The model operation methods of the concept instances mainly include three types, namely *List*, *Get* and *Set*. *List* is used to get all instances of the same type and its properties. *Get* and *Set* are used to read and write the attribute values of instances respectively. In order to maintain the bidirectional synchronization of the concept instances and the scene realtime information, the mapping rules are defined, as shown in Table II and Table III. There are three main mechanisms for the bidirectional synchronization of knowledge graph and the real-time information of scene by configuration information, runtime models and rules respectively. As Table II shown, the attribute *LName* of location L_i is from the configuration like $Get L_i.LName \rightarrow L_i.LName$. And there are similar situations in other instances of concept. The *LName* of the user U and the *Key_m* of the device need to be obtained through the runtime model, such as $Get U_i.LName \rightarrow \mathbf{RTModel}(Get T_i.location)$. The *LName* and *CValue* of the context as well as *LName* of the service need to be obtained by rules, such as $Get C_i.LName \rightarrow Get U_j.LName \left((\exists U_j) U_j \xrightarrow{Sense} C_i \right)$.

B. Relation instances modeling

As illustrated in Table IV, we further define the rules for constructing relation instance to express the relationships between concepts in a smart home scenario. When two instances of a concept meet certain preconditions, the relationship between them is constructed. For instance in Rule 4, if the area *LName* of the service S_i is equal to the context C_j , and *Effect* of S_i is *Increase*, the relationship instance $S_i \xrightarrow{increase} C_j$ is created. In Rule 2 and 3, the relationship *Scence* and *Provide* involve the user's environmental information and the device's features in the real

scenario, so this kind of information needs to be obtained from the developers' configuration data.

Fig. 2. Instance of dependency parsing tree

V. MAPPING NATURAL LANGUAGE TO SERVICES

In this chapter, we first apply dependency parser to information extraction. Secondly, knowledge reasoning rules are specified to transform the results of information extraction into the search of service nodes in the knowledge graph.

Dependent syntax explains the syntactic structure of sentence by analyzing the dependencies between components within a language unit, as shown in Figure 2. According to the characteristics of commands in smart home scene, we chose dependency parsing to extract the information from natural language instructions.

The final goal is to determine the *Service* instance S_i based on the properties $DName(D)$, $LName(L)$, $CType(C)$ and $Effect(E)$ to invoke the $DFunction$. Therefore, the task of information extraction is to identify four kinds of the mentioned information. This will allow us to convert any natural language utterance to a canonical representation, which we can map to services.

A. Rules of Extraction

In this paper, Stanford Parser is applied for dependency parsing. The generation of the extraction rules mainly depends on the Part of Speech (POS) of the extraction task and the dependency characteristics.

TABLE IV
RULES FOR CONSTRUCTING RELATION INSTANCES

	Relation Instance	Precondition
1	$X_i \xrightarrow{Locate} L_j$	$X_i.LName = L_j.LName$
2	$U_i \xrightarrow{Sense} C_j$	—
3	$D_i \xrightarrow{Provide} S_j$	—
4	$S_i \xrightarrow{increase} C_j$	$S_i.LName = C_j.LName \wedge S_i.CType = C_j.CType \wedge S_i.Effect = "Increase"$
5	$S_i \xrightarrow{Reduce} C_j$	$S_i.LName = C_j.LName \wedge S_i.CType = C_j.CType \wedge S_i.Effect = "Reduce"$
6	$S_i \xrightarrow{Assign} C_j$	$S_i.LName = C_j.LName \wedge S_i.CType = C_j.CType \wedge S_i.Effect = "Assign"$

1) *Extraction Rules of "Effect"*: *Effect* is the operation of changing the environment or managing the device in commands given by users. By summarizing the commands for the smart home scene, we found that an operation is usually represented by a single verb or a verb phrase, like "increase" and "turn on". There is a specific dependency "compound:prt" between words in a verb phrase. The dependency path of the verb part of the sentence is shown in Figure 3. In algorithm 1, we elaborate how to extract the "Effect" according to the dependency relationship. The identifier p is used to represent the nodes in the dependency parsing tree. For example, every word in Figure 2 can be expressed as p . We use $p.word$ to describe content of the node p . $p \rightarrow son$ illustrates the child node of p . The part of speed of p is represented by $p.pos$. $p \rightarrow head$ expresses the parent node of p . Above all, we imply $r(p, q)$ to describe the dependency relationship between node p and q .

Fig. 3. Dependency paths of verb part

Algorithm 1 Extracting the "Effect" information

Input: Dependency parsing of the command;
Output: "Effect" information E
Find the node p whose part of speech is "VB", $E=p.word$;
while p has a child node $p \rightarrow son$ and the relationship $r(p, p \rightarrow son)$ is "compound:prt" **do**
 $E=E+(p \rightarrow son).word$;
 $p=p \rightarrow son$;
end while

2) *Extraction Rules of DName, LName and CType*: Mapping the attributes *DName*, *LName* and *CType* to the commands is the information of device, area and attribute of environment or device. The expression of these three kinds of information can be summarized in the following two ways.

- Entity of a single noun, like "light", "temperature", "bedroom".

- Entity composed by phrase. It can be divided into two categories. One is the form of "noun+noun" and their relationship is "compound", like "air condition". The other is the form of "adjective+noun", their relationship is "amod", like "sitting room".

The data stored in the knowledge map is matched with the extracted information to classify. In summary, the extraction rules for the three kinds of information as algorithm 2 shows.

Algorithm 2 Extracting the "device", "location" and "attribute" information

Input: Dependency parsing of the command;
Output: "device" information D, "location" information L, "attribute" information A
Find the node p whose part of speech is "NN", $C=p.word$;
while p has a child node $p \rightarrow son$ and the relationship $r(p, p \rightarrow son)$ is "amod" or "compound" **do**
 $N=N+(p \rightarrow son).word$;
 $p=p \rightarrow son$;
end while
Look for knowledge graph node S_i ;
Judge the type of information N is *DName*, *LName* or *CType*.

B. Rules for Knowledge Reasoning

After information extraction is done, we need to map extracted information to service in knowledge graph through transformation mechanism. Universal rules of knowledge reasoning is proposed in term of different extraction results for matching the services. Rules are listed in Table V.

Rule 1, 2 and 3 outline that the user directly specifies the operation of a device. For example, when the user specifies "'D", "L", "C" and "E", construct rule 1. If there is service instance S_i and the value of attribute *LName* is L , *DName* is D , *CType* is C , and *Effect* is E , call the function interface *DFunction* of service S_i .

Rules 4 and 5 describe the knowledge reasoning based on the user's environment when the information given by the user is insufficient to locate the specific service. For example, when the user gives the operation and device, construct rule 4. Firstly, the location information of the device is obtained according to the *LName* of the current user U_i . Then, we

need to find a service S_j that meets the following conditions. The attribute $LName$ value of S_i is equal to $LName$ of U_i , $DName$ of S_i is D , and $Effect$ is E . Finally, the function interface pointed to by the attribute $DFunction$ of the service S_i is called.

VI. EVALUATION

In this section, we build a prototype system of smart home for the actual scene to evaluate the method. Firstly, we evaluate validity of the modeling method for knowledge graph instances. Secondly, we compare the development difficulty and execution performance of the service with the traditional method. Finally, we discuss the precision of information extraction.

A. Study Case

Fig. 4. Example scenario of smart home

There are 3 areas in the scene, which are the sitting room, bedroom and balcony, as shown in Figure 4. For example, there are some smart devices such as an air conditioner, lights and an air purifier in the sitting room. The scene includes four types of environmental states: temperature, humidity, brightness and particulate matter. There are services such as “turn on”, “turn off”, “increase”, “reduce” and so on for various functions of different devices. Fig. 5 shows the instance of the knowledge graph which is generated with respect to the smart home scene.

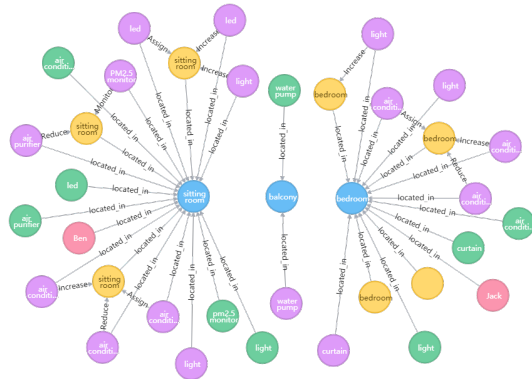

Fig. 5. Instance model of the knowledge graph for smart home

B. Evaluation of the Model

In this section, we develop smart home services based on Java to verify the effectiveness of the method, comparing the process and the difficulty of services development with the method we proposed.

1) *Process of Service Development*: To develop services based on Java, developers must be familiar with the management interfaces of different intelligent devices and realize their interaction. Moreover, because services are based on these management interfaces, their management logic cannot be reused.

We built the runtime model of the smart devices with the help of the SM@RT tool [10] [11], which realizes the data read-write and function invocation of the devices in a unified manner (SM@RT is available from the reference [12]). S-M@RT(supporting model at runtime) is a tool for constructing the runtime software architecture by model-driven, including domain-specific modeling language (SM@RT language) and code generator (SM@RT generator).

SM@RT language allows users to define the meta-model and accessing model of run time software architecture. The meta-model defines the structure and manageable elements of the target system. The accessing model declares the methods of managing these elements in meta-model.

SM@RT generator can automatically generate and maintain the infrastructure of run time software architecture based on meta-model and access model, and reflect the real-time state of the underlying system to the run time model. At the same time, the intelligent device run time model only needs to be constructed once then it can be reused in different smart home scenarios. Therefore, it does not bring extra work.

Based on the run time model of smart devices, developers can automatically build voice control services in smart homes by describing Scenario-Oriented knowledge, configuring the mapping relationship between conceptual instances and smart devices, and describing the environment of service objects.

2) *Difficulty in Service Development*: Table VI compares lines of code for smart home services developed by the two methods. We develop services in Java, and each service is developed independently. When using the method we proposed, developers need to finish the scenario oriented configuration, and the basic code are 115 lines.

For example, it takes 197 lines of code to implement the service S_{11} for temperature adjustment performed by Jack. The workload for these two parts in service S_{11} can be 126 and 71 lines respectively. It only takes 6 lines of configuration code to achieve the same functionality in our method. Implementing these services by traditional method needs 188 lines of code in average, but only 16 lines are required using the proposed method, reducing the workload by 90%.

C. the Accuracy of Information Extraction

We convene 50 volunteers to give natural language instructions based on the prototype system. Because the smart home scene we built is small, the corpus obtained is limited. In the end, we receive 1321 responses regarding what the respondents

TABLE V
RULES FOR KNOWLEDGE REASONING

Condition	Reasoning Rules
D+L+A+O	$(\exists S_i) ((S_i.DName = D) \wedge (S_i.LName = L) \wedge (S_i.CType = A) \wedge (S_i.Effect = O)) \Rightarrow S_i.DFunction$
D+L+O	$(\exists S_i) ((S_i.DName = D) \wedge (S_i.LName = L) \wedge (S_i.Effect = O)) \Rightarrow S_i.DFunction$
L+A+O	$(\exists S_i) ((S_i.LName = L) \wedge (S_i.CType = A) \wedge (S_i.Effect = O)) \Rightarrow S_i.DFunction$
D+O	$(\exists S_j) (\exists U_i) ((U_i.UName = uname) \wedge (S_j.LName = U_i.LName) \wedge (S_j.DName = D) \wedge (S_j.Effect = O)) \Rightarrow S_j.DFunction$
A+O	$(\exists U_i) (U_i.UName = uname) \wedge (\forall S_j) ((S_j.LName = U_i.LName) \wedge (S_j.CType = A) \wedge (S_j.Effect = O)) \Rightarrow S_j.DFunction$

TABLE VI
COMPARISON IN LOC OF TWO APPROACHES

	Basic	S ₁₁	S ₁₂	S ₁₃	S ₂₁	S ₂₂	S ₂₃	S ₃₃	S ₃₄	S ₄₂	S ₄₃	Avarage
Java	0	197	231	181	210	189	140	216	184	140	195	188
Our Approach	115	6	6	6	6	6	6	6	6	6	6	16

want their smart home to do. We extracted the information from these commands and the results of the evaluation are shown in Table VII.

We will discussed the results according to the evaluation data. The accuracy of *DName*, *LName*, *CType* and *Effect* extraction from the table is 93%, 90%, 84% and 80%. Because users have different expressions of the same concept or entity. For example, “sitting room” and “living room”. Therefore, when the user does not use the same word in the knowledge map to perform operations on the device, it will lead to failure of information extraction. The information extraction method of this paper achieves better results when the user follows the scene information.

TABLE VII
THE ACCURACY OF INFORMATION EXTRACTION

Type	Sentence Number	Right Back Number	Precision
DName	867	771	89%
LName	906	815	90%
CType	532	447	84%
Effect	766	612	80%

VII. CONCLUSION

To customize and develop smart home services more efficiently, an approach is proposed to model and execute services based on natural language instructions at runtime. Due to the gap between problem domains and system implementations, accomplishing mapping between them can create significant programming complexity. In order to solve the problem we introduce the knowledge graph serve as a bridge between system requirements and system implementation. Experimental results show that the proposed method can greatly reduce the difficulty and complexity of developing smart home services. But, due to the lack of technical and design capabilities there are some function implementation could be optimized. Firstly, the detection module [13] should be added to check the correctness and completeness of the instance model. Secondly, the information extraction method need to be improved by entity linking to increase the precision.

yudj@hdu.edu.cn, xkhsy@163.com, dongjing.wang@hdu.edu.cn

Abstract—Point-Of-Interest (POI) recommendation assists users to find their preferred places and helps businesses to attract potential customers. However, the data sparsity and the complexity of user check-in behavior pose a big challenge to POI recommender systems. To tackle this challenge, we propose a POI recommendation method named HeteGeoRankRec based on user contextual behavior semantics. First, to mine the fine-grained user behavioral features, we employ the meta path of Heterogeneous Information Network (HIN) to represent the complex semantic relationship among users and POIs and integrate the context constraints (such as time and weather) into the meta paths. Secondly, we propose a weighted matrix factorization model considering the influence of geographical distance to obtain semantic preference through the user-POI semantic correlativity matrices generated by multiple meta paths. Finally, we introduce a ranking-based fusion method, which unifies the recommendation results of different meta paths as the final preference of users. Experiments on the real data collected from Foursquare show that HeteGeoRankRec has the better performance than the state-of-the-art baselines.

Keywords—location-based social network; heterogeneous information network; context information; point-of-interest recommendation; behavior semantics.

I. INTRODUCTION

In recent years, thanks for the widespread of Internet and mobile devices, Location-Based Social Networks (LBSNs) have become increasingly popular. Users explore their preferred locations, such as libraries, restaurants and stores, through the "check-in" behavior provided by the LBSN services. For example, more than 50 million people use Foursquare every month¹. The personalized POI recommendation service is designed to improve the LBSN service experience by mining user preferences through check-in data.

However, POI recommendation faces serious challenges. First, the number of POIs visited by a user usually accounts for only a small portion of all the POIs, which results in the highly

DOI reference number: 10.18293/SEKE2019-178

sparse user-POI check-in data. In addition, the decision-making process for user check-in behavior is very complex and prone to be affected by rich context information [1]. For example, user's mobility is significantly affected by geographical distance [2,3]. In other words, users are more inclined to visit closer locations. Meanwhile, user's visiting preference might be affected by their social relationships [4], meaning a user may follow the suggestions from his friends or some influential people. Besides, the user's preference may also be affected by the time [5] and the weather [6]. Taking Fig. 1 as an example, Mary may prefer to visit the library on rainy days, while Skye may like to go to the restaurant for lunch. Unfortunately, most existing works lack deep mining of user behavior semantics and suffer from the much worse data sparsity problem.

Figure 1. An example of LBSN.

In this paper, we propose a novel POI recommendation model named HeteGeoRankRec, based on user contextual behavior semantics. First, we employ the meta path of Heterogeneous Information Network (HIN) to represent the complex semantic relationships of LBSN. Afterwards, to mine fine-grained user behavioral features, we integrate the context constraints, such as time and weather, to the meta paths. Furthermore, we propose a weighted matrix factorization

¹ <https://foursquare.com/about>

considering geographical distance, from which we obtain the semantic preference through the user-POI semantic correlativity matrixes. Finally, we introduce a ranking-based fusion method, which unifies the recommendation results obtained from different meta paths as the final user preference.

The rest of the paper is organized as follows. After presenting related work in Section II, we introduce the related concepts and problem definition in Section III. Our proposed model is given in Section IV, followed by its experimental evaluation in Section V. Finally, Section VI concludes this paper and outlines the future work.

II. RELATED WORK

The POI recommendation plays an important topic in the field of recommendation systems, attracting the attention from both the academic and industrial fields. The context information, such as geographical influence, has always been regarded as a very significant impact on the recommendation performance [7]. For example, Li et al. [8] considered the user's general interests as a mixture of intrinsic and extrinsic interests, where the former is personal-taste driven and the latter is environment driven. Wang et al. [9] modeled the POI-specific geographical influence between two POIs using three factors: the geo-influence of POI, the geo-susceptibility of POI, and their physical distance. However, only considering the geographical influence is not always enough to represent the user's behavior characteristics.

User's social relationships may affect the user check-in behavior. For example, in [4], Gao et al. held that the social relationships and check-in sequences significantly affect the user's behavior and proposed a fusion model to combine two features to predict user's preference. Besides, Li et al. [10] learned potential locations from three types of friends and incorporated potential locations into matrix factorization model to overcome the cold-start problem. In addition, there are some works considering temporal effect [5] and content information [11]. Although the aforementioned works improve the recommendation performance to some extent by modeling the context information, they lack deep mining of user behavior semantics and suffer from the data sparsity problem.

In recent years, some researches [12,13,14] attempted to apply HIN to the recommendation tasks to integrate more information and represent user behavior semantics. For example, Zhao et al. [13] proposed a HIN-based recommendation method, which uses matrix factorization and factorization machine to solve the information fusion problem. Wang et al. [14] utilized the meta-path-based approach to extract implicit relationships between a user and a POI, and applied logistic regression to establish a prediction model for recommendation. However, they simply regarded the location that the user has not visited as a negative sample, without considering LBSN actually lacks the explicit feedback of POI preferences.

III. THE PRELIMINARY

As an abstract representation of the real world, the information network [15] focuses on the connection between the different types of objects, which is usually defined as follows:

Definition 1. Information Network. An information network is a directed graph $G = (V, E)$, where V is a set of objects and E is a set of links, with an object type mapping function $\Phi: V \rightarrow A$ and a link type mapping function $\varphi: E \rightarrow R$. In other words, each object $v \in V$ belongs to one particular object type $\Phi(v) \in A$, and each link $e \in E$ belongs to one particular relation $\varphi(e) \in R$. When there exists more than one type of object, i.e., $|A| > 1$, or one type of relation, i.e., $|R| > 1$, the network is called a **heterogeneous information network**. Otherwise, it is a **homogeneous information network**.

Definition 2. Network Schema. The network schema is a meta template of information network, denoted as $T_G = (A, R)$, with the object type mapping $\Phi: V \rightarrow A$ and the link mapping $\varphi: E \rightarrow R$.

Fig. 2 shows an example of LBSN heterogeneous information network schema. The network schema serves as a template for a network and tells how many types of objects there are in the network and where the possible links exist, thereby making the heterogeneous information network semi-structured.

Figure 2. LBSN heterogeneous information network schema.

Definition 3. Meta Path. A meta path M is a path defined on the graph of network schema $T_G = (A, R)$, denoted as $M = A_1 \xrightarrow{R_1} A_2 \xrightarrow{R_2} \dots \xrightarrow{R_{l-1}} A_l$.

For simplicity, we denote the meta path as $M = A_1 A_2 \dots A_l$. As shown in Fig. 2, in a LBSN heterogeneous information network, the co-check-in relationship between users can be represented by a meta path $U \xrightarrow{\text{check-in}} P \xrightarrow{\text{checked-in by}} U$, abbreviated as UPU , where U and P represent the user objects and location objects respectively.

Definition 4. Context-constrained Meta Path. A context-constrained meta path is a meta path with the context attribute constraints on relations, denoted as $M_c = A_1 \xrightarrow{\delta_1(R_1)} A_2 \xrightarrow{\delta_2(R_2)} \dots \xrightarrow{\delta_l(R_{l-1})} A_l | S$, where $\delta(R)$ represents a set of context attribute values on relation R , S defines the context of the meta path and the corresponding attribute value constraints.

For example, suppose the whole day is divided into multiple time slices T_1, T_2, \dots, T_n , and the check-in relationship between user U and POI P can occur in multiple time slices. We use $U \xrightarrow{\{T_1, T_2\}} P \xrightarrow{T_1} U$ to indicate that two users check in P at T_1 , and one of them makes a check-in at the T_2 again. Moreover, the path $U \xrightarrow{T_i} P \xrightarrow{T_j} U | \{S: \text{Context} \in \{\text{Time}\}, T_i = T_j\}$ means that two users check in the same POI at the same time slice. Taking Fig. 1 as an example, we can easily find that although three people

all go to the gym, the temporal preferences for Bob and Skye are more similar.

Definition 5. Counting Matrix. For a meta path $M = A_1 A_2 \dots A_l$, we define its counting matrix as $C_M = W_{A_1 A_2} W_{A_2 A_3} \dots W_{A_{l-1} A_l}$, where $W_{A_i A_j}$ is the adjacency matrix between A_i and A_j . The values in the counting matrix represent the number of times the interactions occur between objects.

Problem Definition. Given an LBSN heterogeneous information network G , and a check-in record set S with context information, the problem we try to resolve is to build a personalized recommendation model, and return the Top- K unvisited POIs for each user u .

IV. THE FRAMEWORK

In this section, we present the proposed POI recommendation method, called HeteGeoRankRec, in detail (Fig. 3).

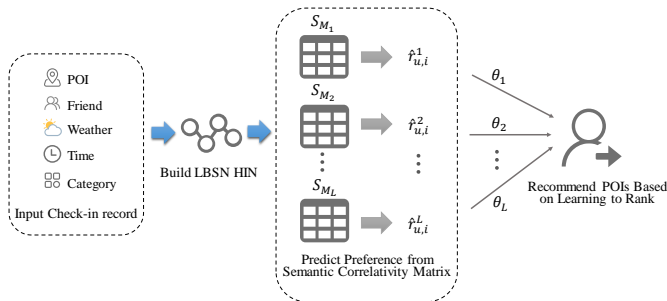

Figure 3. The Framework of HeteGeoRankRec.

A. Build Semantic Correlativity Matrixes Based on Context-constrained Meta Path

1) *Design Meta Paths:* We first employ the meta path to build the semantic relationship sequences for further analysis of user preferences. Taking the path $UPUP$ as an example, it may indicate that users prefer locations where people with common check-in records have checked in, which is a user-based collaborative recommendation. Moreover, the UUP path represents that users prefer the locations checked in by their friends, which is a social recommendation. Therefore, we can make the recommendation more explainable by designing reasonable meta paths to represent different user behavior semantics. Table I lists the meta paths and their corresponding semantics, where C represents the category of POI.

In addition, the context-constrained meta path is used to capture the user's preferences in different contexts (e.g. time, weather). For the meta path like $U * UP$ (e.g. M_3 and M_5 in Table I), we add context constraints as follows:

$$M_C: U \xrightarrow{i} P * P \xrightarrow{j} U \xrightarrow{k} P \{S: Context \in Z, i = j = k\} \quad (1)$$

where $Z = \{Time, Weather\}$ represents a set of context types. Note that weather indicators, such as cloud cover and temperature, can also be divided into multiple numerical

segments. Here, $i = j = k$ indicates that the behavior occurs in same context.

TABLE I. THE META PATHS AND ITS SEMANTICS

Symbol	Meta path	Semantic
M_1	UP	Users prefer locations they have checked in
M_2	UUP	Users prefer locations where their friends have checked in
M_3	$UPUP$	Users prefer locations where people with common check-in records have checked in
M_4	$UPCP$	Users prefer the same category of locations they have checked in
M_5	$UPCPUP$	Users prefer locations where people having checked in the POIs of the same category have checked in

2) *Build Semantic Correlativity Matrix:* We employ the counting matrix defined above as a counting-based correlativity matrix between user objects and location objects, denoted as S_M . This can effectively alleviate the sparsity of the user-POI relation matrix by computing the correlativity through meta path. The counting-based correlativity reflects the idea of high correlativity between nodes with high visibility in the LBSN heterogeneous information network. Such an idea is intuitive and suitable for recommendation task. Taking the time context as an example, the semantic correlativity matrix is built according to Eq. (2), which involves three steps: (a) Divide the time of day into multiple slices T_1, T_2, \dots, T_n , and obtain user check-in records for each slice; (b) Obtain the correlativity matrixes $S_{M_{T_i}}$ by calculating the correlativity from meta paths within each time slice; (c) Add the correlativity matrixes to construct the semantic correlativity matrix S_{M_C} of the context-constrained meta path.

$$S_{M_{T_i}} = (W_{A_1 A_2} W_{A_2 A_3} \dots W_{A_{l-1} A_l})^{T_i}, S_{M_C} = \sum S_{M_{T_i}} \quad (2)$$

B. Predict POI Preference Based on Weighted Matrix Factorization

In this section, we extend the weighted matrix factorization algorithm based on implicit feedback proposed in [16] and optimize the objective function by adding geographical influence factor to make it suitable for POI recommendation.

1) *Calculate User-POI Check-in Probability:* Users are more inclined to visit closer locations. The check-in probability of the user from one location to another x (km) away approximately follows the power law distribution [2], as the following:

$$y = Pr_u(i, j) = a \cdot x^b \quad (3)$$

Let $a = 2^{w_0}$, $b = w_1$, and Eq. (3) is then transformed into Eq. (4) by taking the logarithm:

$$\log y = w_0 + w_1 \log x \quad (4)$$

Let $y' = \log y, x' = \log x$. We then use the linear regression method to optimize the following loss function to obtain the regression coefficient:

$$L = \frac{1}{2} \sum_{n=1}^N (y'_n - p_n)^2 + \frac{\lambda}{2} \|\mathbf{w}\|^2 \quad (5)$$

where w_0 and w_1 are regression coefficients, denoted together by \mathbf{w} , p_n is real check-in probability to the x'_n , and the regularization parameter λ is used to prevent the model from overfitting.

Then the check-in probability from POI i to j for user u is normalized by Eq. (6):

$$Pr_u^G(i, j) = \frac{Pr_u(i, j)}{\max(Pr_u)} \quad (6)$$

where the denominator represents the maximum check-in probability of two POIs among the user records.

2) *Incorporate Geographical Influence*: Suppose the corresponding value in the meta-path-based semantic correlativity matrix is represented as $S_{M_{u,i}}$. We define the user implicit preference as follows:

$$r_{u,i} = \begin{cases} 1 & S_{M_{u,i}} > 0 \\ 0 & S_{M_{u,i}} = 0 \end{cases} \quad (7)$$

In other words, $r_{u,i}$ indicates whether there is a value greater than 0 in the correlativity matrix. Furthermore, we introduce $c_{u,i}$ to measure our confidence in $r_{u,i}$. In general, as $S_{M_{u,i}}$ grows, there is a stronger indication that user indeed prefers the location. Eq. (8) defines $c_{u,i}$, where α controls the rate of increase.

$$c_{u,i} = 1 + \alpha S_{M_{u,i}} \quad (8)$$

We believe that the user's preference for unvisited POIs is limited by the distance between the candidate POIs and the POIs that the user has checked in. Thus, based on matrix factorization, the new user preference can be defined as Eq. (9):

$$\hat{r}_{u,i} = \beta x_u^T y_i + \frac{(1-\beta)}{|D_u|} \sum_{k \in D_u} Pr_u^G(i, k) x_u^T y_k \quad (9)$$

where β is geographical influence factor, D_u represents a set of POIs that user u has checked in, x_u and y_i represents the latent feature vectors under same dimension f for user u and POI i .

Then, we solve the low-dimensional feature vector corresponding to the user and the POI by minimizing the loss function defined as Eq. (10) where λ is used to prevent the model from overfitting.

$$\min_{x_u, y_i} \sum_{(u,i) \in T} c_{u,i} (r_{u,i} - \hat{r}_{u,i})^2 + \lambda (\|x_u\|^2 + \|y_i\|^2) \quad (10)$$

The alternating least squares method is used to optimize the above loss function. For simplicity, we define the following variable:

$$\tilde{y}_i = \beta y_i + \frac{1-\beta}{|D_u|} \sum_{k \in D_u} Pr_u^G(i, k) y_k \quad (11)$$

The updating equations for x_u and y_i are obtained as:

$$x_u = (\sum_i c_{u,i} \tilde{y}_i \tilde{y}_i^T + \lambda I)^{-1} \cdot \sum_i c_{u,i} r_{u,i} \tilde{y}_i \quad (12)$$

$$y_i = (\beta^2 \sum_u c_{u,i} x_u x_u^T + \lambda I)^{-1} \times \beta \sum_u c_{u,i} (r_{u,i} x_u + \frac{1-\beta}{|D_u|} \sum_{k \in D_u} Pr_u^G(i, k) x_u^T y_k x_u) \quad (13)$$

C. Recommend POIs Based on Learning to Rank

Suppose we have designed F meta paths and G context-constrained meta paths, and have obtained $L = F + G$ user-POI semantic correlativity matrixes $S_M^1, S_M^2, \dots, S_M^L$. Each matrix generates the user semantic preference $\hat{r}_{u,i}^l$ through the matrix factorization algorithm described above. After combining the different semantic features, the final preference of user u for POI i can be formulated as:

$$r_{u,i}^* = \sum_{l=1}^L \theta_l \cdot \hat{r}_{u,i}^l \quad (14)$$

where θ_l represents the weight of the preference obtained by meta path l .

LBSN often lacks negative feedback, because we regard the POIs that the user has checked in as the positive samples. However, the POIs where the user has not visited yet does not simply mean that they are not interested in (they may not find this location). Therefore, a direct and effective recommendation model should be able to better rank the POI pairs for users, indicating that the user's preference for the POI with high correlativity is greater than the POI with low correlativity in user semantic correlativity matrix. Here, we adopt the idea of pair-wise learning. More specifically, we use the relative orders of POIs as the samples to learn the weights in Eq. (14).

Based on the method proposed in [17], we use the Eq. (15) to express the probability that user u prefers POI i instead of j :

$$p(i >_u j | \theta) = \frac{1}{1 + e^{-(r_{u,i}^* - r_{u,j}^*)}} \quad (15)$$

where $\theta = \{\theta_1, \theta_2, \dots, \theta_L\}$ is a weight vector, $>_u$ represents the ordering relationship of two POIs.

According to the Bayesian formula, if we want all the POIs to be sorted correctly, we need to maximize the following posterior probability:

$$p(\theta | >_u) \propto p(>_u | \theta) p(\theta) \quad (16)$$

Assuming that the user's ranking preference for POI pairs is independent, the likelihood function can be defined by:

$$p(R | \theta) = \prod_{u \in U} p(R_u | \theta) = \prod_{u \in U} \prod_{(i >_u j) \in R_u} p(i >_u j | \theta) \quad (17)$$

where R represents a set of ordering relationships of the POI pairs.

We assume that $p(\theta)$ follows a Gaussian distribution with zero mean and variance-covariance matrix $\sum_{\theta} = \lambda_{\theta} I$. Thus, the objective function of ranking optimization can be formulated as:

$$\begin{aligned} O(\theta) &= -\ln p(\theta | >_u) = -\ln p(>_u | \theta) p(\theta) \\ &= -\sum_{u \in U} \sum_{(i >_u j) \in R_u} \ln p(i >_u j | \theta) - \lambda_{\theta} \|\theta\|^2 \end{aligned} \quad (18)$$

We employ stochastic gradient descent (SGD) to optimize the above objective function. After obtaining θ , the predicted value of user u for all POIs can be calculated by the Eq. (14). Finally, we select K POIs that user has not visited with the highest predicted value and recommend them to the user.

V. EXPERIMENTS

A. Experimental Setup

1) *Dataset*: The experiments are based on the Foursquare dataset² provided by the author of literature [10], including the real-world check-in data from 2010 to 2011. Each check-in record includes a user ID, a location ID, and a timestamp, where each location has its latitude, longitude and category, and each user is associated with her friends. In addition, we used the API of darksky.net³ to collect the weather information for each $\langle \text{latitude}, \text{longitude}, \text{timestamp} \rangle$ record, including temperature, humidity and cloud cover. To evaluate the performances of the proposed method HeteGeoRankRec⁴, implemented based on LibRec [18], we construct two datasets via extracting the check-in records generated from Los Angeles and San Diego. The detailed statistics of the datasets are shown in Table II.

TABLE II. STATISTICS OF DATASETS

	#Users	#POIs	#Check-ins	Sparsity
Los Angeles	2,026	8,270	51,917	99.83%
San Diego	916	4,919	26,762	99.71%

In order to make the experiments more consistent with real situation, we split training data D_{train} and testing data D_{test} as follows: for each individual user, (a) aggregating her check-ins for each location; (b) sorting the location according to the first time that the user checked in; (c) selecting the earliest 80% to train the model and using the next 20% as testing.

2) *Evaluation Metrics*: We employ two widely used metrics to evaluate the performance of different recommendation methods, namely precision and recall, denoted by Pre@K and Rec@K, where K is the number of recommended POIs. We compute Pre@K and Rec@K as follows:

$$Pre@K = \frac{1}{|D_{test}|} \sum_{u \in D_{test}} \frac{|R_u \cap T_u|}{|R_u|} \quad (19)$$

$$Rec@K = \frac{1}{|D_{test}|} \sum_{u \in D_{test}} \frac{|R_u \cap T_u|}{|T_u|} \quad (20)$$

where R_u represents the Top-K recommendation results for user u , and T_u is a set of POIs visited by user u in D_{test} .

3) *Parameters Settings*: We use the meta paths listed in Table I to calculate the semantic correlativity matrixes and add time and weather context constraints to M_3 and M_5 . We divide the time of day into three slices and the weather indicators into three segments in tertile, and build the semantic correlativity matrixes by the method described in Section IV.A. The parameters of check-in probability are obtained through

learning. In particular, we set the latent feature number f of the matrix factorization model to 10, the geographical influence factor β to 0.8, and the regularization parameter λ to 0.01.

4) *Baseline Methods*: We compare the proposed method with the following baseline methods:

- WRMF [16]: A matrix factorization model for implicit feedback.
- BPRMF [17]: A matrix factorization model which optimizes the ordering of the preference for the observed location and the unobserved location.
- GMF: A matrix factorization model based on that proposed in Section IV.B and check-in matrix (correlativity matrix generated from UP meta path) directly for recommendation.
- USG [2]: A model combining user preferences, social relationships, and geographical influence with collaborative filtering.
- RankGeoMF [3]: A matrix factorization model based on ranking and geographical influence for POI recommendation.
- ASMF [10]: A model which learns a set of user's potential locations from her three types of friends, and then incorporates them into matrix factorization.

B. Experimental Result

1) *Performance Comparison*: The comparisons between the HeteGeoRankRec and other methods in terms of Pre@K and Rec@K is shown in Fig. 4. Both WRMF and BPRMF are recommendation methods for implicit feedback data. Due to the severe data sparsity problem of LBSN, these two methods do not perform well. However, we observe GMF improves WRMF by 55.7% and 19.5% in terms of Pre@5 on Los Angeles and San Diego datasets, respectively, due to the incorporation of geographical influence. Besides, USG exhibits better performance than RankGeoMF on both datasets. One possible reason is that USG integrates geographical, social information and user preference, while RankGeoMF only uses geographical information. Most importantly, on average, the proposed HeteGeoRankRec outperforms its competitors WRMF, BPRMF, GMF, USG, RankGeoMF and ASMF, in terms of Pre@5, by 81.1%, 70.5%, 31.4%, 27.2%, 49.5% and 11.4% respectively.

2) *Context Influence*: The performance comparisons of HeteGeoRankRec with different contexts are shown in Fig. 5, which indicate the limited benefit when it only introduces one type of context information. However, combining the time and weather context will greatly improve the Pre@K and Rec@K on both datasets. Therefore, it can be easily concluded that considering various contexts to mine the user's behavior from multiple dimensions makes the model more accurate.

VI. CONCLUSION

In this paper, we propose a POI recommendation method called HeteGeoRankRec based on the contextual behavioral semantics. It employs meta paths to represent the complex semantic relationship of user behavior, and combines social relationships, location categories, time and weather contexts, and geographical distance to mine the fine-grained user behavioral characteristics. In the future, we will further study the following issues: (a) deeply explore the influence factors of user behavior in LBSN; (b) express more information on the LBSN heterogeneous information network; and (c) study POI recommendation at specific contexts (e.g. time, weather).

Abstract—Point-of-interest (POI) recommendation that consists of location-based social networks (LBSNs) and provides personal services for users has become an important part in the field of recommendation system. Due to the sparseness of user check-in matrix, POI recommendation faces great challenges. However, most researches just consider of spatial and temporal impact on recommendation and do not solve the problem of sparsity. This paper proposes a POI recommendation model called RBMNMF which is based on sparse matrix of user check-ins. Firstly, by stacking restricted Boltzmann machines (RBM), the potential relationship between users and POIs is learned and multiple user-POI matrices are extracted. Second, fill the original sparse matrix by using non-negative matrix factorization (NMF). Finally, fuse those prediction matrices to generate final POI recommendation for users, which is benefit for solving the problem of sparsity effectively. Experiments on real-world data set prove that the model we propose has a better accuracy than traditional algorithms.

Keywords—Point-of-Interest Recommendation, Social Network, Restricted Boltzmann Machine, Non-Negative Matrix Factorization, Hybrid Mode

I. INTRODUCTION

Mobile internet technology has developed at a high speed which makes location-based social networks (LBSNs) become popular such as Foursquare, Gowalla, Yelp and Facebook. Compared with traditional social networks, LBSNs allow users share locations with their friends by check-in on POIs (such as cinemas, amusement parks and restaurants). The number of POIs has increased faster at present, so it's necessary to recommend satisfying POIs to users for saving choice time and improving their experience of life in city. However, mining locations among a large number of POIs that user may have interest in is a great challenge.

Different from traditional recommendation system, the challenge of POI recommendation is bigger because the user-POI check-in matrix is a high-dimension sparse matrix, which makes analysis of user-POI matrix more difficult. From some popular data sets such as Foursquare and Gowalla, we observe that sometimes a user just visited a few locations, leading to unreasonable recommendations under the whole location space. Therefore, data sparsity has become a critical problem for POIs recommendation, which is needed to be emphasized and solved. The classical collaborative filtering (CF) algorithm calculates the similarity between users or recommend locations based on check-ins. But faced with the high-dimension sparse matrix of user check-in data, the similarity calculation of users could not be achieved and CF does not solve the problem of data sparsity.

For overcoming the sparsity, this paper proposes a deep learning model based on sparse user check-in matrix for POI recommendation, which constructs bidirectional analysis of users and POIs and aims to recommend POIs to users that meet users' preferences. The main contributions of this paper are as follows.

- Propose a deep learning model called RBMNMF for POI recommendation that is based on sparse matrix of user check-ins.
- Construct strong correlation values between users and POIs to observe and analyze users' preferences for POIs by calculating bidirectional scores between users and POIs.
- Combine stacking restricted Boltzmann machines with non-negative matrix factorization to solve the problem of data sparsity fundamentally.
- Experiments on real-world data set proves that RBMNMF we propose outperforms other traditional algorithms in terms of data sparsity.

DOI reference number: 10.18293/SEKE2019-156

This paper consists of five sections. Section 2 introduces some related algorithms of POI recommendation in LBSNs. Section 3 explicates the RBMNMf model we propose for sparse matrix of user check-ins. Section 4 shows experiments we have and the performance of our model. Section 5 summarizes this paper and discusses the future work.

II. RELETED WORK

At present, location-based POI recommendation in social networks has attracted wide attention from researchers who comes from different fields. Quan et al. [1] considered that the time factor plays an important role in POI recommendation because users visit different locations in different time periods and proposed a collaborative recommendation algorithm combining time factor. References [2-5] regarded users' mobile trajectories as key information when recommending and mined those trajectories to recommend POIs. Ramesh [6] proposed a fusion algorithm that integrated time, space and social relationships into a unified framework for POI recommendation. There have been many achievements for POI recommendation so far, which can be divided into the following three aspects.

- Collaborative filtering (CF): Although CF is the most famous recommendation algorithm, accurate recognition for similar user is a great challenge to CF because of the sparse matrix of user check-ins. Meanwhile, CF ignores lots of user information that is helpful for recommending. Shu et al. [7] proposed a collaborative filtering recommendation algorithm based on topic model to extract user preference of topics (such as culture, history, landscape and so on) information and recommended comprehensive POIs for users. Yang et al. [8] designed a general semi-supervised learning framework based on context information and reduced data sparsity by smoothing adjacent users.
- POI recommendation based on mobile trajectory: User's daily trajectory of movement is an important behavior pattern. Ya [9] extracted semantic information from user GPS trajectory to recommend POIs for users based on time, space and popularity. Zheng et al. [10] proposed a possible path algorithm for uncertain trajectory based on historical trajectory to reduce the uncertainty of user's trajectory. Thus, it is obvious that trajectory plays an important role for POI recommendation.
- POI recommendation based on geographical impact: Distance of a location has a great impact on user's preference for POI. For example, people will not tend to choose location that is far away from people's current locations. Therefore, recommendation system could filter out distant locations [11-13]. Ying et al. [14] considered user's social intention, preference, location popularity and other factors to calculate prior probability of POIs for users.

All algorithms mentioned above recommend POIs for users only by considering additional information of users' sparse check-in matrix and do not solve the problem of data sparsity effectively. However, some researchers focus on the technologies that aims to solve the problem of data sparsity such as matrix factorization [15, 16]. Yildirim [17] use PageRank

algorithm to improve cosine similarity method and alleviated data sparsity. Moreover, Ruslan [18] used restricted Boltzmann machine to handle large-scale data that achieved good performance.

In this paper, we propose a deep learning model called RBMNMf based on sparse matrix of user check-ins for POI recommendation. RBMNMf combines the neural network with non-negative matrix factorization and calculates strong correlation values between users and POIs from bidirectional way, which makes the final prediction matrix smoother. Moreover, RBMNMf are able to display users' preferences for POIs intuitively and solve the problem of data sparsity effectively. Moreover, RBMNMf has a higher accuracy when recommending and outperform some single sparse matrix filling algorithms.

III. HYBRID MODEL BASED ON SPARSE MATRIX OF USER CHECK-INS

A. Definitions

This section defines the sparse user check-in matrix, elaborates on issues of our research and presents the framework of the model we propose. User historical check-ins based on LBSNs includes user ID, location ID, longitude and latitude, check-in time and so on. For simplicity, table 1 shows the meanings of all the symbols in this paper.

TABLE I. THE MEANINGS OF ALL SYMBOLS

Symbol	Meaning
u	user ID
l	location ID
$s_{u,l}$	User score of location
$s_{l,u}$	Score of correlation between user and location
x_u	User vector
x_l	Location vector
U	Set of all users
L	Set of all locations
$M_{u,l}$	Sparse user-location matrix based on user check-ins
$M_{l,u}$	Sparse location-user matrix based on user check-ins

Definition 1: (POI). If user u has a check-in at a location l , then location l is regarded as a point-of-interest (POI). For example, l_j and l_k are two different POIs that user u has visited.

Definition 2: (Sparse User Check-in Matrix). From the LBSNs data set, construct the check-in matrix $M_{u,l}$ and s_{u,l_j} denotes the number of check-ins of user u_i at the location l_j , where $u_i \in U$, $l_j \in L$.

Definition 3: (Sparse User Check-in One-Zero Matrix). If the values of elements in check-in matrix $M_{u,l}$ are greater than 0, then set those values to 1, otherwise 0. Then we obtain the sparse one-zero matrix ${}^0_1 M_{u,l}$.

Definition 4: (Location-User Correlation One-Zero Matrix). Transpose the sparse user check-in one-zero matrix ${}^0_1 M_{u,l}$ to location-user correlation one-zero matrix ${}^0_1 M_{l,u}$.

Where ${}^0_1 M_{l,u} = ({}^0_1 M_{u,l})^T$ and $s_{l,u} \in {}^0_1 M_{l,u}$ which is the value in the matrix ${}^0_1 M_{l,u}$. s_{l_j,u_i} denotes the score of the correlation for a location l_j on user u_i .

B. Model framework

In order to solve the sparsity problem of user check-in data, this paper proposes a hybrid model called RBMNMF that combines deep learning models with non-negative matrix factorization. The hybrid model considers both user-location and

location-user bidirectional information. The model framework is shown in Fig.1.

Sparse user check-in matrix is inputted into stacking RBMs, NMF model and single RBM respectively, and then fuse result of each part to produce a recommendation list after each part calculates its own prediction matrix. RBMNMF model is composed of three parts mentioned above and each part is independent. Moreover, RBMNMF can effectively solve the problem of data sparsity.

C. Restricted Boltzmann Machine Based on Sparse Matrix

Restricted Boltzmann machine (RBM) is an undirected graph probability model with one layer of visible variables and one layer of latent variables, which is shown in Fig.2.

