extraction of a large number of news, a simple algorithm of low computational complexity saves a considerable amount of time. For example, the contents extraction from a CNN news page costs 6.02 milliseconds averagely (excluding reading news pages from news sites and saving the extraction results into local hard disk), which is more efficient than other developed methods.

VII. Conclusion

In this paper, we have presented an effective and efficient approach to realize the quick and automatic extraction of topic-based Web information/knowledge from news site databases by using the site-side search engines. We proposed an algorithm to extract the news titles and news page URLs from search result pages. We also proposed an algorithm to extract the news full contents from news pages. Our extraction methods are applicable to the general news sites. All the processes of extraction are completed automatically. Our experimental results on several news sites show that our extraction system works well and the proposed approach is very promising.

As future work, we will modify our algorithm to improve the accuracy rate even further, and observe difference in various topics among countries/regions to discover useful information and knowledge from news sites. Moreover, we will extend our approach to different kinds of information/knowledge sites and construct the corresponding analysis system.

Using Contextual Information to Improve Awareness in Software Development

Bruno Antunes*, Joel Cordeiro, Pedro Costa and Paulo Gomes
Centre for Informatics and Systems of the University of Coimbra
Coimbra, Portugal
{bema,jfac,pacosta,pgomes}@dei.uc.pt

Abstract

The use of contextual information is said to improve awareness in software development. But the context of a software developer is something hard to define and capture, as it represents a complex network of elements across different dimensions, that is not limited to the work developed on an IDE. We propose a software developer context model composed of four layers: personal, project, organization and domain. We describe this context model at the personal layer, present a prototype and discuss the results of an experiment conducted with a group of developers. The results show that developers consider the use of contextual information relevant to improve information retrieval, ranking and filtering, but usability plays an important role on how these improvements are perceived.

1. Introduction

The interest in the many roles of context comes from different fields such as literature, philosophy, linguistics and computer science, with each field proposing its own view of context [5]. The term context typically refers to the set of circumstances and facts that surround the center of interest, providing additional information and increasing understanding. The context-aware computing concept was first introduced by Schilit and Theimer [7], with further definitions given by Brown et al. [1] and Dey et al. [3]. In software development, the context of a developer can be viewed as a rich and complex network of elements across different dimensions that are not limited to the work developed on an IDE (Integrated Development Environment). During their work, software developers need to cope with a large amount of contextual information that is typically not captured and processed in order to enrich their work environment.

We propose a software developer context model that takes into account all the dimensions that characterize the work environment of the developer, which is described in section 2. These dimensions can be represented in a model with four layers: personal, project, organization and domain. In section 3, we present a prototype that deals with the first layer of this model, creating and maintaining the developer context model at the personal layer. The contextual information is then used to rank, filter and suggest relevant knowledge to the developer. This prototype was submitted to an experiment, using a group of developers, discussed in secton 4. From the analysis of the results we conclude that the use of contextual information is considered relevant to improve the retrieval, ranking and filtering of relevant information to the developer. But, this study also shows that usability issues may influence the way these improvements are perceived and assimilated by software developers. An overview of related work is given in section 5. Finally, section 6 concludes the work.

2. Developer Context Model

The developer context model we envision is based on a layered model made up of four layers: *personal layer*, *project layer*, *organization layer* and *domain layer*. Each one of these layers focus on different dimensions of the environment where a typical developer works. In this paper, we are focused on the personal layer.

The *personal layer* represents the context of the work a developer has at hands at any point in time, which can be defined as one or more tasks. In order to accomplish these tasks, the developer has to deal with various kinds of resources at the same time, such as source code files, specification documents, bug reports, etc. At this layer, the developer context model comprises a set of artifacts that may be relevant for the task the developer is currently executing. Associated to each artifact is a Degree of Interest (DOI), a concept introduced in [4], that represents the weight of that resource in the developer context model. The context model is captured and maintained through the analysis of the interactions of the developer with the artifacts manipulated in the IDE. An artifact affected by one of these interactions is

*Supported by FCT scholarship grant SFRH/BD/43336/2008.

included in the context model, or gets its DOI updated in case it is already present. We monitor the actions of create, open, edit, focus, close and remove, and each one results in a variation of the DOI value of the affected resource. The artifacts that are related with the affected artifact through "implements", "extends" or "uses" relations, are also added to the context model. As time passes, the DOI values are decreased. The information stored in the context model at the personal layer is used to rank, highlight and filter information taking into account the context of the developer. The way this is accomplished is explained in section 3, where we describe the prototype developed. The *project layer* focuses on the context of the project, or projects, in which the developer is involved. A software development project is an aggregation of a team, a set of resources and a combination of explicit and implicit knowledge that keeps the project running. The project layer represents the people, resources and tasks, as well as their relations, of the software development projects where the developer is included. The *organization layer* takes into account the organization context to which the developer belongs. Similarly to a project, an organization is made up of people, resources and their relations, but in a much more complex network. The *domain layer* takes into account the knowledge domain, or domains, in which the developer works. This layer goes beyond the project and organization levels and includes a set of knowledge sources that stand out of these spheres.

3. Prototype

We have developed a prototype that makes use of the developer context model to improve developer awareness. Here we will be focusing the personal layer of the context model, thus the components that support the remaining layers will not be described in detail. The prototype works in a client/server architecture. The client application is an *Eclipse* plug-in that manages the contextual information of the personal layer and integrates contextual information from other layers directly into the IDE. The server is used for mining and storing contextual information of the project layer, which is then made available for the client applications. The use of contextual information to improve information retrieval directly in the IDE, where developers perform most of their work, increases awareness and reduces the effort put on finding information that would be hidden and dispersed otherwise.

The *browsing* functionality is provided by allowing the developer to navigate in a graph (see section 1 of figure 1), where nodes represent resources (source code, documents, tasks and developers) and edges represent relations between those resources. When the developer expands a node the system shows all the information related with that node. This information includes the entities that are statically related with the node, for instance all the classes that implement an interface, as well as the contextual information that is retrieved from the server. This way, the developer can easily gather information about what artifacts are likely to be related with that artifact, what tasks affected that artifact in the past, and what developers may be of help if extra information is needed. This navigation allows the developer to explore the source code using its static structure while obtaining contextual information about the entities being explored. While navigating in the graph, the context model is taken into account to give more relevance to resources that are closer to the context of the developer. The nodes that are more relevant to the developer stand out from the remaining, because their background color is more intense. The related entities retrieved from the server are ranked and filtered using the developer context model, with only the top five entities being shown in the graph. Also, the weight of the relation is reflected in the width of the edge that bonds the node and a related entity. Stronger bonds have a bigger width, showing the developer that a specific entity may be more relevant than others. The *search* functionality allows the developer to easily search the server repository for artifacts, tasks, and resources, through an integrated and easily accessible interface (see section 2 of figure 1). The search results can be organized by type, package and package hierarchy. Because of the different visualization options available, the search result foreground color is used to represent its relevance, starting with black for top results and fading to light grey as relevance drops. Any search result can be open in the graph, allowing the developer to situate it in the source code structure and understand how does it relate with other entities. The context model is used to rank search results taking into account the query score and the proximity to the developer context. The *suggestion* functionality is used to proactively suggest relevant information to the

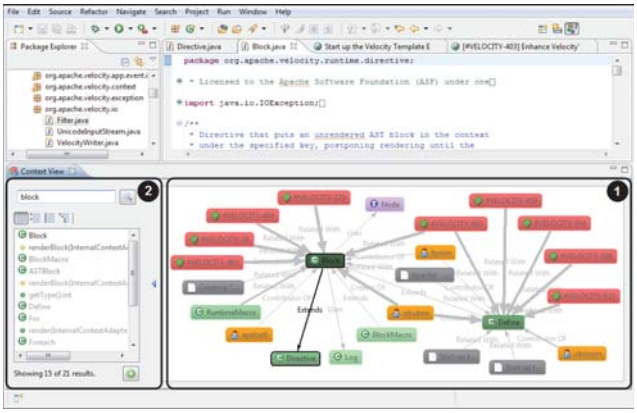

Figure 1. A screenshot of the Eclipse plug-in.

developer. When the developer opens or gives focus to an artifact, the graph automatically opens and expands that artifact, providing suggestions and hints about which entities may be relevant in that context (see section 1 of figure 1). This all happens without the need of the developer to explicitly search for that information. Also, when the developer creates a new entity, the system automatically searches for entities that have a similar name to the one being created, making them accessible through the graph.

4. Experimentation

We have created an experiment to evaluate the acceptance of our prototype among developers. The experiment was executed by a team of 6 developers working in a start-up company that operates in the area of information technology and services. The experience of the developers with *Java* is very varied, ranging from 2 years up to 8, and they have been using *Eclipse* for different periods of time, ranging from 1 year up to 5. We wanted to create a scenario that would encourage the developers to use the prototype, with a complexity that allowed the experiment to take about one hour. We have decided to use a small sized open-source project, completely unknown to all the developers, on which the developers would perform a set of tasks. The project selected was *Apache Velocity*, a Java based template engine, and we asked developers to perform 3 tasks that required them to explore and change the project's source code.

The experimentation environment comprised an *Eclipse* instance running our plug-in and set up with a workspace containing the source code of the selected project. The contextual information extracted in the project layer of the context model (see section 2) was available from a central server. In this server we have indexed the artifacts, tasks and resources provided by the project management tools used in the project, such as the Version Control System (*Subversion*), the Issue Tracking System (*Jira*) and the Collaborative System (*Wiki*). By the end of the experimentation, developers were asked to fill a questionnaire. The objective of the questionnaire was to perceive the opinion of the developers on the relevance and usability of the prototype, as well as the relevance they attach to specific features. We also wanted to know what they liked the most, and the least, and what suggestions they could give us to improve the prototype.

Concerning relevance and usability, the overall results show that developers have considered the application relevant, but usability has been rated as almost neutral (see section Relevance and Usability Questions of table 1). When we analyze the different components of the prototype (search, browsing and suggestion) individually, results are more or less homogeneous, with all of them considered relevant, but having lower scores on usability. From these results we conclude that the application is considered relevant, but usability is a concern that must be addressed in order to improve the experience of the developers.

Table 1. Questionnaire results, ranging from 1 (Very Irrelevant) to 5 (Very Relevant).

RELEVANCE AND USABILITY QUESTIONS	**AVG**	**SD**
Overall, how would you rate the relevance of the application?	3.83	0.48
Overall, how would you rate the usability of the application?	3.50	0.87
How would you rate the relevance of the search component?	4.50	0.87
How would you rate the usability of the search component?	3.67	1.02
How would you rate the relevance of the browsing component?	4.17	0.86
How would you rate the usability of the browsing component?	3.00	0.58
How would you rate the relevance of the suggestion component?	4.17	0.48
How would you rate the usability of the suggestion component?	3.67	1.02
SEARCH FEATURES	**AVG**	**SD**
Sorting of search results based on their relevance to the context of the developer.	4.50	0.87
Coloring of search results based on their relevance.	3.33	1.00
Clustering of search results based on category.	4.00	0.58
Clustering of search results based on package.	3.33	1.02
Clustering of search results based on package hierarchy.	3.67	0.77
BROWSING FEATURES	**AVG**	**SD**
Information about related resources.	4.33	1.02
Information about related developers.	3.00	1.15
Information about related tasks.	3.17	0.86
Color depth of nodes based on their relevance for the developer context.	3.17	1.40
Width of relations based on the relevance of the link.	3.33	0.77
Information filtering by relation type.	3.83	0.48
SUGGESTION FEATURES	**AVG**	**SD**
Proactive suggestion of relevant resources when an artifact is activated.	4.00	0.58
Proactive suggestion of relevant resources when a new artifact is created.	4.00	1.15

The main features provided by the search component were rated as shown in section Search Features of table 1. The use of the context model of the developer to sort the search results was considered very relevant, which shows that developers consider the use of contextual information as being important to improve the process of finding the information they need. The features related with search result clustering were generally rated with close to neutral values, excepting the one based on the package hierarchy, which was considered more relevant.

In relation to the browsing features (see section Browsing Features of table 1), the availability of information about related resources was considered relevant, while information about related developers and tasks was rated as neutral. This can be explained by the fact that information about developers and tasks was not important in the context of this experimentation. We believe that in the context of a real software development project, this information can be valuable, which should be confirmed in future field tests. The use of node colors and relation widths to highlight information based on the developer context model was considered almost neutral, which show that these features must be improved. Although we have implemented these techniques to reduce the information overload, the way they were experi-

enced did not achieve the result we have expected. Finally, some relevance was given to the information filtering features, showing again that the overload of information is a real issue that must be carefully addressed.

The two main features of the suggestion component were rated as relevant (see section Suggestion Features of table 1). This tendency shows that suggestion is a powerful way of retrieving relevant information to the developer, and this is the kind of feature where context plays a central role. The contextual information can be used to determine when to suggested this information and to help filter the most relevant information in that specific moment.

When asked to say what they liked most about the application, many developers referred search as a great feature, because it is an efficient way to quickly find information from different sources. Along with search, the suggestion of relevant information was viewed as important to developers. Other aspects noted as positive were the novelty of the approach and the use of a graph structure, which was considered an interesting way of exploring the source code and related information. On the other hand, the usability of the browsing component was among the things the developers liked the least about the application. Finally, several suggestions for improvements were collected, most of them centered on the browsing and suggestion features. The developers referred the graph layout and overload of information as big issues that must be addressed. To overcome this limitations they suggested that relevance of related resources should be reflected using other techniques, such as their distance to the artifact and the size of the node itself. The overload of information should be addressed with better context-based filtering options.

5. Related Work

Following the line of task management and recovery, Kersten et al. [4] and Parnin et al. [6] propose approaches for capturing the context relevant for a task from the programmer's interactions with an IDE. The focus of these works is the task and the resources present in the IDE that are more relevant for the fulfillment of that task. Our approach aims to define a context model that goes beyond the IDE and explores the knowledge provided by the different systems that support the software development process. Based on the assumption that social dependencies exist between developers implementing modules that are technically dependent, Cleidson Souza et al. created Ariadne [2], a plug-in for the Eclipse IDE that exposes those dependencies through various graph-based views. While the focus here is on finding relationships between code and developers, that are then used to improve awareness, our aim is to use a continuously updated context model of the developer that is used to rank, elicit and filter information through search, browsing and suggestion.

6. Conclusions

We have presented our approach to a software developer context model. The context model is based on a layered structure, taking into account four main dimensions of the work environment of a developer: personal, project, organization and domain. A prototype focusing the personal layer was presented, along with an experiment with a group of developers. The results confirmed our belief that context have a central role when it comes to retrieve relevant information to developers. Furthermore, we have been alerted to the fact that usability may be a serious obstacle to the success of our approach. As future work we plan to take into account the results of the study to improve the prototype.

Abstract—**This paper introduces and evaluates a novel Web service interface annotation and matching scheme designed for processing large sets of Web service interface descriptions. The matching scheme relies on a set of rules, which exploit the structural relationships encoded in an automatically learned ontology to discover matching interface elements. The proposed scheme is evaluated on a Web services interface corpus consisting of WSDL descriptions. The experimental results show that the proposed matching scheme can be used for bootstrapping large-scale Web service interface annotation.**

Keywords-Web service annotation; schema matching; XSD; WSDL

I. INTRODUCTION

Lack of good benchmarks has hindered proper evaluation of proposed Web service discovery and composition solutions in practical settings where many Web services are available. To overcome this shortage, there has been recently some activities [3][4][5] in the field for tackling the analysis of essential properties of web services and their networks with the aim to provide feedback to web services discovery and composition problems from the search space topology perspective. Since semantic annotations enable construction of dataflow- and workflow-based networks, which are needed for analysis, there is a need for a fully automatic cost-effective web service annotation mechanism. Previous works in web service analysis suffer from following drawbacks: a) due to lack of semantic annotations in the vast majority of existing web services only pure syntactic matching has been applied [3]; b) only small sets of semantically annotated web services have been examined [5] due to the high costs related to labour-intensive manual annotation of web services [1]; and c) they rely on the assumption that a supporting reference ontology is provided [4].