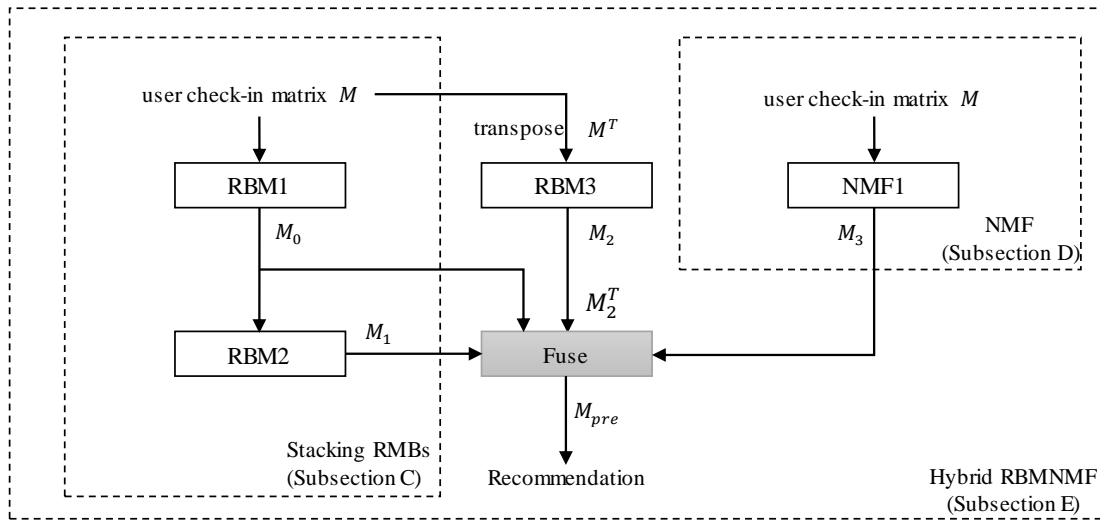

Fig.1 The main architecture of our proposed mode

Fig.2 Structure of RBM

RBM model has been widely used in binary data distribution. RBM is defined as binary random vector $\mathbf{v} \in \{0,1\}^d$ that is an energy-based model. The energy function is as (1), where \mathbf{a} and \mathbf{b} are offset vectors of hidden layer and visible layer respectively. Other symbols will be explained latter.

$$\begin{aligned} E(\mathbf{v}, \mathbf{h}) &= -\mathbf{v}^T \mathbf{W} \mathbf{h} - \mathbf{b}^T \mathbf{v} - \mathbf{a}^T \mathbf{h} \\ &= -\sum_i \sum_j w_{ij} v_i h_j - \sum_i b_i v_i - \sum_j a_j h_j \end{aligned} \quad (1)$$

The specific training process of our RBM model is as follows, where \mathbf{v}^0 and \mathbf{v}^1 are visible-layer vectors (\mathbf{v}^0 is also a binary check-in vector at the beginning), \mathbf{h}^0 and \mathbf{h}^1 are hidden-layer vectors, \mathbf{W} denotes the parametric matrix and β is learning rate.

Calculate \mathbf{v}^0 :

Input a user vector \mathbf{x} and the visible-layer $\mathbf{v}^0 = \mathbf{x}$

Calculate \mathbf{h}^0 :

Calculating the Opening Probability of Hidden-Layer Neurons:

$$P(\mathbf{h}_j^0 = 1 | \mathbf{v}^0) = \sigma \left(\sum_i w_{ij} \mathbf{v}_i^0 + a_j \right) \quad (2)$$

The hidden-layer vector \mathbf{h}^0 is obtained by random values filtered from 0 to 1

Calculate \mathbf{v}^1 :

\mathbf{h}^0 reconstructs visible layer:

$$P(\mathbf{v}_i^1 = 1 | \mathbf{h}^0) = \sigma \left(\sum_j w_{ij} \mathbf{h}_j^0 + b_i \right) \quad (3)$$

The visible-layer vector \mathbf{v}^1 is obtained by random values filtered from 0 to 1

Calculate \mathbf{h}^1 :

\mathbf{v}^1 reconstructs hidden layer:

$$P(\mathbf{h}_j^0 = 1 | \mathbf{v}^1) = \sigma \left(\sum_i w_{ij} \mathbf{v}_i^1 + a_j \right) \quad (4)$$

The hidden vector \mathbf{h}^1 is obtained by random values filtered from 0 to 1

Update Parametric Matrix:

$$\mathbf{W} + \beta \left\{ (\mathbf{h}^0)^T \times \mathbf{v}^0 - (\mathbf{h}^1)^T \times \mathbf{v}^1 \right\} \rightarrow \mathbf{W} \quad (5)$$

$$\mathbf{b} + \beta (\mathbf{v}^0 - \mathbf{v}^1) \rightarrow \mathbf{b} \quad (6)$$

$$\mathbf{a} + \beta (\mathbf{h}^0 - \mathbf{h}^1) \rightarrow \mathbf{a} \quad (7)$$

In order to prevent over-fitting and make our model smoother, data transformation and stacking RBMs are used to train data set, which is shown in Fig.3.

Firstly, input ${}^0_1 M_{u,l}$ that is the original user check-in matrix to stacking restricted Boltzmann machines model for sparse data training and filling, and then predict the location score M_0 and M_1 for users. The combination of two RBMs will enhance the matrix computation and make prediction more reasonable, which is demonstrated from our experiments.

Secondly, input ${}^0_1 M_{l,u}$ to a single RBM and then predict the user score M_2 for locations. ${}^0_1 M_{l,u}$ is the transposition of ${}^0_1 M_{u,l}$. The reason why we take this measure is that most existing works only consider of users' preference for POIs and ignore the POIs attraction to users. Thus, we decide to take transposition into account. The final predictive matrix M'_{pre} of restricted Boltzmann machine model based on sparse matrix is as follows.

$$M'_{pre} = M_0 + M_1 + (M_2)^T \quad (8)$$

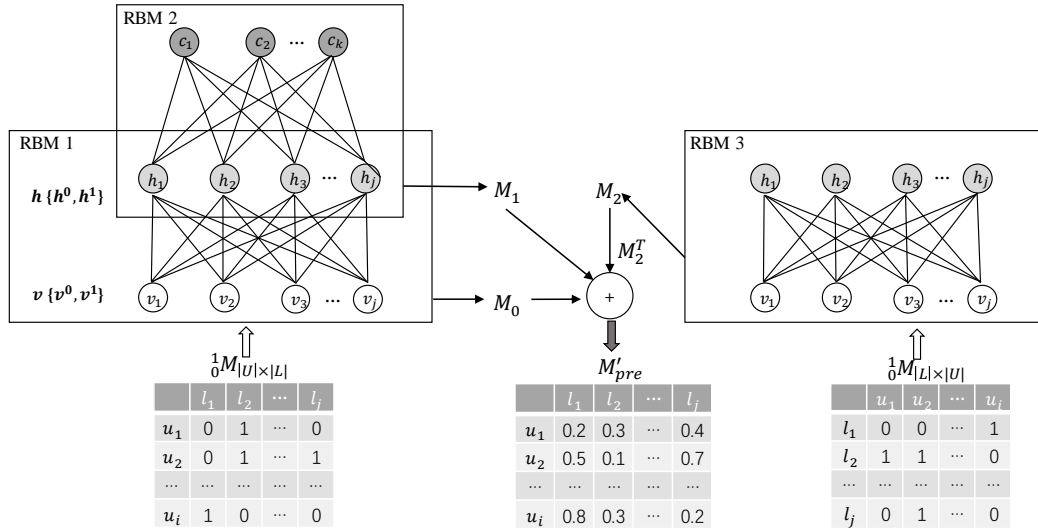

Fig.3 The workflow of stacking RBMs

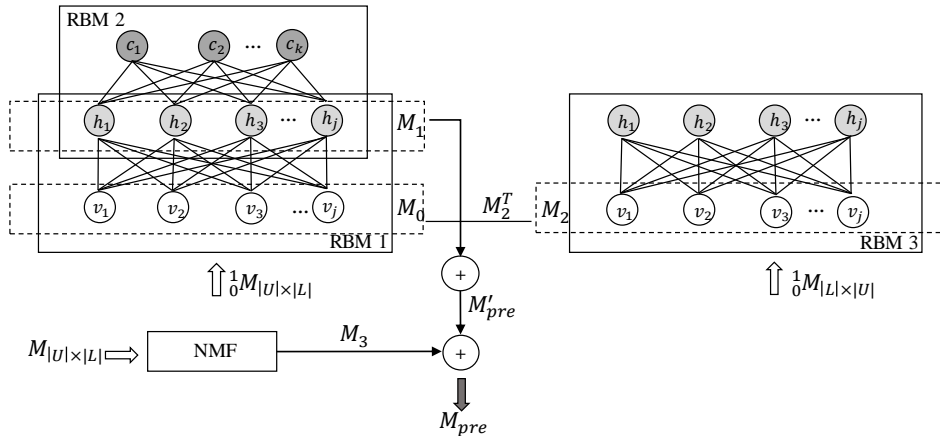

Fig.4 Combination of stacking RBMs and NMF

D. Non-Negative Matrix Factorization Model Based on Sparse Matrix

Values of elements in sparse user check-in matrix are all non-negative. However, the traditional matrix factorization model will get negative values from original matrix, which have no practical significance for user check-in matrix.

Non-negative matrix factorization (NMF) can factorize the user check-in matrix into two non-negative matrices and fill the sparse matrix with positive values. Therefore, it solves the sparse problem of matrix effectively and it's easy to observe the user's preference for locations. NMF is shown in Fig.4. $M_{u,n}$ and $M_{n,l}$ is the result of factorization of $M_{u,l}$. Thereafter, M_3 is the multiplication of them, which is filled with more negative values.

	k_1	k_2	\cdots	k_n			l_1	l_2	\cdots	l_j			l_1	l_2	\cdots	l_j
u_1	0	0.8	\cdots	0	\times	k_1	0	0.5	\cdots	1.9	$=$	u_1	0	1.8	\cdots	0
u_2	2.0	0	\cdots	0		k_2	0	2.3	\cdots	0		u_2	0	1	\cdots	3.8
\cdots	\cdots	\cdots	\cdots	\cdots		\cdots	\cdots	\cdots	\cdots	\cdots		\cdots	\cdots	\cdots	\cdots	
u_i	0	0	\cdots	2.5		k_n	1.2	1	\cdots	0		u_i	3	2.5	\cdots	0
$M_{ U \times N }$						$M_{ N \times L }$						M_3				

Fig.5 The result of factorization of NMF

In $M_{u,l}$, the value of each element represents the times that the user has visited the location. As shown above, using NMF model, predictive matrix M_3 fills the elements of $M_{u,l}$. Each element's value of M_3 denotes the preference of a user for a location.

E. Hybrid RBMNMF Model

In order to make our model smoother, we propose a hybrid model called RBMNMF that fuses the models mentioned in the above sections, as shown in figure 4.

The whole process of RBMNMF is as follows.

1) Input $M_{u,l}$ into two stacking RBMs model for sparse data training and filling. Then predict location score matrices M_0 and M_1 .

2) Input $M_{l,u}$ into a single RBM and predict the location-user correlation score matrix M_2 . Then transpose the M_2 .

3) Factorize $M_{u,l}$ into two non-negative matrices to obtain another location score matrix M_3 for users.

4) Predict the final recommendation matrix as follows.

$$M_{pre} = (M_0 + M_1 + (M_2)^T) + M_3 \quad (9)$$

5) Recommend Top-N POIs to users according to M_{pre} .

IV. EXPERIMENTS

A. Datasets

Foursquare is a social networking site that records a large number of geographic information of users' current locations. This paper uses the data set provided by Quan et al. [1] which contains 342850 check-ins from August 2010 to July 2011 in Singapore. Yuan [1] deletes users whose check-ins are less than 5 and locations checked by less than 5 users. After processing, the foursquare data set contains 2321 users, 5596 POIs and 194108 check-ins. For each user, choose 12.5% of the user's POIs for tuning parameters and another 25% of the user's POIs for testing data randomly. The left POIs are used for training. The formats of each check-in is user ID, location ID, longitude and latitude, check-in time and time ID respectively.

B. Evaluation Metric

We use *Precision@N* and *Recall@N* to evaluate our model, which are as follows.

$$precision @ N = \frac{|R(u) \cap T(u)|}{R(u)} \quad (10)$$

$$Recall @ N = \frac{|R(u) \cap T(u)|}{T(u)} \quad (11)$$

$R(u)$ denotes the list of POIs recommended to user u and $T(u)$ denotes the list of POIs that are actually checked in by user u in the test data. $|R(u)|$ is the total number of POIs in $R(u)$ and $|T(u)|$ is the total number of POIs in $T(u)$. The final precision and recall are the average of all users.

C. Experimental Result

In order to verify the recommendation effectiveness of our RBMNMF model, we compare RBMNMF with single sparse matrix filling algorithms in the same training data and test data. Those algorithms are as table 2 shows. The core of this paper is to integrate non-negative matrix factorization and stacking RBMs. So we focus on comparing our proposed algorithm with single NMF or single RBM but CF is a popular algorithm that we should also consider.

TABLE II. COMPARISON ALGORITHMS

Algorithm	Description
CF	Collaborative filtering (CF) is the most popular and classical recommendation algorithm
RBM	Single restricted Boltzmann machine based on sparse matrix of user check-ins
NMF	Single non-negative matrix factorization based on sparse matrix of user check-ins
RBMNMF	The hybrid model we propose

The experimental results are shown in Fig.6 and Fig.7. We recommend N (N = 5, 10, 20, 30) POIs for each user. The performance of CF is the worst among all algorithms and possibly due to the data set, the precision of CF does not change significantly. No matter what the value of N is, the precision

and recall of RBMNMF are generally better than other single algorithms. Hence, even though there is a lack of user information, RBMNMF we propose are able to fill the sparse matrix well and have an excellent performance when recommending. The results of experiments demonstrate RBMNMF could be used into improving traditional algorithms.

However, there is a limitation in RBMNMF. When stacking RBMs process check-in data, we adopt the behavior of check-in to represent the user's preference for a location by 0 or 1. That treats all locations equally that a user has visited even though they have different numbers of check-ins.

Figure 6. Precision with different N

Figure 7. Recall with different N

V. CONCLUSION

For the sake of overcoming the sparsity problem of user check-in matrix, we propose a deep learning model called RBMNMF that combines stacking restricted Boltzmann machines with non-negative matrix factorization to make the prediction model smoother. RBMNMF fills the user check-in matrix and alleviates the problem of data sparsity effectively. Therefore, we could observe each user's preference value for each POI intuitively and then recommend satisfying POIs to users. In the future, more information will be taken into account such as time, geographical effect and location popularity to improve our model.

Abstract—Code generation is a model-driven engineering approach that enables developers to generate source code automatically and achieves extremely high development productivity. Specifically, generating code from a descriptive text reduces the time and expense of software development significantly. However, the performance of existing methods is not satisfying, since they are either of low accuracy (lack of specifics of the generated code) or too complicated (lack of efficiency in training). In this work, we proposed three novel methods by combining neural architectures and syntax rules, aiming at explicitly capturing the syntactical characteristics of target code. First, we proposed three models based on the Combination of Deep learning and Syntax rules (CDS models). Then, we evaluated CDS models with BLEU metric by comparing our models with existing methods. The results show that our models outperform existing methods for the challenging code generation task. Finally, we conducted a comparative study between the three CDS models. With further analysis we provided advice on the choice of neural architectures by considering both task accuracy and efficiency. Experimental results show that (1) there is a trade-off between speed and accuracy of the model, and (2) one of our CDS models (i.e., the CDS-POOLING model) outperforms other existing methods for the challenging code generation task.

Index Terms—code generation, neural network, abstract syntax tree, encoder-decoder

I. INTRODUCTION

Code generation is a process of generating source code from sentences that describe code functionality [1]–[3]. Firstly, generating code automatically with given descriptive sentences as constraints is significantly faster than writing the code manually. Moreover, the generated code works in an expected way and is more maintainable and extendable. In contrast, with code written manually, different developers tend to use different styles, which may lead to software errors. Thus, code generation is of great significance throughout the software development lifecycle.

However, code generation is challenging because its output must abide by the syntax rules strictly, and the arithmetic speed

Fig. 1. An example of Hearth Stone dataset

for the purpose of practicability should also be considered. Considerable effort has been invested in code generation, which results in several types of code generation approaches. However, they often fail to generate executable code correctly because they hardly capture complicated code structures.

Recently, deep learning approaches based on neural networks have shown significant performance improvement on many artificial intelligence tasks. Public datasets speed up the development of the code generation area. One of high-quality datasets is Hearth Stone¹, which aims to generate Python code based on Hearth Stone card description. An example is shown in Fig 1, in which a piece of code lies along the bottom. Each card is identified by ten attributes (e.g., name and attack) and has a text box to describe the effect of the card.

In this work, we proposed three models based on the Combination of Deep learning and Syntax rules (CDS models). This work involves some neural architectures (e.g, self-attention network, CNN) which have already resulted in significant progress in the field of natural language processing. Meanwhile, considering the essential difference between

¹ available at <https://github.com/deepmind/card2code>

code and natural language, our work also takes syntax rules into account. Specifically, we represented the code in a tree structure. In addition, considering the poor performance of Recurrent Neural Network in existing methods [1]–[4], we adopted the pooling operation and self-attention mechanism in code generation tasks. Moreover, we explored the strengths and weaknesses of our CDS models (i.e., CDS-POOLING, CDS-CNN, and CDS-SAN models).

The key contributions of our study are described as follows:

- a) We proposed three novel code generation frameworks, based on the Combination of Deep learning and Syntax rules (CDS models). To the best of our knowledge, we are the first to use Transformer model (self-attention network) and pooling operation in code generation. And our high-performance models lead to a significant improvement of BLEU score.
- b) We conducted a comparative study between three models we proposed. We also thought that researchers need a comprehensive analysis of the task and should adopt simple and effective networks, when using deep learning methods.

II. RELATED WORK

Generating code in software engineering has a long history. Some early works focus on domain specific languages [5], [6]. For general-purpose code generation, such as [7], which tries to generate the code for parsing input documents. It was presented that data driven methods instead of manual methods are used in manufacturing model, and code could be generated automatically.

There are some early works using syntax rules only. (1) Parser Generation approach: some tools such as template engine [8] were used to automatically generate parser, but it is too complicated and cannot cover every scenario. (2) Model Driven approach: an entire application or just its skeleton is generated. (3) Database-related approach: usually the programmer defines a database schema, from which entire CRUD (Create, Retrieve, Update, and Delete) operations or just the code to handle the database can be generated. (4) Metaprogramming approach: some researchers developed a new language which could manipulate another piece of source code; it means that the source code is just another data structure that can be manipulated [9]. (5) Retrieval-based approach: some researchers leveraged subtree retrieval mechanism, which can explicitly output existing code examples. [10].

Recently, neural networks are introduced to code generation. Encoder-Decoder architecture has shown good performance in practical applications, such as machine translation, dialogue system, and image captioning. The encoder processes an input sequence $x = (x_1, \dots, x_m)$ of m elements and returns state representations $z = (z_1, \dots, z_m)$. The decoder takes z and generates the output sequence $y = (y_1, \dots, y_n)$ left to right. To generate output y_{i+1} , the decoder computes a new hidden state h_{i+1} based on the previous state h_i , an embedding g_i of the previous target language word y_i , as well as a conditional input c_i derived from the encoder output z . Based on this generic

formulation, various encoder-decoder architectures have been proposed.

Recent works on neural machine translation mostly base on sequence-to-sequence models are worth referring for us. [11], [12] and many works following adopt attention based models to get better performance with longer sentences. [13] uses CNNs to build sequence-to-sequence model which is faster and allows to discover compositional structure. Transformer is proposed in [14] first. Although originally used in translation tasks, self-attentive feed-forward sequence models have been shown to achieve impressive results on many sequence modeling tasks [14]–[16]. For code generation task, some researchers attempted to adopt sequence-to-sequence models [1] or models based on abstract syntax tree [2]–[4], [17] to get valid program. The decoder of neural network models above are all based on RNNs except for [17] which uses CNNs to capture information.

Moreover, some researchers found that much simpler word-embedding-based architectures exhibit impressive performance, compared with more-sophisticated models using RNN or CNN [14]. There are some related works which introduced pooling to some tasks. [18]–[20] show that average pooling can obtain impressive accuracy on both sentence and document-level sentiment analysis, factoid question-answering and text classification tasks with much less training time than competing methods.

III. ARCHITECTURE

We first define the code generation task as below:

Given a descriptive text q , our target is to generate code (e.g., Python code), specifically in an AST a format. In this paper, we start with the syntactic code generation model proposed in [2]. It focuses on generating AST from text, and then converting it to concrete code. Formally, our goal is to find a best generated AST \hat{a} as Eq.(1):

$$\hat{a} = \arg \max_a p(a|q) \quad (1)$$

$$p(a|q) = \prod_{t=1}^T p(y_t|y_{<t}, q) \quad (2)$$

where $y_{<t}$ represents $y_1 \dots y_{t-1}$ and T is the number of total time steps.

Our CDS models can be divided into three dimensions: pooling based, CNN based, and self-attention network based. We train these three models independently, with input of (a) predicted structure of AST, (b) name of variables, and (c) name of functions containing syntax information.

A. CDS-POOLING

Word embeddings can learn a lot from rich unstructured descriptive text, which are widely adopted as building blocks in the area of Natural Language Processing (NLP). Word embeddings can cluster similar words in semantical level by representing each word as a fixed-length vector and encoding the linguistic regularities and patterns implicitly. Thus, our

CDS-POOLING model is closely related to Deep Averaging Network, which demonstrates that the average pooling operation achieves tremendous results for some NLP tasks. Pooling operations capture high level semantic features and low level word characters information, just same as a method of information fusion. Moreover, we explored different pooling operations, rather than only average-pooling.

Average Pooling: Average pooling computes the element-wise average over word-vectors for the descriptive text, which average the value of K dimensions for all word embedding. Thus, Average Pooling is able to obtain a representation z with the same dimension as the embedding itself.

$$z = \frac{1}{L} \sum_{i=1}^L v_i \quad (3)$$

Max Pooling: Max Pooling extracts the most salient features from every word-embedding dimension, by taking the maximum value along each dimension of the word vectors.

$$z = \text{Max-pooling}(v_1, v_2, \dots, v_L) \quad (4)$$

where the j -th component of z is the maximum element in the set v_{1j}, \dots, v_{Lj} , where v_{1j} is, for example, the j -th component of v_1 . With this pooling operation, those words that are unimportant or unrelated to our task will be ignored in the encoding process.

Hierarchical Pooling: Both average- and max- pooling do not take word order into consideration, which could be useful for code generation tasks. Thus, we also proposed a hierarchical pooling layer, where the two abstracted pooling features are concatenated together to represent the sentence embeddings. However, Hierarchical Pooling learns fixed-length representations for the n -grams that appear in the corpus, rather than just capturing their occurrences via count features, which is more suitable for code generation.

For all CDS-POOLING variants above, there is no additional network to extract features. We just apply max-pooling after embedding, and then attention mechanism is used to acquire information between features. Finally, two layers of fully connect neural network and a softmax layer is applied to get the classification result. Thus, CDS-POOLING model quickly captures only intrinsic word-embedding information for code generation. In experiments, we proved that the CDS-POOLING model significantly promote the precision and accelerate the calculation speed.

B. CDS-CNN

The Convolutional Neural Network (CNN) [21] is another strategy extensively employed encode text sequences. Convolution operation can be described as using filters $\mathbf{w} \in \mathbb{R}^{h \times k}$ to capture word-level features. For each kernel F , a convolution operation uses a $D \times K$ slide. First, We applied the embedding mentioned above as input, which is a tensor of $D \times L$ dimensions. L represents the length of descriptive sentence and D is the embedding dimensions. Then, for each step, we summed the weighted value in filters and applied nonlinear activation

Fig. 2. Simple Word-Embedding-Based Model

operation to obtain the filter. Finally, the filters become a vector which represents the output. In practice, several layers are applied to capture the hierarchical information.

We learned from [22] and applied residual structure in our model. What's more, we also conducted batch normalization [23] to speed up the training process and improve the model performance. Our CDS-CNN model is showed in Fig 3. The embedding input has the shape of $N \times L \times D$. Our designed interact-CNN takes into account the relationship between natural language and semantic structure. Moreover, we use the concatenation operation to mix the information from natural language and AST together. But attention is needed for our operation of transposing the length-dimension and embedding-dimension to fully mix the information. At the final part of interact-CNN, we applied max-pooling to get the hierarchical information. Through the interact-CNN part, the shape of our tensor is reduced to $N \times D$. At the final part of Fig 3, there are multilayer perceptron (MLP) and softmax layer to generate final AST. CNN can be fully trained in parallel to better exploit the floating-point computation capacity of GPU, compared with RNN in the train step.

Fig. 3. Encoder-Decoder CNN

C. CDS-SAN

Transformer architecture [14] is based entirely on attention mechanisms and achieves best performance in the neural machine translation. In this work, we adopted the self-attention network architecture, which is a modified version of Transformer for two reasons. Firstly, it could be trained fast for its

parallelizable structure, while traditional RNN model is computational and time consuming due to its recurrent structure. Secondly, it naturally constructs the long-term dependence via the attention mechanism, see Eq 4. It implies that Transformer architecture learns non-local dependencies between tokens regardless of the distance between them.

The self-attention network (SAN) is a special case of the attention mechanism, which models the dependencies between tokens from the same sequence [14]. In our work, the self-attention layer aims to create the embedding representations of the original text input. Specifically, given the text $H = (h_1, h_2, \dots, h_L)$ carrying the semantics of the original review along all time steps from the encoder, self-attention network first yields a weight matrix $A^{enc} = (a_1^{enc}, a_2^{enc}, \dots, a_L^{enc})$, computed as $A^{enc} = \text{softmax}(w_2^{enc} \tanh(w_1^{enc} H^T))$, where w_1^{enc} is a parameter vector and w_2^{enc} is a parameter matrix. *Softmax* function is used to normalize the attention weights.

Since embeddings represent linguistic context information weakly, we use self-attention network to encode input for a better representation and drop out the decode part.

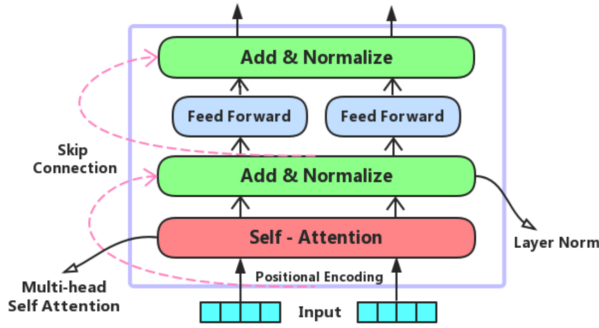

Fig. 4. Self-attention Network

IV. EXPERIMENT

Our experiment aims to answer the following research questions (RQs):

RQ1: How do CDS models perform?

Our work intends to make a comparative study of the differences between our CDS models and existing state-of-the-art methods (e.g., LPN [1], SNM [2], ASN [3], and SEQ2TREE [4] all mentioned above in section II).

RQ2: Can we find a trade-off between training speed and accuracy of the result?

Most models with more expressive composition functions perform well? Speed and accuracy, which matters more in reality? This work includes a rigorous evaluation regarding the added value of sophisticated composition functions.

A. Dataset

We used Hearth Stone dataset introduced by [1] as a practical code-generation application. It has 655 cards in total, 533 cards for training, 66 cards for validating, and 66 cards for testing. Each card is identified by ten attributes (e.g., TYPE

and ATK) and has an functional describe in the text box. Code implementations of these cards implement the game logic and card effects once per turn.

B. Evaluation Metrics

We used bilingual evaluation understudy score (BLEU) [24] as the evaluation metric in our experiment. Although BLEU is developed for translation tasks originally, it can be used to evaluate programs in this work through measuring how close the generated code is to the ground truth code in terms of n -grams.

To obtain the BLEU score, we computed modified n -grams precision (p_n) first. The modified n -grams prediction is computed as follows. All candidate n -grams counts and their corresponding maximum reference counts are collected. In the code generation task, the reference is executable code.

$$p_n = \frac{\sum_{C \in \{Candidates\}} \sum_{n\text{-gram} \in C} Count_{clip}(n\text{-gram})}{\sum_{C' \in \{Candidates\}} \sum_{n\text{-gram}' \in C'} Count(n\text{-gram}')} \quad (5)$$

Then, we define BP to penalize the generated program shorter than ground truth. c is the length of generated code and r is the reference code length.

$$BP = \begin{cases} 1 & \text{if } c > r \\ e^{1-r/c} & \text{if } c \leq r \end{cases} \quad (6)$$

Finally, we get

$$BLEU-N = BP \cdot \exp\left(\sum_{n=1}^N w_n \log p_n\right) \quad (7)$$

In our experiment, we used $N = 4$ and uniform weights $w_n = 1/N$.

Additionally, we also calculated the ACCURACY score which represents the percentage of 66 test codes that can be executed and absolutely correct.

C. Experiment Hyperparameters

For the CDS-POOLING model, our character embedding has 256 dimensions. We used a dropout rate of 0.7; for the CDS-CNN model, we set the embedding size as 128 to concentrated information and hidden-layer size as 128 to extract features. The dropout rate is 0.5 because CNN model is more complicated than pooling. For the CDS-SAN model, we followed the base Transformer [14], with 4 encoder layers of 128 hidden dimensions, and 8 attention heads per-layer. And the CNN filters followed the specifications of [21]. The dropout rate is also 0.5, same as CDS-CNN. We optimized these models with Adam with default hyperparameters and set batch size as 64. It took us 9 hours to train a pooling model on a NVIDIA Tesla P100. We used a beam search for generating the program, and computed BLEU scores to measure performance on the testing set.

TABLE I
EXPERIMENTAL RESULTS

Model	ACCURACY	BLEU
SEQ2TREE	1.5	53.4
LPN	6.1	67.1
SNM	16.2	75.8
ASN	18.2	77.6
CDS-POOLING	15.6	78.9
CDS-CNN	19.7	77.0
CDS-SAN	16.7	77.8

D. Experimental results

Table I presents the results of our CDS models in code generation, in comparison with existing methods, e.g., LPN [1], SNM [2], ASN [3], and SEQ2TREE [4], which are the state-of-the-art models in the code generation area. The results show that adopting CDS-POOLING to capture the syntax rules yields a better performance with much less training time than other methods. Besides, compared with RNN, CNN is better suited to capturing the structural information of long sentences. Finally, the self-attention network based model also outperforms existing methods.

Fig. 5. Loss Function Over Time

E. Result Analysis and Case study

The results demonstrate that CDS-POOLING is particularly better than any other existing methods in both speed and efficiency. As for CDS-SAN, when we made this model more complicated, the ACCURACY score fell but BLEU score rose, which means CDS-SAN can handle the detail better. CDS-CNN model is good at generating more completely correct code.

As mentioned in [3], Hearth Stone contains classes with similar structures, thus the code generation task can predigest into the generation of tree-like AST and what we need to do is to fill in tokens with certain variables and values. Nevertheless, certain errors must occur because that Hearth-Stone's code contains complicated logic, which result in a low accuracy [2]. To see more details, we presented an example of code we generated by CDS-POOLING in table II. It illustrates that our model can handle complicated code syntax effectively. However, our generated code does not absolutely match the reference code, but it is correct in general and can be executed.

To be more specific, the reason why the CDS-POOLING has such an impressive result is that pooling operation builds an

information map to achieve a downsampling-process, which throws away indifferent information. In contrast, the CDS-CNN model tends to generate a structural correct code, which leads to a higher ACCURACY (more absolutely correct codes) but a similar BLEU compared with previous works.

TABLE II
THE COMPARING OF GENERATED CODE AND REFERENCE CODE

Descriptive Text:

```
annoy-o-tron name_end 1 atk_end 2 def_end 2 cost_end -1 dur_end
minion type_end neutral player_cls_end mech race_end
common rarity_end b taunt /b nl b divine shield /b
```

Generated Code:

```
class AnnoyTron(MinionCard) :
    def __init__(self) :
        super().__init__("Annoy-o-Tron", 2,
            CHARACTER_CLASS.ALL, CARD_RARITY.COMMON,
            minion_type = MINION_TYPE.MECH, divine_shield = True)
    def create_minion(self, player) :
        return Minion(1, 2, taunt = True, divine_shield = True)
```

Reference Code:

```
class AnnoyTron(MinionCard) :
    def __init__(self) :

            CHARACTER_CLASS.ALL, CARD_RARITY.COMMON,
            minion_type = MINION_TYPE.MECH)
    def create_minion(self, player) :
        return Minion(1, 2, divine_shield = True, taunt = True)
```

V. DISCUSSION AND ANALYSIS

RQ1: How do CDS models perform?

The results demonstrate that CDS-POOLING is particularly better than any other existing methods in both speed and efficiency. When we made model more complicated, the ACCURACY result fell, but the BLEU score rose (see CDS-SAN), which means that it can handle the details better. And it clarifies CDS-CNN model is skilled at generating more completely correct code. Results also illustrate that simple pooling operation (CDS-POOLING) is surprisingly effective at representing longer sequence. CDS-POOLING figures over all elements of the tensor, and CDS-POOLING can be fully trained in parallel to better exploit the floating-point computation capacity of GPU, compared with RNN in the train step. In addition, CDS-POOLING is more amenable to optimization because the number of non-linearities unit is fixed, moreover, it not be affected by the text input's length. The max-pooling is working as follows: we can consider the embedding size used as 256 represent 256 kinds of semantics, and the max-pooling operator is to extract the semantics in sentences.

RQ2: Can we find a trade-off between training speed and accuracy of the result?

The experiment demonstrated that CDS-POOLING is the most effective approach outperforming other complicated models. This also tells us that a simple and effective method should be a prevailing concern. Additionally, it helps researchers to avoid the blind use of deep learning algorithms when solving software engineering problems.

Considering the nature of this problem, more sophisticated models reveal outstanding results but are excessively computationally expensive, because they need to optimize thousands of parameters, e.g., RNN or CNN. On the contrary, maybe some simpler models can be robust, which only compute the sentence embedding by simply adding or averaging operation over the word embedding, just as our CDS-POOLING. But that also means, such a simple pooling operation does not take word-order information into account. However, pooling operation has the advantage of having significantly fewer parameters, which means it can train much faster and obtain a equally good precision, comparing to RNN or CNN. Thus, there is a trade-off between training speed and efficiency.

VI. CONCLUSION AND FUTURE WORK

In this work, we are the first to introduce pooling operation, fully convolutional model, and self-attention network for code generation tasks to the best of our knowledge. Furthermore, analysis shows that the pooling based model is the most efficient. Thus, we achieved state-of-the-art results in the code generation task. Specifically, on Hearth Stone dataset we outperformed all the previous methods by 78.9 BLEU. In addition, we provided some advice to researchers that they must consider practical reality of target tasks, and do not fall into the trap of using complicated deep learning models blindly. In conclusion, our work has theoretical significance and practical value in the field of software engineering.

In the future, we plan to adopt more models in code generation tasks, aiming at seeking ways to improve the performance. However, there is a syntactic difference between various program languages. Thus, we also plan to apply CDS models into more code generation datasets.

Abstract

Albeit Artificial Intelligent (AI) based systems are nowadays deployed in a variety of safety critical domains, current engineering methods and standards are barely applicable for their development and assurance. The lack of common criteria to assess safety levels as well as the dependency of certain development phases w.r.t. the chosen technology (e.g., machine learning modules) are among the identified drawbacks. In addition, the development of such engineering methods has been hampered by the emerging challenges in AI-based systems design mainly regarding autonomy, correctness and prevention of catastrophic risks. In this paper we propose an approach to conduct a safe-by-design development process for AI based systems. The approach relies upon a method which benefits from a reference AI architecture and safety principles. This contribution helps to address safety concerns and to comprehend current AI architectures diversity and particularities.

Index Terms—safe-by-design, AI, safety, engineering

I. Introduction

The implementation of Artificial Intelligence (AI) based systems has progressed in many aspects. The technology shows increasing levels in tasks automation and adaptation to the context. For instance, for self-driving vehicles, we can cite the DriveMe project on Volvo XC90 series launched in 2013 [1], the Autopilot technology integrated in Tesla vehicles since 2013 [2], and the Waymo project of Google which conducted the world's first self-driving ride on public roads [3] claiming maximum autonomy level (5). Several instances of systems based upon AI technology can be found in the literature, e.g., [4], [5]. The main concerns addressed by those architectures are related to (1) the limits imposed by sensors' detection, (2) the heuristic nature of

machine learning (ML) and deep learning (DL) techniques, and (3) the variability and complexity of context scenarios. Whereas current technology and implementations show approach feasibility and provide some solutions to referred concerns, they are mostly committed to improve system's autonomy letting aside other aspects of the engineering process. In general for AI-based systems development, a variety of engineering techniques are applied and combined with almost empirical parameters, choices which are finally tuned to optimize performance [6]. Despite the engineering process has proven certain effectiveness, it also shows some drawbacks regarding safety assessment. In particular, the lack of a comprehensive process to settle common criteria and thresholds for safety evaluation and certification. To our knowledge, the problem is quite hard to solve and no current approach overcomes related issues: an AI-based system should integrate sensor devices with limited - sometimes opaque - detection capabilities ($\leq 90\%$ in average), deploy algorithms to identify and properly react to complex, rather unforeseen, situational scenarios and, on top of that, ensure negligible likelihood of occurrence for critical hazards and disfunctioning. Moreover, whereas for typical development methods, like the V-cycle, the phases and their sequencing are almost static, it is observed that for AI-based systems, the nature of certain engineering phases and their order may vary. Some of the factors for that to occur are the dependency of the engineering process on the AI technology choices, on the knowledge bases - used for learning - and on their maturity (representativeness of data sets, events, phenomena). Although, it is consensual that safety analyses should be conducted as early as possible and all along the life-cycle, the few initiatives on that respect, like ISO/IEC 23053 [7], are still work in progress. Others, like ISO 21448 [8], provide insights on a safety-integrated process for autonomous vehicles without settling generic criteria suitable for other application domains. Consequently, current

standards landscape is barely applicable to the growing space of AI-based systems, and new safety methods and analysis processes are required to develop them. To tackle the referred issues, the main contribution of this paper is an overall generic iterative (OGI) method to conduct safe-by-design development of AI-based systems relying upon a generic architecture and safety principles.

The rest of the paper is structured as follows. In Section II, the reference AI architecture is introduced. In Section III, some safety relevant aspects to AI-based systems are highlighted. The OGI process for AI-based systems development is described in Section IV, including safety assessment phases. In Section V, the safe-by-design method is applied to the development of an autonomous system. Some related works are explained in Section VI. Finally, a discussion and work perspectives come in Section VII.

II. Generic Reference AI-based Architecture

The specification of a process development for AI-based systems should consider the following particularities:

- *Engineering process dependent on AI technology:* Subsystems or components implementing ML/DL modules are based upon parameters which may require to be set during conception, design, implementation and validation phases. For those subsystems and components, a learning phase should be introduced whereas for other typical (non-ML-based) subsystems and components, the learning phase is non-existing.
- *Engineering process dependent on knowledge bases:* The learning phases strongly depend upon target objectives and external knowledge bases (KBs). For many complex AI-based systems, an iteration on design parameters may be necessary after a validation campaign, *e.g.*, to adjust detection ranges and accuracy. Detailed requirements cannot be elicited before knowing the effectiveness of knowledge bases, ML/DL techniques, and parameters choices.
- *Knowledge bases maturity:* Due to previous aspects, the AI-based systems development shall not only depend upon ML/DL techniques and development methods, but also on building up knowledge bases (KBs) and making them evolve so as to improve coverage and accuracy of objects, events, and phenomena detection. Referred KBs shall be useful for detection and for high level reasoning, *e.g.*, reasoning based upon intuition [9].

We propose to integrate the previous specificities from early stages of design. Since a huge diversity of architectures and process cycles currently exist, the specification of a development process should be as generic and comprehensive as possible. We find suitable to first introduce a generic AI-based architecture aiming to cover

most of them. The Figure 1 illustrates the coarse domains composing our reference architecture which are briefly described in the following items and in section IV.

Fig. 1. Generic reference AI architecture

- *External knowledge sources:* this domain comprises KBs required for training ML/DL modules, for their implementation and validation. At the beginning, these external KBs are not part of the system, but they are integrated as a logical component during the engineering process, for instance, after generation of training sets (*e.g.*, via the feature vectors).
- *Missions/goals:* this domain of the architecture covers the fulfillment of functional and non-functional goals and missions of the system. Certain missions and goals may not require the deployment of ML/DL modules. Thus, they can be deployed by components and subsystems relying upon typical technology.
- *AI knowledge basis:* this domain includes components for the fulfillment of principles, directives and rules which guide the AI-behavior. The modules pertaining to this domain provide a basis upon which missions and goals can be accomplished by the system.
- *Smartness development:* the smartness of the system relies, at least, upon two layers of reasoning. The first layer is in charge of detection of external objects, phenomena, and scenarios. The second layer includes monitoring of system status, self-positioning and reacting to external conditions according to missions and AI-principles. The development of system smartness depends on AI techniques like ML and DL.
- *Overall models:* the development of autonomy and smartness demands an understanding of environmental and internal system elements. As for external elements, a model of the environment is to be settled. Among others, this model allows the interpretation of external stimuli. As for internal elements, the system should be able to have a comprehensive model of itself. Among others, this model allows to assess system self-status. Both models capture the current capabilities of the overall system. To ensure certain independence, the AI-system should be able to learn

from new stimuli and situations and it should be able to integrate and deploy new capabilities.

- *Self-control*: this domain includes the functions deployed to realize autonomy during missions and goals accomplishment. A typical functional path comprises sensors→controllers→actuators that respectively support detection, processing and decision-taking.

III. Safety Concerns for AI-based Systems

Safety is one of utmost relevant concerns when designing AI-based systems. However, it is also a vast and complex subject considering the multiple applications domains where they can be deployed and their related specificities. The main safety related activity affected by the specificities of AI-based systems is the hazard analysis at the concept phase of the system. Indeed, the implementation of ML/DL components rise new concerns regarding emerging categories of hazardous events. Referred hazardous events exhibit an increased risk level (which may even be catastrophic) due to the machine overtaking over former human-based activities. Along with more autonomy, the transfer of duties to AI-based algorithms implies no further human interaction as safety barrier in case of hazards. In addition, certain typical safety criteria like redundancy do not suffice anymore to ensure expected levels of availability and also accuracy. The specific aspects addressed in this paper are described in line. Some of these aspects have already been highlighted in emerging safety standards like ISO 21448 [8] (see Figure 2).

Fig. 2. Hazard events related to ML modules

- *Events indistinguishability*. This issue is mainly due to physical limits of sensors. In particular, because real and virtual images are practically indistinguishable. For instance, the detection of a stop signal can be easily faked by a photo of the same. Light rays and other natural electromagnetic signals used for detection can be reproduced by different objects.
- *Targets variability*. Many objects, elements and phenomena to be detected by AI-based systems exhibit certain variability. Although AI-based systems should cope with referred variability, questions arise if the system may face unforeseen situations beyond its

limits. For instance, sudden deterioration or disfunctioning of context signs may lead to wrong detection of objects.

- *Noises and error propagation*. Along with variability issues, the noises added by the background and environmental phenomena increase hazards impact, in particular in case of dismissed/miscalculated noises and errors propagated through the system. Environmental conditions (e.g., solar winds, snow) may impose additional constraints to system operation and behave as background noises.
- *Human-machine interactions harmonization*. The operation of AI-based systems in real environment is quite novel. Whereas risks related to machine-to-machine or machine-to-environment interactions can be assessed during design phases, predict the outcomes of human-to-machine interactions is far more complex [10]. Although an harmonization phase can be conducted, complex human reactions (e.g., psychological, societal, political) are difficult to assess.

IV. Safe-by-Design Method for AI Systems

In this section, we introduce a method to develop the architectural domains specified in section II. The safety aspects described in section III are integrated into the cycle. The method is illustrated in Figure 3 and is described in the following subsections. The method is iterative and several phases can be conducted in parallel even if interdependencies may appear.

A. AI-based systems development method

The main phases of the OGI process are briefly described in the following items.

- 1) *Missions and goals*. This phase comprises the specification of missions and goals the system should accomplish. The specification mostly targets functional requirements of a typical engineering phase. However, as for safety-critical systems, it also includes the management of non-functional requirements.
- 2) *AI principles structuring*. This phase covers the specification and structuring of AI principles upon which the system relies. As for typical requirements stages, the formalization and validation of consistency between AI principles is a major stake. This principles are processed afterwards in phase 4.
- 3) *De-compositional analysis*. This phase is dedicated to decompose, refine and structure missions and goals up to obtain a layer including detailed functions. This phase mostly follows a typical process of design refinement. However, notice that a subset

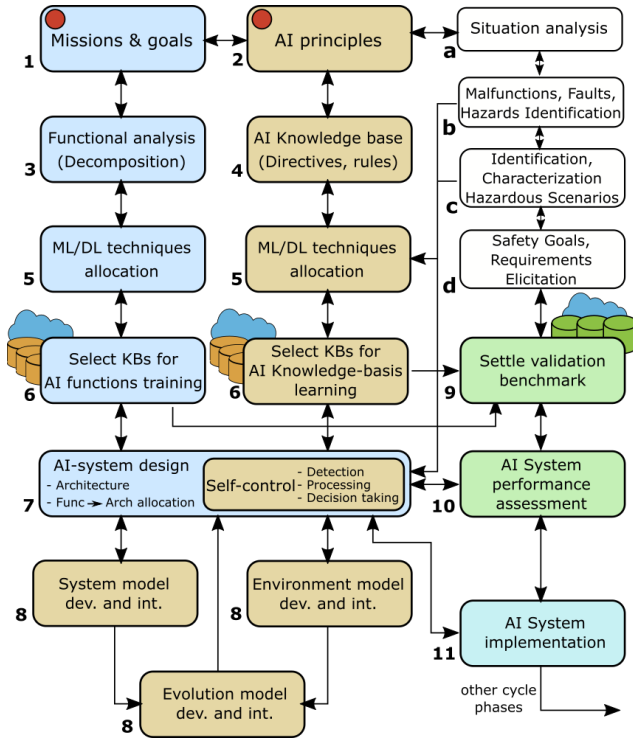

Fig. 3. Method for AI systems development

of functions and blocks are to be carried out by ML/DL-based modules as described in phase 7.