In this paper, we report work in progress in developing and evaluating a semi-automatic cost-effective semantic annotation approach, which combines a previously proposed ontology learning method [6] and a cost-effective semantic annotation method [1], for bootstrapping analysis of large repositories of web services, which do not include semantic annotations. The ultimate goal of the reported work is to provide means for bootstrapping large scale annotation of Web services to enable further advances in the field relying on these annotations.

We evaluate the approach both qualitatively and quantitatively on our corpus of Web service interface descriptions in two stages. First we manually create a so called *golden* ontology and corresponding annotation heuristics, which will be used then for automated annotation as suggested in [1]. Then we automatically learn a reference ontology and corresponding annotation heuristics by using the scheme proposed in this paper for the same corpus as in the preceding stage and assess the quality of completely automatically generated annotations with respect to manually created ones. The evaluation confirms that the proposed matching scheme can be used for bootstrapping annotation of large scale of Web service interfaces in a semi-automatic way with some certain error margins.

The rest of this paper is organized as follows. In Section 2 we outline our Web service annotation and matching scheme. In Section 3, we discuss our approach to evaluate the quality and quantity of applied annotations. Experimental results of applying the annotations and matching scheme are presented in Section 4. Finally, Section 5 reviews related work, while conclusions and future work are presented in Section 6.

II. WEB SERVICE ANNOTATION AND MATCHING SCHEME

Different Web service annotation and matching schemes have been adopted to deal with integration of heterogeneous information sources. We employ our ontology learning approach [6] to first generate a reference ontology from our collection [1] of Web service corpus (ca 15000 WSDL documents collected from various repositories in the Web) and then utilize the generated reference ontology to annotate the services. In the reference ontology, instances are referring to the *terms* while classes refer to conceptual representation of the underlying *terms*. In this work, *term* refers to an XML schema basic element name or a message part name in the

[1]Available online at : http://www.soatrader.com/web-services

web WSDL document and our goal is to annotate the identified *terms*. The extracted *terms* from the WSDL documents in our collection builds up the dataset which is considered for ontology learning, annotation and matching. Our ontology learning mechanism [6] exploits frequently observed naming patterns in the given dataset and relies on morphological analysis to identify concepts and relations between and generate an ontology accordingly. In the generated ontology, instances refer to the *terms* and the conceptual classes are interrelated further using ontological properties namely: *hasProperty*, *isSynonymOf* and *isSimilarTo*. While *isSynonymOf* property conveys that the concepts on the both side of relation are lexically synonyms, the *isSimilarTo* relation expresses a weaker degree of lexical similarity between two concepts.

We employ the heuristic-based annotation mechanism reported by Küngas and Dumas [1] to annotate Web services. In this mechanism annotation heuristics are represented as rules in the following form: *entity_reference* ← *synset* (e.g. *Password* ← *{password, pwd, strPassword, authpassword*, *pass*}). The meaning of such a rule is that an XML schema element matched by any element in the *synset* is mapped to the *entity reference* (in our case a concept identifier in the automatically constructed ontology) on the left-hand side of the rule. A *synset*, or a synonym ring, is a group of labels (i.e. *terms*) that are considered semantically equivalent. We construct *synsets* from the labels of particular instances in an ontology. Thus according to the heuristic rule example – if *Password* is a concept identifier, then *password*, *pwd*, *strPassword*, *authpassword* and *pass* are labels of instances in the generated reference ontology (i.e. *terms*).

By utilizing the generated ontology and annotating respective Web service elements, we promote the process of correlating Web service inputs and outputs from pure syntactic level to ontological instance matching level. The annotation process simply annotates those extracted schema element names/ WSDL message part names (*terms*) with their respective concepts in the generated ontology. In order to match inputs and outputs of Web services through annotated elements, we rely on a set of matching rules. Here matching refers to the process of finding relationship or correspondence between instances (*terms*) in an ontology through utilization of any of following rules adopted from rules proposed by[11][12]. By definition two instances are matched if and only if one of the following matching rules is true:

Rule-1: They both belong to a same concept (e.g. {*loc, location1*} isInstanceOf *Location*).

Rule-2: They belong to lexically synonym or similar concepts (e.g. (*loc* isInstanceOf *Location*), and (*place* isInstanceOf *Place*) where *Place* isSynonymOf *Location* .

Rule-3: One of the instances belongs to a concept which subsumes the concept representing the second instance (e.g. pair of {*ContractId , Id*} where {*ContractId* isInstanceOf *ContractIdentifier*},and { *ContractIdentifier* isSubClassOf *Indentifer*} and {*id* isInstanceOf *Identifier*}

Rule-4: One of the instances belongs to a synonym or similar concept which subsumes the concept representing the second instance (e.g. pair of {*bidUId , Id*} where {*bidUId* isInstanceOf *BidUniqueCode*},{ *BidUniqueCode* isSynonymOf *ContractIdentifier*}

Rule-5: The instances belong to two concepts inter-related by other ontological properties (e.g. *Address* hasProperty *Address_PostalCode*).

III. Evaluation Approach

In our evaluation, we initially employ our annotation scheme to annotate certain elements (terms) from Web service corpus by generating reference ontology. Next, we evaluate quality and quantity of matching cases discovered using our introduced matching rules operating on the reference ontology.

Since automatic Web service matching is the target use-case for annotated Web services, we measure the quality of pair-wise matches between annotated XML schema element/ message part names. In order to be able to verify the quality of the generated reference ontology and subsequent annotations, initially we limit evaluation dataset to 2000 most frequent *terms* extracted from our collection of WSDL documents. Using this dataset we create two independent ontology resources. While the first ontology is handcrafted by a human expert (i.e. an ontology engineer), the second one is constructed automatically using our ontology learning mechanism, explained at [6] . We refer to the former case as *Golden* ontology while the latter one is called the *Generated* ontology. We acknowledge that *Golden* ontology might suffer from bias introduced by the human expert due to the lack of documentation in the underlying Web services. Next, we align the *Generated* ontology with *Golden* one, using Falcon-AO ontology matching tool [8] and harvest only aligned concepts and their underlying instances. We refer to this set of instances as aligned instances and they account for 968 cases [6]. The evaluation goal is to determine how many true matching cases between every two aligned instances we will gain ,provided that the precision and recall of the aligned concepts are ideal (however in practice there exist some limitations and error margin due to the exploited tool [8]).

We adopt Euznat and Shvaiko's[7] terminology to describe our instance matching process. The result of instance matching process is a set of correspondence elements. Each correspondence element implies that a relation holds, according to a particular matching rule, between two instances in an ontology. A correspondence element $Ont_kC_{i,j}$ is a triple $<a_i, b_j, R>$ where $i \neq j$; $i,j=1...N$; N is the number of instances; a_i, b_j refer to *i-th* and *j-th* instance in the ontology referenced by Ont_k; k is the identifier of the ontology, and finally R specifies the matching rule that reveals kind of semantic relationship holding between two instance a_i and b_j. If two instances are not matched, then we use notation of NM (*NotMatched)* instead of the matching rule. For evaluation purposes, we compare the matching rules R and R' in $Ont_{Gen}C_{i,j=}<a_i, b_j, R>$ and $Ont_{Gold}C'_{i,j}=<a_i, b_j, R'>$ where $Ont_{Gen}C_{i,j}$ denotes the correspondence element obtained in the *Generated* ontology (Ont_{Gen}) while $Ont_{Gold}C'_{i,j}$ refers to the

computed correspondence element for the same pair of instances a_i and b_j in *Golden* ontology(Ont_{Gold}).

IV. Evaluation Results

In this section, we present the experiments[2] made using the top 2000 recurrent terms to generate reference ontology, annotate Web service elements and perform Web service element (i.e. instances in the reference ontology) match-making. Automatic instance matching between aligned instances (968 items) using *Golden* and *Generated* ontology results in 2362 and 3797 correspondence elements respectively. We perform evaluation based on comparison between R to R' in $OntGoldC'_{i,j}=<a_i, b_j, R'>$ and $OntGenC_{i,j}=<a_i, b_j, R>$ for all correspondence elements, as pointed out in Section 3. The comparison results are grouped into three groups based on the exploited matching rules:

Matched in both *(R≠NM & R'≠NM)***:** This category embodies the correspondence elements which are matched in both ontologies and it covers 2837 cases (75% of those discovered by *Golden* ontology) and majority of them (2279 cases) are resulted by Rule-1. Our observation reveals that these identified correct correspondence elements belong to those instances with clear lexical semantic, and to some extent having context independent semantic or those conveying concrete concepts, for example *birthday, Social Security Number, ISBN, authCode, pwd*, etc.

Missing matches (*R=NM* & $R \neq R'$)**:** This group consists of instances that are matched by *Golden* ontology but not by *Generated* ontology and it accounts for 952 cases (25% of those discovered by *Golden* ontology). Besides to typical WordNet [15] limitations [10] one major reason is the fact that concepts in *Golden* ontology are more inter-related (well-organized through handcrafted taxonomical relationships) than those in *Generated* ontology. This leads to loss of possible matches between instances by the ground of subsumption relation between representing concepts (i.e. by Rule-3). This flaw is a direct result of inferring taxonomical relation solely relying on linguistic synthesis. For example, terms "Caller" (as person who makes phone call) and "Person" cannot be correlated, because they are neither synonym according to dictionary nor appeared together in a compound noun, whereas in *Golden* ontology they are assigned to two subsuming concepts. This situation can be alleviated by introducing a new module in our ontology organization step where additional domain resources such as domain ontologies, and taxonomies are incorporated to reorganize hierarchy of generated concepts.

Extra introduced matches (*R'=NM* and $R \neq R'$): This is the group of correspondence elements which are only discovered using *Generated* ontology but not *Golden* one and it consists of 1980 cases. Introduction of these extra matches in *Generated* ontology is due to following reasons: 1) *Golden* ontology lacks any kind of property relations (such as *isSynonymOf*, *hasProperty*, etc); hence it cannot correlate instances by ground of Rules 2,4, and 5. The matching cases resulted by Rule-5 are intuitively reflecting *PartOf* or *Having* relationships between matching instances. 2) in few cases there exist kind of lexical similarity between concept labels , which is not covered by *Golden* ontology for example for the cases when two instances convey a similar semantic but in a different context (e.g. {*taskName*, *jobName*}). In both cases we need to assign a confidence degree expressing trustworthiness of the matching (how close is the matching to ideal case based on contextual information).In this work, we rely on human assessment to distinguish correct cases (true positives) from incorrect ones (false positives). It should be noted the accuracy of these introduced matchings should be considered as lower quality matchings compared to those identified in previous group (i.e. "matched in both").

Fig. 1 shows the assessment results over introduced correspondence elements categorized based on the exploited matching rule. Accordingly, the incorrect figures refer to quantity of cases that two instances are matched while they do not have same/related semantic in practice, while correct cases point to semantically meaningful matched pairs. Accordingly, the quantity of incorrect matches resulted from Rule-4 is the highest among all (89%), while Rule-2 and Rule-5 are equally showing the least amount of incorrect matches (around 40%) and Rule-3 lies almost in the border, with 51% incorrect cases. Our observation over cases in group of Rule-3 shows that occurrence of false positive cases are mostly resulted from generic concepts. For example concept *Code* , in *Generated* ontology, is so generic that can subsumes any of *CurrencyCode*, *LicenseStatusCode*, and, *DesignCode* concepts while in *Golden* ontology, these concepts are more accurately classified by looking into their precise semantic of the term in the Web service corpus. For instance *CurrencyCode* refers to the currency abbreviation rather than a digital code like that of *LicenseStatusCode*. This deficiency can be correlated to limitation of using lexical resources as they do not cover with the same detail different domains of knowledge and also many of domain independent terms, as reported by Bergamashi and Sorrentino [2].

On the other hand, it can be seen in Fig. 1 that subsumption (Rule-3) is reasonably convincing for most of the specialized (concrete) concepts, which in our case are mainly compound nouns. For example, *StartDate* can subsumes any of *futureLaunchDate*, *flightDepartureDate* terms. However, without further investigation we cannot provide any firm theory supporting the aforementioned patterns at this point. The high number of false positives of Rule-4 are due to two

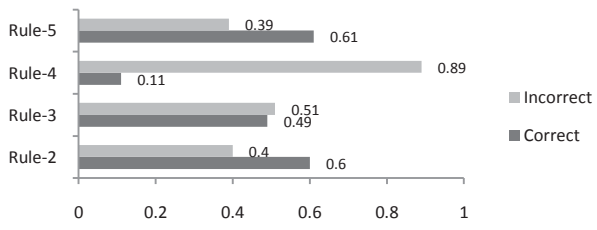

Fig.1 Quantity of "extra introduced mathces" dicovered by matching Rules 2-5 using Generated ontology

[2] Available at: http://www.isk.kth.se/~shahabm/AnnotationAnalysis

reasons: 1) it suffers from subsumption errors; and 2) the rule is based on transitivity of lexical similarity between two terms which is not always true (e.g. the middle term could possess two different meaning in WordNet in different domains). Combination of these two flaws intensifies the vulnerability of this rule. Finally, as there have been no introduced matching cases due to Rule-1, they are omitted from Fig. 1.

According to the aforementioned mentioned evaluations, it can be concluded that without further enhancement, Rule-1, Rule-2 and Rule-5 are the most promising matching rules in our matching scheme. Hence, we exploit only these rules for matching of Web service input and outputs and future analysis of annotated Web service documents.

V. Related Work

Research in knowledge acquisition methods for the purpose of (semi) automatic annotation of Web service interfaces can be roughly divided into the following categories: 1) methods which utilize linguistic resources and NLP techniques; 2) methods which rely on machine learning techniques to classify or cluster similar (or related) names and generalize them to their ontological concepts; 3) the approaches that combine the aforementioned methods with online resources.

The works in the first category, exemplified by [11][12], capture relationships between WSDL elements and transform them into ontological concepts and relationships, typically using simple lexico-syntactic patterns and WordNet dictionary. They exploit textual descriptions of Web services to improve or enrich the quality of the generated ontology.

However, the machine learning techniques, belonging to the second category, exploit NLP techniques only to normalize their input datasets and then continue with machine learning techniques. In this light, Heβ et al. [13] developed a classifier system which initially needs to be trained in order to generalize (semantic of training data) and predict semantic labels for (similar) unseen Web services. As we target a large repository of absolutely non-annotated ad-hoc Web services from different domains, applicability of such techniques is not clear. In contrast the clustering methods such as the one proposed by Dong et al. [14], which relies on the co-occurrence of parameter names as an heuristic for identifying ontological concepts, are more appealing since they do not require any training dataset.

Finally. the approaches in the third category exploit Web resources (such as search engines) as sources for knowledge acquisition and augment the Web results with machine learning and /or NLP techniques. In this direction, Segev and Sheng [9] combined TF/IDF measures with Web search results to discover proper domain concepts representing WSDL elements and then validated it using textual documentations in WSDL documents. The main obstacle of utilization of some of the aforementioned work, namely [9][11][12], is the fact that around 94% of WSDL documents in our collection lack any textual documentation [6], hence, utilization of those approaches is not feasible in our case.

VI. Conclusions and Future Work

In this work, we proposed and evaluated a scheme suitable for automated annotation of a large set of Web service corpus. The experimental results revealed that utilization of certain rules of the proposed matching scheme can be used for bootstrapping large-scale annotation of Web service interfaces in a semi-automatic way. However, we still need to enhance the quality of generated ontologies by potentially incorporating external resources such as domain ontologies or Web resources to the annotation scheme. Since the number of available Web services and therefore our corpus is expected to increase, keeping the generated reference ontology updated will be challenging. Hence, it is not cost-effective to incorporate the entire dataset for ontology learning purpose. As part of our future work, we are aiming to discover and annotate only a subset of whole dataset which its network properties exhibit closer approximation to the already observed properties in the Web service networks [3][4][5].

***Abstract*—This paper presents an analysis and comparison of three existing ontology visualization tools with a new ontology visualization tool developed at the Energy Informatics Laboratory of University of Regina, Canada. The new tool is called Onto3DViz, which is designed as a knowledge engineering support tool for ontology visualization. It aims to address the deficiency that existing tools have in their lack of support for dynamic knowledge visualization. The Onto3DViz is a tool that supports a new approach of visualization in that it supports: (1) dynamic knowledge visualization; and (2) complex ontology visualization in 3-dimensional (3D) computer graphics. This paper also discusses the strengths and weaknesses of the four visualization tool when they are measured against a set of assessment criteria.**

Keywords – Ontology, Ontological Visualization, Knowledge Engineering, 2D Graphics, 3D Graphics

I. INRODUCTION

The Semantic Web (SW) is the next evolutionary step for the web; it aims to provide semantics to data on the Web, enabling computers to more easily share and perform problem solving on the data [1]. SW technology can enable sharing and re-use of knowledge between Knowledge-Based Systems (KBS) in a distributed and heterogeneous environment. Ontologies can enable data on the Web to be structured semantically for machine processing, as well as to become the basis for building KBSs. An ontology is an "explicit specification of a shared conceptualization" [2]. The main benefit of an ontology is that it supports sharing and re-use of application domain knowledge across distributed and heterogeneous software systems [3]. However, the construction of ontologies is time-consuming and costly.

Software tools can help reduce the effort required to construct ontologies and knowledge bases. The general objective of our work is to provide software tool support for ontological engineering. In this paper we present our work in developing a visualization tool for ontological engineering which generates a 3D visualized image of an ontology model. The visualized 3D model can support Knowledge Engineering in two ways. First, it supports better communication between the knowledge engineer and expert, who often are from diverse backgrounds and do not share the same language or vocabulary. A visualized model does not rely on textual descriptions and can avoid difficulties in communication that arise due to language differences. Secondly, a visualized model summarizes the elicited knowledge elements in a 3D model and can support expert validation of the model.

Onto3DViz is an ontology visualization tool, which utilizes 3D graphics to visualize a knowledge model consisting of both static and dynamic knowledge components. The tool has been constructed based on the theoretical framework of Inferential Modeling Technique (IMT) [4], hence Onto3DViz simultaneously supports a developed knowledge engineering method and ontology visualization. The tool aims to address deficiencies of some existing and surveyed visualization tools, which support neither a knowledge engineering method nor dynamic knowledge modeling. Onto3DViz employs 3D graphics to represent knowledge concepts and relationships among concepts. Compared to a 2D graphic representation, 3D graphics can support visualizations consisting of complex and related information in a clear visual model that can be manipulated for flexible views. Onto3DViz was developed in Java, it accepts an input ontology that is represented in an XML-based language document, and it generates a 3D visual ontology model as output. Hence, Onto3DViz is theoretically not limited to any machine platform. This tool has been applied to visualize application ontologies. Figures 1 and 2 show an application ontology visualized in the Onto3DViz. The representations of the knowledge elements are described below:

- Class: Sphere
- Objective: Cylinder
- Instance: Box
- Task: Cone
- Relationship between concepts : Line

More details of Onto3DViz and its applications can be found in [5] and [6].

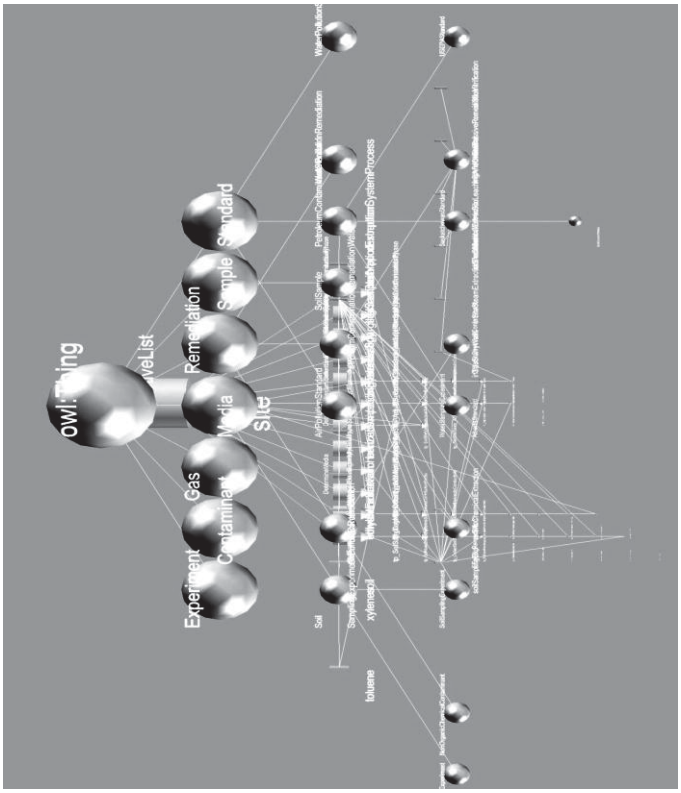

Fig.1 3D visualized model of the application ontology

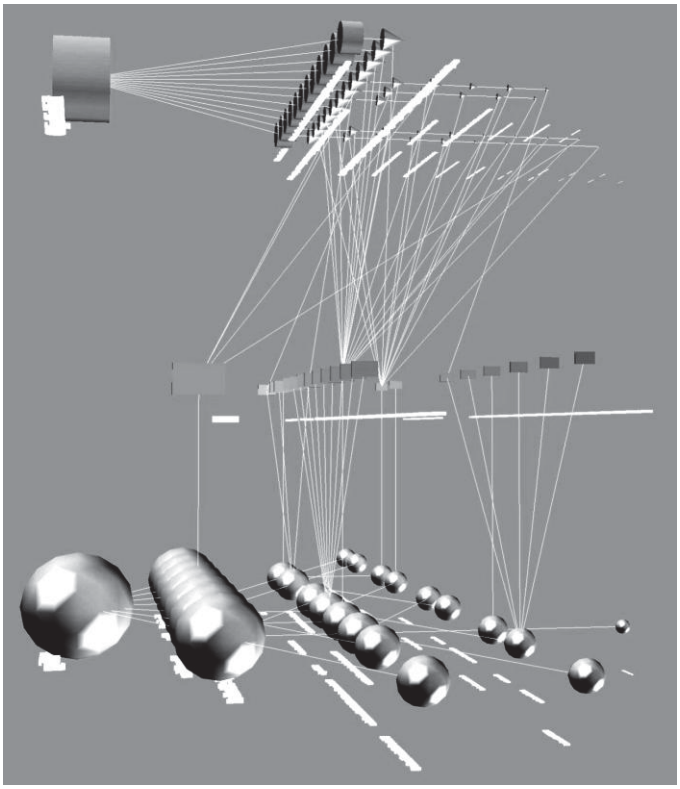

Fig. 2 The side view of the visualized application ontology

The objective of this paper is to present a comparison of Onto3DViz with three other existing ontology visualization tools: OWLViz [7], Jambalaya [8] and OntoSphere [9] against a set of selected criteria. Each of these four tools will be examined and evaluated from the knowledge engineering perspective. The advantages and disadvantages of these tools will be compared and discussed.

This paper is organized as follows. Section II presents relevant background about the field of ontology visualization tools. Section III describes evaluation of the tool. Section IV presents the result of the evaluation, and discusses some strengths and weaknesses of each tool. Section V provides some concluding thoughts and discusses directions for future works.

II. BACKGROUND

Ontology visualization tools can help to improve human understanding of the conceptual model by illustrating the model in visualized graphics. Since visualization can provide an instant picture of the knowledge structure to the knowledge engineer or domain expert, and avoid the need for tedious examination of the detail relationships among concepts expressed in an ontology language, these tools enhance the knowledge acquisition and ontology authoring process. In other words, the user is able to quickly identify the concepts and their relationships with other concepts from the visualized model instead of having to comprehend an ontology from a textual document.

A. Ontology Visualization Tools

Among the ontology visualization tools that have been developed, OWLViz, Jambalaya and OntoSphere are three popular ontology visualization tools that invoked 2D or 3D computer graphic technology. A summary of these tools is given as follows:

OWLViz is a graph type visualization plug-in for the Protégé [10] platform. It can visualize class hierarchies in a graph instead of the default tree view in Protégé. OWLViz supports user interactions, such as zooming and searching in the graph. The class hierarchy is displayed from left to right in a horizontal manner and the class at the most left is the root class.

Jambalaya is a Protégé plug-in that implements the Simple Hierarchical Multi-Perspective (SHriMP) [11] visualization technique. SHriMP represents a hierarchical structure of information as a set of nested graphs. It was originally designed for assisting programmers to visualize object-oriented software programs, and Jambalaya adapted it for representing a domain ontology. Jambalaya provides several viewing perspectives for the ontology model, thereby enhancing user browsing, exploring and interacting with 2-dimensional (2D) ontology visualization. Additionally, Jambalaya provides operations such as browsing, filtering and searching, so that the user can examine the knowledge elements of an application ontology at different levels of abstraction and details.

OntoSphere has been implemented as a Protégé plug in. By employing 3D graphics for visualization, OntoSphere extends the volume of space available for visualizing overcrowded concepts, and it is the only existing ontology visualization tool that adopts the 3D view, which is natural for humans. A main advantage of a 3D representation is that it allows users to manipulate the visualized knowledge elements of the application ontology by means of the actions of zooming, rotating and translating. Through physical manipulation of the concepts, the user can better understand a complex ontology.

B. *Inferential Modeling Technique*

The Inferential Modeling Technique is a knowledge engineering method that supports developing a domain ontology consisting of both static and dynamic knowledge of the problem domain. Static knowledge consists of concepts, attributes, individuals and the relationships among them; dynamic knowledge includes objectives, tasks, and relationships among objectives and tasks. Static and dynamic knowledge are intertwined in that a task is a process that manipulates static knowledge to achieve an objective. The details of this modeling technique can be found in [4].

III. EVALUATION METHODOLOGY

An analysis and comparison of existing visualization tools with Onto3DViz is given in this section. Although comprehensive surveys had been conducted previously, e.g. [12], these works do not include tools that support dynamic knowledge modeling. Also, previous surveys usually emphasize the graphic visualization methodology aspect, and ignore consideration of the ontological engineering methodologies implicit in the tools.

The objective of this analysis is to compare Onto3DViz with several exsisting ontology visualization tools according to a set of criteria selected for assessing the quality of ontology visualization generated by the tools. The tools chosen for comparison include OWLViz, Jambalaya, and OntoSphere, which have been introduced in section II, and Onto3DViz. The criteria for evaluation of these from tools are described below:

1. *Representation of Concept Hierarchy* – is the representation of the hierarchical information among concepts, such as inheritance between classes.
2. *Number of viewing perspectives* – refers to the different graphic layouts that each visualization tool supports. Some tools have only one layout, while others have multiple layouts.
3. *Maximum levels of sub-concepts to be rendered (Max Level)* – is the number of descendant levels that can be shown in the hierarchical representation.
4. *Optimization of rendered space* – measures if the tool can minimize graphic space used in the visualization.
5. *Zoomable* – is a feature that supports magnification of the visualization.
6. *Concept searching* – is a feature that supports searching for a concept by entering its name.
7. *Concept filtering* – is a feature that hides or displays only the selected concept
8. *Concept editing* – is a feature that supports real-time ontology editing of the visualized model
9. *Focusing* – is a feature that supports visualization of only a single concept or a branch of related concepts
10. *Static knowledge visualization* – static knowledge support
11. *Dynamic knowledge visualization* – dynamic knowledge support
12. *Additional visual aids* (such as coloring, sizing) – are additional features that enhance the visualized model.
13. *2D VS. 3D* – indicates if the visualization tool is developed using 2D or 3D graphic technology.
14. *System requirements* (such as ontology modeling platform) – refer to the pre-requisite environment for executing the tool

Some of these criteria are standard factors in assessing general ontology visualization; they include Concept Hierarchy, space, zoomable, concept searching and filtering, focusing [12]. Since IMT includes the concepts of static and dynamic knowledge visualization, hence, the static knowledge visualization and dynamic knowledge visualization are considered in this analysis. The criteria of max level and additional visual aids are used to measure the quality of ontology visualization. The factor of system requirements aims to evaluate the extent to which the tools depend on other systems. The assessment of the four tools against this set of criteria is presented in the next section.

IV. COMPARISON AND DISCUSSION

A summary of comparison of Onto3DViz against the other tools of OWLViz, Jambalaya and OntoSphere according to each criterion is presented in TABLE I, and discussion of the comparison follows.

TABLE I. Evaluation of Ontology Visualization Tools

	OWLViz	Jambalaya	OntoSphere	Onto3DViz
Representation of Concept Hierarchy	Hierarchical tree layout	Rich support for various layouts, like tree, map, etc	Concept hierarchy is not well represented	3D hierarchical tree layout
Number of viewing perspectives	1 fixed layout	Provides 5 graphic layouts	Provides four 3D scenes	1 dynamic 3D view
Max level	Maximum at 10 descendant levels	unlimited	unlimited	unlimited
Space	Limited optimization, cannot fit complex model in a screen	Good optimization, but labels are overlapping	Good optimization, no overlaps	Limited optimization, labels and nodes are overlapped in complex ontology
Zoomable	Not supported	Limited zoom	Flexible zoom	Flexible zoom
Concept searching	Supported	Supported	Supported	Not supported
Concept filtering	Supported by user defining levels of concepts	Supported by collapsing the visual nodes	Supported by user changing 3D perspective	Supported by hiding static or dynamic knowledge only
Concept editing	Supported through Protégé editor	Supported through Protégé editor	Supported through Protégé editor	Not supported
Focusing	Not supported	Support by changing graphic layouts	Support by user changing 3D perspective	Support by user manipulating 3D model
Static knowledge support	Supported	Supported	Supported	Supported
Dynamic knowledge support	Not supported	Not supported	Not supported	supported
Additional visual aids	Limited	Limited	Rich	Rich
2D VS 3D	2D	2D	3D	3D
System requirements	Requires Protégé and GraphViz plug-in	Requires Protégé	Requires Protégé and Java 3D	Requires Java 3D

OWLViz can only do basic ontology visualization in a root tree model generated from left to right on the computer screen. It combines ontology editing with visualization. Hence, the user can edit, search and filter ontology classes in OWLViz, without it being necessary to shift back to the class editor in Protégé. However, OWLViz does not support graphic animation, multi-perspectives, visualization on instance and other visual aids. It has only one view in its visualization. It is difficult for the user to navigate among the classes because it does not optimize on rendering space for the graphical objects within the size of the computer window. Also it does not support either zoom-in or zoom-out. OWLViz cannot render an ontology that has ten or more levels of sub-classes, and it does not support dynamic knowledge visualization. In order to visualize an ontology in OWLViz, a plug-in software called GraphViz [13] is required in addition to the Protégé platform. In general, OWLViz is only suitable for visualizing a simple ontology.