- 4) *AI knowledge basis structuring.* The structured AI principles in phase 2 are first decomposed into a set of high level directives which are afterwards refined up to obtain a set of rules including specific system behaviors. The elicited rules play the role of policies which help to guide - or even enforce - system behavior when needed.
- 5) *Allocation of ML/DL techniques.* This phase is dedicated to allocate concrete ML/DL techniques and modules to the functions and blocks elicited in phase 3, “*De-compositional analysis*”, and to the behaviors elicited in phase 4, “*AI knowledge basis structuring*”. The allocation should (1) accomplish the missions and goals of the system and (2) ensure the compliance with rules refined from AI principles and directives.
- 6) *Knowledge bases selection.* Once the allocation of ML/DL techniques is finished, the KBs for training the respective modules are selected. Of course, building up new or dedicated KBs may be necessary. The KBs are the basis to generate outside-world and system models as well as the evolution model by performing the training tasks (see phase 8).
- 7) *Detailed AI architecture design.* The detailed design

of the AI-based system comprises at least three tasks or sub-phases. The first one consists in proposing the architecture to support the functions specified in previous phases 4 and 5, including allocations. In the second sub-phase, a distribution of functions over the support architecture is conducted. This task covers the exploration of the design space. In the third and last sub-phase, the first layer of intelligence is developed by training the ML/DL modules, *i.e.*, the self-control functions for detection, processing and decision taking.

- 8) *Overall models development and integration.* The second layer of intelligence is developed in this phase: the AI-system should be able to learn from new stimuli and situations. The models of the external world and the system itself have been partially developed and integrated during previous training tasks. Upon outside-world and system models, an evolution model should be elaborated and integrated relying upon (1) specific principles governing AI autonomy, (2) techniques and metrics to assess and filter new stimuli and situations (*e.g.* adaptive decision making [11]) and (3) techniques to integrate new filtered knowledge so as to grow up system and environment models.
- 9) *Settle validation benchmark.* After the allocation of ML/DL techniques, a benchmark for validation can be settled. The benchmark includes a set of target objectives used to assess performance and emit verdicts. The target objectives are refined from missions, goals, AI principles and other requirements *e.g.*, safety requirements. The benchmark also includes the data sets selected or generated to test the performance of ML/DL modules. When applicable, the validation benchmark can be based upon typical validation and verification techniques like testing, simulation, and formal verification.
- 10) *AI system performance assessment.* The system performance is evaluated relying upon the validation benchmark. An iterative process starts in order to fulfill the target objectives non satisfied after the first validation campaign.
- 11) *AI system implementation.* Along with typical technology components, the components including trained ML/DL modules and their parameters are deployed in this phase.

B. Integration of safety aspects into the OGI cycle

The assessment of the specific safety aspects of ML/DL components, introduced in Section III, demands dedicated principles. Referred safety aspects are integrated into the OGI cycle (see Figure 3) as follows:

- a) **Situations analysis.** This activity corresponds to a typical operational situation analysis as in hazard analysis [12]. However, special attention is given to situations in which autonomous functions operate and are at stake.
- b) **Malfunctions, faults and hazards related to ML/DL modules.** Along with classical malfunctions, faults and hazards, the aspects referred in subsection IV-A are considered as sources of new potential malfunctioning and hazardous behaviors. For their identification, each safety aspect is related to the architecture parts potentially impacted. For instance, regarding *events indistinguishability*, ML/DL functions, blocks and components carrying out detection are to be considered; for object *variability* and *noises and error propagation*, the reasoning layer used for environment interpretation is in cause, and for the *human-machine interaction harmonization*, the decision-taking reasoning layer is targeted. In addition, the heuristic nature of ML/DL algorithms as well as their dependency to external KBs demand the definition of a malfunctioning matrix including false positives and false negatives occurrence. The autonomy of an AI-based system can be assessed based on its ability to cope with multiple components malfunctioning and hazards (accidental, misuse, natural). Concretely, for each component C_i and target T_j with background B_j the probability of error should be minimized:

$$P[ErrorC_{(i,j)}] := P[FalsePos_{(i,j)}] + P[FalseNeg_{(i,j)}],$$

$$FalsePos_{(i,j)} := \cup_j \{C_i(Accept, B_j)\},$$

$$FalseNeg_{(i,j)} := \cup_j \{C_i(Reject, T_j)\}.$$

Other factors of components failure can be considered, in particular the failure rate λ_i along with the probability of failure over time $P[FailC_{(i,t)}] = \lambda_i e^{-\lambda_i t}$. Thus, the overall probability of component disfunctioning can be calculated by:

$$P[DisfC_{(i,j,t)}] = \omega_1 P[FailC_{(i,t)}] + \omega_2 P[ErrorC_{(i,j)}],$$

$$\omega_1 + \omega_2 = 1.$$

- c) **Identification and characterization of hazardous scenarios.** Along with classification of typical hazardous scenarios, the hazardous scenarios involving ML/DL components should be characterized. Notice that, the typical scenarios referred in ISO 26262 [13] as “reasonably foreseeable misuse” are no longer under human control and consequently should also be reclassified. To do so:

- Scenarios involving ML/DL components are defined as combinations of external stimuli, system response (internal stimuli) and malfunctions.
- For each scenario S_k , subsets of KBs are selected to evaluate the performance of involved ML/DL components ($\{C_i\}$):
 - Data/features characterizing legitimate targets T_j (true positives)

- Data/features characterizing targets’ backgrounds B_j (true negatives)
 - The likelihood of each scenario $P[S_k]$ is estimated by combining the disfunctioning probabilities $\{P[DisfC_{(i,j,t)}]\}$ of involved components $\{C_i\}$ according to the architecture structure and relying upon basic probability theory.
- d) **Safety goals elicitation.** Elicitation of safety goals based upon ASIL levels is rather coarse and thus inadequate considering the current nature of hazardous scenarios $\{S_k\}$. Since a huge diversity and complexity of hazardous scenarios are possible, three cases are identified from which detailed requirements can be elicited:
- The hazardous scenario S_k can be associated to a concrete behavior which is formalized and monitored. A monitoring formula ϕ including safety threshold θ can thus be elicited. For instance, in the case of autonomous vehicles, a formula for minimal safety distance between them is settled: $\phi \geq \theta$. In this case, the detailed requirements are elicited in terms of a maximum threshold violation: $P[\phi < \theta] \leq \delta$.
 - The hazardous scenario S_k can be associated to a concrete behavior but deriving a safety monitoring formula is not evident. If the behavior can be formalized and a validation test-bench can be settled, then performance tests are conducted. In this case, the detailed requirements can also be elicited in terms of maximum probability of error given by $\{P[DisfC_{(i,j,t)}]\}$.
 - The hazardous scenario or the associated behavior are complex. Conducting performance tests is unfeasible. In this case, the behavior can be formalized and a validation test-bench can be settled relying upon simulation. For sophisticated simulation test-benches, the requirements can be elicited as in previous case, *i.e.*, via $\{P[DisfC_{(i,j,t)}]\}$. Otherwise, safety requirements may depend upon simulation scenarios.

V. OGI Method Tool Support and Evaluation

The modeling and safety assessment framework of the OGI method is implemented in Sophia, a model-based toolset integrated with Eclipse Papyrus editor for UML/SysML models [14]. Sophia uses Papyrus extension mechanisms to support safety and reliability analyses like HARA, FMEA, FTA. We evaluate the OGI method on an ongoing industry-academy experimentation of autonomous shuttles deployment on a sensitive site, as described in [12]. Due to lack of space, the evaluation only focus

on selected method phases. A critical mission of the autonomous shuttle is to adopt a safe reaction in presence of an obstacle on its trajectory. The selected scenario S_k corresponding to the mission is presented in the sequence diagram in Figure 4. The scenario S_k involves the *Percep-*

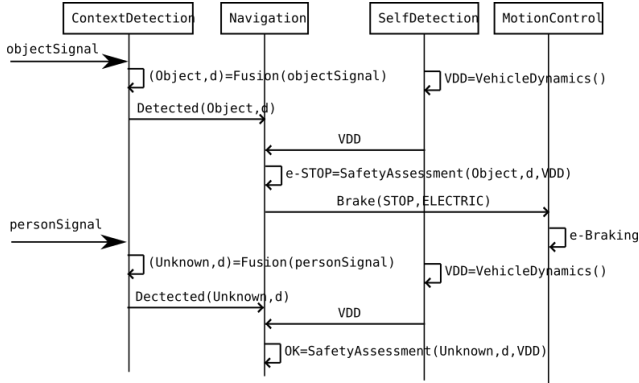

Fig. 4. Shuttle safety critical scenario

tion (i.e. *ContextDetection* and *SelfDetection*), *Navigation* and *Motion control* functions of the system. In the first exchanges, the shuttle detects an object on its route, and is able to brake at safe distance to avoid an accident. In the second iteration, although the system detects an obstacle on its path, it is not recognized as a person due to malfunctioning. Consequently, the shuttle does not take appropriate decision to avoid the collision. Figure 5 presents an excerpt of the architecture design showing the allocation of the scenario functions. The *SelfDetection*

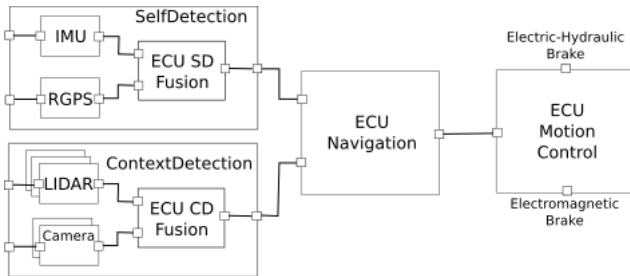

Fig. 5. Excerpt of shuttle architecture design

function (see *Detected()* in Figure 4) is realized by an inertial measurement unit (IMU), a relative GPS (RGPS) and a ML/DL component for data fusion (see *Fusion()* in Figure 4), the latter computes the vehicle dynamics e.g. speed, acceleration, momentum (see *VehicleDynamics()* in Figure 4), thus settling the model of the system itself. The *ContextDetection* relies upon a set of LIDARS and Cameras, and upon an ML/DL data fusion component which structures a model including speed and position of objects within the surrounding vehicle's environment.

The *Navigation* function is also an ML/DL component that interprets the scene and take a decision according to safety and AI-based directives (see *SafetyAssessment()* in Figure 4). The decision is afterwards sent to an ordinary *Motion control* component for action-taking. Decision Trees, Support Vector Machines, Gaussian Mixture Models, Fuzzy Logic, and other unsupervised machine learning are example of techniques to be used for the ML/DL components. In order to acquire their capability of detection, scene interpretation and decision taking, the ML/DL components have been trained with dedicated KBs prior to architecture's definition. The shuttle process development follows the phase 1 to phase 7 shown in Figure 3. Notice that, in the hazardous scenario in Figure 4 (failure in person's detection), since the system was neither able to perform a collision avoidance maneuver, it presupposes that an intelligence layer is missing: the evolution model to face unknown situations is still to be constructed (see Figure 3, Phase 8). The evaluation of the hazardous scenario is conducted based upon our proposed safety assessment method. To do so, an existing hazard analysis of the shuttle [12] is considered which covers the phases a, b, c, d of the OGI cycle (see Figure 3). The concerning fault in the scenario is the non recognition of a person as a such. The overall probability of the hazardous scenario $P[S_k]$ (see section IV) can be calculated in terms of the probability of disfunctioning for each component $P[DisfC_{(i,j,0)}]$ as follows:

$$P[S_k] := \lambda_{LIDAR}\lambda_{Camera} + P[DisfECUCD] + \lambda_{IMU}\lambda_{RGPS} + P[DisfECUSD] + P[DisfECUNavigation] + \lambda_{MotionControl}.$$

A detailed requirement for the scenario can now be specified as $P[S_k] \leq \theta$ which allows to settle a target for the validation benchmark and assess the performance of the system (covering phase 9 and phase 10 in Figure 3).

VI. Related Work

Several works have been presented to identify and integrate safety during AI systems development by industry and academy. In [15], a survey of main AI safety problematics is provided, among them, wrong or cost-ineffective objective functions, and ineffective learning phases. In [16], a preliminary study is conducted discussing different aspects of AI systems' safety. The authors propose the application of classical formal verification principles to AI systems design, like randomized formal methods for training, in combination with design space exploration guided by safety criteria. The authors in [17] present a design strategy for autonomous architectures which maps safety requirements over a global control module. A lot

of proposals exist addressing the optimization of ML/DL based modules performance, *e.g.*, [18]. All previous cited approaches either only cover specific phases of the engineering cycle or are quite specific to a given application domain. On the contrary, the work in [11] presents a holistic approach for autonomous systems development addressing similar safety concerns as in this paper, and also relying upon a layered architecture. Unfortunately, it does not propose any criterion for evaluation of hazardous scenarios nor for safety goals elicitation. The theoretical perspective for a safe AI cycle presented in [19] is quite aligned to the one in this paper, with regard to the integration of KBs into the engineering loop targeting data and software diversity. Being a theoretical work, the elicitation of precise system requirements is nonetheless not covered.

VII. Discussions and Perspectives

This paper presents an overall iterative generic (OGI) method for development of AI-based systems. The method is based upon reference architecture domains dependent upon KBs, environment model, validation benchmarks, among others. In addition, the method integrates assessment activities to tackle specific safety-critical aspects of such systems. The assessment provides an enhancement of the typical hazard analysis method to infer safety goals. In particular, it yields the disfunctioning likelihood of an AI-based component considering the typical failure rate added up with the error probability of ML/DL modules. By applying the OGI method to the autonomous shuttle, a multi-factor uncertainty was identified intervening at different levels of AI systems design. A first uncertainty comes from the accuracy and maturity of external KBs which impact the learning process and performance of ML/DL components. The use of fine-grained approaches, like data diversification [19], is promising to overcome this issue. A second uncertainty is the difficulty to apprehend the infinite usage-scenarios space resulting from a “continuum” of possible environmental-operational contexts, variants and configurations. This often leads to poor system-context specifications not representative enough to characterize the scenarios space. A current trend for this shortcoming is to settle enough specificities, from a safety point of view, to define categories of emblematic scenarios [20] useful in particular for benchmarking but without guarantee of coverage exhaustiveness. The third uncertainty factor comes from the performance limits of AI-based components, *e.g.*, sensors blinding or other still unveiled environment events. Interpretation and decision-taking layers are also at stake when arbitration algorithms face contradictory directives and must solve them in critical scenarios, *e.g.*, between safety requirements and AI-knowledge basis (principles, directives, rules). As of today, there is no ethical solution

that has reached consensus on this sensitive issue. Finally, since AI-based systems may still be unable to properly react to changing environments (as in the case study in section V), deploy new capabilities in real time is of utmost importance to ensure true systems intelligence and autonomy. In future work, we plan to conduct larger-scale application of the OGI method on others safety-critical AI-based systems to strengthen our conclusions and enforce approach validity. We are also assessing the applicability of other standard-preconceived methods, like FMEA and FTA, in the context of AI-based systems. We would further like to complete the OGI method to cover latter stages of the development cycle, *i.e.*, testing and validation.

Abstract—Recent research on the automatic classification of app reviews either focused on grouping app reviews into categories relevant to software evolution, or employed app reviews as the only research data to improve app reviews classification. Although it was reported that app review classification can benefit from supplementing user reviews with the data from other sources, only a few studies employed app changelogs for this purpose. This paper explores how to augment app reviews with changelogs to improve the accuracy and performance of classifying functional and non-functional requirements in app reviews. Specifically, we propose AUG-AC as an approach to extract feature words from app changelogs and construct the augments for app reviews. Next, we designed a series of experiments to evaluate our approach, varying in the length of AC-based augments for app reviews. The results show that AUG-AC outperforms the existing method by using app changelogs as a source of data next to app reviews.

Keywords—app reviews, app changelogs, requirements analysis, machine learning, data-driven requirements engineering

I. INTRODUCTION

With the rapid growth of mobile applications, massive sets of data are provided by the crowds. Particularly, app reviews, a type of explicit feedback from the users, have been recognized as an important source of user requirements for app updating and maintenance [1-3]. However, current research [1-2] mainly concentrated on how to extract features or topics from a large number of app reviews and then classify these topics into categories relevant to software evolution. Several studies [4-7, 14] also explored the use of user feedback from other sources in requirements elicitation. For example, Vu et al. [4] employed user reviews of packaged software in Amazon to pre-extract phrases for mining user opinions from app reviews, while Jiang et al. [5] combined product reviews from Amazon with app reviews as the research data. These authors [4-5] observed that user reviews of software have similar characteristics to app reviews: (1) the number of reviews is increasing rapidly every day; (2) review texts contain many noise words, including emoji, non-English words, misspelled words, user-defined abbreviations; and (3) most reviews are non-informative (as reported in [6], only around 30% of app reviews are informative for app updates). To reduce the manual effort in filtering out non-informative samples and identify valuable information for developers, this paper explores if other information of apps, especially the pieces with less noise (i.e. app changelogs), could be a significant help.

App changelogs are posted by software vendors regularly in weeks or months. These official texts are written in a standardized way and comprise primary changes of the releases. A 2018 ICSE study [7] has successfully employed app changelogs to identify emerging issues in app reviews. We were motivated by these findings, and set out to explore how to use official app changelogs to improve the accuracy and performance of classifying requirements in app reviews. Especially, this paper intends to explore how to make use of app changelogs in the automatic classification of app reviews from the perspective of requirements types, and finally aid developers in the maintenance and updating of apps.

The paper is structured as follows. Sect. II is on related works. Sect. III presents our approach. Sect. IV reports on the experimental results evaluating and comparing the accuracy and performance of our approach with others. Sect. V discusses our findings. Sect. VI is on validity threats. Sect. VII concludes.

II. RELATED WORK

Considering the automatic classification of app reviews, some researchers proposed categories relevant to software maintenance and evolution. Maalej et al. [1] introduced several probabilistic techniques to classify app reviews into four categories, i.e. bug reports, feature requests, user experience, and text rating. Guzman et al. [2] proposed seven categories relevant to software evolution, viz. bug report, feature strength, feature shortcoming, user request, praise, complaint, and usage scenario. The categories proposed in these two studies partially overlap, since the authors intended to help app vendors and developers filter critical reviews relevant to different aspects of software maintenance. Other researchers considered the categories of app reviews from the perspective of requirements types. In particular, our previous works in [8-9] employed classic machine learning algorithms to identify and classify functional and non-functional requirements (FRs and NFRs) from app reviews. Another similar study [10] performed automatic analysis on app reviews for NFRs elicitation and prioritization. In all these studies, however, app reviews were the only type of research data to apply and compare specified classifiers.

To the best of our knowledge, only very few studies employed research data from other sources to analyze app reviews. Those other sources include user reviews of software [4], of products [5], and app descriptions [14], etc. However, both [4, 5] aimed to extract and cluster user opinions, rather than

*: The authors contributed equally to this work.

classifying requirements into different categories. In [14], Liu et al. used app descriptions, another typical data in app stores, to guide the analysis of user reviews. Gao et al. [7] used app changelogs to identify emerging issues from app reviews, instead of identifying and classifying requirements.

In contrast to these previous studies, the focus of our work is mainly on how to augment app reviews with app changelogs in order to improve the accuracy and performance of classifying FRs and NFRs from app reviews.

III. OUR APPROACH

To employ official app changelogs for the automatic identification and classification of requirements from app reviews, we propose an approach, called AUG-AC, to AUGment app reviews with the text feature words extracted from App Changelogs (AC). In this section, we give an overview of AUG-AC to explore how to improve the automatic classification of app reviews by employing official app changelogs. Each step of our approach will be detailed in a subsection.

The experimental data collected and manually labeled in our previous work [13] will be reused to evaluate the performance and AUC-AC. The dataset includes 6000 app review sentences of three apps (one from Apple App Store and two from Google Play) and 2024 app changes filtered from 2005 official changelogs of 30 apps (3 *categories* \times 10 *apps* in Apple App Store). As described in [13], these app review sentences and changes were labeled with six types of requirements, including four types of NFRs defined in ISO 25010 [11] (i.e. *Usability*, *Reliability*, *Portability* and *Performance*), FR, and ‘Others’ - the type referring to those review sentences and app changes that fit neither FRs nor the four NFRs listed above.

A. Overview

Our approach consists of four main steps, as Figure 1 shows.

Figure 1. Overview of AUG-AC approach, focusing on the steps in grey.

The first step is to preprocess the sampled app reviews and changelogs to get respective text feature words of each requirements type (Sect. III.B). The second step (which is the one foci of our work) creates a AC-based feature words dictionary for augmenting app reviews (Sect. III.C). The third step (the other focus of our work) augments app reviews with the text features extracted in the second step to train the classifier and group the app reviews into six pre-specified types of requirements (Sect. III.D). In the last step, those augmented app reviews generated in Sect. III.D construct the training set of the specified classifier. The accuracy of applying this classifier to categorizing app reviews in the test set will be evaluated by the standard metrics Precision, Recall and F-measure (Sect. III.E).

B. Text Preprocessing

In this step, multiple Natural Language Processing (NLP) techniques were applied to the text of app review sentences and changes. Specifically, Natural Language Toolkit (NLTK) was adopted to perform stopword removal, punctuation removal, and lemmatization.

Next, considering each type of requirements, we intended to extract text feature words from the app changelogs and treat them as the candidate augmented words for the app reviews labeled as this type. In general, the concerns of app changelogs grouped in each type of requirements may not always be well represented by the frequency and importance of a word. Thus, for each type of requirements, Latent Dirichlet Allocation (LDA) was employed to extract text feature words in app changelogs. By applying LDA, app changelogs labeled as a certain type of requirements into can be clustered into one topic and produce topic words for this cluster (i.e. each type of requirements). In this work, topic words of each cluster form the initial set of text feature words to be augmented to those app reviews that are labeled as the corresponding type of requirements.

C. Constructing AC-based Feature Dictionary

This step aims to construct an AC-based feature dictionary, consisting of the text feature words that was extracted from app changelogs and to be augmented to app reviews. As already said in the beginning of Sect. III, six types of requirements have been specified as the category labels for both app reviews and changelogs. Accordingly, for each requirements type i , a AC-based feature dictionary D_i is needed (1) to store the text feature words extracted from app changelogs typed as i , and (2) to provide candidate AC-based augmented words for app reviews typed as i . In this paper, D_i is initialized as a set containing the top 20 features words t_{ij} extracted from app changelogs labeled with requirements type i .

Algorithm 1: Constructing AC-based Feature Dictionary	
Input:	D_i – initial AC-based feature dictionary.
Output:	D_i' – extended AC-based feature dictionary.
1	for each requirements type i
2	import D_i ;
3	Insert D_i to D_i' ;
4	for each $t_{ij} \in D_i$
5	insert $Synonym(t_{ij})$ into D_i' ;
6	insert $Antonym(t_{ij})$ into D_i' ;
7	end for
8	return D_i' ;
9	end for

Furthermore, we conducted a pilot study to compare the text feature words extracted from app reviews and changelogs. The preliminary results indicate that the reflection of app reviews on app changelogs is often expressed as the synonyms and antonyms of a certain text feature word, rather than using the same terms. Since more text feature words benefit pre-training of the classifier, the size of D_i is recommended to be extended to cover more candidate AC-based augmented words. For this purpose, WordNet in NLTK was applied to the initial dictionary D_i to generate the extended dictionary D_i' for the requirements type i . More specifically, for each text feature word t_{ij} in D_i , all its synonyms and antonyms identified in WordNet were added

to generate D_i' . Algorithm 1 provides the details of constructing an AC-based feature dictionary for each type of requirements. This results in D_i' , which will be used in the next step of AUG-AC to augment the app reviews labeled as requirements type i . In our work, D_i' consists of two parts, i.e. (1) the top 20 text feature words extracted from the type i -labeled app changelogs and (2) all the synonyms and antonyms of these 20 words.

D. Augmenting App Reviews

In this step, we select text feature words in the AC-based feature dictionary created in Sect. III.C, in order to augment app reviews. These augmented app reviews construct the training set of the classifier for app reviews classification.

To achieve a higher accuracy in requirements classification from app reviews, we proposed to augment app reviews with the text feature words derived from those app changelogs whose requirements type is identic with that of the app reviews to be augmented. Specifically, for each type of requirements, we first used Word2Vec in NLTK to calculate the similarity between the AC-based text feature words and the app reviews labeled as the same type. Below, formula (1) was defined to perform the similarity calculation task, where r_{ik} denotes the type i -labeled app review sentence k expressed by a vector $r_{ik} = (t_{ik,1}, t_{ik,2}, \dots, t_{ik,m}, \dots, t_{ik,n})$, $t_{ik,m}$ denotes the m -th feature word in r_{ik} , t_{ij} denotes the AC-based text feature word labeled as requirements type i , $w_{ik,m}$ denotes the weight of the feature word $t_{ik,m}$ (produced by BoW) in the app review sentence r_{ik} , $\text{sim}(t_{ik,m}, t_{ij})$ denotes the similarity between the AC-based feature word t_{ij} and the app review-based feature word $t_{ik,m}$ (calculated by Word2Vec), and n denotes the number of AC-based feature words to be augmented to the app review sentences.

$$\text{Sim}(r_{ik}, t_{ij}) = \frac{\sum_{m=1}^n (w_{ik,m} * \text{sim}(t_{ik,m}, t_{ij}))}{\sum_{m=1}^n w_{ik,m}} \quad (1)$$

Considering each app review sentence r_{ik} , the similarity between r_{ik} and t_{ij} , i.e. the value of $\text{Sim}(r_{ik}, t_{ij})$, will be ranked. As a result, the top n AC-based feature words will be added to the end of this review sentence as the semantic augment. This means that n can be treated as the length of AC-based augment for app reviews. Algorithm 2 describes how to augment app review sentences with AC-based text feature words extracted in Sect. III.B and generated in Sect. III.C. Note that in our work, the value of n is pre-specified and fixed for augmenting app reviews. How much length of AC-based augments, i.e. the number of feature words augmented to app reviews, could bring more accurate prediction of app review classification will be discussed in Sect. IV.

Algorithm 2: Generating AC-Augmented App Reviews

Input:	AR_i – app reviews labeled as requirements type i n – the length of AC-based augment
Output:	Aug_AR_i – augmented AR_i by adding n words
1	for each requirements type i
2	for each $r_{ik} \in AR_i$
3	for each word $t_{ij} \in D_i'$
4	calculate $\text{Sim}(r_{ik}, t_{ij})$;
5	end for
6	sort $t_{ij} \in D_i'$ by $\text{Sim}(r_{ik}, t_{ij})$ in descending order;
7	add the first n t_{ij} to r_{ik} to produce new_r_{ik} ;

8	insert new_r_{ik} into Aug_AR_i ;
9	Return Aug_AR_i ;
10	end for
11	end for

E. Classifier Training and Evaluation

According to the experimental results in [1,9,13], Naïve Bayes has been reported to outperform other machine learning algorithms in the automatic classification of app reviews. Therefore, this work adopted Naïve Bayes as the classification technique to categorize FR and NFRs from app reviews. To evaluate the performance of Naïve Bayes, 10-fold cross validation was applied to reduce its overfitting in identification and classification of app reviews. In addition, we adopted the standard metrics *Precision*, *Recall* and *F-measure* to evaluate the accuracy of Naïve Bayes on the automatic classification of app reviews.

$$\text{Weighted average } (Precision_i \backslash Recall_i \backslash F - measure_i) = \frac{\sum_{i \in type} (Precision_i \backslash Recall_i \backslash F - measure_i) * Number_i}{\sum_{i \in type} Number_i} \quad (2)$$

More specifically, for each requirements type i , $Precision_i$ is the fraction of the app reviews that are correctly classified as requirements type i , $Recall_i$ is the fraction of the app reviews of requirements type i that are correctly classified as type i , and $F - measure_i$ is the harmonic average of the precision and recall. Furthermore, we introduced weighted average precision, recall and F-measure (see formula (2) below) to evaluate the accuracy of classifying app reviews into categories of each requirements type. In formula (2), $Number_i$ denotes the number of app review sentences labeled as requirements type i in the test set of Naïve Bayes.

IV. RESULTS

This section reports the results of our experimental study and compares the accuracy of Naïve Bayes in the automatic classification of requirements from app reviews. The Naïve Bayes algorithm was programmed with Python. All the experiments were conducted on a 2.50GHz Core i5 CPU with 8GB RAM under Windows 10.

A. Impact of Length of Augments on App Reviews Classification

As mentioned in Sect. III.C, the length of AC-based augments depends on the number of AC-based text feature words that added to the specified app reviews. Figure 2 shows the precision, recall and F-measure of the automatic classification of augmented app reviews with increasing number of AC-based augmented words (from 5 to 70 words) with an interval of 5 words, by applying Naïve Bayes. Note that in these experiments, the maximum length of AC-based augments is set as 70 words. The reasons are: (1) in [9], Lu and Peng have reported that augments with 1.9 times of the length of an app review sentence leaded to the best results in app reviews classification; and (2) in our dataset, the longest app review sentence has 37 words, and 70 words are around 1.9 times of the maximum length of included app review sentences.

As observed in Figure 2, F-measure is growing rapidly when less than 35 AC-based feature words are augmented to app reviews. There are two peaks when the length of augments is 35

and 45 words respectively. When the number of added AC-based feature words is greater than 50, the value of F-measure decreased or fluctuated within a narrow range.

Figure 2. Accuracy of classifying augmented app reviews with varying number of AC-based text feature words.

Furthermore, Table I zooms in the Precision, Recall and F-measure for classifying each type of requirements in app reviews, by employing AC-based augments with different lengths. Typically, the experiments run on the app reviews augmented by 6 (i.e. the average length of app reviews in our dataset) and 37 (i.e. the maximum length of app reviews in our dataset) AC-based text feature words. The results were listed in the columns for precision, recall and F-measure in Table I. We found that for two types or requirements – *Reliability* and *Other*, the accuracy of app reviews classification seldom differs in the lengths of augments for app reviews. Whereas, for *Usability*, *Portability*, *Performance* and *FR* typed app reviews, the longer AC-based augment leads to much higher accuracy of classifying app reviews. Specifically, we analyzed the influence of the proportion of each type of requirements identified in app reviews or changelogs on the accuracy of classifying app reviews with different length of AC-based augments.

As shown in Figure 3(a), for two types of requirements – *Usability* and *FR*, the higher proportion of app changelogs labeled as these two requirements types leads to more accurate identification and classification of these two types of

requirements in app reviews. Similarly, for the other two requirements types – *Portability* and *Performance*, the lower proportion of app changelogs resulted in a lower accuracy of classifying app reviews labeled as these two types. Whereas, it is surprising to find that lower proportion of app changelogs typed as *Reliability* and *Other* produced the two highest accuracy of classifying these two types of requirements in app reviews. Regarding the proportion of six specified types of requirements in app reviews, Figure 3(b) indicates that the higher (lower) accuracy of classifying app reviews labeled as a certain requirements type usually responds to the higher (lower) proportion of app reviews labeled as this type of requirements.

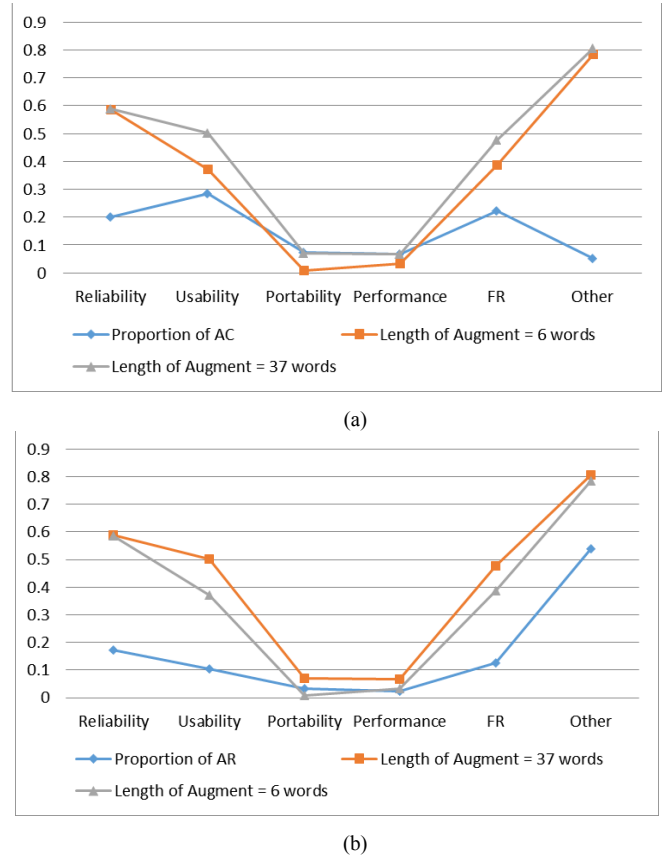

Figure 3. Influence of the proportion of each type in (a) app changelogs and (b) app reviews on the F-measure of classifying augmented app reviews.

TABLE I. PROPORTION OF APP REVIEWS/CHANGELOGS AND ACCURACY OF REQUIREMENTS CLASSIFICATION IN AUGMENTED APP REVIEWS (AC = APP CHANGELOGS, AR = APP REVIEWS)

Type	Proportion of AR	Proportion of AC	Length of Augment = 6 words			Length of Augment = 37 words		
			Precision	Recall	F-measure	Precision	Recall	F-measure
Reliability	0.172	0.199	0.641	0.544	0.586	0.586	0.588	0.587
Usability	0.104	0.285	0.845	0.239	0.370	0.656	0.408	0.502
Portability	0.034	0.073	0.100	0.004	0.007	0.410	0.040	0.071
Performance	0.025	0.068	0.200	0.018	0.034	0.400	0.037	0.068
FR	0.126	0.222	0.582	0.289	0.386	0.468	0.486	0.476
Other	0.538	0.053	0.672	0.951	0.785	0.750	0.873	0.807
Weighted average			0.641	0.665	0.611	0.656	0.678	0.652

B. Comparison with AUG-BoW

Similar to AUG-BoW in [9], our proposed AUG-AC also aims at augmenting app reviews for more accurate classification of app reviews. As we mentioned in Sect. II, AUG-AC differs in employing official app changelogs to augment app reviews for the identification and classification of requirements in app reviews. To compare and evaluate the performance of these two methods, we conducted a series of experiments varying in the methods for generating augments and the length of augments. As listed in the first row of Table II, we repeated AUG-BoW in sampled app reviews in our dataset; while in the second to the fourth row of Table II, the experiments evaluated AUG-AC in the cases that the lengths of augments were the average length of app reviews (i.e. 6.15 words), 1.9 times of this average length, and the maximum length of included app reviews (i.e. 37 words) respectively.

TABLE II. RESULTS ON CLASSIFYING APP REVIEWS AUGMENTED WITH DIFFERENT TECHNIQUES.

Techniques	Length of augment	Precision	Recall	F-measure
AUG-BoW [9]	$1.9 \times \text{length of an app review [9]}$	0.651	0.642	0.569
AUG-AC	6 words	0.646	0.666	0.610
AUG-AC	15 words	0.650	0.674	0.631
AUG-AC	37 words	0.656	0.678	0.652

Our experimental results are in Table II. Therein, we observe that once our proposed AUG-AC was applied to generate AC-based augments for app reviews, the accuracy of app reviews classification increases regardless of the length of augments. That is, our proposed AUG-AC outperformed AUG-BoW [9] by employing app changelogs for classifying requirements in app reviews. Furthermore, we compared the time spent on the automatic classification of augmented app reviews when applying AUG-BoW and AUG-AC in our dataset respectively. For this purpose, the time spent in two typical experiments – in the 1st and 4th row of Table II, was calculated. Note that in this work, we only concentrated on the time spent on augmenting app reviews with app changelogs by these two methods. The reason is that both AUG-BoW and AUG-AC adopted Naïve Bayes as the classifier, and these two techniques may take the same time period to classify augmented app reviews. The results are: (1) AUG-BoW took 1315.77 seconds to construct ‘customized’ augments for each app review in the training set of Naïve Bayes, and (2) AUG-AC took 106.64 seconds to complete the 37-word augments for any included app reviews. It was obvious that app reviews classification based on AUG-AC completed much faster than that based on AUG-BoW.

V. DISCUSSION

A. Analysis on the length of AC-based augments

Regarding the length of AC-based augments, we observed that the longer AC-based augments led to a higher accuracy in classifying app reviews. However, the accuracy did not continuously increase by augmenting app reviews with more than around 40 text feature words. The reason could be that in our AC-based feature dictionary, the AC-based feature words to be added to app reviews were ranked according to their topic

relevance with the specified type of requirements. In turn, the top 40 feature words selected for the construction of AC-based augments were the most ‘type-sensitive’ ones, and also enough, to provide much more accurate results in the app reviews classification.

Next, the proportion of each type of requirements in app reviews and changelogs was not always similar, indicating that these two data sources concentrated on different types of requirements. Taking ‘*Usability*’ NFR as an example, its proportion in app changelogs is around 2.7 times of that in app reviews. This finding implies that although apps may be upgraded to fit different types of user requirements, the official changelogs always pay more attention to this type of requirement. The reason could be that for user, changes typed as ‘*Usability*’ were critical for making decision on whether this release is appropriate for their demands. Regarding to the ‘*Other*’ type, the much lower proportion of app changelogs indicates that they have less noise than app reviews.

Furthermore, we found that the rank of the proportion of different types of requirements in app reviews nearly follow the rank of accuracy in classifying these requirements types in app reviews. The reason could be that both the training and test set of Naïve Bayes consisted of app reviews. In contrast, the rank of the proportion of different types of requirements in app changelogs did not always correspond to the rank of accuracy in classifying app reviews. For example, lower proportion of ‘*Reliability*’ and ‘*Other*’ types in app changelogs contributed to more accurate results in app review classification. One reason could be that for these two types of requirements, the AC-based text feature words that were used to augment app reviews are quite similar to the feature vectors of app reviews. The other reason could be that compared with the other four types of requirements, those that employed AC-based text feature words are much more ‘topic sensitive’ to identify app reviews typed as ‘*Reliability*’ and ‘*Other*’. All the findings are positive to our exploration on using app changelogs to classify requirements in app reviews, and encourage further research on this topic.

B. Comparison between AUG-AC and AUG-BoW

Considering the accuracy of app reviews classification, we found that our proposed AUG-AC method outperformed AUG-BoW provided in [9] – the work that inspired our ideas to improve the accuracy of app reviews classification with app changelogs. Compared with AUG-BoW, AUG-AC spent much less time in augmenting app reviews. The main reason is that in AUG-AC, the augments of app reviews were constructed by calculating the similarity between the AC-based feature words of a certain type of requirements and the app reviews labeled as this type. That is, for each type of requirements, 20 feature words extracted from app reviews and their synonyms and antonyms (around 300 words) selected from WordNet are candidates to be calculated and ranked. Whereas, AUG-BoW augmented app reviews by calculating the similarity between extracted text feature words of a certain requirements type and all the app reviews labeled as any type of requirements. These findings can be deemed as the main advantage of our AUG-AC and the main difference between AUG-BoW and AUG-AC.

VI. THREATS TO VALIDITY

We followed the guidelines in [15-16] to evaluate the possible threats to validity of our experimental results.

Construct validity: Our work reused the dataset in [13]. All the app reviews and changelogs in this dataset were analyzed by three coders independently, on the premise that they had a consistent understanding on different types of requirements, especially on NFR types defined in ISO 25010. As indicated in [13], we believe this threat to construct validity is partially mitigated by following the aforementioned labelling process.

Internal validity: There is an internal threat to validity concerning how the proposed AUG-AC and the Naïve Bayes classifier were programmed. We implemented them by Python. The results of this exploratory study may vary if AUG-AC and Naïve Bayes are implemented in other ways, e.g. in Weka. Thus, how to improve the implementation of AUG-AC and Naïve Bayes remains to be studied. Another internal validity threat is that, not all the app changelogs and reviews were collected from the same platform. Especially, the changelogs of WhatsApp were collected from Apple App Store and the app reviews were from Google Play. Different concerns of users in different platforms may lead to the fact that the AC-based text feature words provide insufficient semantics to app reviews, which may further result in inaccurate classification of app reviews. Therefore, more research is needed on app reviews and changelogs from the same platform.

External validity: We investigated the user reviews of three apps and changelogs of 30 apps which span over three categories and two major mobile operating systems. We believe that the threats to external validity are partially alleviated. Due to the time and resource limitation, we did not cover many apps, and we plan cover more categories of apps to increase the external validity of the study results.

VII. CONCLUSIONS AND FUTURE WORK

This work explored to augment app reviews with official app changelogs, in order to improve the accuracy of classifying requirements, including FR and four types of NFRs, in app reviews. For this purpose, AUG-AC was proposed to augment app reviews with not only the text feature extracted from app changelogs but also their synonyms and antonyms generated by Word2Vec, in the case that both the employed app changelogs and the app reviews to be augmented are labeled as the same type of requirements. Next, a series of experiments was designed to evaluate the performance of AUG-AC by varying the length of AC-based augments. The experimental results indicate that the AC-based augment of app reviews implemented by AUG-AC can improve the accuracy of classifying requirements in app reviews.

To further evaluate the performance of AUG-AC, our next steps are: (1) re-evaluation of AUG-AC on a balanced dataset by leveraging the proportions of different types of requirements in current dataset; (2) evaluation of AUG-AC with app reviews and changelogs of other apps in other categories of Apple App Store

or other app repositories (e.g. Google Play, other Android app stores, etc.); and (3) validation of AUG-AC by using the dataset labeled by more types of NFRs (e.g. Security).

Abstract—Virtual desktop technology aims at accessing a remote desktop by endpoint hardware. Great attention has been increasingly paid to virtual desktop since it can increase the utilization of computing resources and provide more flexible accesses. However, researchers have not yet come up with a comprehensive set of rigorous standards of experimental design and implementation in this field. Therefore, it is difficult to conduct prudent experiments, which is correct, real, and transparent.

In this paper, we assess the experimental evaluations of recently published papers on desktop virtualization. We observe that most works can be further improved, due to the unsuitable experimental environment and the lack of descriptions of experimental settings. In this paper, in order to help researchers, reviewers, and readers, we propose several guidelines for designing correct, real, and transparent desktop virtualization experiment.

Index Terms—Virtual Desktop; Prudent Experiment;

I. INTRODUCTION

Nowadays, with the rapid development of virtualization technology, cloud computing has drawn great attention from both academia and industry fields [1], [2]. The thin client was first proposed in the 1990s, which finally develops rapidly in the form of virtual desktops in the boom of cloud computing [3], [4]. There are many mature solutions in the industry fields [5]. The academic community has also proposed a lot of impressive works [6]. Many desktop virtualization approaches will conduct extensive experiments to verify the performance of the proposed desktop virtualization systems. However, since there is no comprehensive set of rigorous standards of experimental design and implementation in this field, researchers will face numerous pitfalls during the experiment.

In this paper, we investigate issues about the prudent experimental evaluation of desktop virtualization systems. We observe that there are no general experimental standards in this field, which makes it difficult to compare these projects equally. In our previous research work, we notice that it is hard to reproduce the experiments that are conducted in many other approaches. Therefore, we put forward that the existing systems of desktop virtualization could be further improved in a rigor experimental standard. We solemnly declare that we highly respect the existing works. Under the purpose of helping researchers, we point out the current common problems that every relevant researcher, including ourselves,

might encounter. One of these problems is that the description of the experiments in many works is sometimes inadequate. In addition, there are more serious issues that may affect the correctness of the experiments.

Our goal is to establish a set of rigor guidelines for the design, implementation, and description of prudent desktop virtualization experiments. We regard *correctness*, *reality*, and *transparency* as three cornerstones. Based on these cornerstones, we propose guidelines that can help researchers in prudent desktop virtualization experiments. We review existing 17 papers under our guidelines to confirm the validity of these guidelines. Most papers can benefit from our proposed guidelines. Through simple case study, we also validate the existence of some pitfalls encountered in the desktop virtualization experiments.

In summary, our work makes the following important contributions.

- (1) We discover the common pitfalls in desktop virtualization experiments.
- (2) We propose a set of guidelines to help researchers improve the rigor of desktop virtualization experiments.
- (3) We investigate 17 desktop virtualization papers and validate that our guidelines are practical.
- (4) We conduct simple case study to prove that the pitfalls in the desktop virtualization experiments deserve great attention.

II. RELATED WORK

In this section, we summarize existing works related to our research.

Virtual Desktop Infrastructure (VDI): The technology that allows users to run desktop operating systems on virtual machines is known as VDI [6]. VDI manages a virtual desktop, which is a desktop environment in a virtual machine (VM) that runs on a centralized or remote server. A user can access a virtual desktop through a variety of terminals. There are many vendors which provide VDI solutions such as Citrix [5] and VMware [7].

Desktop as a Service (DaaS): DaaS provides the benefit of VDI without the cost and risk of managing physical resources, which allows a user to access desktop applications by any devices in anywhere [8]. Deboosere et al. propose a system

architecture to provide efficient desktop services in a cloud [9], which specifically focuses on mobile users. Therefore, due to resource constraints, virtual desktops are executed remotely. Kim et al. design and implement a desktop virtualization system using lightweight display protocols based on cloud DaaS [10].

Virtual Mobile Infrastructure (VMI): VMI extends the principles that allow VDI to run desktop applications on desktops and mobile devices - only this time, mobile apps are accessed remotely from mobile devices [11]. Su et al. propose vMobiDesk, a prototype system which provides mobile users with remote accesses to virtual mobile desktop such as Android desktop [12].

Prudent Practices for Designing Experiments: The rigor of experiments is very important for all academic papers. Previous researchers have analyzed the experimental rigor in other research fields [13]. However, before our paper, the rigor of desktop virtualization experiments has not been studied.

III. GUIDELINES FOR PRUDENT EXPERIMENT

We propose that the main pitfalls in existing desktop virtualization experiments can be divided into three categories. First of all, reasonable experimental setup and environment are the keys to ensure the *correctness* of the experiment. In addition, only real-world testings can *realistically* demonstrate that the virtual desktop really satisfies the actual needs of users. Finally, a *transparent* description of the experimental details can help the reviewers and readers understand the experimental setup and ensure the reproducibility of the experiment. Based on the above cornerstones, the following content outlines the guidelines of prudent virtual desktop experiments.