Jambalaya provides rich support for ontology visualization. It overcomes the limitations of 2D graphic in terms of not having enough space for rendering a large amount of ontological information, because it employs multi-perspectives viewing and animation graphics. Jambalaya also supports ontology editing and searching within the visualization screen. The user can select and edit concepts from the visualized model without switching back to the Protégé class editor. It can visualize a large scale ontology.

Although Jambalaya has optimized the space to fit all the ontology concepts into the size of a computer screen, overcrowded concepts may have their labels being overlapped with each other. In addition, the visual nodes are too small and too close to each other in some views, which make it difficult for the user to select the nodes. In terms of the *zoomable* feature, Jambalaya only has limited function because it can support only either zoom in or out, and provide either a full view or focus on one concept. The user is not able to use this zoom function to explore a segment of the visualized ontology. Jambalaya does not support *additional visual aids*, and all the visualized concepts in Jambalaya are of one size and color. Hence it is hard to see the *Representation of the Concept Hierarchy*. Jambalaya does not support *dynamic knowledge visualization*; it does not support the versions of Protégé newer than 4.0 because Protégé changed the plug-in architecture since version 4.0. Jambalaya is much more advanced than OWLViz in terms of functionalities. Though Jambalaya can be applied to explore a complex ontology, the lack of visualizing space in a 2D graphics environment is the problem that causes visual objects generated to be overcrowded and labels to overlap with each other.

OntoSphere employs 3D graphics, and is able to generate many perspectives, such as rotating, zooming, and translating the 3D model. It also supports multiple scenes, and the user can switch among four different scenes in OntoSphere to explore the 3D visualized ontology model. For example, the Concept Focus Scene provides the option that OntoSphere only visualizes one concept instead of the entire ontology. OntoSphere can support a large scale ontology, and ontology concept editing and searching. It also provides some visual aids, such as sizing and coloring of the visual objects for distinguishing different concepts in the visualized ontology model.

However, OntoSphere has a limitation when it is used to render hierarchies in the Root Focus Scene. The technique that OntoSphere uses to visualize the entire hierarchical model differs from the general top-down or left-right approaches. Instead, it visualizes all the domain concepts that around a big hyperbolic sphere, which represents the root concept. The problem with this technique is that the inheritance relationship and relationships among concepts cannot be shown. Moreover, OntoSphere does not support dynamic knowledge visualization. Since Protégé has upgraded its plug-in architecture after version 4.0 and OntoSphere did not upgrade accordingly, it is not compatible with newer versions of Protégé after 4.0.

Onto3DViz can successfully render the complex domain concepts and relationships among concepts in a 3D model, thereby creating a visualized knowledge model first formulated with the IMT during the knowledge acquisition process. The user can easily examine and manipulate the 3D model by performing the operations of zooming, rotating, and translating using the computer mouse or keyboard. The 3D model clearly shows the hierarchical structures of the static and dynamic knowledge. For dynamic knowledge, the 3D model supports representing tasks related to each objective by arranging the tasks in the correct prioritized order. Onto3DViz also supports visualizing the relationships between the static and dynamic knowledge models.

Several weaknesses of the current version of Onto3DViz are also noted. First, when the visual objects are too close to each other, the objects and labels become overlapped, which makes it difficult for users to clearly see details of the model. Secondly, Onto3DViz does not currently support a search function. If the user wants to retrieve a particular concept, he or she has to manually examine the 3D model to find the corresponding visual object. This can be difficult if the ontology is complex or consists of a large number of concepts. Thirdly, if an application ontology consists of too many hierarchical levels, it is difficult to see the lower level nodes because they are too small to show in Onto3DViz. This is because the sizes of the visual nodes are reduced quickly by successive applications of the scaling technique. The detail of the scaling technique is described in [5].

In comparison to OWLViz, Jambalaya and OntoSphere, Onto3DViz provides a new solution for dynamic knowledge visualization; this is a feature that existing tools do not support. The implementation reflects an approach which ensures the ontology visualization tool is independent of the ontology modeling platform. The weakness in adopting this approach is that Onto3DViz currently cannot support ontology editing and searching. The benefit of the approach is that Onto3DViz is not restricted by the platform; it can visualize an ontology model as long as the user inputs to the tool a valid OWL or XML file that represents the ontology.

Onto3DViz is designed as a new solution for dynamic knowledge visualization. Due to the complexities of representing both static and dynamic knowledge, it is necessary for Onto3DViz to employ 3D graphics so as to access a larger volume of space for rendering the complex information and relationships. The advantage of 3D technology over 2D technology is still controversial. According to [14], 3D representation only marginally improves upon the screen space while increasing complexity of the interaction. [15] shows that users of a 3D graphic application need to have more computer experience than users of a 2D graphic application. [16] points out that navigation in a 3D space can be difficult for a novice user. In fact, our study has revealed that comprehensive 2D visualization tools like Jambalaya also require a certain level of computer skills on the users' part for manipulating visualized models. Compared to OntoSphere and Onto3DViz, Jambalaya requires the user to perform complex steps for generating effective ontology visualizations. Moreover, the advantage of the 3D image is not shown to its full potential in the dominant 2D display technology we currently have, because the 2D display only shows a 2D projection of the 3D ontology model and the depth of the 3D graphic image cannot be adequately explored. With increasing popularity of the 3D display technology, the true benefits of 3D graphics will become more evident when the user can navigate the ontology model in a real 3D environment.

V. CONCLUSIONS AND FUTURE WORKS

This paper presents an analysis and comparison of Onto3DViz, OWLViz, Jambalaya and OntoSphere against a set of criteria. The advantages and disadvantages of Onto3DViz as compared to the other ontology visualization tools have been discussed. Onto3DViz was designed as a new ontology visualization tool the supports: (1) visualization of an ontology with static and dynamic knowledge; and (2) visualizing a complex application ontology in a new 3D computer graphic architecture. In the future, the new tool of Onto3DViz can be enhanced by implementing concept searching and editing functions, so that the user can quickly identify and edit a concept in the 3D ontology model. Moreover, assigning colors to the visual objects can also assist the user in identifying concepts. For instance, the class objects are assigned the blue colour and instance objects are assigned the yellow colour. This new feature would ensure that the different types of concepts are easily distinguishable in a visualized ontology. A coloring scheme can be added to the tree structure of generated visual nodes so that the root is the darkest shade and the descendent nodes from the root will be progressively lighter in color, to indicate the different layers of the tree structure. As well, more user controls can be implemented which will enhance user-friendliness of the tool. Integrating or interfacing Onto3DViz with ontology modeling platform, such as Protégé [10] is also possible in the future, because Onto3DViz was also develop in Java language.

Abstract— **As the amount of information grows, the major issue is to access these resources, distributed over the network. Since a large number of the data that we might want to retrieve is not text-based, the only way to search within this type of information is by associating metadata. To reach this goal, some projects aim to optimize the annotation scheme in order to have a standard unified ontology model to describe the data and make use of this model to search for information by concept, not only by keywords. The main goal of the paper is to design and implement the information retrieval over a peer-to-peer network to perform high level annotation of scientific talk recordings, offer granular search facilities and complex queries, and enhance the knowledge management of the recordings.**

Keywords: Knowledge management, peer-to-peer architecture, ontology, information retrieval

I. INTRODUCTION

Distribution technologies are constantly expanding. They have faculties unexplored in centralized systems. Their integration with annex systems such as research and registration services can lead to distributed solutions that facilitate and greatly improve the collection of information. In the field of technology research, it is often limited to research in "text mode" which causes a considerable loss of information. Indeed, we know that the information consists mainly of audio-visual content that is searchable only by the associated metadata and not its actual content. This restriction has raised the question of how search and registration technologies can tap into the potential pool of information. This problem has grown to develop technologies that aim to break barriers and allow search engines to index and retrieve information based on content. These search techniques of a new generation would effectively and efficiently provide relevant information in the presence of the exponential growth of distributed multimedia data volumes. Our approach focuses on developing a scalable solution that meets the needs of massively distributed data produced by a variety of services. The magnitude of the problem can be gauged by the fact that almost everything we see, read, listen, write will soon be available for computerized systems.

This paper presents a service based on a P2P architecture that aims at breaking this technological barrier by defining a distributed P2P architecture that allows search of audio-visual content using the paradigm of query by example. Considering that a video is much more explicit than the text, we attempt to introduce information about the content. The combination of research advises with optional metadata annotations of users and the context of social networking has a capacity of research results more accurate and complete. The P2P architecture is based on the ontological model for recording videoconferences, HELO [1] and its uses within the Framework CALIMERA [2]. It models the information and knowledge transmitted in a life cycle of the conference. Using HELO we aim to bridge the semantic gap by providing opportunities to make annotations to the records of granular scientific discourse, and to improve information retrieval and display of records.

II. STATE OF THE ART

The semantic approach to existing Web resources is one of the major challenges for building the Semantic Web. In the state of the art of semantic web tools, we find many that can be useful. But rare are those that use systems that exploit the power of millions of users every day seeking information on the web. Today, many applications of file sharing peer-to-peer exist. These applications do not have a major characteristic: the semantic search. Although most applications of peer-to-peer sharing offer a keyword search based on indexing data, few are actually accessing the data content and use powerful annotation systems that provide detailed information on data. In other words, there are few projects [3; 4; 5] that offer the user the opportunity to describe his desire to search in the most intuitive words and allow an application to extract the necessary semantic and make it understandable to the machine that will perform the recovery action that best suits the user. This absence is due to lack of use of metadata information generated by annotations and ontology models that describe the data content rather than a general description of the file.

Many publications and projects have been designed to manage multimedia information retrieval using a P2P architecture[6; 7; 8]. Some as VIKEF were developed in order to provide support for advanced semantic information, content

production and knowledge acquisition, processing, annotation, sharing and use by empowering information and knowledge environments for scientific and commercial communities. Matterhorn, meanwhile, produce recordings of lectures, manages existing video, provide distribution channels and provide user interfaces for students with educational videos. However, those two projects do not use the possibilities of a distributed system such as the P2P architecture. Indeed, there are projects like PHAROS [9] and Sapir [10] that use the power of P2P to allow the operation of audio-visual metadata by different peer of the architecture. However these projects do not rely on ontology dedicated. These ontologies lack of expressivity needed to model multimedia data generated by scientific events such as video recorded lectures. To resolve this problem, we propose a new model named conference HELO. HELO models the knowledge imparted in a life cycle of a scientific conference and has the advantage of being integrated into a framework designed to manage information about the conference and its recovery. This new ontology associated with a P2P distributed architecture provides an environment conducive to the operation of all the information in a conference through various peer architecture. This framework, named CALIMERA, is introduced in the next section.

III. LOGICAL ARCHITECTURE : CALIMERA

The evolution of the web in the last decades has created the need for new requirements towards intelligent information retrieval capabilities and advanced user interfaces. Nowadays, effective retrieval and usage of multimedia resources have to deal with the issues of creating efficient indexes, developing retrieval tools and improving user oriented visualization interfaces. To that end we put forward an integrated framework named CALIMERA. The framework is based on a High-level modEL for cOnference (HELO) and aims at enhancing the information management, retrieval and visualization of recorded talks of scientific conferences. This section presents the conference model and its uses within the framework: performing high level annotation of scientific talk recordings, offering granular search facilities and complex queries, and enhancing the knowledge visualization of the recordings. As a proof-of-concept we present the prototypes that have been implemented.

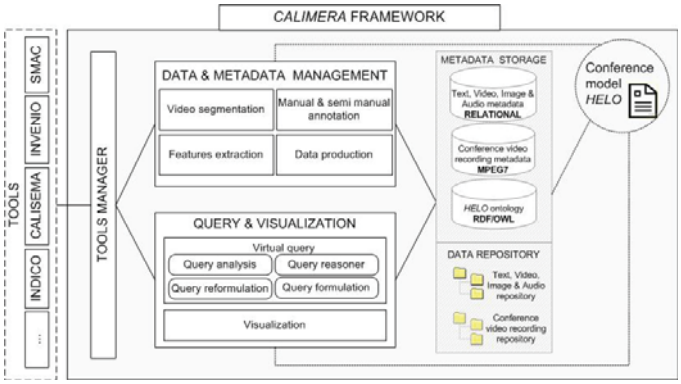

Figure 1. CALIMERA architecture global view

Figure 1 outlines the global view of the framework that is composed of the following modules:

- **Tools manager**: CALIMERA is a tool independent framework. The tool manager allows any user to integrate a tool that may be used for data meta-data management, query and visualization or both.
- **Data and metadata management module** consists of handling the conference high-level information, such as recording talks, segmenting video recordings, annotating video segments, managing the context information of these talks, etc.
- **Data and Metadata storage** integrates existing data and metadata formats such as MPEG-7 which is one of the most widely used standard for multimedia description, RDF and OWL, which are a more semantically oriented standards for multimedia description that integrates high level semantic description.
- **Query and visualization module** queries the data and metadata storage in order to return the video or the set of video sequences of recorded talks the users are seeking for.
- **Conference model**: HELO is a conference model we designed to model the conference high-level information conveyed within a conference life cycle. As cited in the introduction HELO is based on existing ontologies related to conference domain.

To have more information about this logical architecture refers to the *"Conference knowledge modeling for conference-video-recordings querying and visualization"* paper [1].

IV. PHYSICAL ARCHITECTURE : CALIMERA OVER P2P

This chapter will deal with designing a physical architecture that uses a version of the Framework CALIMERA in a distributed way to help expand opportunities and overcome the limitations of information retrieval mentioned above. This p2p architecture matches the logical architecture and allows using independent tools that produce the data and metadata by each user of the p2p network. Thus it offers the possibility to generate that information, which require resources and time cost, by every peer. That information will be accessible by anyone inside or outside the p2p network.

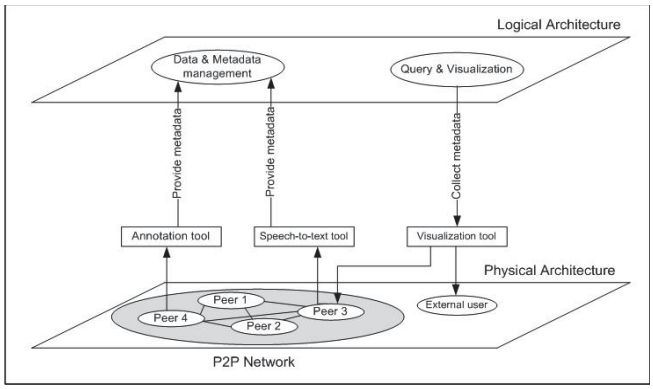

Figure 2. Logical and Physical architecture

The following chapters will address the design of the architecture through the critical inputs that they bring.

A. Data management over P2P networks

The main objective is to develop a file-sharing application for semantic information sharing conference through a network user. The research is based on the model developed ontology conference at the University of Applied Sciences in Fribourg. We also hope that the implementation of the application based on P2P architecture meets four requirements:

- The first one concerns the wide distribution of multimedia data items: each user holds his files at his end device, and geographical distances separate users. With no interest in infrastructure investment, we care for an architecture that could make use of this distribution.
- The second issue, which is vitally related to the first, concerns the dynamicity of the users and of their data. Users must remain free to access and leave the network at any time. They must have all the rights to introduce and remove data files for which they are responsible at any moment. We look for a scalable and dynamically adaptable system.
- The third one is directly related to the retrieval process: since we will be leading a semantic search we are interested to localize data items at any moment during short periods. We wish to discover the location of any item in the network in a reasonable time interval.
- Finally, the fourth issue concerns the retrieval results efficiency and effectiveness: we want to be able to resolve user complex queries. We want a system that processes and retrieves data in a semantically meaningful manner.

Our reflections toward resolving the issues above lead into the choices that we exposed earlier.

The choice of the peer-to-peer architecture eliminated the concerns about distribution. In fact, peer-to-peer takes benefit of this distribution as presented in the state of the art section. It eliminates the need of major infrastructure implementation: users share their simplest resources and contribute in the maintenance of the network. It ensures also that all peers are equal and holding the same privileges.

The choice of the structured decentralized peer-to-peer architecture using the JXTA algorithm addresses the issue of data indexing and network flexibility and scalability. Each peer has the necessary information to correctly localize any data item in the network: each peer performs his own routing calculations and directly addresses responsible nodes. This eliminates the need to dial into central indexes to localize items on the peers. On the other hand, the JXTA algorithm is designed to ensure flexibility and scalability: the distribution of the keys over the nodes adapts as peers get connected or disconnected or when new data items are introduced. Periodic updates of the network are lead by JXTA to recover from unexpected failures such as when a peer leaves the network without notifying its neighbors. By this we maintain a high level of network consistency.

To address the lack of semantic retrievals, we chose to introduce the RDF language as the data description language and the base to formulate queries. RDF triples that describe data items are distributed over the peers by mean of the JXTA keys. Research will be toward finding the triples that match the user's request; the initial results are then RDF triples that mostly describe the user's desire. Those triples will hold information about the file that they describe which by then will be the file that mostly describes the user's desire. File retrieval is then lead in a basic semantically meaningful manner.

B. Metadata management over P2P networks

The architecture is a very generic one. We kept in mind during the design all possible future ameliorations and variations in the network.

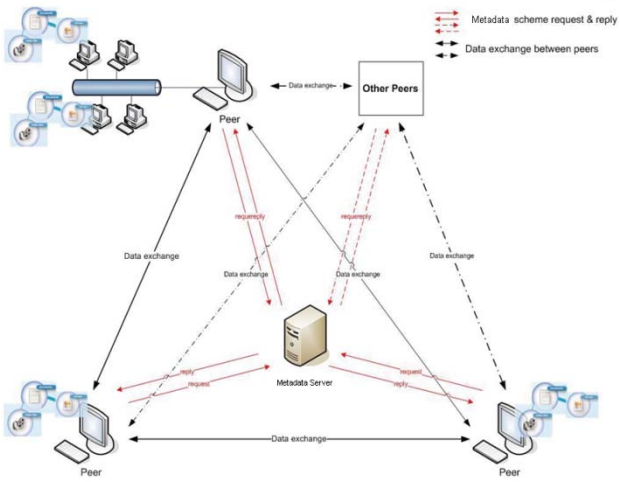

Figure 3. P2P architecture using a routing algorithm

Peers could represent simple end devices or masters of local networks for which they act as access points to the peer network. On another axis, we predicted the presence of the metadata server as necessary, since the users are widely distributed and they might annotate their data differently. They also can produce speech-to-text files metadata that could be reachable by the others peers. Consequently, when a user is willing to share a file[1] over the network, his application contacts the server and downloads the unified metadata scheme proper to the ontology used. The presence of the server is also beneficial if new ontology models are to be implemented over the same network using the same application, in that the network administrator does not have to contact all peers and install the new metadata schemes; they are learned dynamically. It is important to mention that the server has another role: since the server is always present and holding a unique fixed IP, it is responsible for creating the peer to peer network and it offers its URL as the bootstrap URL for the peers that wish to connect to the network. However, the server acts as an ordinary peer on the network when it comes to data

[1] Especially media files, but could also refer to text documents

distribution over the network: it holds no central indexes neither acts like a central storage unit. The JXTA routing algorithm, where each peer calculates his routes locally and performs retrieval actions, handles the discovery of the resources over the network[2]. Data files are kept at peers responsible of them. When a research mechanism points to a file location, a point-to-point connection is established between the requesting peer and the server peer[3] to ensure the channel for data transfer.

As was mentioned earlier in the report, RDF triples, result of the parsing of RDF/XML metadata files, are introduced to the network at three different locations[4] each, by applying a key to an attribute value at each time. Triples are stored at the peers that receive them into files.

V. PROTOTYPE

In this chapter we introduce a prototype that was developed to highlight some features of the architecture implementation. The prototype is based on the JXTA P2P Framework that is described in the next chapter.

A. P2P Networks : JXTA Platform

The information retrieval is performed over a peer-to-peer network with distributed data and a distributed searching technique based on JXTA framework. The Java JXTA platform is a series of classes and methods for managing and transmitting application and control data between JXTA compatible peer platforms. A peer is an identification of a specific instance of JXTA. The concept of peer is similar to the way a computer is named on a LAN, except that the name is not guaranteed to be unique. As a way to make sure that peers are unique, there is a peer ID. The peer ID is generated like other IDs. The concept of peer ID is used because there are multiple methods to reach a peer, so a fixed address or name is not that useful. Also, in the case of computers behind security barriers such as firewalls or NATs, the actual computer name or address is quite useless.

There are different types of peers, divided in two main categories:

- **Edge peers**: these peers are located at the edge of the network; they are the most numerous peers in the network.
- **Super peers**: these peers have specific tasks to accomplish such as keeping a topology of the network, allowing peers behind a firewall to access the network or maintaining a Data Hash Table.

B. Design

There are multiple actions that should be performed using the p2p application. In the first tab of the application interface, the user can annotate the data he wants to share, based on a unified annotation predefined model that includes the type of data and some specific information depending on the type of data being shared. In the second tab, the user can initiate a search using a keyword. The query is sent to the neighboring peers, which will then search for information related to this keyword. The results will appear in the same table, whether they come from an ordinary peer in the network or from an INVENIO[5] server, and the user can then select the document he needs to download. The third tab allows the user to check and manage the files he is sharing with the other peers on the network and the fourth tab allows him to connect to a specific peer knowing its IP address and view the list of peers on the network.

This figure shows the general design of the p2p application

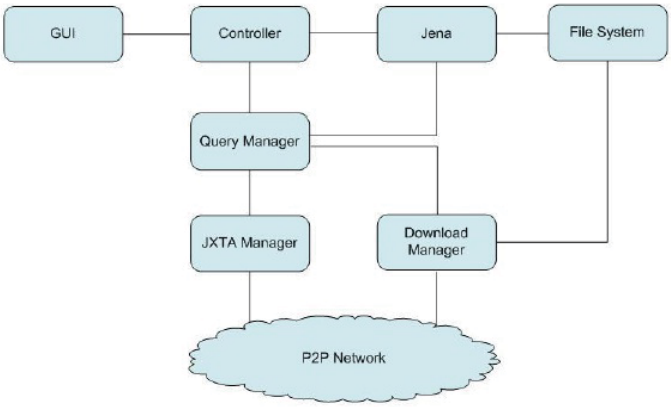

Figure 4. General design of the p2p application

- **GUI (Graphic User Interface)**: it allows the user to interact with the application by sharing and managing the files and sending search queries.
- **Controller**: it collaborates with the user interface to send search and download queries through the query manager and manage the ontology using Jena.
- **Query Manager**: this is the intermediate layer between the application layer (GUI, Controller, Jena) and the network layer (JXTA manager, Download manager)
- **JXTA Manager**: this bloc is responsible of all the connections and the discovery of new peers in the network.
- **Jena**: it is a programming toolkit that manages everything related to the annotation and the ontology.
- **Download Manager:** this bloc is responsible of uploading and downloading the shared files.

1) Communication over the network

[2] Using JXTA successor routing

[3] *Server peer* refers to any peer that holds a data file and contacted by another peer to acquire this file; could be different from the annotation server

[4] JXTA places each *objectID* at the *nodeID* that is equal or higher than it

[5] INVENIO is digital library developed by the CERN, which integrate multimedia data.

In the application developed for this project, we use decentralized network architecture. When the application is launched, the peer connects to the JXTA net peer group then sends advertisements to the peers on the network to exchange some information about their respective sockets. The classes and functions of the JXTA framework provide these functionalities.

2) Nertwork implementation

In the p2p application developed for this project, the class JXTAManager is responsible for connecting the peer to the network. It uses the NetworkManager class provided by JXTA framework and creates a multicast JXTA socket on each peer, allowing it to send and receive requests and responses. The application makes use of the Discovery Service offered by JXTA in order to periodically detect the new peers in the network and connect to them.

3) Metadata annotation and ontology management

When a user wants to share a file, he chooses the type of file he wants to share in the annotation tab of the interface. According to the type of file, the fields to annotate are shown dynamically in the tab. He can decide which fields he wants to fill but he cannot add other fields, which makes him comply with the predefined annotation model.

Once the user clicks on the "submit" button, the local ontology is updated; the name of the new file and its properties are added to the OWL file (p2pontology.owl) that should be located in the same directory as the application itself.

4) Information retrieval and download

The application developed in this project is conceived in a way to allow all types of peers to join the network. In our scenario, we have two types of peers: the "normal" peers that represent the users that might want to share files and search for information and the INVENIO servers that act like super peers. Depending on the type of the peer, the request received is handled differently.

Whether the peer is an INVENIO server or not, the procedure for sending requests and giving back an answer is almost the same. In fact, the results appear in the same table, the only thing that differs is the way the INVENIO server searches in its own information and the peers extract the information from the INVENIO responses.

To decide whether a peer is an edge peer or an INVENIO server, we only have to set the Boolean static attribute INVENIO (in the P2POntology class) to true. The figure 4 shows the UML diagram of the information retrieval class on a server INVENIO.

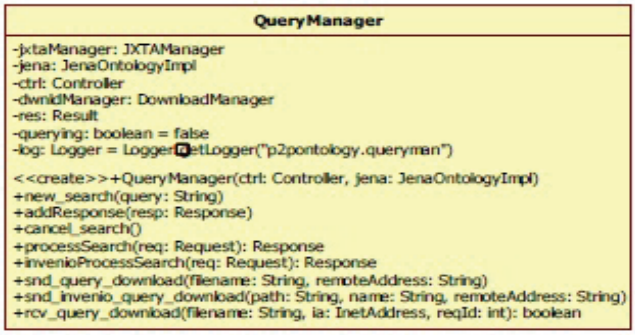

Figure 5. UML diagram of the QueryManager class

5) Jena and ontology search

When the peer is a "normal" peer in the network, using the function processSearch of the QueryManager class performs the search for information related to a keyword. This function uses the Jena Ontology API and is responsible of searching in the local ontology of the peer. Jena can manipulate different programming languages such as RDF and OWL. To find information related to a specific keyword, we search in the OWL file for a match with this keyword and, according to that, we send a response to the peer requesting the information. We will not go into further details about Jena and the ontology search since this is not the aim of this paper.

6) Invenio search

When an INVENIO server receives a search request, it handles the request just like any other peer on the network, which means that it searches for files related to the specific keyword and respond in an XML message, giving some information about the file it finds. The only difference is in the way the INVENIO server searches for the files we need.

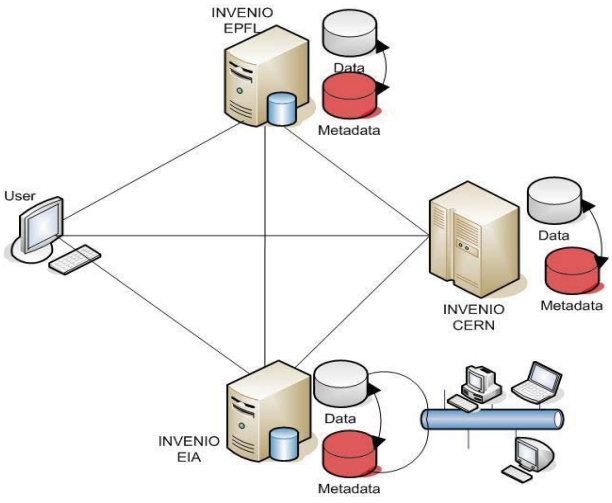

Figure 6. Network topology with different types of peers

We could think of many ways to search within the INVENIO server. Intuitively, the first solution that comes to mind is to create a module that receives the request and uses the search engine of the server to find the results. This solution seems complex for many reasons, one of them being that the programming language used in INVENIO is Python, while the peer-to-peer application is written in Java. This leads us to

think of another simpler solution in order to search within the database of INVENIO. This solution consists of sending an HTTP request to the server and parsing the page to extract the information needed to fill the results table.

When the peer requesting the information receives the response, it can proceed the same way it does with the other types of peers to download the file needed. By right clicking on the selected row, the user can choose to download the page from the server. In this case, since the peer itself might not be connected to the Internet, the user sends a request to the server asking it to provide him with this page. The server then sends another HTTP request with the corresponding web address and returns the page back to the peer.

C. Demonstator

The demonstrator shows how the user can interact with the architecture.

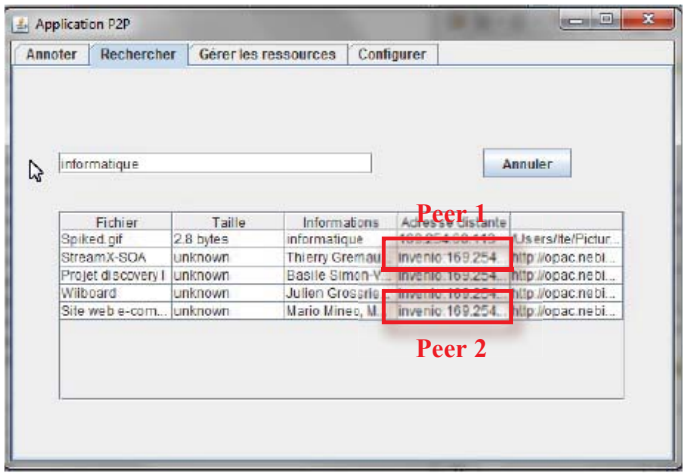

Figure 7. Table showing the results from INVENIO server and other peers

We can recognize the results provided by an INVENIO server by looking at the IP address of the peer that has them (Figure 6). In the column “information”, we can see the names of the authors of the file and in the last column we have a link to this file. Since the peer requesting the information is not necessarily connected to the internet, he can ask the INVENIO server to download the file and send it to him.

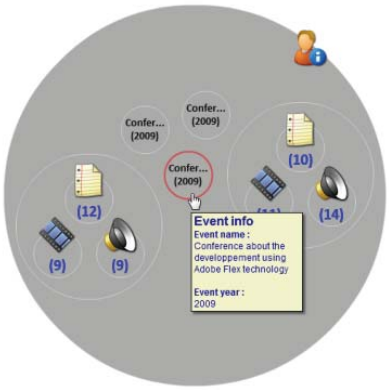

Figure 8. Visualisation of the content of a specific peer

It is also possible to visualize the content of a peer by using a graph interface like the prototype NAVIR [11]. This tool offers the possibility to see the different peers of the network and the data and metadata that each of them provide. It’s a easy way to navigate and access over the p2p network.