A. Correct Setting

1) **Select the appropriate test indicators:** The indicators tested in each desktop virtualization approach are not always the same. It is worthy to point out that the testing of parts of indicators is indispensable. For instance, we observe that many papers do not adequately test response time in virtual desktop experiments. However, for desktop virtualization, the performance of a system is strongly related to user interactions, no matter how appreciative other test results in the experiments are, the lack of response time testing will always be confusing. We emphasize that it is necessary to use appropriate methods to test important indicators.

2) **Comprehensively consider the effects of experimental equipment:** Various devices can be used in the tests of the performance of desktop virtualization systems. Obviously, the equipment used by the researchers is not uniform. It is indeed difficult to require everyone to use the same devices. We will not make such unreasonable demands. However, researchers should realize that different equipment may cause deviations in experimental results. We point out that different devices should be used in the same tests to decrease the experimental bias.

3) **Determine the impact of network settings:** Different network configurations are likely to significantly affect the performance of a virtual desktop. In many existing papers, the authors have configured excellent network connectivity, which is almost impossible in real life. In such a network environment, desktop virtualization systems may perform very well. However, virtual desktops may not perform so well in daily network environments. We propose to configure a variety of network environments for comparison.

4) **Pay attention to the effects of desktop resolutions:** In desktop virtualization systems, desktop data can be encoded with any resolution when it is transmitted. When the same desktop data is transmitted by different resolutions, the amount of the data is different, which will have an impact on the network bandwidth and response time. Therefore, we emphasize that authors must pay attention to the influence of resolutions and evaluate them in their papers.

B. Realistic Tests

1) **Conduct real-world experiments:** Desktop virtualization works need to solve real-life problems, which should be able to work in the real world while satisfying the needs of users. To evaluate the actual performance of a desktop virtualization system, real-world experiments should be conducted. We propose that using the equipment of users to conduct experiments in the real-world working environment is more convincing.

2) **Be cautious about the compatibility:** For various reasons, many papers are evaluated only in a single Operating System (OS) version. However, considering the compatibility, we propose that papers should explain whether the current desktop virtualization system can be applied to other OS versions, or investigate in detail how much work is needed to port the desktop virtualization system to other OS versions.

C. Transparent Description

1) **Detail description of the OS and tools used in the experiment:** Different OS versions and test tools may lead to different experimental results. We insist that the author is obliged to elaborate the OS version and test tools in their paper, such as "Windows 7 64-bit none third-party programs installed", "netperf-2.7.0 released on 21 Jul 2015, download address: <https://github.com/HewlettPackard/netperf/releases>", The detail description can improve the possibility of reproducing experiments by readers.

2) **Explain the reasons for the poor/outstanding performance:** If the virtual desktop does not perform well on a test, we strongly recommend that the author should analyze the possible causes of the poor performance carefully. It is always a respectable practice to propose possible improvement solutions. Even if the desktop virtualization system performs well in the experiments, the author still needs to perform a comprehensive analysis. If the experimental environment, such as the condition of the network, is the reason for the outstanding performance of a desktop virtualization system, then ignore this reason is unfair for other papers.

IV. ASSESSMENT OF GUIDELINES

In this section, we elaborate the assessment of the guidelines presented in previous sections. The assessment method we use is to extract criterions from the guidelines and then apply the criterions to 17 recent papers listed in Table I for analysis. Through this method, we validate the practical value of the guidelines and obtain some observations.

A. Process of Assessment

In order to assess our guidelines, we extract more specific criterions from the corresponding guidelines. Table II shows the criterions we proposed. For researchers who study on desktop virtualization, every criterion we define can be judged directly with the corresponding papers. As shown in Table II, we divide all the criterions into three levels. Among them, level '***' indicates that the experiments in a rigorous paper

TABLE III
OVERVIEW AND BRIEF DESCRIPTION OF OBSERVATIONS.

Criteria	Rating	Yes	Weak	Description
Correct Setting				
Response time test	***	8 (47.0%)	2 (11.8%)	Only about half of the papers performed response time test in a suitable manner. In addition, there are two papers that measured response time, but their conclusions are too sloppy. None of the remaining articles measured response time.
Bandwidth evaluation	***	9 (52.9%)	0 (0%)	About half of the papers do not measure bandwidth consumption at all.
Frame rate test	***	3 (17.6%)	0 (0%)	Almost all papers have not evaluated the FPS of virtual desktops.
Diverse network connectivity	***	5 (29.4%)	0 (0%)	Only five papers configured a variety of network environments for comparison.
Different resolutions	***	6 (35.3%)	0 (0%)	Less than half of papers tested the performance of virtual desktops at different resolutions.
Different devices	**	2 (11.8%)	0 (0%)	Most papers do not mention support for multiple client devices. In this case, client compatibility cannot be evaluated.
Realistic Test				
Real users	***	2 (11.8%)	0 (0%)	Few researchers have invited real users to participate in the evaluation of desktop virtualization systems. In other words, basically only the rigid numerical results are provided.
real-world experiments	**	3 (17.6%)	1 (5.9%)	A majority of papers do not conducted real-world experiment. Only two papers met this criterion. In addition, there was a paper that used tools to simulate different user environments.
Multiple OSes	*	1 (5.9%)	0 (0%)	In only one case the authors conducted experiment with different server OS versions.
Transparent Description				
Introduction of OS version	***	10 (1%)	0 (0%)	Seven papers do not describe the operating system version of the virtual desktop. This puts those who wish to reproduce the experiment into a situation where they have no rules to follow.
Introduction of test tools	***	6 (35.3%)	2 (11.8%)	About half of the papers do not present information about the tool. There are also two papers that just mention the name of the tool but do not detail the version and other information.
Interpretation of poor performance	***	6(35.3%)	1(5.9%)	Only about a third of the papers explain the reasons for the poor performance in the experiment. There is also a paper that only explains a part of the poor performance.
Analysis of good performance	***	3 (17.6%)	2 (11.8%)	The vast majority of the papers just put some numerical results that look very good but do not explain any of the deep reasons behind the excellent results. There are also two papers that only explains a part of the good performance.
Improvement solutions	*	1 (5.9%)	0 (0%)	Only one paper proposes improved solutions after discussing the causes of poor performance.

must comply with these criteria. Level ‘**’ shows that these criteria should be followed, while Level ‘*’ means that it is good to satisfy these criteria.

We leverage each criteria in Table II to evaluate the papers in Table I. Two of our authors conduct a survey for all the papers. Our goal is to investigate the prudence of the experiments through all the available information in the paper. Therefore, in the process of investigating the papers, we follow the rules that only focus on the content of the papers. We do not review the source code or contact the authors of the papers for more details. We use these restrictions because they actually reflect what readers and reviewers face. Reviewers are often not likely to investigate details that the author has omitted. In the case of a double-blind submission, there is simply no way to contact the author. In other words, only the paper itself can be easily accessed by reviewers and readers. It is the author’s obligation to clarify the details in the paper.

B. Observations

Table III lists the statistics results of all the surveyed papers. *Yes* refers to papers adhere to the guideline.

1) Correct Setting: About 47% of the papers conduct experiments to test response time. Two papers take how users feel as a performance measure, which is not suitable. Similarly, half of the papers have bandwidth evaluation. For the frame rate test, more than 80% of the approaches ignore the test. No more than 50% of the papers use different devices to evaluate the proposed systems. Only 27.7% of the papers test different network connectivities. 30% of the works conduct the experiment of different resolutions. We can see that most papers do not include enough correct settings.

2) Realistic Test: The survey indicates that few papers conduct real-world experiments. From the table, we observe that 80% of the papers lack real-world experiments and only one

TABLE IV
SETTINGS FOR OUR EXPERIMENTAL PLATFORM.

Server Host	Processor	3.40GHz Intel Core i7-6700
	RAM	8 GB
	OS	Ubuntu 16.04
	Kernel	Linux 4.4.0
Server Guest	Virtualization tool	VirtualBox 5.2.10
	RAM	1 GB of RAM
	OS	Android-x86-5.1.1
Client Device	Hardware	Google Nexus 9
	OS	Android-6.0
	RAM	2GB
Network	Hardware	NETGEAR R8000
	Frequency	2.4GHz/5GHz
	Speed	1000MB

paper conduct experiments with different OS versions. Few researchers (about 11%) have invited real users to participate in the evaluation of desktop virtualization systems.

3) Transparent Description: Half of the papers do not introduce the OS version that they leverage. 50.5% of the papers do not describe the testing tools. Only half of the papers mention network connectivity. Consequently, in the majority of the cases, readers fail to figure out the experiment setup adequately, nor can repeat the experiments. Meanwhile, we find that more than 90% of the papers incompletely describe experimental results. Only two papers offer improvement solutions to address low-performance problems.

V. CASE STUDY

In order to explain the problems caused by the violation of the guidelines intuitively, we design experiments to prove that the aforementioned pitfalls will affect the evaluation results of a desktop virtualization system.

Specifically, we analyze two experiments related to two criteria: (1) the influence of resolution on experimental results, and (2) the impact of network connectivity. The experiments of the remaining criteria will be updated to *arc.zju.edu.cn*. Based on our previous experience in desktop virtualization, we believe that all the factors in the guidelines will affect the experimental results. The desktop virtualization system used in our experiment is vMobiDesk, which is a relatively new VMI framework [12].

A. Experimental Setup

As shown in Table IV, all tests are performed on a server machine with a 3.40GHz Intel Core i7-6700 processor and 8 GB RAM. The server machine runs Ubuntu 16.04 with Linux 4.4.0 kernel. The guest OS is Android-x86-5.1.1, which runs in a virtual machine created by VirtualBox. The tested client device is Google Nexus 9 running on Android-6.0 OS. A 100 Mbps, 1 ms latency LAN network is utilized to construct local 2.4GHz and 5GHz Wifi communication network between the mobile device and the server.

Fig. 1. Bandwidth consumption with different resolutions.

B. The Influence of Resolution

We measure the bandwidth consumption with different resolutions during browsing web pages by vMobiDesk with *iftop-0.17* (released on 12 Feb 2006, download address For <http://www.ex-parrot.com/~pdw/iftop/download/iftop-0.17.tar.gz>). This experiment uses a 2.4GHz wireless network. The results are shown in Table 1. The higher the resolution, the more data of the virtual desktop system needs to be transmitted. Therefore, the higher the bandwidth consumption is required. When the resolution is 640 x 480, the bandwidth consumption is only 262 KB/s. In contrast, it increases to 449 KB/s when the resolution is 1920 x 1080. The increment is up to 71.4%. Without proper handling, this huge consumption will obviously affect the accuracy of an experiment. For instance, a paper ultimately concludes that the desktop virtualization system takes up quite low bandwidth without claiming the use of 640 x 480 resolution for the experiment, which will lead to misunderstandings since the users still consider that the bandwidth consumption remains so small even with a higher resolution.

C. The Impact of Network Connectivity

We further measure the response time under different network connectivity. We conduct experiments in the wireless network environments of 2.4 GHz and 5 GHz, respectively. The average response time is evaluated by several operations such as opening an application, typing several words in a document and returning back to the home screen, etc.

One obvious result is that the response time under 5GHz Wifi is shorter than that under 2.4GHz Wifi. Regardless of the resolution, this difference caused by the frequency of the wireless network always exists. Taking resolution 1024 x 768 as an example, the response time under 5GHz wifi is 410 ms. However, the response time under 2.4GHz wifi rises up to 680 ms. Although this result is not as shocking as the previous experiments shown, 30% of time increment is also large enough to affect the accuracy of an experiment. Leveraging a 5GHz network in an experiment without elaboration will lead to a misunderstanding of the excellent performance.

Fig. 2. Response time under different network connectivities.

VI. DISCUSSION

As shown in Section V, improper design of experiments, ambiguous experimental descriptions, and other pitfalls will cause deviations in the assessment of virtual desktop and even lead to misunderstanding. We insist that it is the author's responsibility to ensure the *correctness*, *reality*, and *transparency* of their papers. Surprisingly and disappointingly, our research shows that considering rigorousness, the majority of experiments in desktop virtualization papers are subject to improvement. To reiterate, we greatly respect the researchers, including the authors of the papers we surveyed, and the results of their work. However, it turns out that we have not yet come up with a comprehensive set of rigorous standards of experimental design and implementation in the desktop virtualization field. We believe that a reasonable set of guidelines will help everyone greatly improve their efficiency of work and the quality of the paper. We hope our paper can bring some help to reviewers, authors, and readers. This is the initial motivation for us to carry out this work, and it is also our ultimate goal.

VII. CONCLUSION

In this paper, We summarize pitfalls that are often encountered when conducting desktop virtualization experiments. Based on this, we further propose guidelines that help researchers design and implement prudent experiments in desktop virtualization systems. We extract specific criterions from the corresponding guidelines and leverage each of the guideline criteria to evaluate the papers we selected. Our survey results validate that many papers can be improved. Using our proposed guidelines will help improve the quality of the papers in the experimental part. Finally, we conduct experiments and demonstrate the impact of some pitfalls succinctly.

VIII. ACKNOWLEDGEMENT

We appreciate the anonymous reviewers for their helpful suggestions. Our paper is partly based on the work supported by the National Key R&D Program of China (No. 2016YFB0800201).

Abstract—With the trends of developing software on the Internet, many software crowdsourcing platforms are emerging. They attract a lot of developers to bid for crowdsourced projects and develop software systems collaboratively. In this paper, we present CrowDevBot, a *task-oriented conversational bot for software crowdsourcing platform*, that aims to assist online users in completing crowdsourcing-related tasks in a more natural manner. The key idea of CrowDevBot is to: (1) combine a rule-based method and an SVM-NaiveBayes-C4.5 integrated learning method to discover users' intention; (2) employ an integrated CRF (conditional random field) method with novel features to improve the performance of slot filling; and (3) leverage a software service knowledge base to unify entity names and predefine the key slots of user query. We implement CrowDevBot and integrate it into JointForce, an IT software crowdsourcing platform in China. To the best of our knowledge, this is the first time that a task-oriented conversational bot is practically used in software crowdsourcing platform(s). We evaluated our approach on real data set from JointForce. The results show that our intention detecting method achieves F1-score of 87% on the limited training data. For the slot filling, the F1-score of our integrated CRF model reaches 82%, 8% higher than that of the normal CRF model.

Index Terms—Task-oriented conversational bot, software crowdsourcing platform, integrated statistical learning, user intention understanding

I. INTRODUCTION

Software crowdsourcing [1] is a new software development paradigm. In a crowdsourcing process, project requesters and software developers need to complete many tasks, such as recommending qualified developers, searching and bidding projects, querying project progresses, evaluating service qualities, etc. This paper presents a *task-oriented conversational bot* (CrowDevBot) for software crowdsourcing platform. A bot can assist users in completing their crowdsourcing-related tasks through conversation, rather than tedious mouse clicks. Thus it supplements crowdsourcing platforms with strong flexibility. Figure 1 demonstrates how such a bot helps an engineer to complete his/her task.

Though developing bots can benefit crowdsourcing platforms in completing software crowdsourcing tasks in a more friendly manner, it still faces three challenges:

Challenge 1. *How is the cold start problem solved by a task-oriented conversational bot?* Different from online-shopping

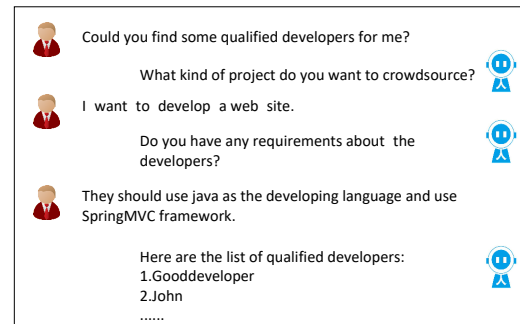

Fig. 1: An example of using CrowDevBot in crowdsourcing

websites, user interactions on software crowdsourcing platform is much less, which brings the cold-start problem. Statistical learning models or deep learning models may also not work well due to limited data.

To solve the cold start problem, several rule-based methods have been proposed for natural language understanding [2] [3] [4]. However, rule-based methods usually have following shortcomings: (1) The accuracy of understanding users' intention relies on the quality of rules. (2) User queries are usually flexible while a pre-defined rule set may not be complete.

Challenge 2. *How is the performance of CRF model improved for user intention understanding?*

CRF (Conditional Random Field) is a widely used model for solving the slot filling problem of user intention understanding. Researches [5] [6] show that CRF can be a general model, while many new deep learning models are not [7] [8] [9].

Due to limited training data, the normal CRF is still unsatisfactory. To improve the slot filling performance of CRF model, there are two key issues: (1) how to define effective features according to the characteristics of software crowdsourcing domain; and (2) how to design an improvement strategy to achieve a more robust CRF model.

Challenge 3. *How can the software service knowledge base be utilized to enhance the capability of the bot?*

Priori knowledge on software crowdsourcing can definitely enhance the capability of CrowDevBot. Inspired by the work of Zhao et al. [10], we build a knowledge base to represent software service knowledge. As far as we know, this is the first time that a task-oriented conversational bot is practically used

*Corresponding author

DOI reference number: 10.18293/SEKE2019-068

in software crowdsourcing scenario. So it will be challenging for us to design and leverage the software service knowledge base in CrowDevBot, to improve its performance.

To address these challenges, we propose a novel approach to developing CrowDevBot. CrowDevBot consists of five key components: *user intention detecting*, *slot filling*, *dialog management*, *task execution*, and *answer generation*. We combine the rule-based method and a SVM-NaiveBayes-C4.5 integrated learning method to deal with the cold start problem when detecting user intentions. CrowDevBot adaptively sets weights for these two methods. For filling slots, we propose an integrated CRF model with novel features, including syntactic and semantic features. We also leverage a software service knowledge base to predefine the key slots of software services and normalize their entity names. So far, we have integrated CrowDevBot into JointForce, one of the biggest IT software crowdsourcing platforms in China. To the best of our knowledge, this is the first time that a task-oriented conversational bot is used in software crowdsourcing platform.

II. RELATED WORK

Storey and Zagalsky [11] propose that bots can act as “conduits between users and services, typically through a conversational UI”. Roughly bots can be divided into two categories [12]: chat-oriented bots and task-oriented bots. In recent years some task-oriented conversational bots have been built both in industry (such as Apple’s Siri, Microsoft’s Cortana) and in academia (such as those proposed by Zhou et al. [10], and Wen et al. [13]). Bots are also rapidly becoming a general interface for software services communication [14]. However, to our best knowledge, few task-oriented conversational bots have been developed for software crowdsourcing platforms.

User Intention Detecting. User Intention Detecting is an important part of task-oriented bots, which can be seen as a classification problem. Particularly, more and more deep models are proposed for this purpose. Kim Y et al. [15] first apply the CNN (convolution neural network) model to solving these problems. Xu et al. [16] use RNN (recurrent neural network) to detect user intentions. Compared to the CNN model, RNN makes use of the sequence information, making it fit for natural language problem. However, no matter how novel the network structure, the performance is poor when data is limited. It requires bots to handle this problem.

Slot Filling. After user intention is detected, the bot needs to parse the user input and recognize the predefined key slots (words to be filled in a sentence). It can be taken as a named entity recognition problem. McCallum [5] et al. use the traditional CRF to solve this problem. Though this model works, it is unable to handle the OOV problem, i.e., it cannot recognize an entity which do not appear in the training data. Thus more novel features need to be designed. Researches [17] apply deep learning methods on solving this problem. But as mentioned before, the restrictions on data reduce the performance of these models.

Cold-Start Problem. When a task-oriented conversational bot is built, it faces with the potential cold-start problems. The cold-start problem is serious for the software crowdsourcing platform as the user data is limited [18]. To solve the cold-start problem in a universal way, Rieser V et al. [4] focus on developing a structured ontology for parsing utterance from user into predefined semantic slots. Zhao Yan et al. [10] present a general solution to the cold-start problem in online-shopping domain. They use crowdsourcing to label training data, while it is not suitable for our situation as data is limited.

III. APPROACH

A. Approach Overview

Our approach overview is shown in Figure 2. The task-oriented conversational bot for software crowdsourcing platform, named CrowDevBot, consists of 5 components.

1) *User Intention Detecting*: Given a user query, CrowDevBot detects the user intentions with a combination method after entity name unification. A rule-based method and an SVM-NaiveBayes-C4.5 integrated learning method is combined by the following strategy: the rule based method is mainly used in the CrowDevBot’s startup process; with data increases, the SVM-NaiveBayes-C4.5 integrated learning method becomes more effective, and thus its weight gets increased.

2) *Slot Filling*: This component gathers the key information (called “slot”) from user queries. We design several key features (including transition feature, start and end features, word and syntactic features), and employ integrated CRF model to fill slots together with probability distribution information to achieve better precision and robustness.

3) *Dialogue Management*: In this component, the interaction process between user and CrowDevBot is managed. CrowDevBot uses a FSM (Finite State Machine) to track the dialogue states. When some slots are missing, it launches new questions to ask. We utilize the software service knowledge base (SSKB) to predefine the key slots for software services. When all of the slots are filled, CrowDevBot invokes *task executing component* to execute the task.

4) *Task Executing*: In this component, the user tasks are executed: once CrowDevBot has identified user intention and filled all slots, it will invoke the corresponding APIs of software crowdsourcing platform and return results to CrowDevBot.

5) *Answer Generation*: As all the supporting tasks are clear and well defined, it can be easy to use a template library to generate answers. CrowDevBot uses FSM to determine which template to be used to generate answers or launch new questions.

Next explains the details of the software service knowledge base, user intention detecting and slot filling.

B. Software Service Knowledge Base

To leverage the domain knowledge of software crowdsourcing, we build a software service knowledge base (SSKB). The main data sources of SSKB includes the knowledge

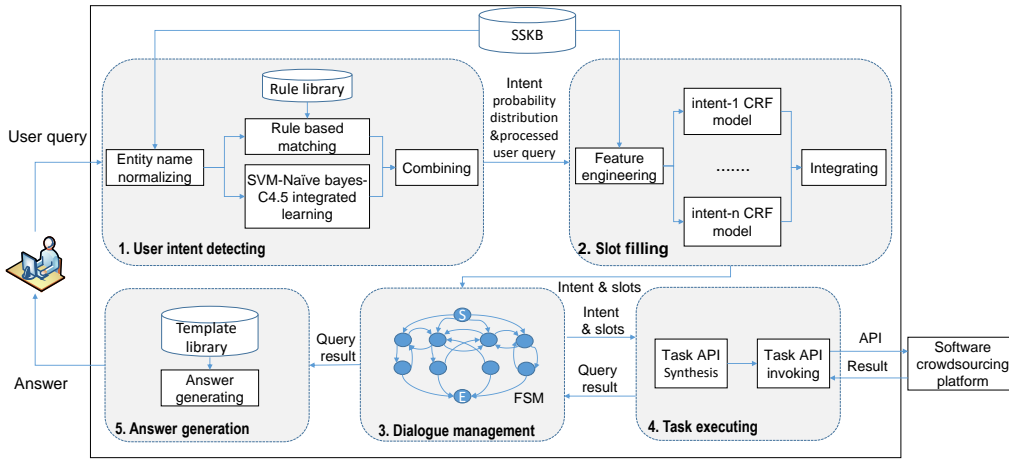

Fig. 2: A general process of CrowDevBot in processing user queries in a software crowdsourcing platform

collected from software crowdsourcing experts, StackOverflow tag synonym system* and Wikipedia†. We apply NLP technology to extract information from these (semi)-structured data, and construct SSKB, which contains category system, technologies, and attributes of software services. For more details, see our project in github‡.

We exploit SSKE to improve the performance of CrowDevBot in two scenarios. The first scenario is entity name unification. In the dialogue with CrowDevBot, users tend to express casually, with various aliases and abbreviations, leading to decreases in precision of intention detecting and slot filling. Thus we build a synonym dictionary using entity synonym attributes in SSKE. During preprocessing, CrowDevBot replaces aliases and abbreviations with standard names.

The second scenario exists in defining slots for software services. For example, in Figure 1, after CrowDevBot receives user input “I want to develop a web site”, it maps the query to the entity “web development” in SSKE. Thus CrowDevBot continuously asks user about the attributes values of “web development” to complement the corresponding slots.

C. User Intention Detecting

User intention detecting can be formulated as a user query classification problem. To solve it, we propose a mixture method, which combines a rule based method and an SVM-NaïveBayes-C4.5 integrated learning method. Weights are dynamically assigned to these two methods. In the startup process, CrowDevBot relies mainly on the rule based method, as it requires less usable training data. After sufficient data is collected, the SVM-NaïveBayes-C4.5 integrated learning method will make more contribution.

1) *Rule-Based Method*: Each kind of intention corresponds to a set of query rules that are used to describe the possible ontology structures of user queries. A rule consists of several

tokens. Each token has 3 attributes: Match_pattern, Weight and Indispensable. Here Match_pattern contains its candidate words, Weight shows the importance of the token to the whole rule, and Indispensable explains the necessities of a token.

The matching algorithm is designed as Algorithm 1 shows.

Algorithm 1 Greedy rule matching algorithm.

Require: A rule (R) and word list (QL) of user query

Ensure: Matching degree (MD) between the rule and query

```

1: for each word or parse  $\in QL$  do
2:   for each unmatched_token  $T \in R$  do
3:     compute the word2vec vector similarity between
        $w$  and each word in  $T.Match\_pattern$ , and record the
       highest  $HS_w$ 
4:     if  $HS > 0.5$  then
5:       mark this token as matched_token and record
       the similarity
6:       goto step 1
7: if all tokens in  $(R.token | R.token.indispensable = 1)$ 
   are matched then
8:    $MD = \frac{\sum_{a \in matched\_token} token_a.weight \times HS_a}{\sum_{b \in R.token} token_b.weight}$ 
9: else
10:   $MD = 0$ 
11: return MD

```

2) *Integrated Learning Method*: CrowDevBot faces with the cold start problem, making deep learning techniques inappropriate to use. Thus we propose an integrated statistical learning method to train the intention classification model. We select SVM, Naive Bayes and C4.5 DT as basic models and combine them following two strategies: Bagging and AdaBoost.

We design three features after manual analysis on these wrong detection cases.

- **Semantic feature.** The feature is produced by POS tagging. The possible values includes noun, adjective, etc.

*<http://stackoverflow.com/tags/synonyms>

†<https://www.wikipedia.org>

‡<https://github.com/SE1405Lab/SSKB>

- N-gram feature. The n-gram feature [19] takes the word sequence-level information to help analyze a sentence. In our method, we take N as 3.
- Word2vec feature. The Word2Vec feature [20] represents words with a low-dimensional vector, which helps understand the semantics of words.

3) *Method Combination*: The results of these two methods above are combined with weights:

$$R = W_1 R_1 + W_2 R_2, \quad (1)$$

where W_1 is the weight of rule-based method, and R_1 is the match degree between user query and each intention; W_2 is the weight of SVM-NaiveBayes-C4.5 method, and R_2 is its probability distribution. The intention with the highest R will be regarded as the final output.

D. Slot Filling

We use CRF [6] as a basic model to fill the slots, as CRF achieves better performance than general models (like HMM [21]). Given the word sequence $X = (x_1, x_2, \dots, x_m)$, CRF computes the conditional probability of a label sequence. It produces a label $y = (y_1, y_2, \dots, y_m)$ sequence to maximize $p(y|x)$.

$$p(y|x) = \frac{1}{z_\lambda(x)} \exp\{\lambda \cdot f(y, x)\} \quad (2)$$

Meanwhile, it is intractable to compute $f(y, x)$. Thus we assume that the value of $f(y, x)$ depends only on the adjacent labels and the formula $p(y|x)$ can be converted into

$$p(y|x) = \frac{1}{z_\lambda(x)} \exp\left\{\sum_{i=1}^{M+1} \lambda \cdot f(y_{i-1}, y_i, x, i)\right\}, \quad (3)$$

where $z_\lambda(x)$ is a normalization factor, and λ the weight vector of feature functions. The training process aims to find a proper λ for the CRF model.

We design several types of features for CRF:

- Transition feature: A transition feature describes the transition between adjacent labels.
- Start feature: A start feature implies that a label happens to be at the start position.
- End feature: An end feature implies that a label happens to be at the end position.
- Word feature: A word feature represents the co-occurrence of a word and a label.
- Syntactic feature: A syntactic feature represents the co-occurrence of a POS tag of the word and a label.
- Semantic feature: Inspired by Li et al.'s work [22], we design the semantic feature using "lexicons", which are clusters of semantically-related word or phrase constructs. A semantic feature describes the co-occurrence of an element in a lexicon L and a label.

We train several CRF models for each intention and integrate them into one mixture model to fill slots of templates. After the slot values are obtained, CrowDevBot uses SSKE to examine whether the key slots are complete and then traces the states using the FSM.

TABLE I: Intention detecting results w.r.t. different models

Model	Precision	Recall	F1-score
Integrated (Bagging)	0.78	0.85	0.80
Integrated (Boosting)	0.83	0.89	0.83
SVM	0.77	0.81	0.78
Naive Bayes	0.65	0.73	0.68
DT(C4.5)	0.75	0.75	0.75
RNN	0.76	0.82	0.78

TABLE II: Intention detecting results with different methods

Method	Precision	Recall	F1-score
Rule Based	0.90	0.61	0.73
Integrated Learning	0.83	0.89	0.83
Combination	0.90	0.85	0.87

IV. EXPERIMENTS

We evaluate our bot on real data from JointForce.

A. Experiment Setup

Three evaluation metrics are selected: Precision, Recall and F-1 score. We have collected 1458 user queries from JointForce[§]. These queries are classified into 6 categories, in each of which we picked up 200 queries with slot information and labeled them manually. We also asked Chinese linguists to design 65 rules such that our rule-based method can be applied.

B. Intention Detecting Experiments

We compared the effectiveness of each single statistical learning model and the integrated model in detecting user intentions. Due to the small amount of our data, we used the BootStrapping method to obtain the training and testing dataset.

The results are shown in Table I. The integrated statistical learning model (with the Boosting training strategy) achieves the highest precision and recall. On the contrary, the deep models are not well supported by a small scale dataset, leading to lower precision and recall.

Next we compared the effectiveness of the rule based method, the integrated statistical learning method and the combination method. The results, as Table II shows, denote that the combination method is slightly better than the statistical learning method. The rule-based method achieves a high precision, indicating the benefits from strictness. The rule matching algorithm implies that, once the user query is matched with one rule, it is much possible to be a true positive.

C. Slot Filling Experiments

We analyzed the feature contributions to slot filling, through an experiment that applies our integrated CRF model with different feature sets. The result is shown in Table III, where iCRF represents our integrated CRF model. It demonstrates that Word Feature (WF), Transition Feature (TF), Semantic Feature (SyF) and Syntactic Feature (SyF) contribute a lot to slot filling, while Start Feature (StF) and End Feature (EF) are less important. Also we can observe that the F1-score of our

[§]<http://www.jfh.com>

TABLE III: Slot filling results with different feature sets

Model	Precision	Recall	F1-score
Normal CRF	0.78	0.71	0.74
iCRF+WF	0.53	0.45	0.49
iCRF+TF	0.38	0.30	0.33
iCRF+EF	0.08	0.04	0.05
iCRF+StF	0.05	0.02	0.03

iCRF+WF+TF+EF	0.65	0.58	0.61
iCRF+WF+TF+EF+StF	0.66	0.60	0.63
iCRF+WF+TF+EF+StF+SeF	0.75	0.68	0.71
iCRF+WF+TF+EF+StF+SeF+SyF	0.86	0.78	0.82

TABLE IV: Results of entity name unification

With Entity Name unification	Precision	Recall	F1-score
Yes	0.86	0.78	0.82
No	0.80	0.75	0.77

iCRF model reaches 82%, 8% higher than that of the normal CRF model.

Besides, in order to evaluate the effectiveness of entity name unification using SSKB, we performed slot filling with and without the preprocessing step. The results are shown in Table IV, which indicate that entity name unification preprocessing improves the performance of our integrated CRF method on the slot filling problem. Obviously, the number of words that are out of vocabulary can be significantly reduced through this preprocessing step.

V. CONCLUSION

This paper proposed an approach to building a task-oriented conversational bot (CrowDevBot) for software crowdsourcing platform. Several experiments are conducted to evaluate our approach and CrowDevBot, using the real data from JointForce. Experimental results show that the F1-score of our intention detecting mixture method is 87% under the limited training data, and the F1-score of our integrated CRF model with novel features to fill slots is 82%, up to 8 points higher than normal CRF. Also the user satisfaction ratio of CrowDevBot reaches 87% in average, which indicates that CrowDevBot really helps online users to finish software crowdsourcing tasks in real situation.

As for future work, we will leverage the reinforcement learning technology to improve the performance of our intention detecting and slot filling approach continuously, with better use of the user feedbacks.

Abstract—Software development depends on diverse technologies and methods and, as a result, software development teams often need to handle issues in which team members are not experts. To address this lack of expertise, developers typically rely on information obtained from web-based Q&A sites such as Stack Overflow, a popular platform to find solutions to specific technology-related problems. However, access to these Q&A websites is currently not explicitly integrated with software development projects. Therefore, software developers often need to search for solutions to similar and recurring issues multiple times. This lack of integration not only hinders the reuse of the knowledge obtained but also compels developers to perform repeated searches for recurring problems. In this paper, we investigate an approach that explicitly associates project tasks with Stack Overflow posts that have already been curated by developers, and use project task similarities to investigate the possibility to suggest curated Stack Overflow posts. Precision and accuracy were 71.60% and 77.78%, respectively. We also found indications that project task elements such as the process activity, influence accuracy and precision if attempting to reuse curated Stack Overflow posts.

Index Terms—Software engineering, stack overflow, project task, text similarity.

I. INTRODUCTION

Software development is a knowledge-intensive collaborative activity [1]. Currently, development changes with a variety of technologies in use. Therefore, new knowledge must be constantly gathered and software engineers need to engage in tasks that are related to knowledge management, such as learning, capturing, and reusing collaborative knowledge during a software project [2]. During the execution of a software development project, knowledge and expertise from developers are vital for the project to succeed [2].

Software development is usually an integrated system of code editors and debuggers [3] in which developers interact to build a software product. To acquire external support (e.g., code snippets), developers frequently switch between the development environment and browsers [4]. In other words, developers must leave the development environment, reason about relevant and accurate terms for searches, open a browser, verify the results of the search, check if the source is reliable, and only then, transfer the knowledge obtained to the software

[5] [4]. Such activity usually occurs more than once, as software projects are large-scale and iterative. We refer to this effort of tapping into sources of support, reasoning about the help needed and choosing among the vast available content, as *curation*. We use curation inspired by humanities, and which is defined as:

”Select, organize, and present (online content, merchandise, information, etc.), typically using professional or expert knowledge.”

Essential sources of knowledge (information software developers use for support while working) are question and answer (Q&A) websites. A famous Q&A website for software engineers is Stack Overflow (SO) [6] [7] [8] [9]. Although SO is widely used during software development [6], there are still issues about explicitly associating the tasks performed during development and the knowledge obtained from a SO post. The lack of integration of the support often needed by software developers with the development project is identified by researchers as an open issue [10] [11]. Some works have proposed solutions to integrate SO with the software project through text overlap, mainly focusing on issues (bugs, exceptions) [11] [12].

Research indicates that developers’ expertise largely contributes to the success of software projects [2]; however, current approaches to selecting SO posts that use text overlap do not consider developers’ expertise. Integrating curated SO posts with software development projects could help developers avoid performing curation multiple times, redundantly. Additionally, integrating SO posts can convey other benefits, such as keeping relevant information into the project, avoiding searches of the same information, helping less experienced developers know how experts are working and reducing workflow interruptions [4].

In this paper, we investigate the possibility to reuse curated SO posts based on project task similarity by performing an investigation on task contexts and submitting these contexts to a similarity retrieval model. Precision and accuracy (the most common metrics identified among our related works) were collected. Two research questions guide the evaluation of the implemented model: RQ1 investigates the precision and accu-

racy of our proposal, facilitating a comparison among other works. RQ2 compares different task contexts to understand how different combinations can influence SO post reuse.

This paper is structured as follows. Section I presents an introduction of the discussed subject. Section II presents the study and implementation conducted to investigate the association of Stack Overflow posts with project tasks. After, Section III evaluates the study and implementation. Conclusion, discussion, and future work are presented in Section IV.

II. STUDY ON RETRIEVING CURATED STACK OVERFLOW POSTS

Curation is the act of searching and selecting useful SO posts for a given problem during software development. The process of curating SO posts is as follows. First, the developer that has a problem or that needs support creates a search string that may retrieve satisfactory results. Second, the search string is submitted to SO. Third, SO executes the search according to internal algorithms and lists the results. Finally, the developer selects one (or a set of) SO post that can be used as support. Each of these steps can be executed repeatedly until developers are satisfied with the results listed and choose a SO post that meets their needs. Once a solution is chosen, curation is over. If results are not helpful, the developer changes the string, exploring new terms that can indicate useful results.

Frequently, after a solution from a SO post is selected, the post from where the solution was extracted is not associated with the project task and, therefore, cannot be reused by developers dealing with similar or recurring tasks. A growing body of literature recognizes the importance of associating external knowledge with the development [13] [11] [14] [10] [15]. Stack Overflow is the source of support considered in this work, and this support is presented in the form of curated SO posts. Through the identification of similar project tasks, SO posts that were once used to support a project task during its solution could be automatically associated with project tasks with similar context(s), therefore making developers aware of this SO post previously used by another developer. After a preliminary investigation [16], this work was further developed. We researched what comprises the context elements of a project task and implemented a process model using the investigated context in Rapidminer¹.

A. Project Task Context

Project Task Context is a set of elements that compose a project task. Investigating possible project task context elements is essential to contribute to clarifying what information from project tasks are available for similarity comparisons. For completeness purposes, we have taken advantage of both academic and industrial perspectives, including project management tools that support project tasks in software development. It is important to consider other sources in grounding research other than formal literature in software engineering [17], allowing a broader theoretical aspect and bringing practical insights to the work.

¹rapidminer.com

From the academic perspective, after an *ad-hoc* literature review, we found that software engineering is knowledge-intensive due to its dynamism and the massive amount of technology used activity [1] [18]. According to Lindvall and colleagues [18], software engineering has two types of knowledge associated with the project: technical and business domain information. Our work does not consider application domain information; it only considers technical information because it aims to be agnostic to business characteristics. We propose a context element that captures technological information about project tasks (e.g., tags). A tag is a piece of information related to an element. In this case, the elements are any technical information directly related to the task that can characterize the task. Each project has a specific context in respect to product [19], such as technical characteristics that every task will inherit necessarily, indicating the need for a project tag.

From an industrial perspective, we analyzed project management tools, by verifying the default elements each tool has for project tasks. In this *ad-hoc* analysis, we concluded that some of the project task context elements identified in the literature were also reported in software development tools that support project workflows. The analyzed tools were JIRA², Trello³ and Redmine⁴, which are broadly used. After performing an analysis of both literature and project management tools contents, we present a list of the identified context elements in Table I.

TABLE I
CONTEXT ELEMENTS.

Element	Description	Source
Project/Board	The name of the project that tasks belongs to	Redmine, Trello JIRA
Project Tag	Tags related to the project	Lindvall et al. [18]
Process	Process information that can be associated with the task	Lindvall et al. [18]
Title	The title of the task	Redmine, Trello JIRA
Description	The description of the task	Redmine, Trello JIRA
Category	A classification used to divide tasks into different niche	Redmine JIRA
Task Tag	Tags related to the task	Lindvall et al. [18], JIRA, Trello

B. Study Implementation

After project task context elements were investigated in both literature and project management tools, we propose an implementation to obtain the similarities between project task context elements. We implemented a process model that is prepared to receive as input a dataset containing project tasks associated with SO posts, and retrieves similarity indexes from pairs of project tasks and evaluates if the SO posts are the same between project tasks with a high degree of similarity.

³trello.com

⁴redmine.org

Fig. 1. RapidMiner process model.

RapidMiner (RapidMiner Studio version 8.2) was used to implement a similarity process model. RapidMiner is a compelling data science platform, requiring a small learning curve to be used, widely adopted in the academic field [20]. The implemented RapidMiner model is illustrated in Figure 1. The model loads a dataset of project tasks, pre-processes the text and executes a Jaccard algorithm [21] to retrieve text similarities. More details can be found in the work of [22] and the source code for the implemented model can be found on GitHub (github.com/glauciams/task2stackRapidMiner).

III. EVALUATION

Based on the guidelines proposed by Shani et al. [23] we verify the effectiveness of using task similarities to reuse curated SO posts, through well-established metrics: precision and accuracy. The research questions for the evaluation are:

RQ1: What are the precision and the accuracy metrics for the collected sample? It is essential to verify these metrics to gather quantitative results while ascertaining the effectiveness of considering similar project tasks to reuse curated SO posts. The metrics precision and accuracy were chosen after being the most common metrics identified in the works that relate to ours.

RQ2: What are the impacts in precision and accuracy when different context elements are combined? We evaluate different project task context combinations because task contexts can vary in each project. A project can maintain records of processes and another project might not, for example. Given this variation, it is essential to understand the impacts of different project task context combinations.

Hypothesis: Project task similarity can provide helpful suggestions for curated Stack Overflow posts. We test this hypothesis by verifying whether similar tasks (similarity above 50%) share the same Stack Overflow posts.

Controlling Variables: Considering this study uses only one dataset, having fixed controlled variables is not a concern. We propose a study considering different variable combinations to analyze the effects of the absence or presence of variables on precision and accuracy.

A. Executing the implemented process model

To execute the implemented process model, a dataset with project tasks has to be loaded to the RapidMiner process model. The selected dataset was gathered from a company in Brazil that has been developing software products for more than 20 years and has a total of 30 employees. The software development projects in this company follow agile guidelines, and the project tasks are managed with the support of a project

management tool. We were able to gather 25 project tasks with associated SO posts to each of the 25 tasks. The software developers and managers of the company provided a dataset of project tasks (context elements and SO posts associated with each task).

B. Results, Discussion and Threats to Validity

After executing the evaluation of the dataset, precision and accuracy are calculated, using the Jaccard algorithm. A confusion matrix is generated by the execution of the RapidMiner process model, which supports the extracted results.

Answering RQ1, the accuracy for the given dataset with the elements identified in Section II is 77.78%, and the precision mean 71.60%. Other works with similar characteristics present different precision and accuracy results. Rahman et al. [24] report 11% of precision and 88% of accuracy. The work of Wang et al. [25] reports 62% of precision.

Answering RQ2, Table II presents the context attributes' combination selected, the precision and accuracy extracted for each combination, and changes made in each combination, as it is not easy to perceive from the attribute list which attributes were selected and which were not in the combination.

TABLE II
RQ2 RESULTS: CONTEXT COMBINATIONS

Precision	Accuracy	Combination changes
71.60%	77.78%	Current Work - RQ1
61.17%	70%	Included Interaction
48.01%	54.69%	Removed Process
69.81%	66.67%	Removed Project Tags and Task Tags
45.64%	37.12%	Removed Title and Description
40.87%	36.57%	Removed Title
45.64%	37.12%	Removed Description
54.76%	38.28%	Removed TaskTags
61.46%	74.47%	Removed ProjectTags
49.01%	41.18%	Removed Category
61.46%	74.47%	Removed Project
77.78%	85%	Removed Project and Project Tags
71.67%	54%	Removed Category, Process, Project, Project Tags and Task Tags
13.51%	22.69%	Removed Category, Process, Project, Title and Description

According to the model proposed by Wohlin et al. [26], the **internal threats** to the validity of this evaluation are the small sample size, which can produce distortions in the expected result and conclusions. A strategy to mitigate this problem can include the use of more extensive or various samples. The lack of another sample can also be characterized as an **external threat** because it can jeopardize the generalization of the study results. As **construction threats**, we can cite the

selection of methods and definitions of measures, which was performed according to the related work, but with no other indication of exactitude or representativeness. Finally, the fact that the same developers can be involved in the study might indicate **conclusion threats**, given the possibility the text of project tasks can be standardized, in case they were written by the same person.

IV. CONCLUSIONS

Identifying similar project tasks during software development could decrease the curation effort of developers, when in need of external support. We performed a study to identify project task context elements, propose an implementation of a process model and evaluate the proposal. The implementation aims to verify if similar project tasks are associated with the same SO posts curated by developers. Precision and accuracy were 71.60% and 77.78%, respectively. We also conclude that there is a significant variation of precision and accuracy when project task context elements are added or removed. When considering the project task context elements initially identified in Section II, precision and accuracy are the highest among all combinations. Results also indicate that the hypothesis of the evaluation Project task similarity can provide useful suggestions of curated SO posts is correct, as the prediction and accuracy are as high as 70%. The model built in RapidMiner can be used with other datasets with similar characteristics, indicating the study is replicable.

Future work might involve the development of a recommendation tool using the proposed strategy, allowing the incorporation of rating mechanisms for given suggestions. The tool was not developed in this work, as we intended to focus on the study of the reuse of curated SO posts using task similarity. A deeper understanding of the role of project task context elements should be pursued, allowing the definition of weights for specific contexts.

Abstract—Software defect prediction is an important way to make full use of software test resources and improve software performance. To deal with the problem that of the shallow machine learning based software defect prediction model can not deeply mine the software tool data, we propose software defect prediction model based on improved deep forest and autoencoder by forest. Firstly, the original input features are transformed by the data augmentation method to enhance the ability of feature expression, and the autoencoder by forest performs the data of dimensionality reduction on the features. Then, we use the improved deep forest algorithm and autoencoder by forest to build software defect prediction model. The experimental results show that the proposed algorithm has higher performance than the original deep forest (gcForest) algorithm and other existing start-of-art algorithms, and has higher performance and efficiency than other deep learning algorithms.

Keywords—Software defect prediction, Deep forest, AutoEncoder by forest, Data augmentation.