VI. Conculsion

In this paper we presented a peer-to-peer architecture that use the scientific conference model HELO (High-level modEL for cOnference) used to enhance the retrieval process of talk recordings (annotation, querying and visualization). We showed that this architecture use the power of P2P to allow the operation of audio-visual metadata by different peer of the architecture.

In the future, our goal is to enhance the retrieval results and to answer the user more efficiently, we could use the Bayesian filter to create users profiles depending on the history of their queries. Each user will have a specific profile as a Professor or student or researcher for example. After profiling by person, people of the same profile could be gathered into a group. This enhances the research also for that users belonging to the same group will be most probably interested with the same topics, this eases and quickens the sharing.

***Abstract*—This paper presents a model that aims to support the visualization of the knowledge stored in digital repositories through semantic images. In this model images contain representations of the real world that are a priori known by the target group, and which have semantic structures that allows identifying the entities of the domain represented in each region. The proposed model is supported by the framework for knowledge visualization proposed by Burkhard and describes the users' interactions with the images. The user through the images can retrieve and view the knowledge related to the entities represented in each region. A prototype was developed to demonstrate the feasibility of the model using images in the biomedical field, the Foundational Model of Anatomy and the Unified Medical Language System as domain knowledge and the Scientific Electronic Library Online database as a document repository. The use of images facilitates the dissemination of knowledge, because these compose user's world view and can easily be related with prior knowledge. Visual representations are processed quickly in the brain and require less effort than the processing of textual information.**

***Index Terms*—knowledge visualization, knowledge retrieval, semantic annotation, ontology.**

I. Introduction

The knowledge dissemination and sharing, are complex tasks for organizations as they often do not know what they have and do not possess systems to efficiently locate and retrieve the knowledge that reside in them [1]. A considerable amount of explicit knowledge is spread across multiple documents within organizations. In many cases, the ability to access efficiently (*i.e.* retrieval) and reuse this knowledge is limited.

Information visualization systems can be used to explore knowledge, to navigate through large volumes of information and to inspect data to make new discoveries [2], [3]. This kind of system is especially useful when people need some information, but they can not translate these needs in key words to search information [4].

In this context, the knowledge visualization field has been researching how the use of visual elements can help the knowledge dissemination process. The use of images that contain representations of the real world, that are part of the users world view, allows that knowledge presented by these images can be easily related to previous knowledge, thus facilitating knowledge dissemination.

This work presents a model that support knowledge visualization by using semantic images. The goal of the proposed model is to use images to construct a support structure for the knowledge visualization process. These images not only contain a visual representation of the real world, but also semantic annotations that help describe its content. The idea is that when a user views an image be able to quickly recognize which regions have associated knowledge and can to retrieve the documents related to the regions by selecting only the region of interest.

This paper is structured as follows: after this introduction, we present the literature review about knowledge visualization and semantic images annotation. Subsequently, the proposed knowledge visualization model is described. In the following sections, we present the material and methods used for model development and discussion. Finally, the last section, we present the conclusions.

II. Literature Review

A. Knowledge Visualization

The knowledge visualization can be defined as the use of visual representations to improve the transfer of knowledge between at least two persons or group of people [5], [6]. Making knowledge visible so that it can be accessed, discussed, valued, appreciated or managed is a long-standing goal in knowledge management. Because of this the knowledge visualization has recently become the focus of attention in academic and business communities [7].

The benefits provided by the visualization seem to be dependent on the fact that it acts as a frame of reference or as a temporary storage area for the processes of human cognition. Visualization enhances the memory of humans to provide an extensive set of work to analyze and reflect, and thus becomes an external facilitator of cognition [4]. According to Ware [8] there are two main theories in psychology that explain how the vision can be effectively used to realize elements and shapes. At low level, the theory of pre-attentional processing explains that some visual elements can be processed quickly. At the highest level, the Gestalt theory describes some principles used by our brain to understand an image.

The knowledge visualization systems are designed to make use of the skills that humans have to process images. The

images are pre-attentive and these are processed before the text [9]. Moreover, the use of images that contain representations of the real world, which are known a priori by the target group and are part of his world view, allows the knowledge presented to abeam of these images can easily be related to prior knowledge of individuals, facilitating learning and memory [5], [9].

Aiming to guide the knowledge visualization application within organizations, Burkhard proposed a framework based on five perspectives that respond to five key questions [5], [6]: What kind of knowledge needs to be viewed? 2) Why should knowledge be visualized? 3) Who is being targeted? 4) In what context should be viewed? and 5) How can knowledge be visualized?

B. Semantic Image Annotation

The annotation can be defined as the process of making explicit the interpretation of the document. Creating metadata by annotating documents is one of the major techniques for putting machine understandable data [10]. Metadata can be attached to a wide range of documents; can be expressed in a wide range of languages and with a wide range of vocabularies [11]; and can be performed manually, automatically or semi-automatic [11]–[13].

Ontologies have been used to annotate documents [10], [11]. Ontological structures may give additional value to semantic annotations allowing inferences and conceptual navigation [10].

The metadata associated with images can be classified as i) independent content metadata, where metadata are related to the image but not described, for example: names of authors, dates, location, etc; ii) content-dependent metadata, where metadata is related to low-level features and/or intermediate level, for example: color, texture, shape; and iii) descriptive content metadata, where metadata is related to semantic content. It has to do with relations of the entities of the image with the real world entities [14].

The descriptive content metadata can be provided at two levels of specificity: i) descriptive content associated with the full image [15], [16] and ii) image segmentation with links to the descriptive content in each segmented region [17], [18].

III. Proposed Model for Knowledge Retrieval

The proposed model was designed in order to facilitate knowledge visualization using semantic images as support structures. The conceptual model described in the figure 1, consists of four components: the semantic images, document repository, knowledge repository and visualization. To the knowledge linked to the images can be recovered efficiently (*i.e.*, semantic search), both images and documents have been previously enriched with semantic content (letters a and b in figure 1) obtained from the knowledge repository (*i.e.*, ontologies, taxonomies, thesauri).

The process starts when the user has to satisfy some information need. The user selects the image (1 in figure 1) from which the knowledge will be visualized. The selection criterion will depend directly of the user information needs,

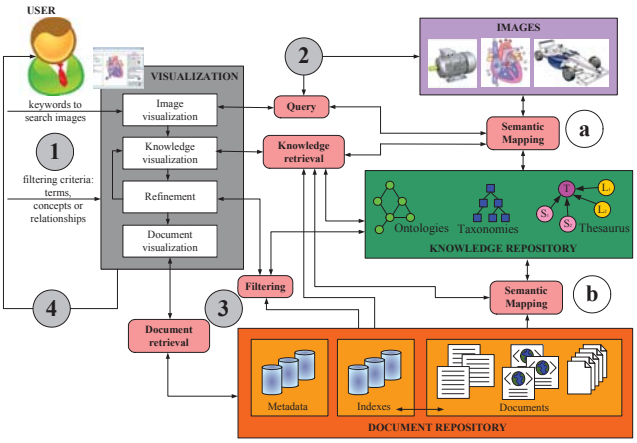

Fig. 1. The proposed model for Knowledge Visualization

taking into consideration the concepts represented in each image. For example, if the user need to visualized knowledge associated with the heart, he must select an image in which the heart is represented.

Once selected the images, the visualization process is executed (2 in figure 1). The visualization process aim to provide users the knowledge stored in document repositories. The results visualization is done over the images, so that users quickly realize the amount of documentation associated with each image region. This is reflected in the image, for example, changing the color of the regions in which concentrates most / least amount of documents or include the number of documents retrieved on each region. From the image, the user can restrict the search space (number 3 in figure 1) and is able to use the metadata provided by document repositories or concepts defined in knowledge artifacts, thus initiating a new visualization process. Next, we briefly describes each component.

A. The Semantic Images

In the model, the images are enriched with semantics structures that allows to represent graphically the domain concepts in which each of its parts is specified in an explicit and formal way. It is defined on three levels (figure 2): the *descriptive level* aims at identifying and describing the visual representations; the *structural level* provides information about the internal structure in order to make explicit the region images; the *semantic level* aims at describing the semantic mappings.

B. Document Repository

In the model, document repositories are characterized by a semantic layer that allows to formalize the information contained in documents. They are defined in four levels: the *descriptive level* aims at identifying the repository; the *metadata level* aims at describing the information structure; the *content level* provides the structures needed to store documents and metadata. The document repository also has a semantic level that aim at linking the semantic content of documents.

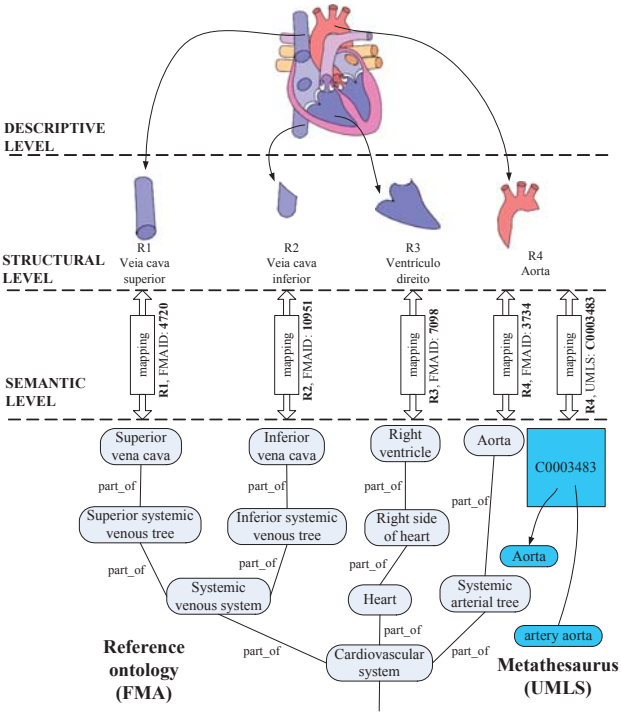

Fig. 2. Semantic images

C. Knowledge Repository

This component is composed by the artifacts used to represent the knowledge domain to perform both the semantic mapping of the images and documents as well as to make inferences, when possible, on the concepts used in the visualization processes.

D. Visualization

The visualization component is responsible for presenting the user search results. This component is based on tasks defined by Shneiderman [19] to visualize information: first obtain an overview of the data, then concentrating on items of interest and filter out irrelevant items, and finally to provide details on demand. The data overview is done using the semantic images, where the visual elements are changed in order that user can easily identify the regions where exists knowledge.

IV. Prototype Model

In order to demonstrate the feasibility of the proposed model, we developed a prototype applied to the biomedical field. The knowledge repository was composed by the Foundational Model of Anatomy ontology (FMA) [20], [21] and the Unified Medical Language System Metathesaurus (UMLS) [22]. As documents repository a copy SciELO (Scientific Electronic Library Online) database was used.

In figure 2 we can see an example of a semantic image. Four regions in this image were made explicit: the superior vena cava, the inferior vena cava, the right ventricle and the aorta. To annotate the images region, we used the FMA. Each region was linked to a FMA class incorporating to the

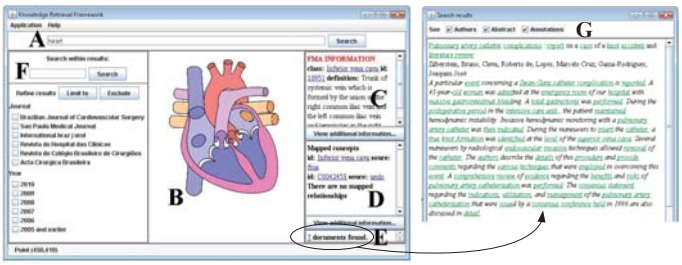

Fig. 3. Semantic annotation of documents

semantic image, all explicit knowledge in the FMA ontology. For example, when linking the R1 region (labeled with *veia cava superior*) to the class *Superior vena cava*, the model now "understands" that the region is part of the cardiovascular system (class *Cardiovascular system* in FMA ontology) which is also known as *Anterior vena cava* (synonym in English) and *Vena cava superior* (equivalent name in Spanish). Figure 2 also shows how the region R4 (labeled *aorta*) is mapped to the UMLS concept *C0003483*. Using UMLS relations, the model "knows" that *Aneurysm* is an aorta disease.

In figure 3 we can see the prototype's main interface. To search for the semantic images the user enters the search terms in the text box in the upper panel (figure 3-A). The tool recovers all the semantic images associated by processing the query terms in both the structural level (*i.e.*, text search for the name of the regions) and in the semantic level (*i.e.*, conceptual search by mappings). When the processing is done on the semantic level, the terms are processed in domain concepts. This transformation allows the query to be executed semantically, making the search language independent. For example, to search for semantic images related to heart, the user can enter search terms such as words like *corazn* (heart in Spanish), or *corao* (heart in Portuguese). In all cases, the process returns the same results.

After retrieving the semantic images, it is placed in the center pane (figure 3-B). The user can use it in two ways: to obtain knowledge related to the concepts represented in the regions or to retrieve documents that mention the concepts.

Information related to the concept appears in the top right pane (figure 3-C). In this prototype version, this information is presented using the FMA ontology. In this panel the user can view the name, identification and description of the class. Using the button "View additional information", the user can get additional information such as names in other languages or anatomical entities that constitute it. The concepts mapped in each region can be observed in the right pane in the center (figure 3-D). This information is obtained from the semantic level of the image.

When selecting an region in the image, in addition to presenting to the user information about the concept, also shows the number of documents related to the concepts mapped in each region.

V. Discussion

In the proposed model both images as the repositories of documents have been enriched with semantic content enabling

the integration of these two components. The semantic content allows that the model can to "understand" what are the concepts represented both in images and in the documents thus facilitating conceptual search. One advantage of this is the recovery of knowledge independently of the language of written documents. Due to this "understanding", the model is able to retrieve documents related to the concepts represented in the images helping the user in the search process. This retrieval mechanism can be seen in the prototype in which to retrieve documents, the user only need select one region of the image without specify the search terms as in traditional retrieval systems.

The idea of the model is that search results are presented in the images changing the color of the regions where it concentrates the largest number of documents. This model behavior is consistent with the visualization tasks defined by Shneiderman [19].

The reason for using images containing representations of the real world is based first on the humans' skills to process images quickly and secondly in the ease of individuals to relate prior knowledge associated with an image already known.

The proposed model is generic and can be used in any domain that allows the concepts representation by images. It can also be used on any document repository where these can be mapped into knowledge representations (*i.e.*, ontologies or taxonomies).

VI. Conclusion

One of the advantages offered by the model is the ease of documents retrieval using only regions of the images. In traditional IR systems, users translate their information needs in search terms, they return a list of items that match the most relevant documents according to the terms informed. In the proposed model users have to translate their information needs also in terms, but these are not used to directly seek the documents, but rather to seek the image to be used in visualization process.

Another model advantage is the component integrations by semantic mappings. The images and information repositories are all integrated by means of semantic information, this allows a single image can be used to view documents in different repositories. For example, the image of the heart, shown in previous sections, can be used to retrieve scientific articles, organizational competencies, projects, clinical studies, indicators, medical imaging, among others. This semantic integration also allows to the model to infer new information about a particular concept. When render the heart image, the model can retrieve information related to concepts that are not explicitly defined in the image, but can be inferred, such as certain diseases. In heart image when selecting the aorta, for example, and using the UMLS relations could be recovered documents related to the aneurysm, a disease that affects the aorta.

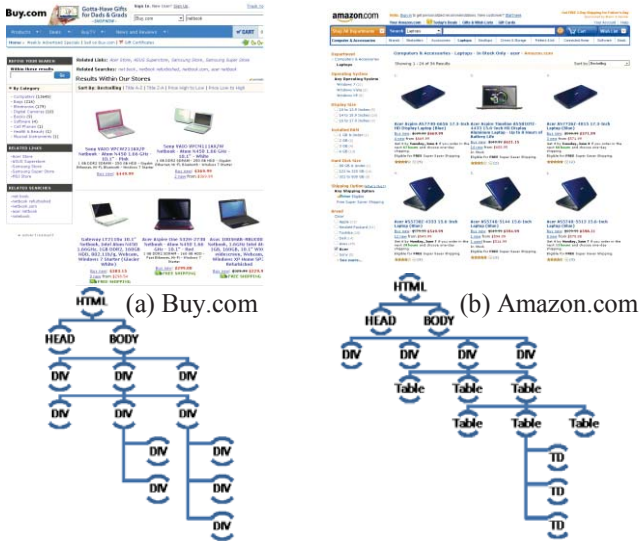
***Abstract*—Web data extraction becomes a hot topic after the invention of World Wide Web, because the large amount of information on the Web makes it challenging to retrieve useful information. Due to the diverse designs and presentations of information on different Web sites, it is hard to implement a general solution to extract data across different Web sites. This paper presents a novel method based on graph grammar to extract the same type of information from different Web sites without the need of training or adjustment. Our approach formalizes a common Web pattern as a graph grammar. Then, based on the visual layout and HTML DOM structure, a Web page is abstracted as a spatial graph that highlights the essential spatial relations between information objects. According to the defined graph grammar, a spatial parsing is performed on the spatial graph to extract structured records. We have evaluated our approach on twenty one different Web sites, and achieved the F1-score as 97.49% which shows promising performance.**

Keywords: Web Data Extraction; Graph Grammar; Wrapper

I. INTRODUCTION

Exploring useful information becomes increasingly difficult as the volume and diversity of available information rapidly grow. To efficiently discover knowledge from the vast amount of heterogeneous digital data on the Web, it is critical to extract meaningful contents from Web pages and organize extracted information in a structured format, i.e. *Web data extraction.*

HTML DOM structures could be very diverse among different Web sites. For example, some Web designers may use *table* to present tabular data while others use *table* to divide space into different grids for layout purpose. Therefore, even if two Web pages have similar layouts, their HTML source codes may be completely different. For example, Figure 1 presents two Web pages that have similar layouts but different DOM structures. Due to the diversity, it is challenging to make a wrapper applicable to different Web sites of the same category. In addition, a DOM structure is complex. For example, even the DOM structure of Google homepage includes 110 HTML tags. The complexity of DOM structures could further increase the diversity and reduce the accuracy. Recently, layout based analysis receives more and more attention [3, 14, 19]. In order to provide efficient Web browsing, Web pages that include similar information in general are presented with consistent layouts even though those pages may be implemented completely differently. Therefore, layout based analysis addresses the diversity issue to a certain degree. However, existing layout-based approaches have limited applicability. Some approaches [19] need training before they are applied to a Web site. Some approaches are optimized for a specific type of domains, and may not be easily adjusted to another domain. For example, the Visual Wrapper [3] is powerful to extract news stories while it is not applicable to other domains.



(a) Buy.com (b) Amazon.com

Figure 1. The same visual layout with different DOM structures

This paper presents a novel approach that combines layout and DOM structure analysis. Our approach extracts structured records by analyzing the screenshot of a Web page that is coherent with human's cognition of visual perception. In our approach, the screenshot of a Web page is first abstracted as a spatial graph, in which a node is an information object (such as text or image) and an edge indicates a close semantic relation between two information objects. Instead of using machine vision technique to recognize images and texts, our approach recognizes information objects based on the DOM structure. Though a DOM-structure based recognition is not as powerful as the machine vision technique, it is efficient and sufficient to recognize texts, links and images that are useful in information extraction. Based on the spatial graph, we are using the graph parsing technique to extract structured records.

The graph parsing assumes that Web designers usually follow some guidelines or patterns to present information on the Web. This is a valid assumption in practice since a consistent layout style can provide effective browsing for end users and ease the efforts of development and maintenance. This assumption has been validated by our evaluation on different Web sites and also by other researchers [15]. Those common guidelines are referred to as patterns that are visually specified through graph grammars [7] in our approach.

This work is supported in part by ND EPSCoR Grants #FAR0015845.

Since the input of data extraction is a Web page that is abstracted as a spatial graph and the output is a tree, the process of data extraction can be considered as transforming from one graph to another one that can be naturally specified through the graph grammar technology. Graph grammars provide a solid theoretic foundation to define computing in a two-dimensional space. In our approach, a graph grammar visually yet formally defines a Web pattern, and then the data extraction is implemented as a process of graph parsing that searches in a spatial graph the sub-structures consistent with the defined pattern. In order to minimize the manual effort of designing a graph grammar, we implemented a graphical interactive tool to facilitate the design of graph grammars. We have evaluated our approach on 21 Web sites to extract product information. The results are promising and the performance of our approach measured in terms of F1-Score (See Section V for further detail) is high.

II. RELATED WORK

With a clear structure to specify the layout of a Web page, the HTML source codes have been commonly analyzed to extract structured data records [1, 4, 5, 6, 8, 9, 10, 11, 12, 16, 18]. Several approaches [6, 8, 11] use the machine learning technique to automatically derive a wrapper based on a set of manually labeled training data. Though the above approaches apply different technologies to derive a wrapper, they all require a set of training data, which are manually labeled by human experts. Several approaches [1, 4, 5, 12] automatically derive a template from sample Web pages and use the extracted template to discover structured records. These approaches do not require manually labeled data, which greatly reduces the manual effort in the data extraction process. However, they require that Web pages being analyzed must follow the same template as the sample Web pages. MDR [10] and DEPTA [16] generate an HTML tag tree based on table and form related tags, e.g., *table*, *form*, *tr*, *td*, and etc. This HTML tag tree significantly reduces the complexity of the original Web page. Based on the HTML tag tree, they use the string comparison technique to divide a Web page into different regions. In each region, it identifies data records by calculating similarity between tag strings. Zhai *et. al.* [18] rendered a Web page and allowed users to select information objects in the screen shot to define a data pattern. Different from our approach, this data pattern is defined on the DOM structure, not on the visual layout. Laber *et. al.* [9] used some statistical analysis to analyze the DOM tree elements and identify the relevant information objects. All of the above methods use HTML DOM structure as the main source for data extraction. Instead, our approach, i.e. *Visual Grammar Based Extractor - VGE*, implements data extraction based on the information presentation. The visual analysis can address the issues of complexity and diverse usages of HTML DOM structures to a certain degree. By actually rendering a Web page, our approach supports dynamic information objects which are generated at run time.

Recently, the visual perception technique has been applied to extract structured data since it is independent from the detailed implementation underlying a Web page. These approaches [3, 14, 19] basically calculate the visual similarity among different Web pages to group semantically related information. [3, 19] are limited to extract news stories, and are not applicable to other domains. ViPER [14] is implemented on statistical models that emphasize on extracting repetitive data records.

The Hybrid method takes benefits from both DOM Structure and Visual Perception, and combines them together. ViNTs [17] automatically recognizes different content shapes based on the visual position of information objects. Afterward, a wrapper is generated based on an HTML structure which represents each shape. This approach still extracts information based on HTML DOM structures, though the wrapper is derived from visual analysis. Instead, our approach specifies extraction rules from both the layout and the DOM structure. ViNTs is limited to search results, while our approach is general to different domains.

III. A GRAMMAR BASED APPROACH

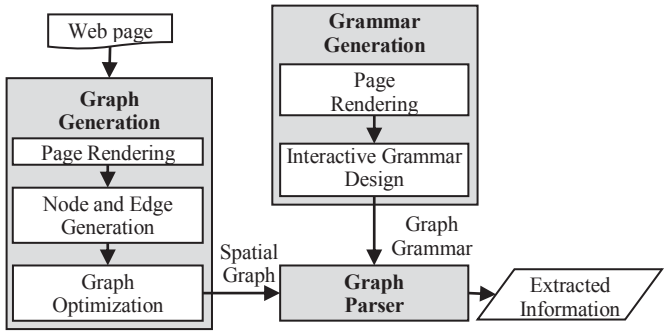


Figure 2. A Graph Grammar based Extractor

This paper presents a novel and robust approach, i.e. ***Visual Grammar based Extractor - VGE***, to extracting structured information. Our approach consists of three components as shown in Figure 2. The graph generation component abstracts a Web page as a spatial graph that simplifies the original Web page and highlights important semantic relations between recognized information objects. The graph generation proceeds in the following steps: (1) render a Web page on the screen, (2) recognize information objects and divide a Web page into different regions according to its DOM structure, (3) calculate semantic relations between recognized information objects based on the layout information, and finally (4) optimize the spatial graph. Based on the generated spatial graph, the data extraction is implemented as a graph parsing process that searches in the spatial graph sub-graphs satisfying certain spatial properties. Those spatial properties are visually defined through a graph grammar. The grammar generation component provides an interactive grammar design tool that allows end users to define a graph grammar by directly manipulating the screenshot of a Web page. This interactive grammar design tool eases the process of developing a graph grammar and improves the usability of our approach.

A. Graph Generation

HTML is a very flexible language. Information with the same presentation could be implemented in many different ways. Being coherent with the HCI principle that consistent presentations can improve the usability of an interface [13], Web designers across different Web sites commonly use similar layouts to present the same type of information.

Therefore, our approach extracts structured records by analyzing the layout of a Web page. The visual analysis can address the diversity of HTML usages and make our approach applicable to different Web sites. The process of graph generation is a critical step in our approach since it simplifies original Web pages and eliminates variations among different Web pages. The simplification only preserves essential information objects. Especially, the graph generation process removes (1) style and layout elements, which do not include any real content, (2) advertisements and (3) menus in the border areas. The simplification effectively reduces the complexity of HTML pages and removes potential noises in the data extraction. The graph generation process proceeds in three steps: Web page rendering, node and edge generation, and graph optimization.

The first step in the graph generation is to render a Web page. The visual layout of a Web page is determined by three variables, i.e. (1) the actual HTML source code that specifies the DOM structure of the page, (2) data items such as text and picture and (3) style sheets and client side scripts which are executed by a browser at run time. We can access all HTML elements, especially dynamic elements which are generated on the fly, only by actually rendering a Web page. Also, the page rendering determines the position and size of each element.

Based on the dynamic and static HTML elements and their spatial properties, the second step generates a spatial graph in which a node represents an information object for data extraction and an edge indicates a close semantic relation between the pair of connecting nodes. Contents are stored in three types of nodes, i.e. image, text and link. The contents enclosed in the <img> or <a> tags are recognized as an image node or a link node, respectively. However, it is challenging to identify a text node since one complete sentence may be separated by several HTML tags and it is necessary to consolidate those information pieces together. For example, inside the text block of a sentence, formatting and styling tags (such as <b>, <br>, <font>,) can divide the sentence into several pieces. In the graph generation, all those formatting and styling tags are removed and adjacent contents are consolidated as one single text node.

After identifying atomic information objects as nodes, it is critical to calculate semantic relations between information objects and use an edge to connect two nodes that are closely related in semantics. In a two dimensional space, an information object can have an arbitrary spatial relation with adjacent nodes. A complete spatial parsing that analyzes different spatial properties in a graph could be time consuming. Our approach first derives the semantic relation between adjacent nodes, and each close semantic relation is represented as an edge in the spatial graph. Based on the derived semantic relations, we can limit the spatial parsing to objects that have semantic relations and thus reduce the search space to speed up the parsing process. We have extensively investigated different Web sites and found that a small distance strongly indicates a close semantic relation between two objects. This observation is consistent with the Human Computer Interaction principle that closely related objects should be grouped together and placed in proximity [13]. Accordingly, we derive the semantic relation by calculating the distance between two objects. Also, an HTML DOM structure provides valuable hints for deriving semantic relations. Web designers group related objects together by using a container, such as *table* or *div*. In general, two objects belonging to two containers are not related. For example, in Figure 3, though *text* objects 4 and 5 are placed in proximity, they are not semantically related since they belong to two different containers. Our approach uses HTML DOM structures to recognize the containers, and semantic relations are limited to information objects that have one common (ancestor) container. In order to accommodate different image sizes and variations in Web pages, we propose a novel approach to calculating distance and deriving semantic relations. The size of an information object *a* is extended to a certain degree. If the extended object *a* is overlapping with at least two corners of another information object *b*, *a* has a semantic relation with *b*.

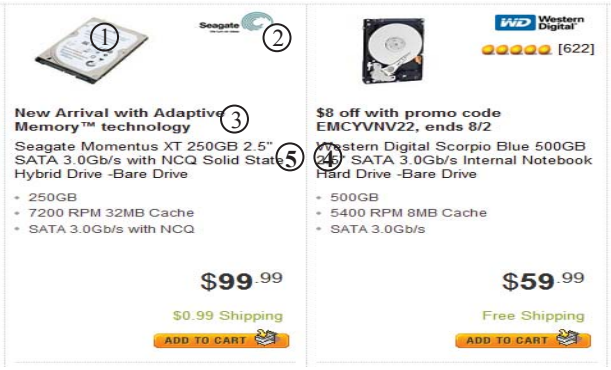

Figure 3. Different containers in a Web page

The last step in the graph generation is to optimize the generated spatial graph. In a spatial graph, some nodes may be considered as noises (such as advertisements and menus), which do not contribute to the data extraction process. Since those objects in general are placed in the border areas of a Web page, we can remove them according to their position. Another type of noise is small repetitive pictures, such as the "*Add to Cart"* icon in Figure 3.

B. Grammar Generation and Parser

The graph generation component generates a spatial graph, and the data extraction is performed on a spatial graph to search for information objects having certain spatial relations. In order to support efficient browsing, the same type of information in general is presented similarly across different Web sites. Those consistent spatial features among information objects are summarized as a Web pattern that is visually specified through a graph grammar. A graph grammar defines computation in a multi-dimensional fashion based on a set of rewriting rules, i.e. *productions*. Since the input of data extraction is a graph and the output is a tree structure that represents structured records, the data extraction is essentially a process of graph transformation that can be naturally specified through graph grammars. Furthermore, a graph grammar is powerful to handle the variations among instances of a Web pattern. This paper selects the Spatial Graph Grammar (SGG) [7] as the specifying formalism. With the capability of spatial specification in the abstract syntax, SGG provides the flexibility to define a pattern from both the edges (i.e. close semantic relations) and spatial features (e.g. directions).

Instead of designing a graph grammar from scratch, we designed an interactive design tool that allows users to design a graph grammar visually and intuitively. This interactive tool renders a sample Web page on the screen, and highlights recognized information objects in the Web page. Users can directly select one or more information objects in the Web page to make a production. This tool supports a direct manipulation interaction on the grammar design that reduces the gap between a concrete Web pattern and an abstract graph grammar. With the help of this tool, even users without much training in graph grammars may design a graph grammar.