I. INTRODUCTION

As software systems continue playing a key role in all areas of our society, defects arisen from these software have had a major impact on businesses and the lives of people. However, due to the significant increase in the size and complexity of software code libraries, it has become increasingly difficult to identify defects in software code [1], [2]. The importance and challenges of defect prediction make it an active research area in software engineering [3], [4]. Extensive research has been used to develop predictive models and tools to help software engineers and testers quickly narrow down the most likely defective parts of the software code base [5], [6]. Early defect prediction helps prioritize and optimize the effort and cost of inspections and testing, especially when faced with cost and deadline pressures [7], [8].

Machine learning techniques have been widely used to build defect prediction models [9], [10]. Those techniques derive a number of features (i.e. predictors) from software code and feed them to common classifiers such as Naive Bayes [11], Support Vector Machine [12] and Random Forests [13]. But these methods are all shallow machine learning, and

can not perfectly express the complex relationship between unstructured data. When the amount of data reaches a certain level, the learning ability of shallow algorithm is not as good as the deep learning algorithm.

Due to the huge computational hardware requirements of deep neural networks and the dependence of deep neural networks on a large number of hyper parameters, the software defect prediction methods based on deep neural networks are difficult to train to the optimal degree. Zhi-Hua Zhou [14] put forward a deep forest, make up the blank of the decision tree in the field of deep learning. Deep forests have much less parameters than deep neural network and the advantages of higher classification accuracy. Further, Zhi-Hua Zhou [15] put forward EncoderForest (eForest), a kind of auto-encoder, to do data reduction or feature extraction for training model. Therefore, *why not use deep forest and eForest to build software defect prediction model?*

In this paper, we present software defect prediction model based on improved deep forest and autoencoder by forest. First of all, we propose an improved deep forest algorithm for the lack of multi-grained scanning in deep forests through data augmentation. Then, the improved deep forest algorithm and eForest are applied to software defect prediction problem. Finally, we use this model to experiment with the Eclipse bug dataset [16]. The experimental results show that the proposed algorithm is better than existing start-of-art algorithms and less time than the deep neural network algorithm. The contributions of our paper are as below.

- (1) We apply the deep forest and eForest to software defect prediction problem and get better results.
- (2) In our prediction system, the features are automatically learned through the forests model, thus eliminating the need for manual feature engineering which occupies most of the effort in traditional approaches.
- (3) An extensive evaluation using real open source data provided by Eclipse repository demonstrates the empirical strengths of our model for defect prediction.

The outline of this paper is as follows. *Section II* reviews the works of defect prediction, deep forest and autoencoder by forest. *Section III* describes how our prediction model is

*Wenbo Zheng and Shaocong Mo contribute equally to this study. They are both the corresponding author.

built. We report our experiments to evaluate our approach in Section IV. In Section V, we conclude the paper and outline future work.

II. RELATED WORK

A. Defect Prediction

In the field of software engineering, it is impossible to detect and eliminate all software defects by any means of detection and verification. It is impossible to develop a software system without any defects in an actual engineering project. Even if the developer is careful and refined, it cannot be ruled out that there are still some errors or unexpected defects in the software system. Software defect prediction is an important way to rationally use software testing resources and improve software performance. Software defect prediction technology can be used to predict more defects that may also exist as early as possible according to the metrics information and defects found in a software product, then testing and validation resources are allocated based on the result appropriately.

The machine learning based defect prediction technology can comprehensively and automatically learn the model to find defects in the software, which has become the main method of defect prediction. For constructing software defect prediction models, many algorithms such as KNN, neural networks [17], SVM [18], Nave Bayes [19], random forest [20] and ensemble learning method [21] can be used. Moreover, there are mainly three techniques are used for implementing the software defect prediction models, as classification, regression and clustering. However, none of these algorithms can perfectly express the complex relationship between unstructured data. When the amount of data reaches a certain level, the learning ability of shallow structure algorithms is not as good as that of deep structure algorithms.

B. Deep Forest

Zhi-Hua Zhou and Ji Feng [14] propose gcForest (multi-Grained Cascade Forest) shown in Fig. 1(a), a novel decision tree ensemble method. This method generates a deep forest (DF) ensemble, with a cascade structure which enables gcForest to do representation learning. Its representational learning ability can be further enhanced by multi-grained scanning when the inputs are with high dimensionality, potentially enabling gcForest to be contextual or structural aware. The number of cascade levels can be adaptively determined such that the model complexity can be automatically set, enabling gcForest to perform excellently even on small-scale data, which makes it possible to control training costs according to computational resource available. Moreover, contrast to DNNs, the gcForest has much fewer hyper-parameters and its performance is robust in different hyper-parameter settings. From experiments results, gcForest gets excellent performance by using the default setting, competitive to DNNs on a broad range of tasks, even across different data from different domains. Deep forest offers an alternative when deep neural networks are not superior, e.g., when DNNs are inferior to random forest and XGBoost.

C. AutoEncoder by Forest

After gcForest, Zhi-Hua Zhou and Ji Feng [15] propose autoencoder by forest called eforest, which is the first tree ensemble based auto-encoder. As we know, auto-encoding is a significant task; take convolutional neural networks (CNN) as an example, it is achieved by deep neural networks (DNNs) in auto-encoding way. This method presents a procedure for enabling forests to do backward reconstruction by utilizing the Maximal- Compatible Rule (MCR), as show in Fig. 1(b), the rule is defined by the traversing backward decision paths of the trees. Encoding and decoding are the two basic function for an auto-encoder. The eForest makes a tree ensemble to do forward encoding and backward decoding, so it is possible for forest to construct an auto-encoder. In addition, the eForest can be trained in both supervised or unsupervised way.

For encoding tasks, there is no difficulty for forest to do that. Here is the encoding procedure: Once the input data traverse down to the leaf nodes which belong to a trained tree ensemble model contained T trees, the procedure will give back a T dimensional vector.

For decoding task, here is the encoding procedure: Firstly, each path can be identified by the leaf node without uncertainty; Secondly, each path corresponds to a symbolic rule; Thirdly, the Maximal-Compatible Rule (MCR) can be calculated to reconstruct the original sample.

In all, auto-encoding task can be achieved by the eForest's forward encoding and backward decoding operations. Experimental results shows eforest has the following advantages: lower reconstruction error contrast to CNN or MLP based auto-encoder, faster training speed, damage-tolerable and high dataset adaption in same domain.

III. SOFTWARE DEFECT PREDICTION MODEL BASED ON FORESTS

We propose our method in this section. Firstly, we propose an improved deep forest algorithm for the lack of multi-grained scanning in deep forests through data augmentation. Secondly, the improved deep forest algorithm and eForest are applied to software defect prediction problem, as shown in Fig. 2.

A. Improved Deep Forest Algorithm

Despite the superior performance of deep forests, there are still some shortcomings when using them to build the software defect prediction model.

- Software defect prediction is a binary classification problem, which is to analyze the quality of software modules. According to the classification rules, it is divided into fault-proneness or non-fault-proneness class. Because the main purpose of software defect prediction is to predict whether the modules in the software have fault-proneness modules, so we would set the fault-proneness module as a positive example, and the non-fault-proneness module as a negative example. Multi-grained scanning and cascade structures are used the process that generated class vectors to be aggregated into enhanced feature vectors.

(a) Multi-Grained Cascade Forest [14]

(b) Traversing backward along decision paths [15]

Fig. 1. Deep forest and autoencoder by forest

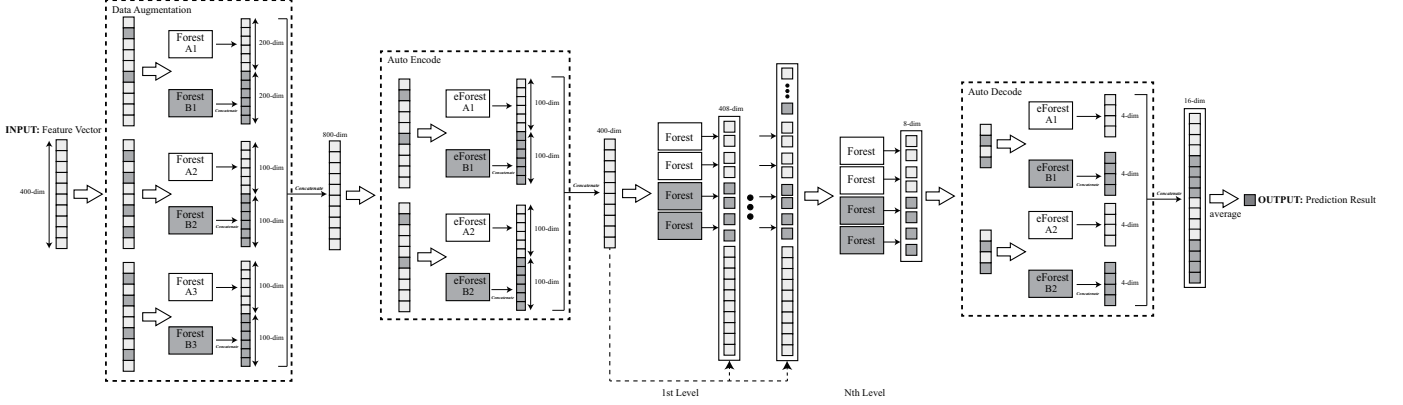

Fig. 2. Software defect prediction model using Forests

But this process can cause redundancy of the feature space. For the software defect prediction problem, the sum of the probability of the module belonging to the positive class and the probability of the module belonging to the negative class is 1, that is, the two probabilities are linear correlation. If two probabilities are both used to fuse the feature vectors, which can cause feature space redundancy and increase the space complexity of the algorithm.

- Multi-grained scanning has significant effects on spatially related features, such as image matching and speech recognition, while features that are spatially uncorrelated (such as software defect prediction, text classification, etc.) may lose important information. The reason is that for spatially uncorrelated features, multi-grained scanning reduces the importance of the the first and the last feature. In the multi-grained scanning process, the first feature and the last feature are only scanning once, that is, these two features are used only once. If the first feature or the last feature is very important, multi-grained scanning can not effectively use this important feature.

To solve the problem that multi-grained scanning in deep forests may lose important information, data augmentation method is used to transform the original input features. Our data augmentation method is to randomly extract features from different original scales from the original input features from the defective/non-defective training samples. The vector by data augmentation is treated as a defective/non-defective instance. The instances which is the same size are combined

Fig. 3. The process of data augmentation as an example

to form a training entity. The all training entities would train a random forest and a complete random forest, respectively, to predict to generate class vectors. We transform class vectors to enhanced feature vectors.

To be specific, assume that the original input features are 400-dimension, we use randomly sampled methods 200 times, and each sample size is 100-dimensional feature. Each 100-dimensional sample feature is to form an instance. So a total of 200 instances are generated. The 200 instances is called an entity. The entity would be trained using a random The forest and a completely random tree forest, respectively, and then we get two class vectors which is 200-dimension. We transform two 200-dimensional vectors to one 400-dimensional vector, that is, the 400-dimensional original feature vector corresponds to the 400-dimensional enhanced feature vector. The process is shown in Fig. 3.

Similarly, we transform the two 200-dimensional features sampled from each original input feature to generate two 200-dimensional enhanced features vector. We do the concatenate

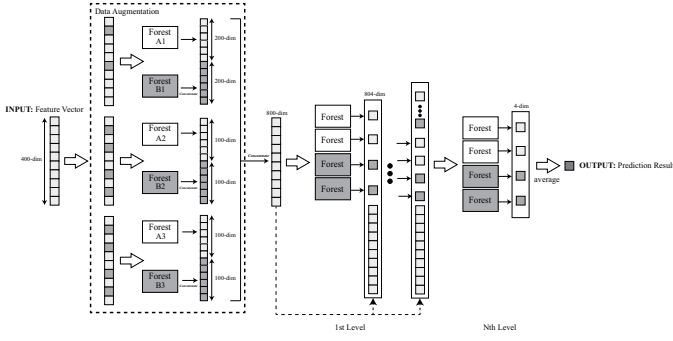

Fig. 4. The pipeline of improved deep forest based on data augmentation

operator to transform the three enhanced feature vectors to a 800-dimensional transformed feature vector. This is the re-representation of the original input features by data augmentation. In other words, each 400-dimensional original feature vector is re-represented by the 800-dimensional transformed feature vector.

The 800-dimensional transformed feature vector would be passed to the cascade forest structure. If each layer of cascade forest consists of 4 forests (two random forests and two completely random forests), the 804-dimensional feature vector would be obtained at the end of the first layer. Then, input the feature vector into the cascade forest structure of the next layer. Repeat the process until the verification performance indicates that the extension of the cascade forest structure should be terminated.

In the test phase, given a test example, we first get the corresponding 800-dimensional transformed feature vector through the data augmentation process, and then predict through the cascade forest structure until the last layer. The final prediction result is decided on the 4 probabilities of 4-dimensional feature vector in the last layer, and the average of the 4 probabilities is the final prediction result. If the average value is greater than or equal to 0.5, the test instance is predicted to be a positive class, otherwise it is a negative class. The process is shown in Fig. 4.

B. Software Defect Prediction Model using Forests

We use data augmentation algorithms to increase the amount of data, challenging the time and efficiency of our algorithm. Therefore, we use the eForest [15] to do data reduction. The process is shown in Fig. 4.

First, we transform original 400-dimensional features to 800-dimensional transformed vectors using data augmentation.

Then, the 800-dimensional transformed feature vector would be passed to the autoencoder using eForest. If autoencoder consists of 4 eForests, the 400-dimensional feature vector would be obtained. The 400-dimensional feature vector would be passed to the cascade forest structure. Because each layer of cascade forest consists of 4 forests (two random forests and two completely random forests) and we reset each forest to output 2-dimensional class vector, the 408-dimensional feature vector would be obtained at the end of

the first layer. Then, input the feature vector into the cascade forest structure of the next layer. Repeat the process until the verification performance indicates that the extension of the cascade forest structure should be terminated. We get a 16-dimensional feature vector through cascade forest structure.

Finally, the 16-dimensional feature vector would be passed to the autodecoder which is the inverse structure of autoencoder. We get 8-dimensional feature vector. The final prediction result is decided on the 8 probabilities of 8-dimensional feature vector in the last layer, and the average of the 8 probabilities is the final prediction result. If the average value is greater than or equal to 0.5, the test instance is predicted to be a positive class, otherwise it is a negative class.

IV. EXPERIMENT RESULTS AND ANALYSIS

Reporting the average of precision/recall across the two classes (defective and clean) is likely to overestimate the true performance, since our dataset is imbalance (i.e. the number of defective files are small). More importantly, predicting defective files is more of interest than predicting clean files. Hence, our evaluation is focus on the defective class.

A confusion matrix is used to store the correct and incorrect decisions made by a prediction model. For example, if a file is classified as defective when it is truly defective, the classification is a true positive (tp). If the file is classified as defective when it is actually clean, then the classification is a false positive (fp). If the file is classified as clean when it is in fact defective, then the classification is a false negative (fn). Finally, if the issue is classified as clean and it is in fact clean, then the classification is true negative (tn). The values stored in the confusion matrix are used to compute the widely-used Precision, Recall, and F-measure.

- Precision: The ratio of correctly predicted defective files over all the files predicted as being defective. It is calculated as:

$$pr = \frac{tp}{tp + fp} \quad (1)$$

- Recall: The ratio of correctly predicted defective files over all of the true defective files. It is calculated as:

$$re = \frac{tp}{tp + fn} \quad (2)$$

- F-measure: Measures the weighted harmonic mean of the precision and recall. It is calculated as:

$$F - measure = \frac{2 \times pr \times re}{pr + re} \quad (3)$$

All experiments were conducted using a 4-core PC with an Intel Core i7 6700HQ with the NVIDIA GTX 1080, 16GB of RAM, and Ubuntu Linux in practice.

To verify the advancement and robustness of our model, we designed two experiments:

- (1) *Ablation Experiment*. In order to verify the advancement and rationality of our model, we experimented with each component.
- (2) *Contrast Experiment*. In order to verify the robustness of our model, in the experiment separately to

realize the Naive-Bayes-Based method [11], Support-Vector-Machine-Based method [12], Random-Forests-Based method [13], Deep Tree-based method [22] and DNN-based method [23], Eclipse standard dataset on the experiment and comparing with the result of the experiment.

Note that in the experiment, the hyper-parameter settings we used were consistent with the reference gcForest [14] and eForest [15].

The data used in this experiment is derived from the Eclipse standard dataset which is one of the most widely used public datasets in software defect prediction research. Since this paper studies the software defect prediction of the classification task, and the Eclipse data set gives the number “post” of defects (refers to the number of defects after the software is released), it is necessary to convert the number “post” of defects into a defective class “hasDefects”. The conversion method is:

$$hasDefect = \begin{cases} 0, & post = 0 \\ 1, & post \neq 0 \end{cases} \quad (4)$$

Since the structure of the “file” level data of the Eclipse data set is same, one of the versions of the data is used as the training data to learn the model, and the three versions of the data can be predicted separately, so that the “file” level data can be used for 9 predictions and verifications.

When the training set and the test set are from the same version, the ten-fold cross-validation is used, that is, the data set is equally divided into 10 parts, one of which is taken as the prediction set, and the 9 remaining data are used as the training set to construct the software defect prediction model and do classification prediction. The experiment was carried out for 10 rounds, and the average of 10 rounds of experiments was taken as the final result.

A. Ablation Experiment

In order to verify the advancement and rationality of our model, we experimented with each component. We use the accuracy rate, precision, recall rate and F-measure to evaluate the experimental results in the experiment. From Table.I, we know our method is better than others. This shows that the design of our algorithm is reasonable.

B. Contrast Experiment

In order to verify the robustness of our model, in the experiment separately to realize the Naive-Bayes-Based method

[11], Support-Vector-Machine-Based method [12], Random-Forests-Based method [13], Deep Tree-based method [22] and DNN-based method [23], Eclipse standard dataset on the experiment and comparing with the result of the experiment. We use the accuracy rate, precision, recall rate, F-measure and the time of test to evaluate the experimental results in the experiment.

From Table. II, we can get two points:

- In terms of performance, our algorithm is optimal in all cases. Therefore, the robustness of our algorithm is optimal among all methods.

- In terms of test time, our algorithm is not the least time in all cases, but our algorithm is the least time in all cases of deep learning. It shows that our algorithm has obvious advantages in efficiency compared to other deep learning algorithms.

From these two points, we know that our algorithm has good robustness and efficiency.

V. CONCLUSION AND FUTURE WORK

In this paper, in order to solve the problem that the shallow machine learning algorithm can not deeply mine the software data features in the current software defect prediction, software defect prediction model based on improved deep forest and autoencoder by forest is proposed. Firstly, the original input features are transformed by the data augmentation method to enhance the ability of feature expression, and the autoencoder by forest performs the data of dimensionality reduction on the features. Then, we use the improved deep forest algorithm and autoencoder by forest to build software defect prediction model. The experimental results show that the proposed algorithm has higher performance than the original deep forest (gc-forest) algorithm, and has higher performance and efficiency than other deep learning algorithms. However, the algorithm does not consider unbalanced data problem. In future, we will be to study how to further improve the prediction performance of the algorithm and consider a solution to the problem of data imbalance in the training set.

Abstract

Software defect prediction can make software quality assurance (SQA) process more efficient, economic and targeted. Previous studies mainly focused on classifying software modules as defect-prone or not. However, predicting the number of defects for a new software module is rarely investigated. Moreover, these studies built models independently for each project, which may ignore the relatedness among multiple projects. To effectively utilize the relatedness, we propose a novel approach MPR (multi-project regression) for SDNP (software defect number prediction). To verify the effectiveness of MPR, we perform experimental studies on 30 real-world projects and compare our approach with 6 state-of-the-art baselines (i.e., LR, NNR, SVR, DTR, BRR and DBR). AAE (Average absolute error) and ARE (average relative error) performance measures are used to evaluate the performance of MPR. The results show MPR can achieve better performance in most cases, which indicates the competitiveness of MPR in the context of SDNP.

1 Introduction

Software defects are introduced unconsciously during the development process of software projects. After the software projects are deployed, defects in the software will produce unexpected behaviors, even cause huge economic loss in worst cases. Therefore project managers want to use software quality assurance methods to detect defects as many as possible. Due to the limitation of testing resources, project managers hope that they can resort to effective methods to identify potential defective modules as early as possible. Software defect prediction [1–3] is one of such effective methods. It helps to identify defective software modules before the testing phase by analyzing some underlying characteristics of the software system and thus subsequently helps in allocating software testing resources optimally and economically. It constructs defect prediction models by mining software repositories (such as version control systems, bug tracking systems) and uses the constructed models to identify potential defective modules in the new projects.

Many studies have been conducted for software defect prediction by using different statistical and machine learn-

ing techniques. Most of these studies have focused on classifying whether a software module has defects or not. That means previous studies discretized defect number of program modules into two categories: defective or non-defective [4]. However, such simple data preprocessing may lead to information loss. In addition, predicting defect number for program modules can assist in sorting program modules and then allocating more testing resources to these modules with more defects. In this way, the allocation of testing resources can be further optimized.

To the best of our knowledge, previous studies mainly focused on classifying software modules as defect-prone or not. Only a few studies built and evaluated models for defect number prediction [5–7]. These studies built models independently for each project, which may ignore the relatedness among multiple projects. In this paper, to fully utilize the relatedness among projects and propose a novel approach MPR (multi-project regression) for defect number prediction. To verify the effectiveness of MPR, we perform experimental studies on 30 real-world open-source projects and compare our approach with 6 state-of-the-art baselines (i.e., LR, NNR, SVR, DTR, BRR and DBR). AAE (Average absolute error) and ARE (average relative error) are used as performance measures. The results show MPR can achieve better performance in most cases.

The main contributions of the paper can be summarized as follows: (1) to our best knowledge, we firstly propose a novel approach MPR for predicting defect number on multiple projects. This approach can utilize the relatedness among projects and builds many predictors simultaneously. (2) we conduct empirical studies on real-world software projects to demonstrate the effectiveness of MPR. The final results show that MPR can achieve a statistical improvement over classical baselines.

2 Related Work

Previous studies mainly investigated regression based methods for this SDNP. Graves et al. [5] considered a generalized linear regression method and conducted empirical studies on a large-scale telecommunication system. They found a significant correlation among module's age, changes made to the modules and the age of changes. Ostrand et al. [6] employed negative binomial regression (NBR) method. Wang and Zhang [8] proposed BugState,

which is based on a defect state transition model. Janes et al. [9] considered three methods (i.e., NBR, zero-inflated NBR, Poisson regression) for 5 real-time telecommunication systems and found that zero-inflated NBR method achieved the best performance. Then Gao and Khoshgof-taar [10] further performed empirical studies on two industrial software projects and their results confirmed the best performance of zero-inflated NBR. Chen et al. [11] conducted empirical studies for 6 regression algorithms. Then found that using decision tree regression can achieve the highest performance in both within-project prediction scenario and cross-project prediction scenario. Yu et al. [12] explored resampling (i.e., SMOTEND and RUSND) and ensemble learning (i.e., AdaBoost.R2) methods. Then they proposed two hybrid methods (i.e., SMOTENDBoost and RUSNDBoost) and these two methods can achieve higher performance. Rathore and Kumar [13] explored the capability of decision tree regression in two different scenarios (i.e., intra-release prediction scenario and inter-release prediction scenario). They [14] compared six methods for SDNP, such as genetic programming, multi-layer perceptron, linear regression, decision tree regression, zero-inflated Poisson regression, and negative binomial regression. Recently, they [15, 16] further considered ensemble learning methods for SDNP.

Based on the above analysis, when performing SDNP for many related projects, we found that the models proposed in previous studies can merely build one model for one project per time and they can not use useful information in other related projects. Different from previous studies, we propose a novel method to build multiple regression models simultaneously for many related projects.

3 Our Proposed MPR Approach

This section first gives the preliminaries on multiple linear regression based on multi-task learning [17]. Then it describes our proposed MPR approach in detail.

3.1 Preliminaries

Definition 1 (*Multiple Liner Regression*) Suppose there are m projects to be learnt $\{P^i\}_{i=1}^m$, where all the projects or at least a subset of them are related. A multiple linear regression model, which aims to improve the learning of a model for P^i by using the knowledge contained in the m projects, can be represented as the following: $Y^i = X^i W^i + B^i, i = 1, \dots, m$, which can build many liner regression models simultaneously.

In this definition, $Y^i = (y_1^i, \dots, y_{n^i}^i) \in \mathbb{R}^{n^i}$ represents the responds for the i -th project, regressed on the training instance matrix $X^i = (x_1^i, \dots, x_{n^i}^i) \in \mathbb{R}^{n^i \times F^i}$, where n^i and F^i represent the number of training instances of the i -th project and the feature space of i -th project respectively. $B^i \in \mathbb{R}^{n^i}$ is a bias vector. There are m tasks in total. For

convenience, we transform these quantities into matrices. That is, $Y \in \mathbb{R}^{n^i \times m}$ represents the responses of the regression model, $W \in \mathbb{R}^{F^i \times m}$ represents the regression parameters and $B \in \mathbb{R}^{n^i \times m}$ represents the noise.

According to this definition, it is not hard to find that the parameter W is very important since it contains the relatedness among different projects. For convenience, we represent the parameters W as a matrix, where each column corresponds to a project, and each row corresponds to a feature. Meanwhile, not only different projects have the common characteristics, but also they have the personalized characteristics. Therefore, both the shared information and non-shared information are included in this parameter W . It seems to be that any one structure might not fully capture all of those information, but a decomposition of the structure might [18]. Therefore the matrix W should be decomposed into two component matrices P and Q , i.e., $W = P + Q$. In particular, some rows of W would have many non-zero entries, which are corresponding to features shared by several projects ("shared information"). We use a row-sparse [18, 19] matrix P to represent such shared information, where each row is either all zero or mostly non-zero, and the number of non-zero rows is small. Some rows of W would be project-sensitive, since they correspond to those features, which are relevant for some projects but not all ("non-shared information"). We use an elementwise sparse matrix Q to represent such non-shared information. It is obvious that some rows of W would have all zero entries, since they correspond to those features that are not relevant to any project.

The proposed method MPR uses the multiple linear model [18] to explicitly model the relatedness among different projects. MPR estimates a sum of the two parameter matrices P and Q with different regularizations for each to encourage row-sparsity in P and elementwise sparsity in Q , therefore MPR can effectively capture shared and non-shared information among related projects.

3.2 The details of MPR Approach

Previous methods can build one regression model for one target project at a time [11, 13, 14], while MPR can build multiple regression models for multiple target projects at a time. Fig. 1 presents the overall framework of MPR. In particular, some data preprocessing operations are performed on these projects. For example, we normalize the numerical features for all these projects. The number of related projects to be learnt equals to the number of models outputted by MPR. Relatedness of different projects is a core concept in multiple linear regression learning. In this paper, we simply consider two type of relatedness. The one is whether these project are developed by the same organization. The other is whether these project have the same feature space.

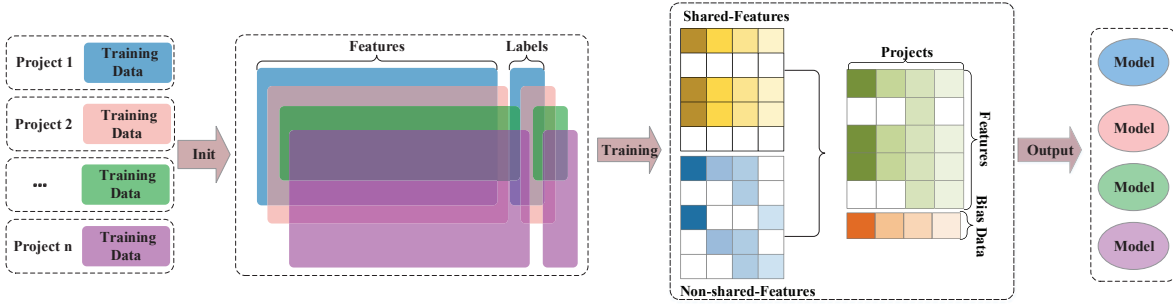

Figure 1: The Framework of MPR

The process of MPR can be described in Algorithm 1. In particular, MPR firstly needs to initialize the start points. In our implementation, we simply initialize the start points with a zero matrix (Line 1). In fact, the starting points can be initialized to a guess value computed from data or a specified point. MPR defines some variables which control the process of searching for optimal value for S , NS and B (Line 2). Then, MPR goes into a loop block with $maxIter$ iteration times (Lines 3-24). In this loop, MPR updates $Shared$, $NonShared$ and $Bias$ with the search factor α (Lines 4-5). Later, it computes performance value and gradients of the current search points (Line 6). Next, MPR goes further into a inner loop in which it can only be terminated when a specific terminating condition is satisfied (Lines 7-18). In this inner loop, the Armijo Goldstein line search scheme [20] is used to compute the optimal shared and non-shared information structure together with the optimal bias data (Lines 8-17). After reaching the termination of the inner loop, it stores previous search points and does preparation for the next iteration. If the difference between the latest two performance meets the requirements of maximum tolerance, MPR can jump out of the outer loop block and return in advance (Lines 19-21). If not, MPR will go to the next iteration with the updated change factor (i.e., t', t) (Lines 22-23). At last, it returns the best value for S , NS and B after given iterations (Line 25).

4 Experiment Design and Result Analysis

4.1 Experimental Subjects

In our empirical studies, 30 projects from PROMISE are used to verify the performances of MPR. These projects can be downloaded from PROMISE and they are widely used in previous empirical studies [11, 12, 15, 16, 21, 22]. The characteristic of these projects are shown in Table 1, which includes project name, number of modules, number (percentage) of defective modules and the maximum defects contained in the modules. Each project use 20 metrics (i.e., features) to measure extracted modules, which are designed

based on the code complexity and the characteristic of object oriented program. Notice that the granularity of extracted program modules is set to class.

Table 1: Statistic of Experimental Subjects

Project (Versions)	# Modules	# Defective Modules	% Defective Modules	Max
ant(1.3,1.4,1.5,1.6,1.7)	125-745	33-338	10.92%-26.21%	(3,3,2,10,10)
camel(1.0,1.2,1.4,1.6)	339-965	14-522	3.83%-35.53%	(2,28,17,28)

prop(1.2,3,4,5,6)	660-23014	79-5493	9.6%-15.3%	(37,27,11,22,19,4)

4.2 Performance Measures

To evaluate the performance of MPR for SDNP, average absolute error (AAE) and average relative error (ARE) performance measures are used.

AAE measures the average magnitude of the errors in a set of predictions. It shows the difference between the predicted value and the actual value and is defined as:

$$AAE = \frac{1}{n} \sum_{i=1}^n |\bar{Y}_i - Y_i| \quad (1)$$

ARE calculates how large the absolute error is compared with the total size of the object measured and is defined as:

$$ARE = (1/n) \sum_{i=1}^n |\bar{Y}_i - Y_i| / (Y_i + 1) \quad (2)$$

In Formulation 1 and Formulation 2, \bar{Y}_i is the predicted number of defects for i -th software module, Y_i is the actual number of defects for this module and n represents the number of modules. For ARE, sometimes Y_i may be zero. To mitigate this issue, we add the actual value of Y_i to one at the denominator to make the definition always well-defined [10]. Notice that the smaller the value of AAE and ARE, the better performance of the constructed regression model [23].

4.3 Experimental Setup

To evaluate the performance of MPR, we consider 6 baselines (i.e., LR, NNR, SVR, DTR, BRR and DBR). To

⁰<http://openscience.us/repo/>

Algorithm 1 Multiple Projects Regression (MPR)

Input:

$X^{(n \times F) \times m}$: all the data of related projects;
 $Y^{(n \times 1) \times m}$: the corresponding responses of all related projects;
 $maxIter$: the number of maximum iteration;
 $maxTol$: the tolerance of the performance between two iterations;

Output:

$Shared^{F \times m}(S)$: all shared information among projects;
 $NonShared^{F \times m}(NS)$: non-shared information for each project;
 $Bias^{m \times 1}(B)$: the bias data for regression;

```
1: Initial the start points: filling  $Shared$ ,  $NonShared$ ,  $Bias$  with a zero matrix;  
2: Let  $t=1$ ,  $t'=iter=0$ ,  $\gamma=1$ ,  $\gamma_{inc}=2$ ,  $\alpha$ =Initial search factor, which controls the search for optimal value of  $S$ ,  $NS$ ,  $B$ ;  
3: while ( $iter < maxIter$ ) do  
4:   Set  $\alpha = (t' - 1)/t$ ;  
5:   Find next search point for  $S$ ,  $NS$ ,  $B$  with  $\alpha$ , and store them into  $S_{tmp}$ ,  $NS_{tmp}$ ,  $B_{tmp}$ ;  
6:   Compute the whole loss value and gradients of the current search points with  $S_{tmp}$ ,  $NS_{tmp}$  and  $B_{tmp}$ , and return  $gW_{tmp}$ ,  $gC_{tmp}$  and  $L_{tmp}$ ;  
7:   while (true) do  
8:      $S_t = proximal_{L_{1,\infty}}norm(S_{tmp} - \frac{gW_{tmp}}{\gamma}, \frac{BRP.\alpha}{\gamma})$ ;  
9:      $NS_t = proximal_{L_{1,1}}norm(NS_{tmp} - \frac{gW_{tmp}}{\gamma}, \frac{BRP.\beta}{\gamma})$ ;  
10:     $B_t = B_{tmp} - gC_{tmp}/\gamma$ ;  
11:    Evaluate performance and save it in list of  $funcVal$ ;  
12:    Use the Frobenius norm operation on the delta of  $\{S_t - S_{tmp}, NS_t - NS_{tmp}, B_t - B_{tmp}\}$ , respectively, then sum them up;  
13:    if (reach termination conditions) then  
14:      break;  
15:    else  
16:       $\gamma = \gamma \times \gamma_{inc}$ ;  
17:    end if  
18:  end while  
19:  if ( $abs(funcVal(end) - funcVal(end - 1)) \leq maxTol \times funcVal(end - 1)$ ) then  
20:    break;  
21:  end if  
22:   $iter++$ ;  
23:  Update  $t'$  and  $t$ , i.e.,  $t' = t$ ,  $t = 0.5 \times (1 + \sqrt{1 + 4 \times t^2})$ ;  
24: end while  
25: return  $S$ ,  $NS$ ,  $B$ 
```

avoid the errors in model implementation, we use these regression models implemented by scikit-learn library, which is a popular machine learning toolkit written by python language. Notice our experiments use the default hyper-parameter settings for different regression models. That is, we do not perform hyper-parameter optimization for each regression model. 6 regression models are briefly described as follows:

Linear Regression (LR) is always used to solve the least squares function of the linear relationship between one or multiple independent variables and one dependent variable.

Nearest Neighbors Regression (NNR) is based on the k -nearest neighbors algorithm, and the regression value of an instance is calculated by the weighted average of its nearest neighbors. Then, the weight is set proportional to the inverse of the distance between the instance and its neighbors.

Support Vector Regression (SVR) is the extended from the Support Vector Machines, which only depends on a subset of training data, because the cost function for building a SVR model ignores any training data close to the prediction results of the model.

Decision Tree Regression (DTR) learns simple decision rules to approximate the curve of a given training data set, and then predicts the target variable.

Bayesian Ridge Regression (BRR) is similar to the classical Ridge Regression. The hyper-parameters of such type of models are introduced by prior probability and then estimated by maximizing the marginal log likelihood with probabilistic models.

Gradient Boosting Regression (GBR) is in the form of an ensemble of weak prediction models. Several base estimators are combined with a given learning algorithm to improve the prediction accuracy over a single estimator.

For MPR, we train and test the regression model on all projects simultaneously. Besides, 10-fold cross validation (CV) are used in our experiments. In particular, we split the original dataset into 10 folds equally. Then, the 9 folds are treated as the training data, while the remaining one fold is treated as the test data. For those baselines, we also use 10-fold CV to train and test regression models on all each project independently. To overcome possible bias in the data split process, we perform 10-fold CV for 10 times and report the average performance values.

To check the significance of performance comparison, we conduct Wilcoxon signed-rank test [24], which is a non-parametric statistical hypothesis test. For all the tests, the null hypotheses are that there is no difference between the trained predictors, and the significance level α is set to 0.05. If p -value is smaller than 0.05, we reject the null hypotheses, otherwise we accept the null hypotheses.

4.4 Result Analysis

RQ: How effective is our proposed approach MPR for SDNP? How much improvement can it achieve over the baselines?

Motivation. Our main goal is to propose an approach to improve the performance of model for addressing regression issues by using the knowledge contained in related projects. However, to show the feasibility of this approach, we must analyze how effective it is in its prediction performance and whether it can perform better than baselines. The answer for this RQ would shed light on how much our approach advances the state of the art of SDNP.

Approach. To answer this RQ, we compare MPR with LR, NNR, SVR, DTR, BRR and GBR to investigate whether MPR has competitiveness over these baselines. AAE and ARE are used to evaluate the performance of these approaches. In addition, we run all these approaches 100 times independently.

Results. Table 2 and Table 3 show the comparison results among MPR and 6 state-of-the-art regression approaches (i.e., LR, NNR, SVR, DTR, BRR and GBR) based on AAE and ARE respectively. In both of these two tables, the first column presents the names of projects. Here we assume that all projects have a certain relatedness, since they consider the same features. The remaining 7 columns list the performance values of seven approaches in terms of different performance measures (i.e., AAE and ARE). In each row, the best results are in bold. Notice that all these results of different methods are calculated by 100 independent runs.

Considering the performance of AAE in Table 2, MPR can achieve better performance in most cases. In particular, MPR achieves 4/5 wins, 3/4 wins, 1/3 wins, 4/4 wins, 3/3 wins, 3/3 wins, 2/2 wins and 4/6 wins on ant, camel, ivy, jedit, synapse, xalan, xerces and prop, respectively. MPR has dominate performance in jedit, synapse, xalan and xerces. However, MPR achieves pool performance (e.g., 0.44 on prop-4). Besides, DTR achieves good performance in three projects (i.e., 0.11 on ivy-1.4, 0.23 on prop-4 and 0.17 on prop-6). Considering the performance of ARE in Table 3, MPR can achieve better performance in most cases. In particular, MPR achieves 3/5 wins, 3/4 wins, 1/3 wins, 4/4 wins, 3/3 wins, 3/3 wins, 2/2 wins and 3/6 wins on ant, camel, ivy, jedit, synapse, xalan, xerces and prop, respectively. MPR also achieves dominate performance in jedit synapse, xalan, xerces and prop. However, MPR obtains pool performance (e.g., 0.27 on ant-1.5). Besides, DTR achieves good performance in four projects (i.e., 0.13 on ant-1.5, 0.08 on ivy-1.4, 0.15 on prop-2 and 0.14 on prop-4).

To check whether the performance differences among MPR and six baseline approaches are significant, we conduct the Wilcoxon signed-rank test. Table 4 shows the results in detail. Considering thirty projects from PROMISE, the p -values of “MPR vs LR”, “MPR vs NNR”, “MPR vs SVR”, “MPR vs DTR”, “MPR vs BRR” and “MPR vs GBR” are all less than 0.05, which indicates that MPR performs statistically better than the baseline methods.

Conclusion: By utilizing the relatedness among projects,

Table 4: p -Value of the Wilcoxon Signed-Rank Test Among MPR and Baseline Methods.

Performance Measure	MPR vs LR	MPR vs NNR	MPR vs SVR	MPR vs DTR	MPR vs BRR	MPR vs GBR
AAE	7.76E-07	1.37E-05	2.08E-07	1.08E-05	3.06E-06	8.19E-06
ARE	5.75E-06	2.65E-04	6.28E-06	9.99E-05	2.48E-05	1.23E-04

MPR can achieve better and stable performance for SDNP in most projects.

5 Conclusion and Future Work

In this paper, we propose a novel approach MPR, which mainly based on multiple linear regression. To show the effectiveness of MPR, we use two widely used regression performance measures (i.e., AAE and ARE) to assess the capability of MPR for SDNP on 30 projects. The results show the competitiveness of MPR when compared with six state-of-the-art baselines.

Abstract—Although the machine learning-based software defect prediction (SDP) method has shown promising value in software engineering, yet challenges remain. To improve the performance of SDP, some researchers have used deep learning algorithms to extract the semantic and structural features of the program. However, in more practical cross-project defect prediction (CPDP) tasks, whether deep learning-generated features can be directly used should be explored due to the data distribution shift that usually exists in different projects. In this paper, we propose a Transferable Hybrid Features Learning with Convolutional Neural Network (CNN-THFL) framework to conduct CPDP. Specially, CNN-THFL mines deep learning-generated features from token vectors extracted from programs' abstract syntax trees via convolutional neural network. Furthermore, CNN-THFL learns the transferable joint features simultaneously considering deep learning-generated and handcrafted features by applying a transfer component analysis algorithm. Finally, the features generated by CNN-THFL are fed to the classifier to train a defect prediction model. Extensive experiments verify that CNN-THFL can outperform referential methods on 72 pairs of CPDP tasks formed by 9 open-source projects.

Keywords—Software defect prediction, Cross-project defect prediction, Transfer learning, Semantic feature learning

I. INTRODUCTION

Under the trend of increasing software scale and complexity, how to effectively ensure the reliability of software has become a popular research topic. Software defect prediction (SDP), as a novel proposition of quality assurance technology, has received a great deal of attention from researchers [1]–[3]. It is designed to build a predictive model with the machine-learning model and historical software defect data before detecting the defect-prone modules or files in the software. Effective defect prediction can help software quality assurance teams or code reviewers allocate testing resources more reasonably.

SDP usually consists of two phases: extracting features from program files and training the predictor via the machine-learning [4] method. In previous studies, the discriminant features adopted to construct predictive models were elaborately extracted. These handcrafted features mainly include Halstead features [5] based on operators and operands, McCabe features [6] based on dependencies, and CK features [7] based on the object-oriented concept. In recent years, some researchers [4], [8] have suggested that it is not enough to only consider handcrafted features. To expand the features available in SDP for improving predictive performance, they tried to

use the deep-learning methods (e.g., Deep Belief Network, DBN and Convolutional Neural Network, CNN) to mine the semantic and structural features hidden in the software program. The main idea of these methods is to extract the deep learning-generated features from the token vectors generated by programs' Abstract Syntax Trees (ASTs) and feed to the data with these generated features to the machine-learning classifier to obtain the SDP model. Their experiments show that DBN and CNN methods are superior to the traditional SDP methods that use only handcrafted features in the cross-version defect prediction tasks [9].

In practice, it is often difficult to establish an accurate defect predictor for new projects due to the scarcity of defect labels. To overcome this problem, cross-project defect prediction (CPDP) [7] was proposed as an alternative solution to defect predictors that learn new projects (called target projects) by using labeled data from mature projects (called source projects). Then, in the tasks of CPDP, there is a research question of whether deep learning-generated features extracted from the source project can be directly used for the SDP task of the target project. In [10], Wang et al. explore the effect of DBN-generated features on CPDP tasks; however, their experiments were based only on the assumption that the semantic features generated by DBN can capture the common features of defects, which means the features obtained from a project can be used in other projects. In this paper, we posit that this assumption may not always hold. We suggest that, because the data of the source and target projects usually have different distributions, the deep learning-generated features should not be used directly in CPDP tasks.

Let us use an example to show this distribution discrepancy. As shown in Figure 1, we present the data distribution of two real projects, Apache Lucene v2.4 and Apache Ant v1.7. Using these two projects, we can form a sample based on DBN-generated features (Figure 1a) and a sample based on CNN-generated features (Figure 1b). For a comparable demonstration, we selected two-dimensional features to be drawn on the X and Y axes, respectively. We normalized the data to be displayed with min-max scaling and charted the main distributions in the coordinates. In Figure 1, the discrepancy of the data distribution is clearly shown to exist in the two projects ($Pr(X_s) \neq Pr(X_t)$). As we know, if the distribution of training and test data do not match, we are facing sample selection bias or covariate shift problems that will greatly

affect the performance of the predictive model [11].

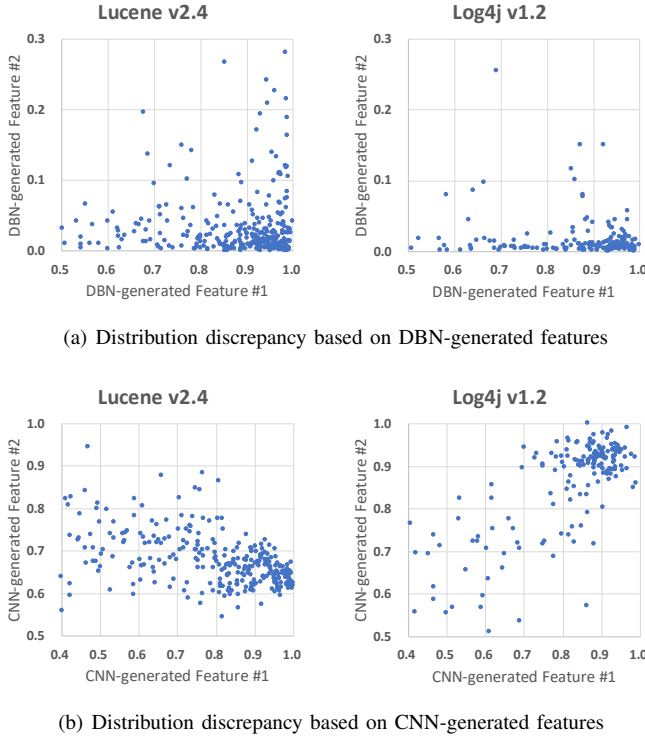

Fig. 1: The distribution discrepancy existed between projects.

To solve this problem, we proposed the Transferable Hybrid Features Learning framework with Convolutional Neural Network (CNN-THFL) to perform CPDP. Specifically, we parsed the source files into ASTs and selected representative nodes on the AST to form token vectors. By converting the token vectors into integer vectors, we adopted CNN to extract the deep learning-generated features. In the process, we concatenated deep learning-generated features with the traditional handcrafted features to construct the hybrid features [4]. To enhance the transferability of hybrid features in CPDP tasks, we attempted to learn transfer components across projects in a reproducing kernel Hilbert space (RKHS) using transfer component analysis (TCA), which could match the data distribution between projects. Finally, the transferable hybrid features generated by CNN-THFL could be fed to the base classifier to train the CPDP model.

The main contributions of this paper are:

- We propose a features-learning framework called CNN-THFL, which jointly considers the transferability of deep learning-generated and handcrafted features in cross-project programs, to handle the distributions discrepancy between projects in CPDP tasks.
- To validate the effectiveness of CNN-THFL, we evaluate it on 72 pairs of CPDP tasks formed by 9 open-source projects. The experimental results show that in terms of average MCC, CNN-THFL improves the TCA by 30.1%

and the DP-CNN by 62.8%.

- By experimental comparison, we found that when using CNN or DBN to mine deep learning-generated features, better results can be attained if this is simultaneously combined with handcrafted features and TCA algorithm, indicating the necessity of using hybrid features and considering their transferability.

We have organized the rest of this paper as follows. In Section II, we review some related works. In Section III, we show the high-level framework of CNN-THFL and elaborate its steps. In Section IV, we provide the experimental setup. In Section V, we show the experimental results to validate the effectiveness of CNN-THFL framework. In Section VI, we discuss the threats to validity. We conclude our work and point out the potential future works in Section VII.

II. RELATED WORK

In this section, we briefly review the related CPDP works.

To effectively apply the SDP technique early in the software lifecycle, CPDP is proposed as a more feasible solution. Its central concept is learning a defect predictor for a new project (target project) by using labeled data from a mature project (source project). In a previous study of CPDP, Zimmermann et al. [12] conducted a large-scale experimental study on its feasibility. They selected 12 real-world projects and analyzed a total of 622 pairs of CPDP tasks. The results show that only 3.4% of tasks were able to achieve acceptable performance. To enhance the performance of the CPDP, Ma et al. [13] developed a transfer Naive Bayes model (TNB) that uses the weighted source data based on target set information to train a weighted Naive Bayes classifier. Nam et al. [14] applied a transfer-learning approach TCA+, which extended TCA [15] with customized normalizing rules, to make data distributions in source and target projects similar. The experimental results show that TCA+ can improve the performance of CPDP by transferable feature learning.

However, the aforementioned methods only use handcrafted features (e.g., Halstead [5], McCabe [6], and CK features [7]). In fact, if we can reasonably mine and use the semantic and structural information of the programs, it will be possible to further improve the performance of SDP. Recently, Wang et al. [10] tried to leverage DBN to automatically learn semantic features using token vectors extracted from the programs' ASTs. Their evaluation of 10 open-source projects shows that the DBN-learned features improve the performance of SDP. Based on the framework of DBN method, Li et al. [4] proposed that CNN is more advanced than DBN in capturing local patterns. They proposed a framework called Defect Prediction via Convolutional Neural Network (DP-CNN) to extract semantic and structural features from token vectors. The experimental results show that on average, DP-CNN improves the performance of SDP. It is worth mentioning that DP-CNN concatenates the CNN-learned feature vectors with traditional handcrafted feature vectors to avoid losing potential

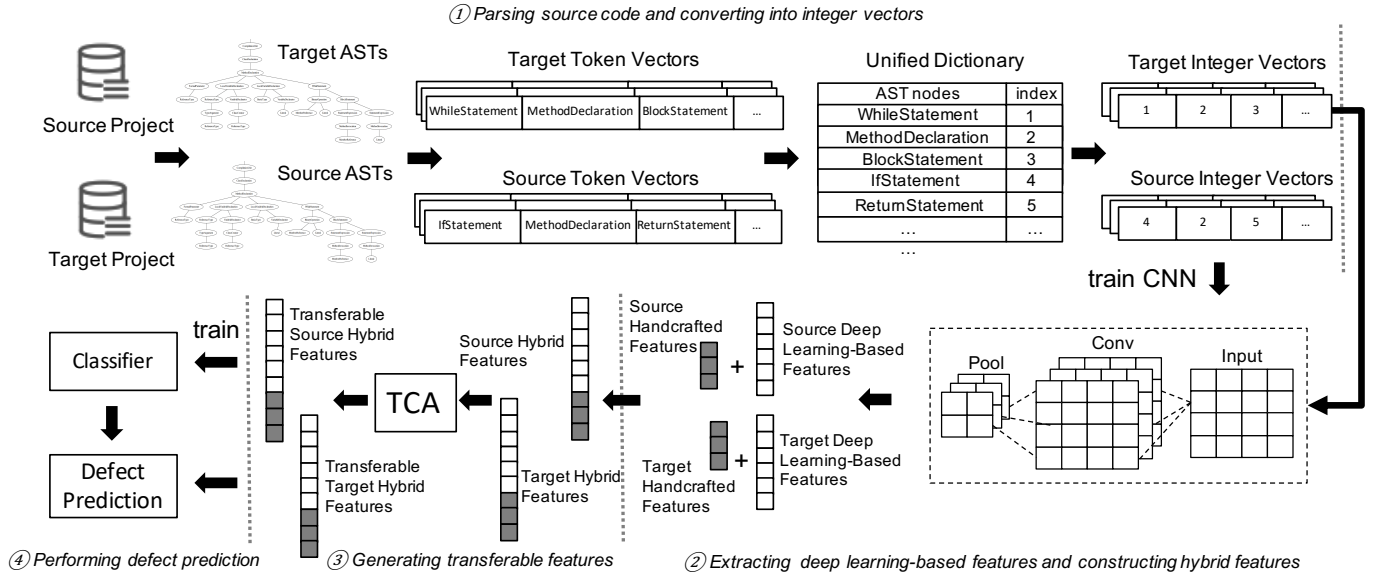

Fig. 2: Overview of our CNN-THFL framework to perform CPDP.

information in the latter. However, neither the DBN nor the CNN has considered the situation that there is distribution discrepancy across projects in CPDP tasks (Wang et al. [10] only assume that semantic features can capture the common features of defects and directly use DBN-generated features in CPDP tasks). Furthermore, this situation is exactly what we want to study and handle in this paper.

III. METHODOLOGY

A. Overall Framework

As presented in Figure 2, our CNN-THFL framework consists of four major steps: 1) parsing source code into tokens and converting them into integer vectors; 2) leveraging the CNN to automatically extract deep learning-generated features and constructing hybrid features; 3) generating transferable hybrid features via TCA; and 4) building classifier and predicting defects.

B. Parsing Source Code and Converting into Integer Vectors

AST is a tree representation of source code, and each structure in the source code can be represented as a node in the tree. Related work [10] has proven that ASTs can be used to detect the integrity and defects of source code. In this paper, we used the *Javalang*¹, an open-source Python package, to parse the Java files and generate corresponding token vectors. Table I lists the node categories and types used in this report. We use the name of the node type as the identifier for each node in the token vector. Considering that the names of methods, classes, and types are project-specific [8], we also used the type name (e.g., MethodDeclarations and ClassInvocation) to label nodes instead of the specific name used in [4].

The token vector extracted by Javalang cannot be directly used as input for CNN model training. To solve this problem,

TABLE I: The selected AST nodes.

Node Category	Node Type
Nodes of method invocations and instance creations	MethodInvocation, SuperMethodInvocation, ClassCreator
Declaration-related nodes	PackageDeclaration, InterfaceDeclaration, ClassDeclaration, ConstructorDeclaration, MethodDeclaration, VariableDeclarator, FormalParameter
Control-flow-related nodes	IfStatement, ForStatement, WhileStatement, DoStatement, AssertStatement, BreakStatement, ContinueStatement, ReturnStatement, ThrowStatement, TryStatement, SynchronizedStatement, SwitchStatement, BlockStatement, CatchClauseParameter, TryResource, CatchClause, SwitchStatementCase, ForControl, EnhancedForControl
Other nodes	BasicType, MemberReference, ReferenceType, SuperMemberReference, StatementExpression,

referring to [4], we established a mapping dictionary between tokens and integers so that the same token would be represented as the same integer. In this way, we could convert the token vectors into integer vectors. Furthermore, because CNN requires input vectors to have the same length, all input vectors would be filled with zero to the length of the longest vector.

C. Extracting Deep Learning-Generated Features and Constructing Hybrid Features

In this study, we applied CNN's feature-generation capability to capture the semantics and local structure of source code [4]. Our CNN included an embedded layer, a convolutional layer, a maximum pool layer, a full-connection layer, and the last output layer as input to the base classifier. All other layers adopted the ReLU activation function except the

¹<https://pypi.org/project/javalang/0.9.2/>

output layer, which used the sigmoid as the activation function. We implemented CNN by *Pytorch*², which has efficient tools for neural networks construction and enables fast, flexible experimentation.

To apply the knowledge carried in the handcrafted features at the same time, we stitched the these features of each project with the deep learning-generated features. The handcrafted features used in this paper were drawn from the metrics used by Jureczko and Madeyski in their defect prediction work [16]. Notice that we used the same handcrafted features from the source and target projects. We spliced deep learning-generated feature vectors with handcrafted feature vectors using the *Concatenate* method of Python to obtain hybrid feature vectors as the input for the next step.

D. Generating Transferable Features

In this study, we hoped to find transferable feature representation to handle the distribution discrepancy between source and target projects. TCA [15] is a transfer-learning method that allows knowledge of defects from a source project to be transferred to a target project. TCA attempts to learn some of the transferable components in the RKHS using maximum mean discrepancy [17]. In the subspace spanned by these transferable components, the properties of source and target data are preserved, and the data distributions in different projects are similar to each other. Therefore, through the new mapping data in this RKHS, we could train the base classifier in the source project, which was also available for the target project.

E. Performing Defect Prediction

For this paper, we chose logistic regression (LR) as a base classifier. We followed the aforementioned steps to process the files in the source and target projects and obtain the transferable hybrid feature for each file. After we fed the TCA-handled data of source project and corresponding label to the LR model, the weights and deviations in our LR would be obtained. Then we used the trained model to predict whether the instances of the target project were defective.

IV. EXPERIMENTAL SETUP

A. Evaluated Projects

To assess the CNN-THFL framework, we collected 9 Java open-source projects from the PROMISE repository, which has been commonly used in recent CPDP researches [18]–[20]. Table II presents the basic information for the 9 projects. Each project consists of a collection of Java files, their corresponding 20 static code attributes (the detailed descriptions of which can be found in [18]), and a label (defective or clean). To verify the generality of our approach, the data sets were composed of several projects with different sizes (ranging from 205 to 815) and defective rates (a minimum value of 11.4% and a maximum value of 98.8%). In our CPDP task, given one of the projects as the training data, another eight projects could

TABLE II: The 9 projects selected from the PROMISE repository.

Project Name	Project Version	Instance Count	Defect Rate
Ant	1.7	745	22.3%
Camel	1.6	965	19.5%
Ivy	2.0	352	11.4%
Log4j	1.2	205	92.2 %
Lucene	2.4	340	59.7%
Synapse	1.2	256	33.6%
Velocity	1.6.1	229	34.1%
Xalan	2.7	909	98.8%
Xerces	1.4.4	588	74.3%

be used as the test data, respectively (e.g., using the data of Ant v1.7 as a training set and the data of Camel v1.6 as the test set). Thus, 72 pairs of CPDP tasks could be performed in this study.

Software defect data have the typical characteristic of imbalanced distribution [21], [22], with the number of minority instances being less than the number of majority instances (e.g., in the Ivy-v2.0 project, the number of defective instances is far less than that of clean instances). In this study, we used the method of random oversampling to avoid imbalanced data that would degrade the performance of our model.

B. Evaluation Metrics

The metric of predictive performance is very important. Although the F1-score has been widely used in recent years [18], [19], we believe that it has problems in SDP tasks [3], especially when there are imbalanced data sets. For example, F1-score excludes true negatives (TN) from calculations, which may be problematic. The test manager will be happy to know whether the component is truly defect-free. Thus, we adopted the Matthews Correlation Coefficient [23] (MCC), as a metric of predictive performance.

As shown in Table III, there may be four outputs when using the dichotomous classifier in the SDP task.

TABLE III: Confusion Matrix

	Truly Defective	Truly Clean
Predictively Defective	TP	FP
Predictively Clean	FN	TN

MCC is the geometric mean of the regression coefficients of the problem and its dual. Based on the confusion matrix, MCC is calculated by the following formula:

$$MCC = \frac{TP \times TN - FP \times FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}$$

As a correlation coefficient, MCC measures the relationship between predictive class and true class by taking into account all components of confusion matrix. Its return value is on a scale [-1,1] where 1 means a perfect positive correlation and

²<https://pytorch.org>

-1 means a perfect negative correlation. Specifically, MCC can take into account TN, and it is less sensitive to the imbalanced data set.

C. Comparative Methods

We compared CNN-THFL with 9 methods including:

- **LR**. Traditional method, which builds a LR classifier only using handcrafted features.
- **TCA**. A classic transferable features learning method [15].
- **DBN**. A standard DBN model to extract semantic features for SDP [10].
- **DBN-TCA**. A variant of DBN, which applies TCA to obtain transferable DBN-learned features.
- **DBN-DP**. An improved version of DBN proposed by [4], which concatenates the DBN-learned features with the handcrafted features.
- **DBN-THFL**. A variant of CNN-THFL framework which adopted DBN to generate deep learning features.
- **CNN**. A SDP method that extracts deep learning-generated features via standard CNN.
- **CNN-TCA**. A variant of CNN that applies TCA to obtain transferable CNN-learned features.
- **CNN-DP**. A state-of-the-art SDP method that is an improved version of CNN proposed by [4].

Regarding the implementation of DBN, we adopted the same network architectures and parameters as in [10], i.e., 10 hidden layers and 100 nodes in each hidden layer. When implementing CNN, referring to [4], we set the batch size as 32, the epoch number as 15, the embedding dimension as 30, the number of hidden nodes as 100, the number of filters as 10, and filter length as 5. To make fair comparisons, we followed the same code-parsing process to generate integer vectors for neural networks. For TCA, we used the source code provided by its author [15]. For LR, we used the same implementation of *LogisticRegression* in *sklearn.linear_model*, and we adopted default parameters settings by *sklearn*. Considering the process of random oversampling and batch shuffle involve randomness, we conducted each method 20 times, recording their average result of MCC.

V. RESULTS

Because some data sets tend to produce over- or under-performing models, we adopted the Scott-Knott ESD [24], [25] test to compare the performance of the methods we examined (see Figure 3). The Scott-Knott ESD test used here is a mean comparison method that leverages hierarchical clustering to divide a set of MCCs into statistically distinct groups with non-negligible differences. The approach of this test consists of two steps: (1) finding the partitions that maximize the MCC means between groups, and (2) splitting into two groups or merging them together in one group. A detailed description of the Scott-Knott ESD test can be seen in [24]. We can use the *sk_esd* function of the *ScottKnottESD*³ R package to implement the test easily and quickly.

³<https://github.com/klainfo/ScottKnottESD>

Fig. 3: The Scott-Knott ESD ranking of 10 different methods across the 72 CPDP tasks. The blue diamond indicates the average MCC of our studied methods.

Figure 3 presents the Scott-Knott ESD test of the MCC results (including for 72 CPDP tasks). By comparing 9 referential methods, the average MCC of CNN-THFL was 0.18, which respectively outperformed DBN-THFL, CNN-TCA, LR, TCA, DBN-DP, CNN-DP, and CNN by 8.9%, 10.5%, 17.1%, 30.1%, 50.8%, 62.8%, and 76.1%.

The following two points can be observed from Figure 3:

- 1) DBN-DP and CNN-DP, which consider concatenating the deep learning-generated features with the handcrafted features, will perform better than pure DBN and CNN.
- 2) Better prediction performance (in terms of MCC) can be obtained by combining the THFL framework with deep-learning methods. Among them, CNN-THFL can perform better.

In summary, our CNN-THFL framework improves the performance of CPDP tasks with the consideration of distribution discrepancy between projects. It is worth mentioning that not only CNN-THFL but also DBN-THFL will achieve better performance than the methods without THFL, so we recommend using hybrid features and adapting the distribution discrepancy between projects when performing CPDP. We believe that this improvement of SDP would provide more effective help to test teams for detecting software defects and reasonably allocating test resources.

VI. THREATS TO VALIDITY

A. Implementation of DBN and DP-CNN

In this study, we compared the DBN method [10] and DP-CNN method [4], which are the state-of-the-art deep learning-based SDP methods. Because their implementations have not been publicly released, we tried to reimplement the corresponding methods by *Pytorch* with the same network

structures and parameters. However, we still cannot guarantee that the effects of DBN and DP-CNN that we re-implemented are exactly the same as those in [10] and [4]. However, in our experiments, we used the unified processes (e.g., code-parsing and oversampling steps) and tools (e.g., *Pytorch* and LR classifier) to implement the CPDP framework. As such, our comparative experiment should be fair.

B. Experimental Results Might Not Be Generalizable

In our experiments, 9 open-source projects were selected from the PROMISE repository to access the CPDP methods. The experimental results of these 9 projects (72 CPDP tasks) do not represent all cases. For some other programming languages and commercial software, our proposed method might obtain better or worse results.

C. MCC Might Not Be the Only Appropriate Measure

In our work, we used MCC as the metric of predictive performance. In fact, other metrics (e.g., F-score and G-measure) can also be used in the SDP task. In this paper, we recommend using MCC because it can take TN into account, and it is less sensitive to the problem of imbalanced data sets.

VII. CONCLUSION AND FUTURE WORK

In this paper, we proposed a features learning framework called CNN-THFL to improve the performance of CPDP. CNN-THFL aims to mine both transferable deep learning-generated and handcrafted features between source and target projects. An important advantage of CNN-THFL is that it explores the necessity for distribution adaptation of hybrid features that concatenate deep learning-generated features with the traditional handcrafted features in a CPDP task. CNN-THFL is robust to differences in distribution between projects. A large number of experiments on 9 projects with 72 CPDP tasks have been carried out to verify that the proposed framework can achieve better performance in terms of MCC than the advanced referential methods. In future work, we plan to investigate the up-to-date distribution adaptation method to reduce the distribution discrepancy between projects. In addition, we will try to solve the defect prediction across multiple projects with CNN-THFL.

Abstract—Software defect prediction can help software testers to focus on software modules with more defects. Many ensemble methods have been proposed for software defect prediction to divide software modules into defect-prone and defect-free, and these ensemble methods have been proved to be more effective than single learning algorithms. A few ensemble approaches have been applied to predict the number of defects in software modules, and they also perform well in most cases. The good performance of ensemble approaches implies that ensemble algorithms might not only improve the accuracy of software defect classification models, but also improve the performance of defect ranking models. Therefore, we propose an ensemble method based on Yang et al.'s learning-to-rank approach in this paper. Experimental results show that the learning-to-rank-based ensemble approach performs better than the single learning-to-rank approach, which means that the idea of ensemble can improve the performance of the learning-to-rank approach to sort modules in order of defect count. We also conduct a comparison study of ensemble approaches for cross-version defect prediction over 30 sets of cross-version data, which indicates that the ensemble technique of random subspace is more appropriate than boosting over these experimental data sets.

Index Terms—Software defect prediction; Ensemble approaches; Ranking task; Learning-to-rank

I. INTRODUCTION

Software testing activities play a key role in software development, which consume a great amount of resources including time, money and personnel [1]. Timely detecting and repairing defects before releasing the products are critical for software quality assurance [2], [3]. Software defect prediction (SDP) employs software metrics (also referred to as features or attributes) to predict the defect information of software modules (classes, files, etc) in order to support software testing activities [4]. The most frequently investigated tasks of SDP include the classification task [3] and the ranking task [4]. We focus on the ranking task in this paper.

SDP for the ranking task, by sorting software modules in order of defect count, can help testers to focus on software modules with more defects and identify defects more quickly [1], [5]–[7]. Firstly, data is collected from software modules according to software metrics, such as 'response for a class' [8]. Subsequently, modelling approaches are used to construct

a model based on data from modules with known defect numbers. Finally, the model is used to predict defects of software modules with unknown defect numbers, and thus an order of these modules based on the predicted values is obtained, which can help allocate testing resources (for instance, more testing resources for modules with more defects) [7].

Many methods have been employed to construct SDP models for the ranking task, such as linear regression [9], negative binomial regression [1], recursive partitioning, Bayesian additive regression trees, and random forest [10]. Yang et al. proposed an effective learning-to-rank (LTR) method for this task [4], which constructs SDP models by directly optimizing the ranking performance. That random forest [4], [10] performed well for this task implies the usefulness of ensemble algorithms to improve the performance of defect ranking models. Therefore, in this paper, we investigate an ensemble method based on Yang et al.'s LTR approach, in order to see whether the idea of ensemble can benefit this approach.

Considering that the use of ensemble methods for SDP with ranking task was explored by very few researchers, Rathore and Kumar presented a study of different ensemble methods for the prediction of number of defects over three Eclipse data sets [11]. To further compare the ensemble approaches for this task, we conduct a comparison study of ensemble approaches over 30 sets of cross-version data [7].

The main contributions of this paper include: (a) a novel ensemble method based on Yang et al.'s LTR approach, and a comparison study of the proposed ensemble approach with the single LTR approach [4]; and (b) a comparison study of ensemble approaches for cross-version defect prediction for the ranking task.

The rest of this paper is organized as follows. Section 2 presents related work. In Section 3, we describe the proposed ensemble method. The experimental methodologies are detailed in Section 4 and experimental results are reported in Section 5. Section 6 presents the threats to validity, and Section 7 draws the conclusions.

II. RELATED WORK

Data and model construction methods are key factors for software defect prediction (SDP). Because we focus on en-

Corresponding author: Xiaoxing Yang (yangxx27@mail.sysu.edu.cn). DOI reference number: 10.18293/SEKE2019-113

semble approaches for cross-version defect prediction for the ranking task, this section mainly presents the related work from two aspects: methods for constructing SDP models for the ranking task, and ensemble methods in SDP.

A. Methods for Constructing SDP Models for the Ranking Task

Compared with methods for constructing defect prediction models for the classification task, there are fewer approaches particularly proposed for constructing defect prediction models for the ranking task. Most studies employed existing methods to construct models to predict the number of defects. For example, Yang and Wen [7] used two penalized regression methods to construct prediction methods, and experimental results showed that both penalized regression performed better than linear regression and negative binomial regression for cross-version defect prediction. Gao et al. [12] compared eight count models, and the comparative study showed that zero-inflated negative binomial regression, hurdle negative binomial regression and hurdle Poisson regression with threshold 2 were more effective. Weyuker et al. [10] compared four approaches (negative binomial regression, random forest, recursive partitioning and Bayesian additive regression trees) for predicting the number of defects in software modules, and the study showed better performance of negative binomial regression and random forest models than the other two models. Considering that existing SDP models, which are optimized to predict explicitly the number of defects in a software module, might fail to give an accurate order because of the difficulty to predict the exact number of defects in a software module due to noisy data, Yang et al. [4] proposed a LTR approach to directly optimize the ranking performance measure, and the experimental results showed that the LTR approach and random forest were better than other methods to construct SDP models for the ranking task.

B. Ensemble Methods in SDP

Most existing work of ensemble methods for SDP dealt with classification problems instead of ranking problems. For example, Wang and Yao [13] investigated different types of class imbalance learning methods, including re-sampling techniques, threshold moving, and ensemble algorithms, and they found that AdaBoost.NC showed the best overall performance in terms of the measures including balance, G-mean, and area under the curve. The authors also proposed a dynamic version of AdaBoost.NC to adjust parameter automatically during training. Kumar et al. [14] applied ensemble methods to develop models to predict whether software modules are defect-prone or not using 45 datasets from the PROMISE repository. They concluded that ensemble method learning algorithm outperformed individual classifiers. Yohannese et al. [15] evaluated the capability of ensemble learning algorithms in SDP for the classification task using eight NASA software defect data sets. The experimental results revealed that the combined technique could improve the performance. There

are other studies of ensemble methods for SDP for the classification task [16]–[18].

Compared with the work of ensemble methods for defect prediction for the classification task, there exist fewer studies of ensemble methods for defect prediction for the ranking task. A commonly used ensemble method in SDP for the ranking task is random forest. Random forest has been proved to be effective in many studies [4], [10]. Yu et al. [19] explored the potential of using re-sampling techniques and ensemble learning techniques to learn from imbalanced defect data for predicting the number of defects. They studied the use of an ensemble learning technique (i.e., the AdaBoost.R2 algorithm) to handle imbalanced defect data for predicting the number of defects. Experimental results showed the effectiveness of these approaches. Rathore and Kumar [11] performed an empirical study of different homogeneous ensemble methods for predicting the number of faults based on three Eclipse datasets. Experimental results showed that overall ensemble methods produced better performance than a single fault prediction technique. According to their conclusion, random subspace produced better results than other ensemble methods such as boosting and bagging, and decision tree regression was a better base learning technique than multilayer perceptron and linear regression. These studies imply that ensemble algorithms might not only improve the accuracy of software defect classification models, but also improve the performance of defect prediction models for the ranking task. Therefore, we want to investigate the ensemble method that uses the LTR approach as the base learning technique, to investigate whether the idea of ensemble can improve the LTR approach for SDP.

III. THE LEARNING-TO-RANK-BASED ENSEMBLE APPROACH

In this section, we briefly describe Yang et al.'s learning-to-rank (LTR) approach [4]. Subsequently, we present our proposed ensemble method based on this approach.

A. Yang et al.'s Learning-to-Rank Approach

Given a vector of metrics of a software module $\mathbf{x} = (x_1, x_2, \dots, x_d)$, (x_i : the i^{th} metric, and d : number of metrics), the goal of SDP for the ranking task is to predict its relative defect number, which is denoted as $f(\mathbf{x})$ as Equ.(1).

$$f(\mathbf{x}) = \sum_{i=1}^d \alpha_i x_i \quad (1)$$

where α_i s are parameters obtained by training. Once α_i s are fixed, the model is learned. The LTR approach optimizes performance of defect prediction models directly to obtain the parameters using composite differential evolution (CoDE) [20]. Details can be found in Yang et al.'s study [4].

B. The Learning-to-Rank-Based Ensemble Approach

When adopting the LTR model as the base learner, the values of $f(\mathbf{x})$ can vary greatly in the same ranking performance. For this reason, when computing the final output combining all base learning models, we use sigmoid function

to transform the predicted values by the base learning models. When the values of $f_k(\mathbf{x})$ (the predicted values achieved by the k^{th} base learning models) are large, the values of the corresponding sigmoid function are similar. In order to better distinguish these values, we set a coefficient $C1$ for $f_k(\mathbf{x})$, which will not affect the monotonicity. In addition, we set different weights for different base learning models according to their performance over the training set. Assuming that P_k is the training performance of model $f_k(\mathbf{x})$, the final output $G1(\mathbf{x})$ that combines all base learning models is computed as Equ.(2):

$$G1(\mathbf{x}) = \sum_{k=1}^{N1} P_k^W * S(f_k(C1 * \mathbf{x})) \quad (2)$$

$$= \sum_{k=1}^{N1} P_k^W / (1 + \exp^{-C1 * f_k(\mathbf{x})})$$

where $N1$ is the number of base learning models, and W is the power that controls the contributions of different base learning models to the final output according to their training performance. When W equals to 0, the contributions of all base learning models to the final output are the same, regardless of the training performance of these base learning models.

Rathore and Kumar's study [11] showed that random subspace produced better results than other ensemble methods such as boosting and bagging, and random forest [21] (which adopts random subspace) has been proved to be effective in many studies [4], [10]. Therefore, we learn from the selection process of random forest. Assuming that there are d metrics, a subset of $N2$ metrics are selected randomly. Subsequently, the best $N3$ metrics are selected from the $N2$ metrics for constructing base learning models. In this paper, we adopt fault-percentile-average (FPA) [10] as the model performance measure, which is detailed in Section IV. The effectiveness of one metric can be evaluated by directly computing the FPA value of the model based on the metric.

The detailed process of the learning-to-rank-based ensemble approach (LTRE) are shown as follows.

1) **Input:**

M training vectors: $\mathbf{x}_i = (x_{i1}, x_{i2}, \dots, x_{id})$, i : 1 to M , d : number of metrics; Number of base learning models: $N1$; Number of alternative metrics: $N2$; Number of used metrics: $N3$; Coefficient: $C1$; Power: W .

2) **Process:**

- a) for $j = 1, 2, \dots, d$
 - i) compute the performance of model based on training data with only the j^{th} metric, and obtain the corresponding performance F_j .
- end for
- b) for $k = 1, 2, \dots, N1$
 - i) select $N2$ metrics from all metrics randomly
 - ii) select the best $N3$ metrics from the selected $N2$ metrics according to F_j values

- iii) use the training vectors with the best $N3$ metrics to train a model and obtain its performance:
 - A) model: $f_k(\mathbf{x}) = \sum_{j=1}^{N3} \alpha_{kj} x_j$, j belongs to the $N3$ metrics, α_{kj} s are obtained using CoDE.
 - B) training performance of model $f_k(\mathbf{x})$: P_k .

end for

- 3) **Output:** for a testing vector \mathbf{x} , compute the predicted value using Equ.(2)

IV. EXPERIMENTAL METHODOLOGIES

In this section, we detail our experimental data sets, the performance measure and implementation.

A. Datasets

In order to facilitate others to reproduce results, we use 41 data sets from 11 open-source projects in PROMISE repository [7], [22]. The characteristics of these experimental data sets are shown in Table I. The columns of 'faulty modules', 'range of defects', and 'total defects' respectively record the number of modules having defects (with the percentages of faulty modules in the subsequent brackets), the ranges of defect numbers in the corresponding data sets, and the total number of defects in all modules of the corresponding data sets. The metric number of these data sets is 20. Details of the specific twenty metrics can be found Jureczko et al. 's work [8].

B. Performance Measure

As mentioned in Yang et al.'s study [4], models with higher prediction accuracy (smaller average absolute errors or relative errors) might give a worse ranking, while fault-percentile-average (FPA) [10] takes into account both practical use and the whole ranking performance of prediction models, which is consistent with cumulative lift chart [23] for measuring a ranking [4]. Therefore, we adopt FPA as the model performance measure.

Considering n modules f_1, f_2, \dots, f_n , listed in increasing order of predicted defect number, k_i as the actual defect number in the module f_i , and $k = k_1 + k_2 + \dots + k_n$ as the total number of defects in all modules, the proportion of actual defects in the top m predicted modules to the whole defects is $\frac{1}{k} \sum_{i=n-m+1}^n k_i$. Then FPA is defined as follows [10]:

$$\frac{1}{n} \sum_{m=1}^n \frac{1}{k} \sum_{i=n-m+1}^n k_i$$

Larger FPA means better ranking performance.

C. Implementation

There are two main objectives in this paper:

- 1) investigating whether the idea of ensemble can improve Yang et al.'s LTR approach;
- 2) and comparing ensemble approaches for cross-version defect prediction for the ranking task.

According to the two objectives, we first compare the learning-to-rank-based ensemble method (LTRE) with the single LTR

approach. Subsequently, we conduct a comparison of six ensemble methods over 30 sets of cross-version data: LTRE, random forest [21], Bagging [24], Extra-Trees [25], gradient boosting [26], and Adaboost [27].

Because we use the same data sets as Yang and Wen's paper [7], we directly use their experimental results of both LTR and random forest in this paper. LTRE is implemented in Java. For LTRE, N1 is set to 100, N2 is set to half of all metrics, N3 is set to 2, C1 is set to 0.1, and W is set to 3. Bagging, Extra-Trees, gradient boosting, and Adaboost are implemented in Python, and their parameters are tuned by GridSearchCV method which provides the grid search that exhaustively generates candidates from a grid of parameter values specified in advance. For each method, only a small subset of parameters which play an important role are tuned, while others are set as their default values. Because the best parameters for different data sets are different, we choose the most frequently occurring ones. Bagging uses decision trees as base estimator, the number of trees is set to 200, and the

number of metrics is set to 0.4 of all metrics. To be noted, the number of metrics for Bagging is not all metrics (the performance of all metrics is worse than 0.4 of all metrics), so the Bagging here is not the traditional Bagging [11]. The number of trees in Extra-Trees, gradient boosting and Adaboost is also set to 200, the number of metrics in Extra-Trees and gradient boosting is set to 1/3 of all metrics, and the learning rate in gradient boosting and Adaboost is set to 0.1.

In order to simulate the actual situation, we adopt cross-version defect prediction, whose merit has been shown in Shukla et al.'s work [22]. SDP models constructed according to one version are used to predict defects of the next version, which is similar to actual use. All methods run 10 times for the same set of data. We use Wilcoxon rank-sum test [28] (which is called ranksum for short) to test whether 10 results by one method is significantly larger than those by another method using the same training and testing data.

V. EXPERIMENTAL RESULTS

In this section, we firstly show the comparison of the learning-to-rank-based ensemble approach (LTRE) and the single learning-to-rank approach (LTR) in order to see whether the idea of ensemble can improve LTR for SDP. Subsequently, the results of all compared ensemble approaches for cross-version defect prediction are presented.

A. Comparison of LTRE with LTR

In this subsection, we compare LTRE and LTR. Experimental results are shown in Table II. 'Ant-1.3-1.4' in Table II means using ant-1.3 as the training set and ant-1.4 as the testing set, and others are similar. Hence, there are totally 30 sets of data (each set includes one training version and one testing version). The columns of 'LTRE' and 'LTR' respectively record their mean FPA testing results, and the column of 'pvalues' records the p-values of ranksum test between 10 results achieved respectively by LTRE and LTR over the same set of data. We use bold type to mark the significantly larger results at the 0.05 significance level.

In Table II, '22' in the row of 'larger times' means that LTRE achieves larger mean FPA values than LTR over 22 sets of data. '18' in the row of 'significantly larger times' means that LTRE achieves significantly larger mean FPA values than LTR at the 0.05 significance level over 18 out of 30 sets of data. From these results, the idea of ensemble can benefit LTR for SDP for the ranking task.

B. Comparison of Six Ensemble Approaches

In this subsection, we show the experimental results of six ensemble approaches: LTRE, random forest (RF), Bagging, Extra-Trees (ET), gradient boosting (GB), and Adaboost (Ada). Table III shows the mean calculated over ten testing FPA results in ten runs for these methods. We use bold type to mark the largest results.

The best methods for different sets of data are very different: one method achieves best results over some sets of data, but

worst results over other sets of data. For example, LTRE achieves best result over ant-1.4-1.5, but worst result over xerces-init-1.2. As a whole, LTRE and random forest achieve maximum mean FPA values in most sets of data (eight for each method). These results imply that LTRE is comparable with other ensemble methods.

Bagging achieves larger mean results than Extra-Trees, gradient boosting, and Adaboost over more data sets. In addition, Extra-Trees and Adaboost perform better than gradient boosting over more data sets. To be noted, as mentioned in Section IV, the number of metrics for Bagging is set to 40% of all metrics because the performance of all metrics is worse than partial metrics. And thus the Bagging here is actually a combination of bagging and random subspace. This implies that random subspace might be better than boosting methods for these data sets.

VI. THREATS TO VALIDITY

In this paper, we investigate cross-version defect prediction based on 41 data sets from 11 projects in PROMISE repository, which reflects that the obtained results are strongly related to the SDP domain. However, there are some threats that may have an effect on our experimental results.

One threat is that only a few parameters of all experimental approaches are tuned in a small range, and the results might be different with other parameters setting.

In addition, the experimental data sets are only a very small part of all data sets, among which there are many data sets

based on industrial software systems [12] that are not publicly available. Other data sets might include different metrics and totally different modules. The conclusions over these data sets might not hold for other data sets.

The compared ensemble methods are only a small part of all ensemble methods. We use decision tree regression as the base learner for the compared ensemble methods in this paper. When other base learners are used, the conclusion might be different.

VII. CONCLUSIONS

Many studies have been conducted to sort software modules according to the number of defects [5], [10]. Random forest performed best in some previous studies [4], [10]. The good performance of random forest for SDP implies that the idea of ensemble might be useful to improve the performance of defect ranking models. Yang et al. proposed a learning-to-rank method (LTR) particularly for SDP [4], and their experimental results showed its effectiveness. Therefore, we propose a novel ensemble method based on LTR, which is called the learning-to-rank-based ensemble method (LTRE), in order to see whether the idea of ensemble can also improve LTR for sorting module in order of defect count.

Experimental results over 30 sets of cross-version data show that the proposed LTRE perform better than LTR, which implies that the idea of ensemble can benefit LTR for SDP.

In addition, we conduct a comparison study of six ensemble approaches for cross-version defect prediction for the ranking

A Multilevel Analysis Method for Architecture Erosion

Tong Wang, Dongdong Wang, Bixin Li
School of Computer Science and Engineering
Southeast University, Nanjing, China

Abstract—During the evolution of software, improper change operations may cause architecture erosion. Architecture erosion creates problems on evolutionary costs, software performance and software quality. Many methods have been proposed to analyze architecture erosion. Architecture depends on the implementation of code, that is, architecture erosion is caused by code. However, few methods analyze the reasons for architecture erosion based on code. Besides, architecture is eroded with software evolution, but most methods do not analyze architecture erosion based on the change of software. In this paper, we propose a multilevel analysis method for architecture erosion. Our method contains three steps. Firstly, we detect the changed pairs based on two architectures by performing a multilevel change detection method. Secondly, we detect whether the corresponding code elements of changed pairs are erosion points by calculating erosion degree. Thirdly, we establish a cost-benefit model of repairing architecture erosion for repairing architecture erosion more effectively with repaired few erosion points. We illustrate our method through an open source project, and the experimental results indicate that our method can detect the erosion points of each level and the cost-benefit model is effectively.

Index Terms—architecture erosion, multilevel change detection, the cost-benefit model

I. INTRODUCTION

Software is continually evolved to meet new requirements. With the evolution of software, architecture erosion often occurs [1], [2]. Architecture erosion creates problems such as the increase of software evolutionary costs [3], the decrease of software performance [4], and the degradation of software quality [5]. In a word, uncontrolled architecture erosion has a negative impact on software [6]. In order to reduce the negative impacts, analyzing software architecture erosion in time is an important task during the development and maintenance of software [7].

Some researchers propose analysis methods for architecture erosion based on multiple types of indicators. Zhang et al. detect architecture erosion based on the design decision of architectural pattern [8], and Herold et al. detect architecture erosion based on a common ontology [7]. The purpose of detecting and repairing architecture erosion is reducing the effects on architecture quality [9], that is, the decrease of architecture quality is an important sign of architecture erosion, but few methods analyze architecture erosion based on quality. Besides, architecture depends on the implementation of source code [10], but few methods analyze architecture erosion based

on code. Also, there may be many erosion points, but it is impossible to repair all erosion points, so how to reduce the erosion degree of architecture effectively by repairing fewer erosion points is an important problem.

To overcome the above limitations, we proposed the multilevel analysis method for architecture erosion. In our method, we first detect the changed pairs of each level by performing the multilevel change detection method. Then, we detect whether the corresponding code elements of changed pairs are erosion points by calculating the erosion degree. Finally, we establish the cost-benefit model for providing the repairing priority of erosion points.

To sum up, this work makes the following contributions.

- We detect the erosion points based on architecture quality which is an important sign of architecture erosion.
- We analyze reasons for architecture erosion based on the implementation of architecture by using the multilevel change detection method.
- We establish the cost-benefit model of repairing architecture erosion, in order to more effective repairing architecture erosion by repairing fewer erosion points.

This paper is organized as follows. Section II introduces the details of our method. In section III, we illustrate our method though an open source project. Section IV presents related work. In Section V, the threats to the validity of our method are analyzed. In Section VI, we make a conclusion and discuss future work.

II. OUR METHOD

A. Method Overview

Architecture erosion leads to the gradual deterioration of software quality [11], that is, the deterioration of quality is an important sign of architecture erosion. So, in this paper, we define architecture erosion as follows.

Definition 1 architecture erosion: It is a phenomenon that occurs when architecture quality is decreased with software evolution.

The component dependency graph is a widely acceptable representation of architecture, in our method, we use it to represent architecture. The component dependency graph consists of the component and the dependency between components. A component is a code element of the high abstraction level, and it consists of multiple files. A file consists of multiple statements. According to the granularity of code elements, we

B. Li is the corresponding author. E-mail: bx.li@seu.edu.cn
DOI reference number:10.18293/SEKE2019-046

divide architecture into three levels, component level, file level, and statement level.

The architecture contains multiple components. In an eroded architecture, not all components are eroded. Similarly, in an eroded component, not all files are eroded. And in an eroded file, not all statements are eroded. In order to narrow down the range of erosion for reducing the repairing cost, we analyze architecture erosion from architecture to component level, then from component level to file level, finally from file level to statement level.

Architecture is eroded with software evolution, so does components, files, and statements. In order to analyze whether components, files, and statements are eroded, we should first detect changed pairs of each level by using a multilevel change detection method. After detecting the changed pairs, we detect whether the corresponding code of changed pairs are eroded.

Definition 2 changed pair: Let $A1$ be a original architecture. Let $A2$ be a current architecture. Let $C1$ and $C2$ be two code elements of the above architectures. If $C1$ is evolved to $C2$, the two code elements constitute a changed pair. If $C1$ is deleted and $C2$ is a new code element, then they respectively constitute changed pairs with a virtual code element.

According to the above analysis, the overview of our method is shown in Figure 1. The first step is detecting the changed pairs of code elements, where add, delete and update operations are denoted in the green, red and blue border. The second step is calculating erosion degree to detect whether the corresponding code elements of changed pairs are erosion points, and the erosion points are denoted in gray nodes. The third step is establishing the relations between the number of repaired erosion points with the degree of decline in architecture erosion, that is, we establish a cost-benefit model of repairing erosion points. The model demonstrates how to reduce more erosion degree of architecture by repairing fewer erosion points.

Fig. 1. An overview of our method.

B. Detecting changed pairs of each level

In order to detect changed pairs at file level and statement level, we perform the change detection method named the two-step multilevel program analysis tree matching method [12].

The method can detect multilevel changes effectively, such as method level, class level, and file level.

We perform the following steps to detect changed pairs at component level: calculating the similarity between components and identifying change operation based on component similarity.

The component similarity indicates the degree of similarity. The component consists of multiple files, so we calculate the component similarity based on the contained files. The formula is shown in Formula 1.

$$Sim(i, j) = \frac{2 * |S_i \cap S_j|}{L_i + L_j} \quad (1)$$

where $Sim(i, j)$ is the similarity between the i_{th} component and the j_{th} component, S_i is the file set contained in the i_{th} component, $|X|$ is the number of elements of the set X and L_i is the number of code lines.

The components of the original architecture and the components of the current architecture are matched based on the component similarity to detect which components constitute a changed pair. We consider the following three change operations at the component level.

Add(C): A new component C is added in V_2 .

Delete(C): In V_2 , the component C is deleted.

Update(C_i, C_j): The component C_i is updated to C_j .

In order to identify the above change operations based on the component similarity, we define two thresholds. The first threshold is *HighThreshold*. If the component similarity above *HighThreshold*, we deem that the two components are the same, that is, the component is not changed during the evolution process. The second threshold is *LowThreshold*. If the component similarity above *HighThreshold* but below *LowThreshold*, we deem that the change operation between the changed pair is updating. If the component similarity below *LowThreshold*, we deem that the two components of the changes pair are respectively the new component of the current architecture and the deleted component of the original architecture. The algorithm of identifying change operations is shown in Algorithm 1.

C. Calculating erosion degree

In this step, we detect whether the code elements of each changed pair are eroded, that is, whether the code elements are the erosion points.

Definition 3 erosion point: Let A_i and A_j constitute a changed pair which respectively belong to the original architecture and the current architecture. If the change operation between A_i and A_j causes architecture erosion, A_i and A_j are the erosion points.

The decrease in architecture quality is an important sign of architecture erosion. When architecture quality is decreased, it indicates that architecture is eroded, correspondingly, if architecture quality is increased, architecture is nor eroded.

In this paper, we take the change of understandability and testability as the indicators of architecture erosion. Understandability and testability are important quality attributes

Algorithm 1 The algorithm of identifying change operations**Input:** The component list of the original version *oriCom*The component list of the current version *curCom*The threshold of similarity *threshold***Output:** The list of the adding change *add*The list of the deleting change *delete*The list of the updating change *update*

```

24:  end for
25: end for
26: delete = oriCom - oriMatched
27: add = curCom - curMatched

```

for architecture [13]. Firstly, we measure the two quality attributes.

Testability determines the required resources during testing and making test plans [14]. Its calculating formula is shown in Formula 2.

$$Testability = 1 - \frac{\sum_{i=1}^N \frac{O_i}{N}}{N} \quad (2)$$

where T is the measurement of testability, N is the number of elements, i denotes the i_{th} code element, O is the fanout of the i_{th} element.

Understandability denotes the difficulty of understanding architecture [15]. Its calculating formula is shown in Formula 3.

$$Understandability = \frac{\sum_{i=1}^N f(C_i)}{N} \quad (3)$$

where U is the measurement of understandability, N is the number of elements, i denotes the i_{th} element, L_i is number of code lines of the i_{th} element, $f(C_i)$ is the density of cognitive complexity of the code element C_i . The calculating formula of the density of cognitive complexity is shown in Formula 4.

$$f(C_i) = \begin{cases} 1 & \frac{C_i}{L_i} \leq 0.05 \\ 0.8 & 0.05 < \frac{C_i}{L_i} \leq 0.1 \\ 0.6 & 0.1 < \frac{C_i}{L_i} \leq 0.2 \\ 0.4 & 0.2 < \frac{C_i}{L_i} \leq 0.3 \\ 0.2 & 0.3 < \frac{C_i}{L_i} \leq 0.4 \end{cases} \quad (4)$$

where $f(C_i)$ is the density of cognitive complexity of the code element C_i , L_i is number of code lines of the i_{th} element and C_i is the cognitive complexity of the i_{th} element. Cognitive complexity can yield assessments of control flow that correspond to programmers intuitions about the mental, or cognitive effort required to understand those flows.