IV. SYSTEM IMPLEMENTATION

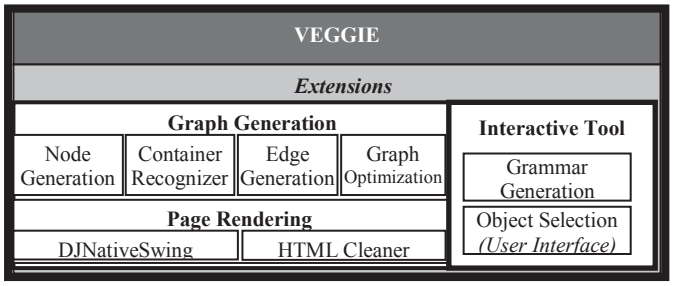

Figure 4. The VGE system architecture

We have implemented a prototype for our approach. Our prototype is built based on VEGGIE - **V**isual **E**nvironment for **G**raph **G**rammars: **I**nduction and **E**ngineering [2]. VEGGIE is a general visual programming environment, and supports the Spatial Graph Grammar specification and parsing. VEGGIE mainly consists of three independent editors (i.e., the Type Editor, the Grammar Editor, and the Graph Editor) and an SGG parser. The three editors provide GUIs for designers to visually design a graph grammar, and are closely related and seamlessly working together in VEGGIE. Grammar designers can visually create visual objects, i.e. node types, in the Type Editor, or import existing node types from a file in the form of GraphML. Then, based on these defined nodes, the designer can define productions in the Grammar Editor. The designer can visually draw or import a host graph to be analyzed by the SGG parser. As shown in Figure 4, we have extended VEGGIE with two subsystems, both implemented in Java. The first sub-system is responsible to generate a spatial graph from a Web page. The generated spatial graph is fed to the SGG parser for a spatial parsing. The second sub-system provides an interactive graphic tool to design a graph grammar.

The Graph Generation sub-system has several components. The *Page Rendering* component renders a Web page, extracts size/position information and passes the output to the *Node Generation* to generate nodes. Containment relations are identified by the *Containment Recognizer*. The *Edge Generation* derives semantic relations based on containers and spatial properties. The *Graph Optimization* component optimizes a generated spatial graph by removing noises.

The *Page Rendering* component renders a Web page based on the DJNativeSwing Browser (http://djproject.sourceforge.net/ns/). The HTML Cleaner component (http://htmlcleaner.sourceforge.net) solves syntactical problems (e.g., unclosed tags and markup errors). The HTML Cleaner returns a clean and well-structured HTML DOM tree that includes all static and dynamic elements. Based on this DOM tree, the graph generation component, including *node generation*, *container recognizer*, *edge generation* and *graph optimizer*, generates an optimized spatial graph for data extraction. The second sub-system eases the process of designing a graph grammar. It consists of two components, i.e. *object selection* and *grammar generation*.

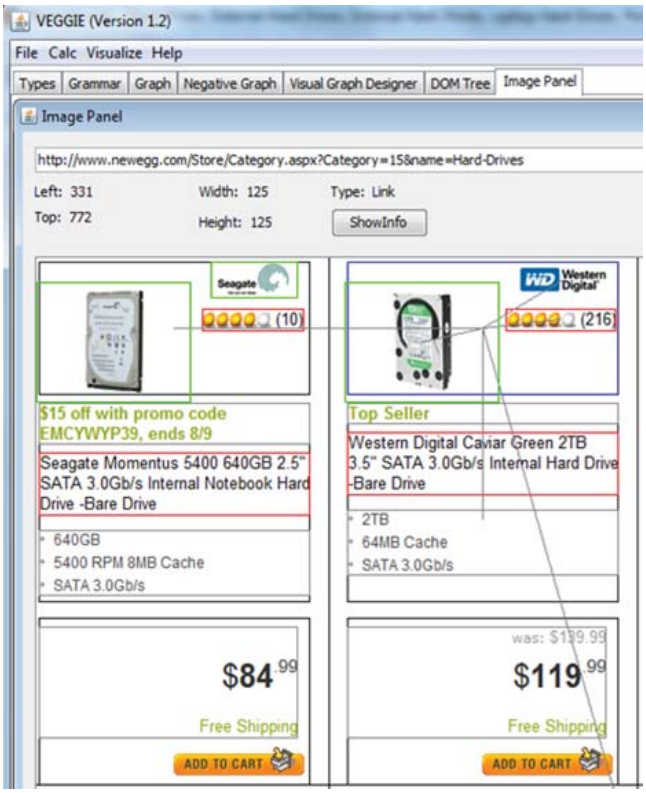

Figure 5. Browsing a Web page

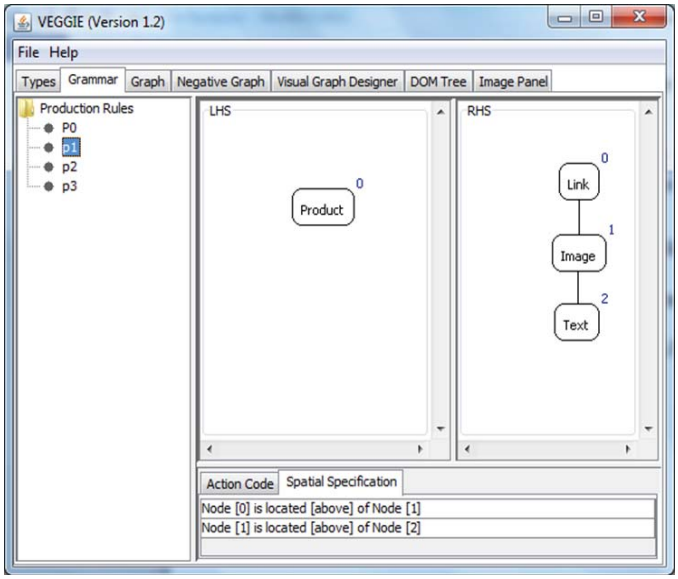

Figure 6. A grammar editor

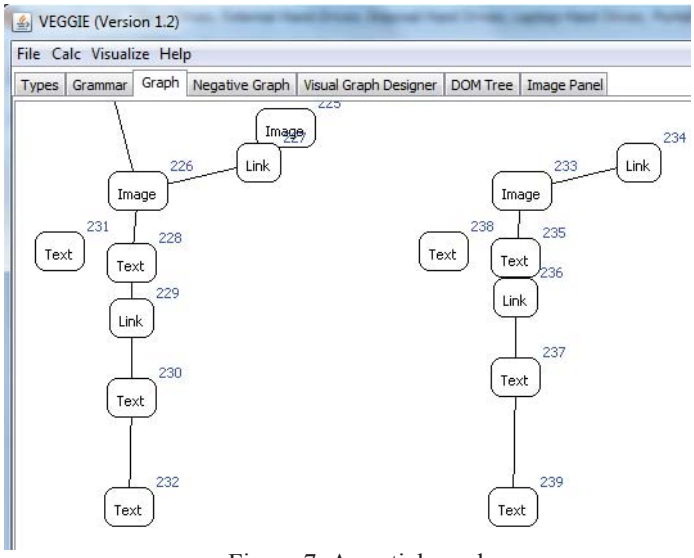

Figure 7. A spatial graph

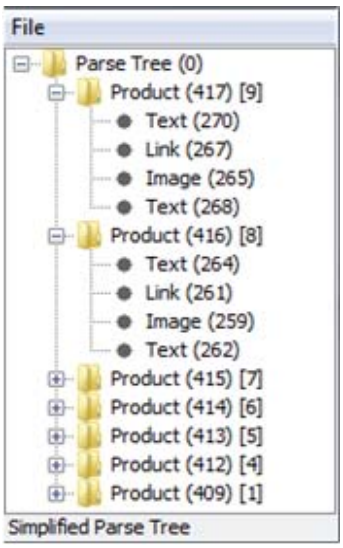

Figure 8. Parsing result

The prototype provides a complete system to support data extraction, from the specification of extraction knowledge (i.e. defining a graph grammar) to the visualization of extraction results. At first, a user uses the *Image Panel*, as presented in Figure 5, to display a Web page. In Figure 5, recognized information objects are highlighted with rectangles, and edges indicate close semantic relations. Based on the screenshot of a Web page, a user can select related information objects to intuitively design a graph grammar. After a graph grammar is defined, the user can go to the VEGGIE Type Editor or Grammar Editor (as presented in Figure 6) to elaborate the designed graph grammar. Once a graph grammar is finalized, a user can use the prototype to extract structured records that are consistent with the defined graph grammar. A user first inputs the URL of a Web page in the image panel. Then, the corresponding spatial graph is automatically generated and can be retrieved in the graph panel, as presented in Figure 7. By applying the defined graph grammar to the spatial graph, a small popup window shows up to present the extracted records, as shown in Figure 8.

V. EXPERIMENT

This section discusses the primary experiment on VGE. We first discuss the design of the experiment, and then present the results.

A. Setup

Experiment web pages: We have evaluated our approach on 21 ecommerce Web sites, which include well known Web sites, such as ebay.com, lycos.com, amazon.com, compusa.com, and etc.

Measurement: We measured the performance with the standard metrics: $recall = \frac{Ecorrect}{Ntotal}$; $precision = \frac{Ecorrect}{Etotal}$;

Where *Ntotal* is the number of data records contained in a Web page; *Ecorrect* indicates the total number of correctly extracted data records; and *Etotal* denotes the total number of data records extracted from a Web page. We also calculated the F1-Score, which is the harmonic mean of *precision* and *recall* and is defined as $\frac{2\times recall\times precision}{recall+precision}$. The F1-Score has been commonly used as a metric to evaluate the overall performance in many approaches [3, 9].

Execution Platform: We have evaluated our approach on a desktop with a Core 2 Duo CPU 2.26 GHz and 4 GB RAM, running Windows 7 Professional.

B. Evaluation

Precision/Recall/F1-Score: The evaluation results are presented in Table 1. The recall of our approach is 99.5. The high recall rate in our approach indicates that graph-grammar-based visual analysis is powerful to recognize structured records. The precision of our approach is 95.5%. Our approach may falsely recognize some records, which are mainly caused by noise. For example, if an advertisement is placed in the central area and its overall layout is similar to our selected pattern (e.g. including a link, a picture and several lines of textual description that are displayed vertically); this advertisement may be recognized as a product record. In order to improve the precision, it is critical to improve the graph generation process by removing potential noise. F1-Score shows the overall performance. Our approach has a high F1-Score of 97.49%. In summary, the results indicate our approach has a good performance in terms of both precision and recall.

VI. CONCLUSION

This paper presents a novel and general solution to extract data across different Web sites. Our method works based on graph grammars to extract the same type of information from different Web sites without the need of training and adjustment for different Web sites. Our approach utilizes both the visual features of a rendered Web page and the HTML DOM structure to extract structured records. We have implemented a prototype and tested the prototype on 21 Web sites. The evaluation shows promising results. Our approach has a high F1-Score as 97.49%. The evaluation results indicate our approach has a good performance in terms of both precision and recall. The main advantage of our approach lies in its ability to distinguish the most important contents from less important and noisy information and to convert the complex HTML DOM structure to a simple spatial graph. The generated spatial graph significantly reduces the complexity of the original Web page. Based on the simplified spatial graph, our approach is efficient to extract structured records through a graph parsing.

In the future work, we will identify more spatial relations between information objects, and optimize the graph generation algorithm. These optimizations may increase the quality of generated spatial graphs, which can affect both the precision and recall.

***Abstract*— On-line analytical processing (OLAP) provides tools to explore data cubes in order to extract interesting information. Nevertheless, it cannot offer any explanation of relationships that could exist within data. To achieve this goal, the association rules were performed on data cubes. We focus in this work on a particular class of association rules which is the cyclic association rules. The latter aims to discover rules that occur in user-defined intervals at regular periods. Generally, the generated patterns do not take into consideration the specificities of the multi-dimensional context *i.e.*, the measures and their aggregations. In this paper, we propose a new method of extraction of cyclic association rules from both dimensions and measures. In addition, we redefine the quality metrics of the derived patterns using the summarizability of measures through applying the suitable aggregation functions. To prove the utility of our approach, we undertake an empirical study on a real data warehouse.**

I. Introduction

Coupling of OLAP with data mining can bring explanations of the correlations that may exist between the multidimensional data. Recently, many works focused on mining association rules from data warehouses. Some of them were mainly interested in mining association rules from data cubes. A particular form of the generated association rules is the cyclic ones. In fact, cyclic association rules (CAR) are defined as rules that occur in user-defined intervals at regular periods throughout a dataset. Compared to the stampede algorithmic effort for extracting CAR ([1],[9],[6],[13], [14]), only few works study the CAR drawn from multi-dimensional context [3] which does not take enough advantage of the data cube structure. However, many research works exploit the aggregate function in order to generate association rules, such as the COUNT function or the SUM function [4]. Nevertheless, in analysis process, users generally focus on multi-dimensional data and their associations according to more elaborated measures than simple frequencies or summations. So, restricting the considered aggregate functions to the SUM and the COUNT limits the possible considered measures or eliminates the concept of the aggregation measure during the mining process. In fact, some measures can not be summarized using addition across any dimension. Such non-additive measures are frequent and experts highly need to extract association rules from both measures and dimensions. To better illustrate our contribution, we assume that the table $\mathscr{T}$ shown in table I, is defined over three dimensions, namely: the `Time` T of the transactions, the `Location` L where the transactions took place (Jordan, Yemen) , the `Range` R (let us consider both *Licensed Range* and *Model Hospital*) as well as the three measures, namely: the `sold Quantity` Q of the range R, the `Exchange Rate` ER, the `External Turnover` ET. The `sold quantity` cannot be aggregated along the time dimension, similarly, the `exchange rate` cannot be meaningfully summarized using addition across any dimension, and the `external turnover` cannot be expressively summarized through addition along all dimensions. For instance, we aim at building rules combining several dimensions and measures like " *Every odd quarter, the* `sold quantity` *of the licensed range which is at the rate of 77520 units is sold in Jordan with an* `external turnover` *reaching 750 in the respect of an* `exchange rate` *equal to 1,948%*". The interestingness measures of such a rule are articulated on the semantic aggregation of measures using the fitting aggregation function. For example, 77520 and 750 are occurrences of different measures and should not be evaluated using the same criteria. Therefore depending on the summarizability of each measure, we employ the suitable aggregation function to qualify the importance of each value on the dataset.

Time	Location	Range	Sold Quantity	Exchange Rate	External Turnover
T	*L*	*R*	*Q*	*ER*	*ET*
Q1 of 2007	Jordan	Licensed Range	77520	1,948%	750
Q2 of 2007	Jordan	Licensed Range	75000	1,947%	550
Q3 of 2007	Jordan	Licensed Range	77520	1,948%	750
Q4 of 2007	Jordan	Licensed Range	80000	1,946%	1000
Q1 of 2008	Yemen	Model Hospital	71100	1,382%	450
Q2 of 2008	Yemen	Model Hospital	80000	1,382%	800

TABLE I

TABLE $\mathscr{T}$

To the best of our knowledge, few works address the cyclic patterns mining issue from multi-dimensional context containing semi or non-additive measures. The originality of our approach is to combine dimensions and measures during the mining process. We aim to investigate such measures that cannot be aggregated using any aggregate functions, especially the COUNT or the SUM function and to redefine the quality metrics of these generated rules through the appropriate aggregation functions. In order to mine cyclic rules from by coupling dimensions and measures, we extend our approach which exclusively takes into account the measures on the mining process [2]. This paper is organized as follows. In Section 2, we give a brief overview of our chosen discretization technique of quantitative attributes, specially in the multidimensional context. Then, we represent the cyclic patterns. After that, we review the multidimensional association rule mining approaches. To close this section, we