According to the above formulas, we the measurements of understandability and testability, then we use the erosion degree to represent the change of architecture quality before and after evolution.

Definition 4 erosion degree: Let A_o and A_c be architectures before and after software evolution. Let $A_o[i]$ be a code element of A_o and $A_c[j]$ be a code element of A_c . If architecture quality is decreased, the difference between $A_o[i]$ and $A_c[j]$ is the erosion degree. If erosion degree is a negative value, it indicates that the changed pair does not damage architecture quality instead of increasing architecture quality.

The erosion degree is calculated based on a pair of code elements before and after software evolution. To architecture, the erosion degree depends on the change of the contained components. Similarity, to a component, the erosion degree depends on the changes of the contained files. Then, to file, the erosion degree depends on the changes of the contained statements.

The elements of the pair respectively belong to the original architecture and the current architecture. When a code element is deleted from the original architecture, and when a code element is added in the current architecture, there is not a corresponding code element in another architecture, so we use the average measurement as the threshold to calculate the erosion degree of the new code element and the deleted code element.

The formula of erosion degree is shown in Formula 5.

$$f(E_i, E_j) = \begin{cases} M_j - M_i & E_i \text{ is evolved to } E_j \\ M_j - AVG & E_j \text{ is a new code element} \\ AVG - M_i & E_i \text{ is a deleted code element} \end{cases} \quad (5)$$

where E_i is the i_{th} code element, $f(E_i, E_j)$ is difference between the measurements of E_i and E_j , M_i is the measurement of the i_{th} code element and AVG is the average measurement of the previous architecture.

D. Establishing the cost-benefit model

Considering the number of erosion points and the repairing cost, in actual development process, it is impossible to repair all erosion points. In order to more effective repair architecture by repairing fewer erosion points, we establish the cost-benefit model based on erosion contribution.

Definition 5 erosion contribution: Let C be an erosion point. The erosion contribution of C denotes that, compared with other eroded code elements of the same level, the degree of influence on architecture erosion.

The formula of the erosion contribution is shown in Formula 6.

$$EC(P_i, C_j) = \frac{f(P_i, C_i)}{\sum_{(a,b) \in S} f(P_a, C_b)} * PEC(P_i, C_i) \quad (6)$$

where O_i is the i_{th} code element of the original architecture, C_i is the i_{th} element of the current architecture, $EC(O_i, C_j)$ is the erosion contribution of the changed pair constituted by O_i and C_j , $f(O_i, C_j)$ is the erosion degree of the changed pair constituted by O_i and C_j , S is the set of changed pairs which are erosion points, $|S|$ is the number of the elements of S , (a, b) is the element of S and it denotes the changed pair constituted by O_a and C_b , and $PEC(P_i, C_i)$ is the erosion contribution of the changed pair which is the corresponding higher abstraction elements of O_i and C_j . The component level is the highest abstraction level in our method. If O_i is a component, the value of $PEC(O_i, C_i)$ is 1.

The higher erosion contribution indicates that the corresponding point has caused more negative effects on architecture. So the erosion contribution denotes the relative urgency degree of repairing. The order of repairing erosion points is based on the erosion contribution from high to low.

Unlike the erosion degree, the erosion contribution is a comparative value, because it is calculated based on the erosion of other code elements of the same level. The sum of erosion contribution of all erosion points is 1. The sum of the erosion contribution of all repaired erosion points denotes the degree of repairing architecture erosion, so it is used as the indicator of the benefit.

Architecture depends on the implementation of the code, and in the actual development process, developers repair architecture erosion by modifying the code. So in our model, we only take the erosion points belonging to statement level into consideration.

Lines of code (LOC) is an important indicator for estimating software costs, so we use the number of repaired erosion points as the cost. With repairing erosion points, the erosion degree of architecture is reduced which is caused by repairing erosion points, so we use the sum of erosion contribution of the repaired erosion points as the benefit.

The erosion contribution denotes the degree of effects on architecture erosion. We sort all erosion points according to the erosion contribution from high to low. There is a relation between the number of repaired erosion points and the sum of erosion contribution, and the cost-benefit model is established based on the above relation.

III. ILLUSTRATIVE EXAMPLE

In this section, we choose an open source project as the case to illustrate the process of our method. *commons-lang* is a package which provides some basic APIs for some general

operations, such as automatically generating *toString()* results, automatically implementing *hashCode()* and *equals()*, etc. *commons-lang* has received 1.5K stars in *GitHub*.

We choose four versions as cases to detect architecture erosion. There is not a document about the architecture of *commons-lang*, so we perform the recovery method proposed by Kong et al. [16] to obtain its architecture. The basic information of *commons-lang* is shown in Table I, where the first column is the version number, the second column is the number of code lines, the third column is the measurement of testability, and the fourth column is the measurement of understandability.

TABLE I
THE BASIC INFORMATION OF COMMONS-LANG

Version	LOC	Testability	Understandability
3.1.0	52.8K	0.800	0.760
3.2.0	61.6K	0.733	0.667
3.3.0	63.5K	0.834	0.667
3.4.0	66.0K	0.834	0.760

Table I shows that, compared with the measurements of version 3.1.0, the measurements of version 3.2.0 are decreased. The decreasing measurements indicate that the architecture is eroded in the evolution process, so we analyze the evolution process. The erosion degree of understandability is -0.093, and the erosion degree of testability is -0.067.

The first step is detecting changed pairs. We implement the multilevel change detection method to detect the changed pairs of file level and statement level, and detect changed pairs of component level based on the component similarity. The number of changed code elements of each level is shown in Table II, where the first column is the change operation, where the second column to the fourth column are respectively component level, file level, and statement level. As the table shows that, there are six changed pairs at the component level, 220 changed pairs at the file level, and 6829 changed pairs at the statement level.

TABLE II
THE NUMBER OF CHANGED PAIRS OF EACH LEVEL

Type	The number of changed code elements		
	Component level	File level	Statement level
Add	1	29	3416
Delete	3	0	822
Update	2	191	1798
Move	\	0	803
Total	6	220	6839

The second step is calculating erosion degree of each changed pairs. We first calculate the erosion degree of changed pairs of the component level, and the values of the erosion degree are shown in Table III, where the first column is the change operation of the component level, the second column is the erosion degree to testability, and the third column is the erosion degree to understandability. In the first column, we

use *update*, *add* and *delete* to represent the change operation, and the corresponding element is the changed component. As shown in Table III, *Add(src-1)* has the highest erosion degree of testability, and *Delete(common\lang3-2)* has the highest erosion degree of understandability.

TABLE III
THE EROSION DEGREE OF CHANGED PAIRS OF THE COMPONENT LEVEL

Change operation	ED_Test.	ED_Under.
Update(common\lang3)	2.380	-2.400
Update(src)	-0.571	-5.700
Delete(common\lang3-1)	0.142	4.100
Delete(common\lang3-2)	-0.570	3.950
Delete(lang3\text)	-0.714	1.850
Add(src-1)	0.333	-0.800

There are 220 changed pairs of file level and 6839 changed pairs of statement level. Due to the limitation of space, we only show the erosion degree of some changed pairs in Table IV, where the first column is the change operation of file level, the second column is the erosion degree of testability, and the third column is the erosion degree of understandability. As shown in Table IV, *Update(TypeUtils.java)* has the highest erosion contribution to testability, *Add(Conversion.java)* has the highest erosion contribution to understandability.

TABLE IV
THE EROSION DEGREE OF CHANGED PAIRS OF FILE LEVEL

Change operation	ED_Test.	ED_Under.
Add(Conversion.java)	0	0.363
Add(InheritanceUtils.java)	0	0.233
Update(CharSequenceUtils.java)	0	0.215
Update(StrSubstitutor.java)	0	0.114
Update(FastDateFormatTest.java)	0	0.112
Update(TypeUtils.java)	0.376	0
Update(FastDateFormat.java)	0.233	0
ADD(TypeLiteral.java)	0.108	-0.057
ADD(FastDatePrinter.java)	0.108	0.087
ADD(Triple.java)	0.108	0.028
ADD(NotImplementedExceptionTest.java)	0.067	-0.086
Update(StringUtilsEqualsIndexOfTest.java)	0	-0.009

The third step is establishing the cost-benefit model based on erosion contribution. There are 6839 changed pairs of statement level, according to the erosion degree of them, we find that, 1027 changed pairs are erosion points for testability and 1453 changed pairs are erosion points for understandability. We sort these erosion points according to the erosion contribution from high to low. We respectively numbered them from 1 to 1027, and from 1 to 1453, then we establish the cost-benefit model. Due to the limitation of space, we only demonstrate the cost-benefit model of testability in Figure 2, where the x-axis represents the number of repaired erosion points, and the y-axis represents the sum of erosion contribution of the corresponding repaired erosion points.

As Figure 2 shows that, the growth rate of the sum of erosion contribution declines with repairing more erosion points, that is, the average benefit is reduced gradually. In

Fig. 2. The cost-benefit model of testability.

the example, we follow the Pareto principle which states that 80% of the effects come from 20% of the causes, so we only repair the top 20% erosion points.

We repair erosion points by rolling back them to their corresponding version. After rolling back the architecture is denoted as the new architecture. We detect erosion degree again based on the 3.1.0 version and the new architecture. The comparison of architecture quality is shown in Figure 3.

Fig. 3. The comparison of architecture quality.

According to Figure 3, we can draw two conclusions. First, compared with the version 3.2.0, the contribution degree is decreased, so the erosion points are detected and repaired. Second, only 20% erosion points are repaired, but the erosion degree falls by over 25%, so the cost-benefit model proposes the repairing priority effectively.

IV. RELATED WORK

The purpose of analyzing architecture erosion is how to locate the erosion points and how to repair the erosion points [10], so we compare our method with related work from the above aspects.

In the aspect of locating the erosion points, most researches propose analysis methods for architecture erosion based on one certain version. There are two main types of indicators, the inconsistency between the requirements and the actual implementation and the improper architecture pattern. Medvidovic et al. use the inconsistency as the indicator [17]. Zhang et al. detect architecture erosion of architectural pattern by the design decision [8]. Herold et al. detect architecture erosion of architecture pattern by the common ontology [7]. However, the above effects of architecture erosion all threaten the architecture quality [7], that is, avoiding the effects on

software quality is the ultimate goal. So, in our method, we use the architecture quality as the indicators to detect architecture erosion.

In the aspect of repairing the erosion points. Terra et al. provide an approach to provide recommendations for removing architectural violations detected by the dependency constraint language [10]. Mair et al. propose a heuristic search method for adequate repairs using formalized and explicit knowledge of software engineers [9]. However, the actual architecture is implemented by its source code [10], so architecture erosion need be repaired by modifying code. So, our method analyzes architecture erosion from multiple levels.

In addition to the above aspects, our method establishes the cost-benefit model for repairing architecture erosion. In order to provide the repairing priority.

V. THREATS TO VALIDITY

Construct validity. We choose the component dependency graph as the representation of software architecture. Due to the limitations of the documents of architecture, we obtain architecture by implementing an architecture recovery method. There may be some deviations caused by the limitations of the recovery method. However, the recovery method has high accuracy, and in the future, the recovery method can be replaced by other better methods.

Internal validity. In our example, we roll back erosion points to their previous version. The experimental results indicate that, after rolling back, architecture erosion is repaired. However, rolling back erosion points may be not effective for maintaining functionality. However, the cost-benefit model is still useful for providing the priority of repairing erosion points.

External validity. In this paper, we choose testability and understandability as the indicators to detect architecture erosion. The two quality are quantified based on the attributes of components and dependencies, so we can use other quality as the indicators if it is quantified based on the features of components and dependencies.

VI. CONCLUSION AND FUTURE WORK

In this paper, we propose a multilevel method for analyzing architecture erosion. Firstly, we detect changed pairs of each level by calculating component similarity and performing a multilevel change detection method. In this step, the changed code elements are matched. Secondly, we detect which changed pairs are the erosion points by calculating erosion degree. Thirdly, we establish the cost-benefit model of repairing architecture erosion based on the erosion contribution of each erosion point. The cost-benefit model is useful to obtain more benefits with less cost. We illustrate the process of our method through an example, and the experimental results indicate that our method can detect erosion points and the cost-benefit model is useful for more effective repairing architecture erosion by repairing fewer erosion points.

In future work, we will investigate how to propose more suggestions for repairing architecture instead of rolling back.

The Affinity Platform:

Modular Architecture based on Independent Components

Alexandru Ardelean, Kuderna-Iulian Benta

Department of Computer Science

Faculty of Mathematics and Computer Science, Babeş-Bolyai University

Cluj-Napoca, Romania

ardeleanalexandru3@gmail.com and benta@cs.ubbcluj.ro

Abstract—This paper presents the Affinity Platform, a plugin platform for developing software systems centered around the idea of Independent Components. “Independent” refers to the ability of a plugin to run on a machine not just as part of a software system but also on its own. This way, software systems can be built out of chains of Independent Components, making it easier to partially reuse their Components and also to extend these systems in the future. The Affinity Platform uses a graphical user interface to represent a software system in the shape of a diagram. By analyzing this diagram, it can generate linking scripts for Components. The Affinity architecture also facilitates the development of distributed and parallel software systems, as Components are capable of operating independently on different threads and machines. The Affinity Platform was used in the development of an emotion recognition application in a multimodal setup running on a mobile and resource-scarce medium. In this scenario, the strongest points of the platform were the ability to offload code to other machines, the ease of adapting the system to different sensor setups, and the convenience of developing Components individually and only having to connect them at the end.

Keywords - CBSE, Independent Component, plugin architecture, platform, chaining.

I. INTRODUCTION

As software systems are becoming more open, modular, reusable, distributed, parallel, and context-aware, developers seem to have a hard time molding their software applications around all these requirements. Extending such systems is also continually becoming more challenging. And the list of must-have features is only getting longer. As the complexity of software systems rises above the level at which a manageable team can efficiently tackle it, new ways of organizing software systems must be developed.

Inspired by audio plugins based on the audio in/audio out paradigm, the Affinity architecture was envisioned for building data flows. The building blocks of the Affinity Platform are called Components [1]. A Component is abstracted as a data-processing unit with multiple channels for input and output and various configuration options. Components can be any software program capable of extracting, processing or delivering data over a medium, requiring at a minimum a channel for data input or a channel for data output. Components can be linked together into chained systems that can be automatically parallelized (on a

per-Component basis) or distributed among multiple machines. Locally available Components are connected via a piping mechanism, while connectivity between Components located on different machines is achieved by interpolating between them other Components responsible for sending and receiving data over the desired medium.

The scenario in which this architecture was tested is that of a context-aware software application for emotion detection. The data flow of the app starts with a Component running on a secondary device (A, a smartwatch) extracting data from multiple sensor setups and sending its output to a more powerful device (B, a smartphone). Device B runs a machine learning algorithm for emotion recognition that processes the data and sends the result over to a remote server (C, a cloud-based API). Device C is represented by a Component that computes a virtual diagram based on the data received from multiple A-B setups. A visual representation of this example is illustrated in Figure 1.

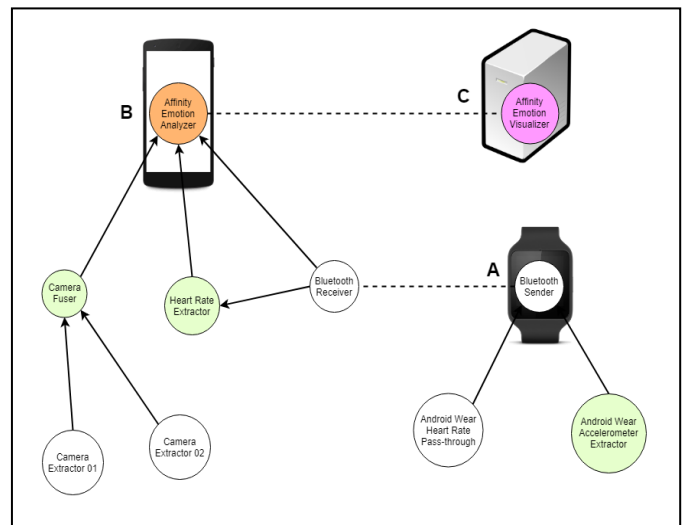

Figure 1. Informal diagram of the main test scenario

The Affinity Platform can be seen as an additional layer on top of regular software systems that connects them together in a protocol-agnostic way. This layer being also language-agnostic and OS-agnostic (Operating System), brings into the discussion a new, higher level programming where applications are written

by simply interconnecting Components. Given a sufficiently large repository of Components, complete software systems could be built from already developed Components.

The main objective of this architecture consists of the realization of chained data systems that can be easily distributed and offloaded among various devices, such as mobile phones, wearables, or autonomous vehicles. This system is meant to serve as an enabler for data science fields but is not limited to them, as this technology has the potential to substantially reduce development time and greatly improve collaboration between vastly different fields.

II. RELATED WORK

Most plugin architectures rely on strict application programming interfaces (APIs) [2] and give little customization options. Other systems, as for example Emacs [4], can be fully customized - including their internals, but have the disadvantage of requiring developers to learn a new and often cumbersome scripting language. Eclipse [5] exemplifies another category of plugin architecture - in Eclipse everything is a plugin, every item included in its menus and submenus. Every plugin has a manifest file that describes the way the plugin works and what interface it requires. Eclipse-like plugins seem to strike the best balance so far, but they are still too hard to use for regular users. React Components [6] are also greatly appreciated by the developer community. They are similar in functionality to plugins but have the advantage of being able to work independently of their parent system. The Affinity Platform builds on these predecessors but adds the concept of treating even fully-fledged applications as possible Components. This, together with its high level of generality, makes Affinity stand out among traditional plugin architectures and gives it the status of a platform for plugins. A comparison of these traits is presented in Table I.

Chimera [7] was chosen as the best fitting solution for linking Components due to its closely related philosophy to the Affinity Platform. It is a language-agnostic component-based framework capable of orchestrating independent applications. It is boasting similar ease of use and compatibility to the UNIX pipe system [8] while being more advanced, adding support for features like distributed and parallel computing.

TABLE I. COMPARISON OF THE AFFINITY PLATFORM FROM THE POINT OF VIEW OF PLUGIN ARCHITECTURES

	Plugin Architectures			
	<i>Emacs</i> [4]	<i>Eclipse</i> [5]	<i>React</i> [6]	<i>Affinity</i>
Extendable	✓	✓	✓	✓
Full customizability of resulted systems	✓	X	✓	✓
Full control over the granularity of plugins	✓	✓	✓	✓
Independent plugins	X	X	✓	✓
Easy to use for individuals	X	X	✓	✓
No previous programming knowledge required	X	X	X	✓
High level platform	X	X	X	✓

Chimera was considered as the starting point of the Affinity Platform but needed a series of improvements. The main complaint with Chimera is that it requires users to learn the CHIML [9] markup language. To improve on this, a graphical user interface (GUI) was designed in ordered to empower users to easily discover Components and connect them together. It makes use of diagram representations to express software systems in a way that can be easily managed and understood. Main features of this GUI include the ability to search for the desired Component, add a Component to the diagram, change the configuration options of a Component, and connect the channels of two Components. In the end, a diagram can be used to automatically generate the corresponding CHIML script. This interpretation phase allows for certain optimization procedures to be carried out, such as seamlessly adding parallelization to the resulting script.

In order to chain Components running on mobile devices, the terminal emulator Termux was used to achieve compatibility with the Node.js run-time environment on the Android operating system. Making use of Termux, CHIML scripts were able to run on an Android mobile phone. The main differences between the mentioned piping mechanisms are illustrated in Table II.

III. OVERVIEW

The Affinity Platform is built on the concept of fully independent Components. They are considered the building blocks of Affinity-developed software systems but are fully capable of operating completely on their own outside of their parent system. This kind of architecture closely follows core software engineering principles such as being low in coupling and high in cohesion.

Compatibility is a strong point as any existing application can be easily integrated into the Platform as long as it can be invoked by using the command line or is actively listening for data. Each Component must define a number of input channels and output channel, together with a set of configuration options that can be specified by the user. These characteristics can be defined using JavaScript Object Notation (JSON) in an “affinity_component.json” file or, for applications built using Node.js or related frameworks, they can be included straight into the “package.json” file.

TABLE II. COMPARISON OF THE AFFINITY PLATFORM FROM THE POINT OF VIEW OF SOFTWARE PIPING MECHANISMS

	Piping Mechanisms		
	<i>UNIX Pipe</i> [8]	<i>Chimera</i> [7]	<i>Affinity</i>
Language agnostic	✓	✓	✓
Distributed computing	X	✓	✓
Parallel computing	X	✓	✓
Support for mobile platforms	X	X	✓
No previous programming knowledge required	✓	X	✓
Visual interface	X	X	✓

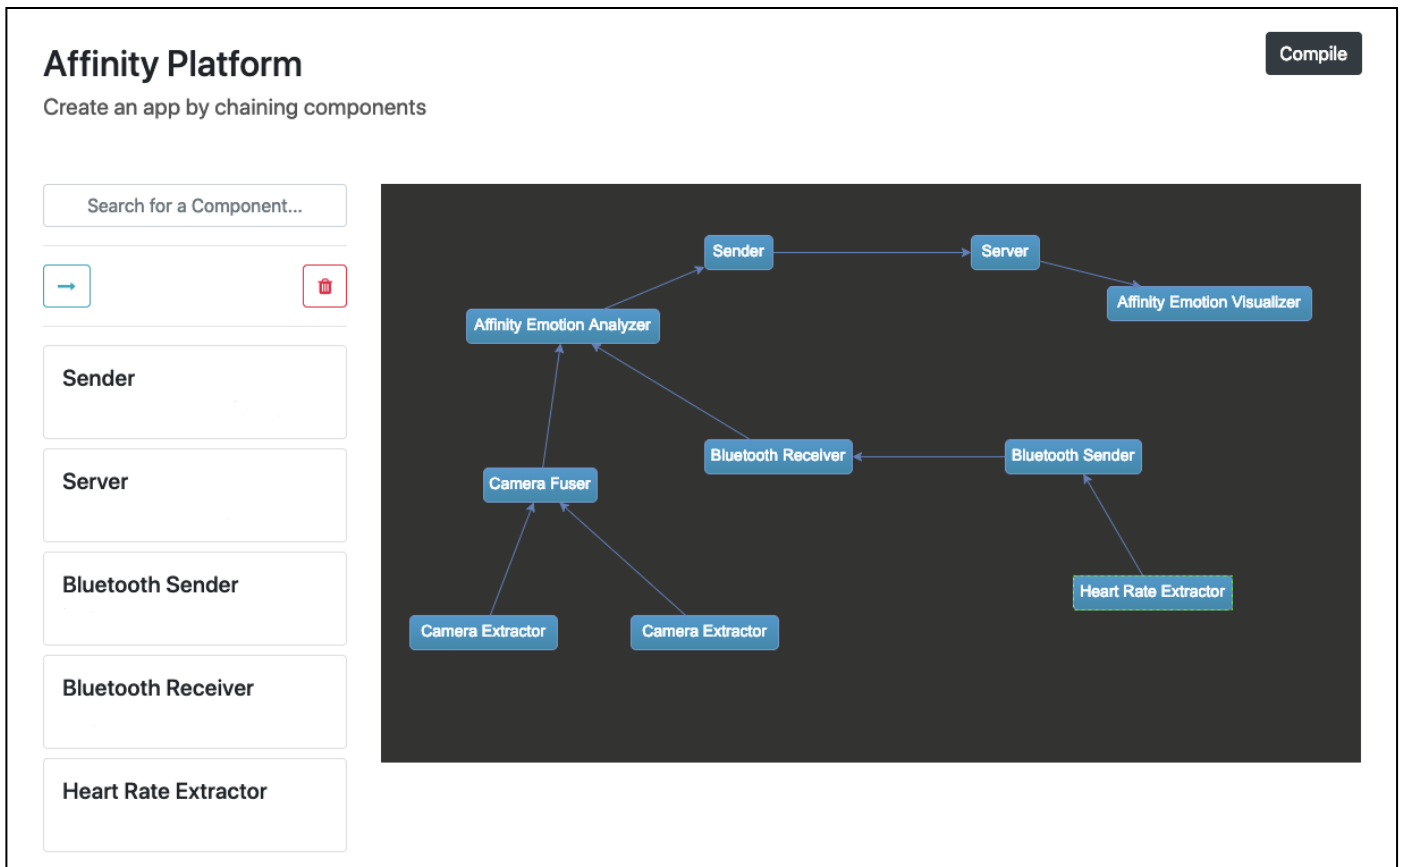

Figure 2. The graphical user interface of the Affinity Platform

Other than building software systems from scratch, the Affinity Platform can also be used to add plugins support to already existing applications. This is done by simply exposing input and/or output channels of the app, transforming it into a Component. Afterward, new modules can be added by connecting other Components to these channels.

Connections between Components are specified from an output channel to an input channel and can be routed in varying degrees of complexity. Interpolating Components gives developers abilities like broadcasting data to multiple Components, selectively sending data to the best available machine, and fusing together data coming from multiple Components before it gets processed.

The way inputs and outputs are connected is described in a CHIML configuration file. To make writing these files easier, a GUI application for generating CHIML configurations out of system diagrams is made available to developers. Diagrams are built using the mxGraph [10] JavaScript library, making advanced editing options readily available. The current state of the visual interface employed by the Affinity Platform can be observed in Figure 2. At the moment, finishing touches are added to analyzing these diagrams and generating optimized CHIML files out of them. Scripts auto-generated from diagrams can be edited in case a lower level of control is desired.

Components can be connected through the Chimera piping system or through any communication channels such as

Hypertext Transfer Protocol, WebSocket, Remote Procedure Call, Bluetooth Low Energy etc. implemented by other Components. The inter-compatibility of input and output channels is not guaranteed as Components are not limited by the communication medium or data representation. These are left as choices and they are not imposed as a responsibility of the Component. Developers can easily achieve compatibility between dissonant Components by defining inputs and outputs that support different data representations or by incorporating additional Components to act as translators between common data representations or communication mediums.

IV. RESULTS

The Affinity Platform was envisioned during the development of the main Affinity software application. A simpler way of making the Affinity Emotion Analyzer and its related algorithms available to the public was needed. A high level of reliability and ease of use were desired in order for other researchers to not just be able to extend and reuse this work but to actually make it easy to do so.

Using the Affinity Platform, the main Components of the Affinity application are exposed in an individual manner. This means, for example, that if somebody wants to use just the Affinity Emotion Analyzer, it could easily take it out of the system and integrate it.

The results confirm that using the Affinity Platform can improve the reusability of a software system and its Components up to a state where they can be considered future-proof. In this regard, the life expectancy of a Component is similar to that of an audio plugin. A Component becomes obsolete only when there is no longer a machine that can run its code or in the improbable case that its communication medium is not supported anymore and there is no way of adapting it to a different medium. This is different from the way in which regular plugins are added to an application as it doesn't require strict version compatibility. In extreme cases, a component could be run on a totally different system, in a Docker container for example, where all its dependencies are already met and thus ensuring long-lasting compatibility.

What is even more impressive is that this is achieved with minimal overhead on the part of developers. The only change that they need to make is adding a simple manifest file to their apps in order for the Affinity Platform to be able to identify them as Components and manage their input and output channels. This manifest file contains only the critical information about how to invoke a Component, how to transfer data through it (more specifically, its channels), and what configuration options are available for it. Usually, this file is only a few lines long. An example of how a minimal manifest file looks like is given in Figure 3.

V. DISCUSSION

The results obtained in this experiment are indicative of the potential of the Affinity Platform. Nonetheless, these are only early results and what could be accomplished goes far beyond what was presented in this experiment.

At this moment, the Affinity Platform is built around the concept of Components but, as better understanding is gained over the capabilities of these Components, we start to see how smart and independent they could become in the future. Components with the ability to reshape the connections of the system that they are part of are an interesting proposition. They could be the basis for integrating intelligent agents [11] in the Affinity Platform, using them to create smart connections between Components - connections made as a result of the data the agent has about its other Components. For now, the platform is closer related to component-based systems but it has strong ties to intelligent agents and might prove to be a powerful tool for building agent-oriented systems [12].

Concrete challenges of such a platform could be better understood when an affective aware developer aims for high precision in multimodal mobile affective applications [13].

  "out": ["Fused features"],
  "command": "camera-fuser -2"
}
```

Figure 3. Example of an affinity_component.json file

Real life (mobile) facial expressions recognition systems are also demanding for high computing resources [14].

VI. CONCLUSION AND FUTURE WORK

This paper discusses the practical and theoretical aspects of using a data-driven plugin architecture in Affective Computing [3] and, more specific, context-aware applications.

Another area where this architecture could lead to substantial advancements is in Artificial Intelligence (AI) systems for writing software programs. As Components become more specialized, they start to represent more granular pieces of programming code, chunks of code similar to the ones that programmers write intuitively after they get accustomed to solving a recurring problem. AI could use these pieces to write complete programs on its own by simply making connections between Components. By gaining knowledge about the Components used in a system, AI could also describe the use of a system and make educated guesses about what it can do.

Currently, intelligent agents are thought to be the next step in developing the Affinity Platform. Integrating Components that can alter the inner linking of a system in order to better adapt to their goal brings forward new ways of thinking about the platform.

Abstract—In the past few years, data lakes emerged as a trending topic in big data technologies. Although literature presents different points of view related to its functionalities, it serves mainly to store a variety of data in a big data context. In this paper, we aim to identify and analyze data lake definitions and possible architectures. Our methodology was composed of a systematic literature mapping based on PRISMA, software engineering best practices to perform reviews, and Kappa method to assess results' quality. We performed the search in eight different electronic databases to achieve a wide variety of publishers in Computer Science. We first identified 662 papers matching our search criteria; after filtering, we selected 87 papers for review. We found that the term data lakes was first defined by James Dixon in 2010. We also found that the term is often related to raw data repositories. From the identified definitions, we propose a new one as a means to better state what data lakes refer to and improve how the community use them. Moreover, we found that Hadoop and its ecosystem compose the most used toolset to create data lakes, revealing that this is the mainstream in architectures for data lakes as of today's available technologies.

Index Terms—Data lakes, Big Data, Literature review, PRISMA, Hadoop.

I. INTRODUCTION

Data lakes are a recent and trending topic in big data context [24], [81]. It is often referred as an architecture to store big data. They are often compared to traditional data warehouses, but both concepts differ in several aspects. For instance, unlike data warehouses, data lakes can easily scale and have the ability to store schema-less and multivariate data that will be processed just when information needs to be extracted from the stored dataset [8], [13], [38], [44], [80]. This native characteristic makes data lakes quite suitable for big data ecosystems.

Although the concept was first used in earlier 2010 [20], it was adopted by academia only a couple of years later. Thus, there is no consolidated and universally accepted definition, and its functionalities vary according to the context. For example, some say it is only a data repository [30], [43], [86], while others say it is a complete ecosystem, from data acquisition to information visualization [9], [55], [62]. By having these different functionalities, data lakes also present different possible architecture configurations.

The foundation architecture to create a data lake may be different according to some variables, such as its purpose, the skills of the people responsible for creating it, the available

infrastructure, and tools. For example, when considering the Hadoop Ecosystem, there are more than a hundred tools available for it [22], with thousands of possible combinations among their use. Knowing which ones are most commonly used or those that are most commonly reported in the literature may be useful for novices on big data, who need to set up an initial data lake, and also for those who are more experienced users, who might want to know new tools to add advanced features to an existing data lake.

Therefore, the aim of our literature review was to better understand what definitions have been used by the research community for the term 'data lake', and to propose a more comprehensive definition to facilitate and improve its use. Additionally, we also aimed to identify which big data architectures are used to build a data lake as well as to map the associated tools to do so.

More specifically, we performed a systematic mapping study in eight electronic databases. From the 662 identified papers, we selected 87 papers for review after filtering. We used the PRISMA checklist [59] to help us improve the quality report of our study, and the process suggested by Kitchenhan et al. [11] to plan the steps to be followed. To enhance results quality and measure the level of agreement between the researchers, we used the Kappa [54] method. To reduce bias, two researchers analyzed the selected papers and two others were consulted to resolve disagreements.

Our study revealed that James Dixon was the first author to use the concept of data lake to refer to a solution to store raw data in a Hadoop ecosystem, in 2010 [20]. The first conference paper to cite the term is from 2014, by O'Leary [63]. We also found that the terms most frequently associated to data lake are: *store*, *raw*, *repository*, *formats*, *analysis*, *storage*, *processed*, and *sources*. About data lake architectures, Hadoop is the most commonly used, stand-alone or in combination with other tools, such as Spark and NoSQL databases. The remaining sections present our study and results in details.

II. MATERIALS AND METHODS

A systematic mapping study, also known as mapping study (MS), is a type of literature review, a research method largely used to understand the state of art of some subject, and it allows us to map its origins and also how it developed over time, based on research questions. To develop our MS, we follow the process defined by Brereton et al [11]. These authors suggest three phases, namely Plan, Conduct, and Document

TABLE I
PICO AND PICO DEFINITIONS

PICO	PICO
Population: Big data systems	Population: Big data systems
Intervention: Data lakes	Interest: Definitions and architectures
Comparison: Definition of data lakes	Context: Data lakes
Outcome: Definition of data lakes and big data architectures in data lakes ecosystems	

the review, having ten stages to develop these phases. We also use the Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols (PRISMA-P) [59] checklist, that has a set of items that must be addressed to report a systematic review, as described next.

A. Plan Review

In the Planning Phase, we defined research questions, and developed and assessed the review protocol. This phase must be done carefully because of its basis all subsequent research.

1) *Specify Research Question:* Our main objective is to answer the following Research Question (RQ): ***What are the definitions and possible big data architectures in data lake ecosystems?*** To better explore the papers, we splitted RQ into two, so each accepted paper can answer one or two questions: 1) *What are the most common definitions to the term data lake?* 2) *Which system architectures are reported to be used in data lake ecosystems?*

Aiming to limit and clarify our scope, we followed the PICO (Population, Intervention, Comparison, and Outcome) and PICO (Population, Interest, and Context) methods. These were initially developed by Sacket [72], to facilitate the elaboration of research definitions. PICO are most used for quantitative studies, while qualitative studies usually apply PICO [89]. As a MS can contain both qualitative and quantitative data, we used PICO and PICO to help us elaborate our research question. We present the scope of our research in Table I.

2) *Develop Review Protocol:* We developed and applied our search protocol using digital libraries available in the internet. We defined control studies so we could validate our search strings. A control study is an primary study resulting from systematized research, and which is known to answer our research questions. We used it to check if the search strings are adequate: if the control papers are not returned during string adjustments, the strings need to be adjusted until they do so. We used the two papers listed in Table II as control papers. Table III lists the used electronic databases and search strings.

TABLE II

TABLE III
SEARCH STRINGS FOR EACH ELECTRONIC DATABASES.

Database	Search String
Springer	search?query="data+lake"&facet-language="En"&date-facet-mode=between&showAll=true&facet-discipline="Computer+Science"
Google Scholar	allintitle: "data lake"
Scopus	TITLE-ABS-KEY (data lake) AND (LIMIT-TO (SUBJAREA , "COMP")
Web of Science	(from all databases): TOPIC: ("data lake") OR TITLE: ("data lake") OR AUTHOR IDENTIFIER: ("data lake")
IEEE Xplore	((("Document Title": "data lake") OR "Abstract": "data lake") OR "Author Keywords": "data lake")
Science Direct	Title, abstract, keywords: "data lake"
arXiv	order: -announced_date_first; page_size: 50; primary_classification: cs; terms: AND all="data lake"
ACM	acmdlTitle:(+data +lake) AND recordAbstract:(+data +lake) AND keywords.author.keyword:(+data +lake)

It is important to note that we did not set a data range for the search. Returned results from as early as 1969 to 2013 referring to data lakes, upon inspection, were identified to discuss geological lakes. Thus, given that these do not relate to Computer Science, we discarded them; having the first paper of interest reported in 2014.

3) *Validate Review Protocol:* Two researchers developed the review protocol, who made several trials changing the search string to obtain results relevant and aligned to the research question. Then, the protocol was validated by two other senior researchers with a PhD degree in Computer Science. One of these researchers is a domain specialist in databases and big data and the other in research methodology. The study was conducted based on the updated protocol upon their reviews, as presented next.

B. Conduct Review

We conducted the study as per the defined protocol.

1) *Identify Relevant Research:* We applied the defined search string and, from the results, generated a bibtex file format for each electronic database. Bibtext is a plain-text file-format that contains lists of references, with information about all paper that matches our search criteria.

2) *Select Primary Studies:* To reduce bias, we splitted the papers to be analyzed between two researchers. We start selection phase with 1st researcher reviewing and marking each paper as accepted or rejected. Then, we perform three review rounds, based on Kappa method [54], each one containing a random sample of 5% of the papers population that was reviewed by the second researcher. We used the Kappa statistic [54] to measure the level of agreement between the researchers. Kappa result is based on the number of answers with the same result for both observers [46]. Its maximum value is 1, when the researchers have almost perfect agreement, and it tends to zero or less when there are no agreement between them.

TABLE IV
KAPPA RESULTS, BASED ON LANDIS & KOCH [46].

Kappa values	Agreement	1° round	2° round	3° round
<0	Poor			
0 – 0,20	Slight			
0,21 – 0,40	Fair			
0,41 – 0,60	Moderate	0.42		
0,61 – 0,80	Substantial		0.64	
0,81 – 1	Almost perfect			0.82

For each round, the 2nd researcher received a sample, analyzed each paper, and marked each one as accepted or rejected. Then, we compared the answers: if 1st and 2nd researchers accepted the same paper, we have an agreement in that paper. Then, we calculate Kappa value for the round. After that, in the papers where there is no agreement, the two main researchers discuss about the paper to reach a consensus. If there is still no consensus, the other researchers are contacted to help decide.

Landis & Koch [46] define a scale to interpret the Kappa results (see Table IV). We can also see in this table the results from the 3 rounds of analysis. We can see that the level of agreement increased, from moderate in the 1st round to substantial in the 2nd one, and in the last we achieved almost perfect agreement. In each iteration, we discussed the results and the reasons why some papers had been selected and other had not, improving the agreement between the researchers on the next iteration. From that, the second researcher received the second-half of papers to independently review.

3) *Assess Study Quality*: In order to retrieve interesting results related to the research topic, we defined inclusion and exclusion criteria for the papers. To be accepted, papers must meet all the following criteria: 1) Be a qualitative or quantitative research on data lakes in data management; 2) Present a complete study in electronic format; 3) Be a conference paper, review or journal. On the other hand, papers we rejected meet at least one of the following criteria: 1) Incomplete or short paper (less than 3 pages); 2) Unavailable for download; 3) Not about data lakes in data management; 4) Duplicated study; 5) Written in another language than English; 6) Conference proceedings index.

4) *Extract Required Data*: To help us organize and classify the papers, we used a tool named StArt (State of the Art through Systematic Review)¹. StArt was developed by the Federal University of São Carlos, Brazil, and it helps researchers in the process of systematic literature reviews. StArt has a execution phase with 3 processes: studies identification, selection, and extraction. We first register the protocol, and then we register each database and import its bib file, then use StArt to help keep record of selected papers. After finishing all data extraction using StArt, we exported the results to a Google Sheets, so we could analyze the data.

5) *Synthesize Data*: We used Google Sheets to help analyze and summarize our results. It also helped to work collabora-

tively, as Google Sheets is available online.

C. Document Review

1) *Write Review Report*: After finishing answering the questions of the MS, we use our protocol as a basis to document the Review. Results are presented in Section III.

2) *Validate Report*: Once we finished the report, it was independently reviewed by three senior researchers. Each one read and suggest improvements that were adjusted to this final version.

III. RESULTS

We started with 662 papers retrieved from the initial search through the web engines. During the process, we identified that 155 are duplicated, and 419 were rejected according to exclusion criteria previously explained. At the end of MS process, we accepted 87 papers, published between 2014 and 2018. Table V presents the distribution of papers per database. In this table, we can see that most of the papers came from Springer and Google Scholar. It happens because Springer does not allow us to refine the filter of the studies, so results contains lots of books and books chapters, which we reject, as we explained in inclusion and exclusion criteria. Google Scholar, in the same way, does not allow complementary filters, frequently redirects to other engines, and it also brings a lot of websites and non-scientific reports among the results.

Among the rejected papers, 75 were published before 2010, when the term data lake was first used in big data context. We have to manually reject the older ones due to the fact that in most electronic databases we cannot filter results to show only Computer Science related studies. The papers previous to 2010 are mostly from Geology or Civil Engineering. We found that there is an increasing interest in data lakes, since 2014, with most papers being published in 2018.

Other interesting aspect we can see in Table V is that more than half papers we accepted are from Scopus. It happens due to the fact that Scopus is the largest database of abstracts and scientific citations, compiling more than 71 million records, 23 million titles and 5,000 publishers, among them ACM, Elsevier, IEEE, Springer, etc. So, we probably accepted papers

¹ Available at: http://lapes.dc.ufscar.br/tools/start_tool

from other databases using Scopus reference, and then it was marked as duplicated in the original database version.

From the 87 papers we accepted, 71 present data lake definitions. We read each one and copied the definition they present to the term data lake. Then, we created a unique text containing all definitions, and we passed through a web tool to count the words. This tool removed the stopwords, the most frequent terms in English, that are usually removed before natural language processing. Then, it returned a list containing all the other words and the amount of times they appear in the text. We analyzed the resulting list and grouped the variances in the same word, by the most frequent one: e.g.: *analyses*, *analyzing*, and *analysis* were grouped into *analysis*. Table VI presents the top 30 most frequent words. Then, based on the most frequent words, we create a word cloud (Figure 1) and a new definition to the term data lake, presented below.

During our analysis, we mapped who the authors of the papers references when using a definition for data lakes. We found that James Dixon was the first one to use the term lake in big data context, in a post in its blog in 2010 [20], and he is referenced by ten papers [4], [6], [17], [32], [38], [44], [62], [63], [67], [91]. The first author to reference Dixon’s Concept in academic context was O’Leary [63], in a paper published in 2014. We also discovered the most cited academic definition for data lakes is from Terrizzano et al. [87], mentioned in twelve papers [5], [26], [27], [33], [34], [52], [66], [78], [82], [84], [91], [93].

TABLE VI
30 MOST FREQUENT WORDS RELATED TO DATA LAKE DEFINITIONS.

B. Which system architectures are reported to be used in data lakes ecosystems?

1) *Ingestion*: Class of tools that work on data acquisition and collection, from the most varied sources. In this group, the most cited tool is Apache Kafka, which consists of a high-capacity, low latency distributed streaming platform for real-time data processing.

3) *Processing*: Tools in this group are responsible for analyzing, processing and transforming the raw data, so we can extract information from it. In this group, Apache Spark is the most cited in all papers, besides Apache Hadoop. It is a framework for distributed computing that provides an interface for clustered programming with parallelism and fault tolerance.

TABLE VII
ARCHITECTURES: THE MOST USED TOOLS IN DATA LAKES

Tool	Amount	Papers
1) Ingestion

Apache Ambari	2	[55], [71]
Apache Knox	2	[31], [71]
Apache Sentry	2	[31], [71]

5) *Security*: Includes tools to manage system authentication and authorization, assure data security, permit auditing, and allow data encryption. Apache Ranger is the most mentioned. It is a framework for activating, monitoring and managing data security in the Apache Hadoop ecosystem. According to our analysis, the Apache Software Foundation (ASF) develops most of the tools reported in the studies for data lake architectures, helping creating the most used ecosystems.

IV. CONCLUSION

In this paper, we presented a systematic mapping study to better explain data lakes definition and architecture. We started with 662 papers, and we end up with 87 in the final set, after our criteria selection. The papers we selected are from 2014 to 2018, and came from eight different electronic databases.

We learned that the term data lake was first used in 2010 to designate a big data system. We proposed a new definition from the selected papers in our study for the concept data lake. We also found that Hadoop and its ecosystem comprises the most frequent architecture to built data lakes.

One limitation of our study is that we choose to limit the search only to the papers that have the term "data lake". We know that many researchers can be working with data lakes without using this buzzword, but as we want to know its definition, we chose to accept that limitation. For future work, we plan to further the investigation on the used tools and architectures, discussing the categories we listed and building a framework to help beginners to choose the best configuration according to its needs.

Abstract— Collaborative e-learning based on several means of electronic communication mechanism specifically internet and web2.0 (such as forum, virtual classroom, videoconference, etc.) has become the current trend in e-learning systems. The cloud computing environment presents itself an important infrastructure for supporting these collaborative e-learning systems and for optimizing these service-based systems in a multi-tenant way. In this paper, we discuss the problem of discovering multi-tenant e-learning processes. For this, we propose an architecture for a configurable learning process discovery environment and the allocation of resources (Saas, Paas, Iaas) necessary for the execution of the corresponding learning activities.

Keywords- *Discovery e-learning process; collaboratif e-learning; business process; resource allocation; cloud computing.*

I. INTRODUCTION

E-learning is defined as Internet-enabled learning [1]. E-Learning components can include multi-format content, knowledge sharing, inclusion of collaboration tools, and social networking. It is important to emphasize the value of collaboration and knowledge sharing between learners and teachers in e-learning systems. In this context, great attention is given by researchers, developers and educators to collaborative learning through Learning Management Systems (LMS). However, several studies in literature show some limitations of these e-learning platforms (LMS) [4] [5] [6]. These limitations are mainly at the level of collaboration and interaction between different actors of an e-learning activity; they based mainly on texts and photos. The form and effect of collaboration and interaction are relatively simple and limited.

DOI reference number: 10.18293/SEKE2019-136

So, it is unrealistic for each school to offer its own e-learning system that responds to learner expectations and manages the new neo-digital society. In order to remedy these different LMS deficiencies, we have contributed in previous work [7] to a general, collaborative, configurable and multi-tenant e-learning system. The collaboration we propose is synchronous and asynchronous. And we also suggest using the business process line approach (BPL) inspired by the Software Product Line (SPL) approach for the development of multi-tenant e-learning applications. The proposed general e-learning process could be implemented in a variety of contexts and accommodates the different needs of universities and teachers. However, all variants of our model share a set of common elements / activities and others differ by some variable activities.

Thus, the adoption of an SPL and BPL approach in the field of e-learning seems to be a promising solution. On the one hand, it overcomes the limitations of LMS systems, and on the other hand, it provides institutions with e-learning applications tailored to their needs.

Motivated by the difference and diversity of the needs of tenants (teachers / learners), institutions are looking for e-learning systems available outside their organizations that are rapidly adapting to the new demands of their teachers and learners and reducing costs of development and maintenance. Cloud computing is the best solution because of its ability to outsource service-based learning processes with a pay-per-use model.

According to the National Institute of Standards and Technology (NSIT), cloud computing is a model that allows providers to share their resources (services, networks, storage servers, and applications) and the users who access them in a ubiquitous, and convenient way of request [8]. In a multi-tenant environment, the use of a configurable learning process provides configurable learning that can be configured by different tenants based on their specific needs

[9]. Different approaches for modeling multi-tenant configurable processes have been proposed; mainly they focused on configurable business process discovery and focused on configurable resource allocation. Thus, in this sense, we propose a discovery architecture of learning services considered as business processes in the cloud. In our architecture, we also offer discovery of other SaaS, PaaS, IaaS cloud services and collaborative web2.0 services that facilitate the deployment and execution of all types of learning activities in different contexts. But some activities require a wide bandwidth or a very powerful CPU; other activities require collaborative web2.0 applications and SaaS services to be executed.

In order to overview all these aspects, this contribution is arranged as follows.

In Section 2 we introduce the main concepts of Cloud Computing, e-learning including its infrastructure and main layers, configurable learning process, multi-tenant and resource allocation.

Next, Section 3 describes our proposed architecture. Finally, the main concluding remarks are given in Section 4.

II. PRELIMINAIRES

In this section, we give a brief description of related topics, which are utilized in this work.

A. Configurable learning process

The world of education and training has embraced new methods and new pedagogical tools. Since the computer, at first, and the Internet, then, have appears in classrooms, departments but also and especially in the daily life of each of the actors involved, the school (in the most generic sense of the term) is engaged in a real race to stay the more possible in line with the reality of society. Each school faces a major challenge, which is the development of a learning system that manages IT innovations and meets the needs of teachers / learners knowing that they do not cease to evolve. Starting from this point, there comes the idea of developing a configurable e-learning process. A configurable process model allows the sharing of a process between different tenants, which can be customized according to specific needs. To model a configurable learning process, one must study the variability of this process. In our work, we view the e-learning process as a multi-tenant business process and each tenant can choose a sub-process (configuration) of the overall process. With respect to business process variability, tenants can have varying business workflows. Therefore, the application must allow configuration and customization to meet the tenant's goals and requirements [23]. In previous work we have presented the modeling of a multi-tenant configurable general e-learning process [7,24].

B. Cloud computing and e-learning

Cloud computing uses a new technology that develops applications in a way that allows both the execution of the application and the storage of data to be performed ubiquitously for all users. Cloud architecture provides user support at different levels that vary according to their

different characteristics. The different levels can be described as follows [3]:

- Infrastructure as a Service (IaaS): remote management and control of hardware resources provided by a system.
- Platform as a Service (PaaS): offers the cloud platform along with a series of libraries to develop applications in which the distribution of tasks, the persistence and other layers are transparent for the developer.
- Software as a Service (SaaS): consists in offering different applications to be used through the internet as opposed to a local installation.

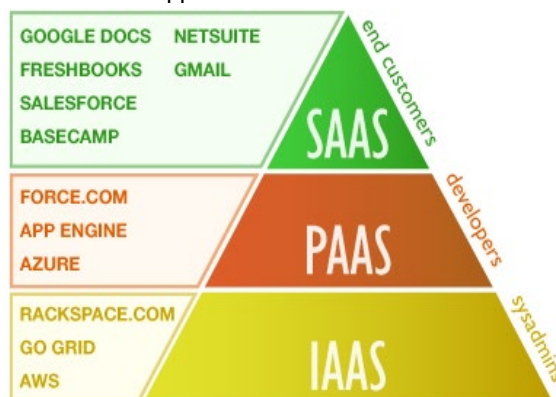

Figure 1. Illustration of the layers for the Services Oriented Architecture [12]

There are incipient developments that broach the topic of cloud technology and e-learning [2], however few studies incorporate both concepts. The success of the solution software as a service (SaaS) is real and is easily applicable for e-learning. Cloud computing, SaaS and e-learning are completely complementary. Accordingly, we note that the focus on changing traditional e-learning systems to more collaborative interactive learning environments has increased. J. Méndez & J. Gonzalez [3] highlights limitations of traditional e-learning pointing that system creation and maintenance are placed inside the educational institutions, which can cause a lot of problems including huge investments with no gain and lack of development potential. In 2009, cloud computing is presented by [20] as a new computing model to implement e-learning ecosystem to overcome the problems in the traditional system. The author considers that cloud computing is able to add some critical features to e-learning ecosystem, such as: configuration at real-time, utilization of resources, on demand resource sharing and better management for software or hardware [20]. The cloud-based system supports the construction of a new generation of e-learning systems that is accessible from a wide range of hardware devices, while storing data inside the cloud.

B. Dong & al., [22] proposes a platform architecture based on the integration of cloud computing and web 2.0 for developing intelligent virtual learning community and makes the learning environment more productive, scalable, flexible and adjustable towards students demands and needed

information and communication technologies. The author states that the usage of cloud computing and web2.0 for e-learning affects the way e-learning software projects are managed and the proposed intelligent virtual learning community enhances the efficiency of learning environment, provides up-to-date resources, constancy, guaranteed quality of service, dependability, scalability, minimized time, efficient usage of resources, flexibility, and maintaining of e-learning system.

Within the same context, Ouf, Nasr and Helmy [21] have proposed an e-learning system based on the integration of cloud computing and Web 2.0 technologies to meet the requirements for e-learning environment such as flexibility and compliance towards students' needs and concerns, improve and enhance the efficiency of learning environment.

Aljenaa & al., in [23] introduced the main components of a system of effective e-learning through using cloud computing technology. The authors insist on the importance of the following components:

- "Cloud software platform" which contains the LMS platform and the necessary tools of collaboration and communication to meet the needs of learners throughout the process of learning;
- "Operational and management components" to make the management of the learning process;

C. Multi-tenancy

Multi-tenancy being one of the key features of service in cloud, the service providers can offer single application to multiple users. A multi-tenant application caters a personalized customer experience improving performance and efficiency and provides a flexible space for customers to efficiently pursue new business demands. From the software vendor perspective, such multi-tenant applications, improve resource utilization and reduce the operational costs in delivering the software as a service. Each of the tenants may have unique requirements that differ from each other. Customization plays a vital role to converge specific requirements of every tenant. It is up to the vendor, what extent of customization to be offered to the tenant [10]. Two main goals of multi-tenancy are isolation and sharing, which are contradictory [11]. As we discussed in the introduction, the primary motivation of multi-tenancy is to enable management of the needs of universities/learners that are rapidly changing and diversified. However, at the same time, each user needs complete isolation and often does not want to know even the existence of the other users. Furthermore, a multi-tenant setup will inevitably attract more requests, and therefore must be scalable. Scalability in a multi-tenant setup has several dimensions: that is supporting large number of requests, processes, and tenants [11].

D. Resource allocation in cloud-based Business process

In previous work, we considered e-learning processes as business processes, because of the similarity between the two in the orchestration of learning activities and that of business

processes [7]. Thus, we use the BPFM approach for modeling configurable e-learning processes in the cloud. Running a learning process requires IaaS-level resources that can be distributed across virtual machines (VMs), SaaS services and applications, and PaaS platforms. Until today, research on business process discovery in the cloud and resource allocation has been rare. There are works such as [13, 14], which focus on the allocation of human resources. Some other works explicitly consider the characteristics of the cloud: In [18], the authors proposed an approach for configurable cloud resources allocation in multi-tenant business process. Their aim is to shift the cloud resource allocation from the tenant side to the cloud process provider side for a centralized resource allocation management. Through configuration, different tenants can easily customize the selection of the needed resources taking into account two important properties: elasticity and shareability.

S. Schulte & al. In [15, 16] develop a Platform for Elastic Processes, which combines the functionalities of a BPMS with that of a Cloud resource management system. Recently, work in the area of configurable process modeling has been proposed with perspectives for resource allocation. La Rosa & al. In [25] Offer C-EPC (configurable event driven process chains) with resource, data and physical object capture capabilities. However, they focus on human resources and there is no support for cloud resources. In [17], A. Hallerbach & al. Extend process variants with options (Provop) to properly model and manage large collections of process variants. Juhnke & al. [18] provide an extension to a standard BPEL workflow engine, which allows the use of Cloud resources to execute business processes. The same applies to the work by Bessai & al. [19], who also assumes that workflows are composed of single software services. The authors offer different methods to optimize resource allocation and scheduling, pareto-optimal solution covering both cost and time. E. Hachicha & al. [26] proposed an approach for configurable cloud resource allocation in multi-tenant business processes and to shift the cloud resource allocation from the tenant side to the cloud process provider side for a centralized resource allocation management. Table I summarizes these approaches and relates them to properties that are important in a cloud setting. We observe that resource variability, cloud features, and allocation are only partially covered or not at all. In the following, we aim to fill these gaps by the definition of our novel approach which allows the configurable e-learning process discovery and allows the cloud resources allocation needed for the learning activities execution such as IaaS, PaaS and SaaS.

E. Discussion

We can conclude by considering that all these research works concerning the systems of e-learning in the cloud, integrating the multi-tenant aspect and allocating the resources needed to execute an e-learning process suffer from some limits namely:

The absence of a complete initiative or approach for the construction of an agile and reconfigurable process of learning adaptable to change and being able to evolve to meet the needs of learners;

- Lack of collaboration in learning processes and limited re-use possibilities from the processes deployed by other universities/teachers;
- The allocation of resources in the cloud is limited to the infrastructure level.

In our research work, we considered an e-learning process as a multi-tenant configurable business process in the cloud (BPaaS) and to achieve this goal we combined the Software Product Line (SPL) and Business Process Management approach (BPM).

In the next section we will:

- Provide an approach for discovering a multi-tenant configurable e-learning process and configurable cloud resource allocation.
- The allocation of cloud resources (IaaS, PaaS, SaaS) configurable in multi-tenant e-learning process.

III. MULTI-TENANCY AWARE CONFIGURABLE LEARNING PROCESS AS A SERVICE DISCOVERY ARCHITECTURE

The goal of this research work is the development of multi-tenant, configurable and collaborative learning process, that utilizes BPM and SPL for modeling the learning process and cloud computing. In cloud computing environments, there are two actors: the providers and the cloud computing users. On the one hand, suppliers hold massive resources in their large data centers and rent these resources to users. On the other hand, there are users who have applications with various loads and rent resources from the providers for running their applications. Once the final deployment solution has been defined and the learning process is deployed, multi-tenant configurable learning process description are created and published by learning process providers into service registries hosted in cloud data centers. In the datacenter registers, there are also descriptions of other cloud services namely SaaS, PaaS, IaaS and others collaborative Web2.0 services that have been used in the execution of the process. Published learning process as a services artifact are specified as business processes. The proposed discovery architecture provides personalized learning process configurations for tenants as presented in figure 2.

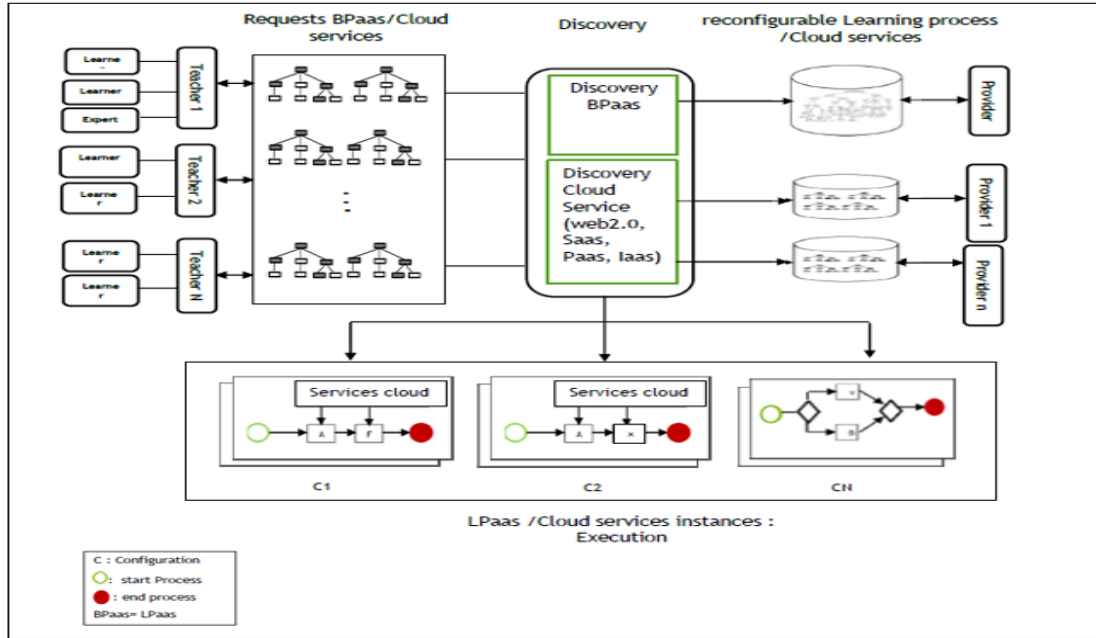

Figure 2. Conceptual architecture of Multi-tenant aware configurable learning process as a service discovery architecture and allocation of cloud resources

The discovery system consists of a modular architecture organized into separate modules: Request BPaaS/ Cloud services, Discovery, Reconfigurable learning process/ Cloud services, LPaaS/ Cloud services instances (execution).

Each module is composed of one or more components cited as follows:

- **Reconfigurable learning process / cloud services:** Our configurable learning process is created and published in configurable service registries hosted in cloud data centers. Thus, cloud services such as SaaS, PaaS, IaaS and collaborative web2.0 services are published by several cloud service providers. These services will be used in the execution of the e-learning process. This is what the allocation of resources required for the execution of such activity requires.
- **Requests BPaaS/ Cloud services:** Tenants who are in our case Institutions / Teachers look in the registers for configurable e-learning process configurations. They can formulate their required process configuration by selecting a set of activities. So, they look for cloud services that they want to use in running selected activities.
- **Discovery:** this module consists of two sub-modules: BPaaS discovery and cloud services discovery. The "BPaaS Discovery" module run to locate, discover and generate the appropriate configuration. This module uses another cloud service discovery module "discovery cloud service" to discover collaborative web2.0 services and other services (SaaS, PaaS, IaaS). These services will be used to carry out the selected activities, collaborate with experts, share knowledge and pedagogical resources, and strengthen the infrastructure to carry out such a task.

- **LPaaS / cloud services instances (runtime):** The return of the discovery module are instances of BPaaS / cloud services that respond to a request configuration. Once the recommended configuration is generated, it will be run as a business process in the cloud.

The multi-tenant aware discovery of configurable business process as a service is one of the most important and difficult issues, because of multiplicity and non-standardization of their description in cloud. In this paper, we introduce the combination of BPM approach and SPL approach for modeling collaborative, configurable e-learning process; then we introduce our architecture for discovery of the learning process in cloud. Our approach empowers multiple tenants to discover their desired learning process service configured variants, considering individual variants. To do so, we reduce the problem of configurable matching to a tree matching problem and we are going to adapt existing algorithms for this aim. We are doing the necessary experiments to show the feasibility of our approach.

IV. CONCLUSION

In this work, we exposed the limitations of existing e-learning systems (LMS) and discussed our contribution in previous work on modeling a collaborative, configurable and multi-tenant e-learning process. with the use of the Business Process Feature Model (BPFM) approach. Subsequently, we exposed the basic concepts of deploying a learning process as a business process (BPaaS) in the cloud: the different layers of cloud computing, the multi-tenant aspect and the supply of resources for running a process in the cloud.

For this, we propose an architecture of a discovery framework of a learning process and the allocation of resources cloud computing which allows the personalization

of e-learning services and the selection of collaborative web 2.0 services, services to infrastructure level and platform level.

In our future work, we are going to engage in showing the feasibility of our architecture where we rely on the structural matching approach and the graph-edit distance for e-learning BPaaS discovery in the cloud.

An Empirical Study about Software Architecture Configuration Practices with the Java Spring Framework

Quentin Perez, Alexandre Le Borgne, Christelle Urtado, and Sylvain Vauttier

LGI2P, IMT Mines Ales, Univ Montpellier, Ales, France

{Quentin.Perez, Alexandre.Le-Borgne, Christelle.Urtado, Sylvain.Vauttier}@mines-ales.fr

Abstract

Software architecture modeling plays a key role in software development and, beyond, in software quality. The Spring framework is widely used in industry to deploy software. This paper evaluates whether Spring fosters good practices for architecture definition. It describes the results of an empirical study, based on a corpus of open-source Spring projects. Analysis shows that a strong (70%) majority of projects mixes all Spring architecture definition features. This can be considered as a pragmatic use of a very flexible tool. However, few good practice documentation and tool assistance exist to prevent hazardous architecture constructions. The paper highlights these situations and concludes on recommendations to assist developers.

Keywords: Software architecture, architecture deployment, architecture configuration, empirical software engineering, Spring framework, GitHub open-source project.

1 Introduction

Architecture design is a critical issue that impacts software engineering [5]. Architectures are the natural consequence of modularity: They compose software from elementary components that can easily be developed, tested, maintained or reused.

Spring is a popular industrial framework designed for architecture development in Java. As established by a survey involving 2044 developers¹, it is the most used framework for web-service development. Spring has evolved over time with technologies (*e.g.*, adoption of Java annotations) or ap-

plication needs (*e.g.*, automation of deployment). Spring now provides developers with multiple features, that complement one another and sometimes overlap, for the architecture definition.

The remainder of this paper is organized as follows. Section 2 motivates this work. Section 3 first describes the features provided by the Spring framework then compares them with respect to expected qualities. Section 4 describes the empirical study on developers' practices. First, the methodology used for GitHub data extraction is presented. Then, the statistical analysis is developed before identifying threats to the study's validity and presenting the implemented tool that supports our study. To conclude, Section 5 presents related works and Section 6 draws perspectives for this work.

2 Motivations

Architecture models are used in nearly all steps of the software lifecycle, from its early design, as an abstract, ideal solution to meet users requirements, to its actual deployment and execution. Academic research has proposed many architecture description languages (ADLs) to support architecture conceptual design [11] whereas industry has proposed frameworks for runtime architecture deployment and management [4]. The ideal technology should both be flexible and easy to use for software developers and help document the architecture, increase component reusability and maintainability and manage change for software architects.

Defining a software architecture amounts to describe its components and their connections (the links that support their interactions). In the case of Java software, this amounts to define the constituent objects and the reference bindings to be created at runtime. When no specific archi-

¹<https://zeroturnaround.com/rebellabs/java-tools-and-technologies-landscape-2016/>

texture management feature is available, architecture construction is classically hard-coded in the main procedure. Otherwise, an architecture deployment descriptor can be defined through a framework to set the architecture up. To compare their modeling capabilities, we have established a set of expected qualities:

Explicitness. Explicit architecture models are defined with dedicated elements, clearly separated from source code.

Declarativity. Declarative architecture models are defined by abstract elements, that specify the expected instantiated structures, not the instantiation code.

Encapsulation. Encapsulated architecture model definitions are not scattered across source code but gathered into modules.

Assistance. Assisted architecture design is supported by tools that verify consistency, use of good practices or architectural styles, and control evolution to prevent architecture drift or erosion [13].

The purpose of this study is to compare the different kinds of architecture descriptors provided by Spring and to run an empirical analysis to determine whether industrial practice is influenced by architecture model qualities.

3 Spring Features and their Qualities

Since Spring 4 (2013), three closely related architecture definition features are offered to developers:

XML descriptors. Architectures are defined by several XML descriptors that are parsed and interpreted at runtime by the Spring container. Architecture components are declared by the `<bean>` tag, which must define an identifier (*id*) and the instantiated class (*class*). Listing 1 defines a small home automation architecture composed of an *Orchestrator* object connected to a *Lamp* and a *Clock*. Connections are defined by binding bean properties to bean references, as declared by *property* tags. Bean properties correspond to component dependencies (actually instance attributes). These component dependencies are supplied by the Spring container using the declared beans in the XML descriptor (dependency injection).

Configuration classes. Architectures can alternatively be defined by specific Java classes, identified by the `@Configuration` annotation (see Listing 2). Configuration classes are automatically detected by the Spring container and executed to build the architecture. Beans are declared by methods annotated by `@Bean`. This enables to program all the necessary pre- or post- bean instantiation treatments required to manage complex settings. Connections are handled by passing bean references to bean constructors, as for the *myOrchestrator* bean in Listing 2, or to bean property setters. In Listing 2, the *clock1* and *lamp1* methods are thus used to retrieve the bean references passed to the *myOrchestrator* constructor. Being genuine Java, configuration classes

leverage IDE tools and compile-time verification, as type-safe bean connections and scoped identifiers.

Self-annotated classes. Architecture definition is integrated to the code of the supporting classes thanks to annotations. The `@Component` annotation identifies the classes that will be automatically instantiated by the container to create architecture beans (see Listings 3 and 4)². Similarly, the `@Autowired` annotation, which can be associated to attributes, setters or constructors, identifies dependencies (*i.e.*, connections) that will automatically be supplied by the container, using corresponding existing beans (retrieved by name or type). On the one hand, self-annotated classes are the most declarative way to define architectures. On the other hand, architecture definitions are scattered through and mixed with source code.

Moreover, Spring also supports any combination of the aforementioned architecture definition features.

Feature Quality Analysis. XML descriptors and configuration classes enable explicit and encapsulated architecture definitions. Regarding modularity, configuration classes leverage the object-orientation of Java. Considering these three qualities, configuration classes are the best choice and self-annotated classes the worst. This analysis is coherent with technical literature that recommends to limit the use of self-annotated classes to small projects [8, 14, 15]. Besides, self-annotated classes define architectures only with singleton classes. Rather than a limitation, this constraint is intended to enforce strong cohesion between class and architecture structures. Two antagonist approaches of architecture definition are thus supported: architectures that are orthogonal (generic and flexible) or integrated (to avoid architectural drifts) to the code of classes. Self-annotated classes therefore are recommended for projects that are subject to frequent changes [1, 2, 14]. When it comes to choosing features for architecture definition, technical literature only provides scarce guidance, often considering this choice as a matter of developers' tastes [16, 17, 15]. Furthermore, to our knowledge, the qualities of architecture definition mixing features have not yet been studied. We expect that these feature combinations result from rational decisions of experienced developers that use the most adapted feature to different parts of architectures.

4 Empirical Study of Developers' Practices when Using Spring Framework

Data Extraction. A corpus of 524 projects has been extracted from GitHub. In order to consider only significant, quality projects, we applied the selection criteria proposed

²Specialized annotations, like `@Service`, `@Repository` and `@Controller`, have been derived from `@Component` to identify the roles of beans in specific architecture kinds, like web-service architectures.

```
<beans
xmlns="http://www.springframework.org/schema/beans">
  <bean class="my.smartHome.Clock" id="clock1"/>
  <bean class="my.smartHome.Lamp" id="lamp1"/>
  <bean class="my.smartHome.Orchestrator" id="myOrchestrator">
    <property name="time" ref="clock1" />
    <property name="light" ref="lamp1" />
  </bean>
</beans>
```

Listing 1: XML descriptor bean configuration

```
@Configuration
public class BeansConfiguration{
  @Bean
  public Clock clock1(){return new Clock();}
  @Bean
  public Lamp lamp1(){return new AdjustableLamp();}
  @Bean
  public Orchestrator myOrchestrator()
  {return new Orchestrator(clock1(),lamp1());}
}
```

Listing 2: Annotation-based bean configuration

```
// Clock.java file extract
@Component
public class Clock implements Time {/...*/}
// Lamp.java file extract
@Component
public class Lamp implements Light {/...*/}
```

Listing 3: Annotated components

```
// Orchestrator.java file extract
@Component
public class Orchestrator{
  @Autowired
  private Time time;
  @Autowired
  private Light light;
}
```

Listing 4: Autowired configuration

in Jarczyk *et al.* [7], like the numbers of forks and stars. We thus extracted the last commit of projects with 100 stars or more, forked at least 10 times, written in Java, containing the “Spring” keyword and created after 2010-01-01 (*i.e.*, after Spring release 3). For reproducibility purposes, our metadata is available online³.

Empirical Analysis. To understand the state-of-practice, we first analyzed which Spring features were used in the studied corpus. Surprisingly, a majority of Spring projects mixes architecture definition features ($\simeq 69.3\%$) and, despite their qualities, configurations classes are only used in a minority of projects ($\simeq 6.5\%$). They are challenged by XML descriptors ($\simeq 12.6\%$) and self-annotated classes ($\simeq 11.6\%$). Apart from routine, in the case of XML descriptors, which are the oldest proposed feature, declarativity may thus be a key quality in developers’ decisions. Figure 1 presents the distribution of all the combination of architecture definition features, depending on the size of the projects measured with the Source Lines Of Code (SLOC) metric. As expected, self-annotated classes alone are only used in small projects. Surprise comes again from configuration classes, that are used alone in only rather small projects. Explicit and encapsulated architecture descriptions do not appear to be a primary concern. Again, declarative features are rather used in bigger projects and even the biggest ones. More interestingly, the biggest project seems to require the support of all the features together.

To confirm the intuition that project size has an impact on used features, we evaluate two hypotheses using a non-parametric statistical Kruskal-Wallis test:

Null hypothesis	Alternative hypothesis
\mathcal{H}_0 : No influence of architecture definition features on project size.	\mathcal{H}_1 : Influence of architecture definition features on project size.

³<https://github.com/DedalArmy/MISORTIMA/tree/data-study-spring-deploy-features>

Defining risk $\alpha = 5\%$, the result of the test is $H \simeq 93.68$ with a p -value of $\simeq 5.196^{-18}$. As p -value $\leq \alpha$, the null hypothesis \mathcal{H}_0 is rejected with a 5% risk. This demonstrates that architecture definition features have a significant influence on project size. As the choice of architecture definition features by the developer obviously does not determine the size of the project, we can infer that the correlation we measure is the reciprocal relation of the actual situation: the choice of architecture definition features is influenced by the size of the project. It would be interesting to study whether the choice of the technique is done *a priori* or evolves, depending on the size of the project.

Finally, we also analyzed isolatedly the use of self-annotated classes on the corpus of 524 Spring projects, depending of their size, using a chi-square test. This test rejects the hypothesis of a relation between project size and use of self-annotated classes, confirming the intuitive analysis of Figure 1. Usage of self-annotated classes thus seems definitely motivated by declarative convenience rather than sound modeling capabilities.

Figure 1: Distribution of architecture definition features regarding SLOC

Threats to Validity. One of the major issues regarding validity of our study is its generalization. This paper focuses exclusively on the Spring framework although Spring is only one among many architecture definition frameworks. This focus might bias the study. It would thus be interesting to explore developers' practices while they use other frameworks in order to compare results with those of this paper. Moreover, by using data provided and mined through the GitHub API we are confronted to the threats already identified by Kalliamvakou *et al.* [9].

5 Related Works

Several works on the deployment of component architecture have already been carried out. Parrish *et al.* [12] modeled the deployment of component architectures in a formal way. It makes it possible to describe several deployment strategies while ensuring deployment safety in terms of installation and component compatibility. Dearle [3] compared the different methods for architecture deployment and showed that dependency injection, as implemented in Spring, is a desirable mechanism for component lifecycle management. Another study has shown that Spring reduces the developers' workload, in particular by extra flexibility, as compared to Java EE [6]. To our knowledge, there is a lack of research on architecture definition combinations and different practices in terms of deployment configuration even if a strong technical literature exists on the subject [8, 14, 15, 16, 17].

6 Conclusion

The empirical analysis we have run on a corpus of 524 projects extracted from the hosting GitHub service about the usage of the architectural definition features provided by the Spring framework leaves opened questions. It shows that usage is strongly related to project size and thus results from rational developer decisions. However, usage seems to be motivated by rather practical than quality concerns, as shown by the predominant use of combined features including self-annotated classes in any size of projects. A first perspective is to study more precisely how Spring features are combined according to project size or domain. We also plan to compare features from other technologies (languages) and frameworks.

Previous work has shown that it is possible to recover an explicit architecture documentation by mining Spring XML configuration files and compiled source code [10]. However, the relevance of results depend on the quality of the architecture modeled in the code. The goal of the on-going work presented in this paper is complementary: fostering the best architectural qualities when source code is used as a standalone model in agile processes.

A more practical perspective is to pursue the development effort to try and better assist developers in their architecture deployment activities by visualization and development of assistance tools.

Recover and Optimize Software Architecture Based on Source Code and Directory Hierarchies

Tong Wang, Yelian Zhang, Xufang Gong, Bixin Li
School of Computer Science and Engineering
Southeast University, Nanjing, China

Abstract—Software architecture helps developers understand and maintain software, so how to obtain accurate architecture is critical. The architecture recovery technique is a widely used method for obtaining architecture. In order to improve the accuracy and efficiency of the architecture recovery technique, we propose a method for recovering and optimizing software architecture based on source code and directory hierarchies. Our method consists of three steps: first, we extract architecture-related information from source code and directory hierarchies and construct a file dependency graph; then, we preprocess and cluster code elements to construct a preliminary architecture; finally, we optimize architecture by clustering code elements based on the structural similarity and renaming components. We perform our method on four representative open source projects and compare our method with representative architecture recovery techniques. The experimental results show that the architectures recovered by our method has higher accuracy with higher efficiency than the compared architecture recovery techniques.

Index Terms—architecture recovery; clustering; architecture optimization

I. INTRODUCTION

Software architecture provides a high-level abstraction view to developers, so it is useful for understanding software to make evolution plans, reduce development costs, improve software performance [1] and improve software quality [2], [3], so how to obtain accurate software architecture is a hotspot issue.

The automated recovery technique mainly includes two phases, information extraction and information-based recovery. In the information extraction phase, the data sources commonly include source code and directory hierarchies [4]. The directory hierarchy is set by developers, so it reflects the logical relations between files [5]. These data sources provide valid information for software architecture recovery. However, most architecture recovery techniques usually only use one of them to recover architecture resulting in the low accuracy. In the information-based recovery phase, there are many types of recovery algorithms. However, there is a huge amount of code elements in large scale programs, so how to improve efficiency is also an important problem.

In summary, the current automated architecture recovery technique has the following problems. a) The data source is single. When information is missing, the accuracy would be reduced. b) In a large scale program, the number of code

elements is huge, so it will take a long time to recover architecture.

In order to solve the above problems, we propose the method for architecture recovery and optimization based on source code and directory hierarchies (ARO). The main contributions of this paper are mainly reflected in the following three aspects.

- The architecture-related information is extracted from source code and directory hierarchy to improve accuracy. The information of source code reflects the specific implementation of the architecture. The information of directory hierarchies is related to developers' design.
- The file dependency graph is preprocessed to improve efficiency. The file dependency graph is preprocessed to reduce the number of clustered code elements for reducing the time consumed, then we perform K-center-hierarchy algorithm to cluster code elements around the core code.
- The architecture is optimized. We optimize architecture by clustering based on the structural similarity and renaming components.

II. RELATED WORK

The automated recovery technique mainly includes two phases, information extraction, and information-based recovery.

Mainstream data sources contain the following types. a) Source code. Text analysis or feature localization of the source code of the program by constructing a platform similar to lexical analysis and grammar analysis, and the use of information retrieval technology to discover associations between documents. b) Documents. Documents related to software are collected, such as software design documents, UML diagrams, code comments, user manuals, etc., to establish the concept [6]. c) Directory hierarchy. Some methods consider the information to identify components, that is, it is a supplement to the information obtained by other methods and improves the accuracy of partitioning components [4].

Mainstream methods of information-based recovery contain the following types. a) Domain knowledge. Domain-based methods are performed in a top-down process or a bottom-up process. In the top-down process, the documents related to architecture materials are used to recover architecture. In the bottom-up process, according to the comments, the declaration of variable names, etc., using domain knowledge to recover

B. Li is the corresponding author. E-mail: bx.li@seu.edu.cn
DOI reference number:10.18293/SEKE2019-045

architecture [7]. b) Clustering. This type of method uses mathematical methods to study and process the classification [8]. c) Machine Learning. The information of code elements is trained to recover architecture. Machine learning-based methods are generally not used alone, but as a supplement to clustering algorithms to improve the accuracy of clustering. d) Pattern Matching. The recovery process is modeled as a mapping between the high-level abstraction and the code elements. It is a semi-automated technique that requires manual participation, and graph matching also requires a lot of computer resources and time [9].

According to the above analysis, we find that only the clustering algorithm and the machine learning method do not require additional manual intervention. However, it is difficult to obtain the training set [10]. Therefore, the clustering algorithm is more widely used in the automatic recovery architecture technique.

III. OUR METHOD

Our method contains the following steps: extracting information, preprocessing and clustering code elements, and optimizing architecture.

A. Extracting information

The information of source code is extracted by automatically analyzing source code, such as the dependency information between code elements and the basic information of code elements. The process of extracting information from source code contains two steps. a) Construct an abstract syntax tree. The source code is converted into an abstract syntax tree which is an intermediate representation. b) Analyze the abstract syntax tree. By analyzing the abstract syntax tree, the information between the code elements is extracted. A code element is a unit of code, such as a file, a package, and so on. The dependency between code elements can be divided into multiple types, such as the reference dependency between files, the generalization dependency between classes, and so on. Then we integrate dependency information to construct the file dependency graph.

The information of directory hierarchies reflects the logical dependencies between files, and it is mainly used in the following two aspects: a) Aggregating components. In source code, some files do not have dependencies with other files, such as test case files. These files are presented as an independent component in architecture. A large number of independent components have effects on the understandability, so we cluster independent files into an independent component. b) Adjusting components. The relations between files of the same directory do not strictly comply with the high cohesion principle and the low coupling principle, so we adjust components based on the dependencies between directories.

B. Preprocessing and clustering code elements

Before we perform the clustering algorithm, we preprocess the file dependency graph to reduce the number of files, resulting in reducing the time consumed.

In the preprocessing process, independent files are clustered as early as possible, which is beneficial to reduce the number of nodes in the dependency graph and to comply with the high cohesion principle and the low coupling principle. Then, we preprocess the file dependency graph by clustering code elements which are related to the types of strong dependency and the structure of strong dependency. The dependency type between code elements indicates the degree of the closeness between them. The common types of strong dependency between code elements contain the following types: the generalization dependency, the implementation dependency, the combination dependency, the definition dependency, and the declaration dependency. Five dependency structures belong to the structure of strong dependency. The structure of strong dependency contains the following structures: the single dependency, the tightly coupled, the closed-loop dependency, and the open-loop dependency.

After preprocessing the file dependency graph, we cluster code elements based on the distance between code elements. The distance is calculated based on the dependence intensity and the similarity of the directory.

Dependency Intensity(DI) represents the degree of the closeness between two code elements, and it depends on the dependency type and the number of dependencies. The DI between the code element x and the code element y is calculated as the following formula.

$$DI_{ab} = \frac{\sum_{i=1}^N \alpha_i Num(i, A, B)}{\ln(LOCA)} \quad (1)$$

where N represents the number of dependency types between a and b , i represents the i_{th} dependency type, $Num(i, a, b)$ represents the number of i dependency between a and b , α_i represents the weight of the dependency type.

Directory similarity(DirSim) describes the degree of the similarity between directories. If two code elements are in the same directory, the directory similarity is 1. The directory similarity between the code element a and the code element b is calculated as the following formula.

$$DirSim(a, b) = \frac{|Dir(a) \cap Dir(b)|}{|Dir(a) \cup Dir(b)|} \quad (2)$$

where $DirSim(a, b)$ is directory similarity between the code element a and the code element b , the $Dir(a)$ represents the directory path of a , $|Dir(a)|$ represents the directory depth of a .

Element distance(ET) is used to describe the distance between two code elements. We consider the distance between code elements based on the directory similarity and the dependency strength. The ET between the code element a and the code element b is calculated as the following formula.

$$ET(a, b) = DirSim(a, b) * DI_{ab} \quad (3)$$

where $ET(A, B)$ is the code element A and the code element B , $DirSim(A, B)$ represents the directory similarity between A and B , and DI_{AB} represents the dependence intensity between A and B .

The clustering efficiency is low when it deals with large amounts of code elements. Therefore, ARO first performs the K-center clustering algorithm to reduce the number of code elements. The K-center clustering algorithm contains four steps. Firstly, the code elements are sorted according to the sum of fanin and fanout of them. Secondly, the top K code elements are the clustered centers. Thirdly, the nearest code elements of them are clustered into centers. Fourthly, if the number of code lines is less than the threshold, ARO performs the first three steps iteratively. The purpose of performing the K-center algorithm contains the following aspects. Firstly, the number of code elements is reduced. Secondly, code elements are clustered around the K centers, and the K centers are the core code, that is, code elements are clustered around the core code.

After performing the K-center algorithm, the K clusters are used to construct the $k * k$ structure, and $L(K)$ denotes the level of the k_{th} cluster, and the distance between the cluster (r) and the cluster (s) is represented as $d[(r), (s)]$. The details of the clustering process are as follows.

1) There are k clusters in the structure D , and each cluster is composed by a code entity. Let the number m is 0, and the $L(m)$ is 0.

2) The minimum of the distance in the D is represented as min , and the cluster is (r) and (s) .

3) (r) and (s) are clustered together into a new code entity (r, s) . Let the number m is $m + 1$, and the $L(m)$ is $d[(r), (s)]$.

4) The D is updated, and the columns and rows of (r) and (s) are deleted. The new cluster (r, s) is added into D . Let the distance between cluster $k - 1$ and (r, s) is $mind[(k), (r)], d[(k), (s)]$.

5) Step 2 to step 4 are performed iteratively until the number of code lines of the code elements is greater than the threshold.

The K-center-hierarchy clustering algorithm is shown in Algorithm 1.

C. Optimizing architecture

The first step of optimizing architecture is clustering code elements based on the structural similarity. The structural similarity between the code elements is equal to the average of the fanin and the fanout. $RelativeSim(a, b)$ denotes the structural similarity between the code element a and the code element b . The formula is as follows:

$$RelSim(a, b) = \begin{cases} \frac{C \sum_{i=1}^{|O(a)|} \sum_{j=1}^{|O(b)|} RelSim(O_i(a), O_j(b))}{|O(a)||O(b)|} & a \neq b \\ 1 & a = b \end{cases} \quad (4)$$

where $O(a)$ denotes the fanout of a , the parameter C is a damping factor. If $O(a) = O(b) = A$, then $RelSim(a, b) = C * RelSim(A, A) = C$, so $C \in (0, 1)$. If two the structural similarity between two nodes is higher than the threshold, the two nodes are clustered into a new node.

The second step is renaming components. The file name and the directory name are set by developers based on the function of the source code, so we rename components based on their corresponding directory names. The renaming process

19:       $i=i-1$ 
20:      Until all the clusters beyond the cluster size
21:    end if
22:  end for
23: end for

```

contains the following steps: a) Identify the corresponding component of each directory. b) All files are traversed to find out whether there is a specific directory contains most files of the component, if there is, then the component is named the directory name. c) All code elements are traversed to find out whether there are three generations of relatives that contain most of the files in the component, if there is, then the component is named as their common grandparent directory.

IV. EXPERIMENTS AND EVALUATION

In this section, we evaluate ARO by comparing it with some related methods to answer the following research questions:

RQ1: Does our method improve the accuracy of the recovered architecture?

RQ2: Does our method improve the efficiency of the recovered architecture?

A. Accuracy evaluation

MoJoSim is an indicator of evaluating the similarity between the recovered architecture and the ground-truth architecture, and it is used in much related work [11], [12]. In this paper, we use it to evaluate the accuracy of ARO. MoJoSim is calculated as follows.

$$MoJoSim(RA, GA) = (1 - \frac{mno(RA, GA)}{n}) * 100\% \quad (5)$$

where RA is the recovered architecture, GA is the ground-truth architecture, $mno(A, B)$ is the minimum number of *Move* and *Join* operations of converting A to B , n is the number of clustered code elements. If MoJoSim is 100%, it indicates that the two architectures are the same, and 0% indicates that the two architectures are completely inconsistent.

Table I shows the MoJoSim range of the nine methods and our method.

TABLE I
THE MOJOSIM RANGE OF EACH METHOD

Data source	Method	MoJoSim
Our paper	Our method	0.55-0.75
Bittencourt and Guerrero et al. [13]	EQ	0.20-0.60
	KM	0.40-0.80
	MQ	0.30-0.70
	DSM	0.35-0.75
Wu et al. [17]	CL90	0.40-0.48
	CL75	0.45-0.52
	ACDC	0.28-0.35
	SL75	0.10-0.15
	SL90	0.07-0.10

As shown in Table I, our method has a higher MoJoSim value than other methods. DSM, KM, and our method cluster elements based on the distance, but only KM and our method cluster elements around the core code. In a word, the architecture recovered by our method is closer to the ground-truth architecture, so the accuracy of our method is higher than the above methods.

B. Efficiency evaluation

Bittencourt et al. [12] proposed a cluster-based architecture recovery method, then Michele et al. [13] introduced fold-in and fold-out based on Bittencourt's method. Both of the above methods have been widely recognized, so we compare our method with the above two methods to evaluate efficiency of ARO.

PostgreSQL is an open source project, and it is often used as an experimental case for architecture recovery. We choose 30 versions as the experimental cases. The time consumed of the above three methods is shown in Figure 1.

Fig. 1. The time consumed of the three methods

As shown in Figure 1, the average time consumed of the above three methods is 835.288 seconds, 495.568 seconds and 81.814 seconds, respectively. Bittencourt's method takes the longest time, and our method takes the shortest time. In a word, compared to the two methods, our method has higher efficiency.

V. CONCLUSION AND FUTURE WORK

In this paper, we propose a method for recovering and optimizing software architecture based on source code and directory hierarchies to improve accuracy and efficiency. ARO

extracts specific information about the implementation of architecture from source code and directory hierarchies to improve accuracy. Then ARO improves the efficiency by preprocessing the file dependency graph and the K-center-hierarchy algorithm. Finally, ARO optimizes architecture. Experimental results indicate that compared with the representative architecture recovery methods listed in this paper, the architectures recovered by ARO has higher accuracy with higher efficiency.

In our future work, we will extract more information about architecture to improve accuracy, such as the compiled build files, architecture documents, and other files.

Automated user-oriented description of emerging composite ambient applications

M. Koussaifi, S. Trouilhet, J.-P. Arcangeli, J.-M. Bruel
IRIT, University of Toulouse, France

Abstract—Ambient environments consist of components surrounding the user and offering services. Applications can here be composed opportunistically and automatically by an intelligent system that puts together available components. Thus, applications that are a priori unknown emerge from the environment. The problem is in the intelligible presentation to an average user of those emerging composite applications. Our approach consists in automatic generation of user-oriented application descriptions from unit descriptions of each component and service. For that, we propose a well-defined language for component description and a method for combining descriptions. A prototype has been developed and used to experiment the generation of different composite application descriptions. Based on these experiments, we assess the degree of fulfillment of the requirements we have identified for the problem.

I. INTRODUCTION

Applications of the Internet of Things, ambient and cyber-physical systems consist of fixed or mobile connected devices. Devices host independently developed and managed software components that provide services specified by interfaces and, in turn, may require other services [1]. Components are building blocks that can be assembled by binding required and provided services to build composite applications.

Due to mobility and separate management, devices and software components may appear and disappear without this dynamics being foreseen. Hence, the environment is open and its changes are out of control. Humans are at the core of these dynamic systems and can use the applications at their disposal. Ambient intelligence aims at offering them a personalized environment adapted to the current situation, anticipating their needs and providing them the right applications at the right time with the least effort possible.

We are currently exploring and designing a solution in which components are dynamically and automatically assembled to build new composite applications and so customize the environment at runtime. Our approach is rather disruptive: unlike the traditional goal-directed top-down mode, applications are built on the fly in bottom-up mode from the components that are present and available at the time, without user needs being made explicit. That way, composite applications continuously emerge from the environment, taking advantage of opportunities as they arise: for example, a slider on a smartphone can opportunistically be composed with a connected lamp and provide

the user with a lightening service when entering a room. Here, contrary to the traditional SOA paradigm, the user does not specify a service or search for it in “pull mode”, but context-adapted applications are provided in “push mode”.

Automated composition is supported by an assembly engine in line with the autonomic computing principles and the MAPE-K model [2]: it senses the existing components and decides of the connections (it may bind a required service and a provided one if their interfaces are compatible) without using a pre-established plan. The heart of the engine is a distributed multi-agent system where agents, close to the software components and their services, cooperate and decide on the connections [3]. To make the right decisions and offer relevant applications, the engine (*i.e.*, the agents) learns at runtime by reinforcement. Thus, the engine assures proactivity and runtime adaptation in the context of openness, dynamics and unpredictability.

In such a context of automation based on artificial intelligence, we believe that, whatever the engine's decisions are, the deployment of emerging applications should remain under user control. So, she/he must first be informed of the new application. Then, depending on its interest, she/he must be able to accept it or not, possibly to modify it (provided that she/he has the required skills) and so to contribute to the customization of her/his environment. So, the user must be put “in the loop” [4]. In addition, the user's actions about the emerging application (acceptance, rejection, modification) are sources of feedback for the engine's learning. Based on them, the engine builds a model of the user's preferences and habits. Unknown a priori, this model is built at runtime and evolves dynamically.

Therefore, it is essential to assist the user in the appropriation of the emerging applications pushed by the engine. For that, applications must be presented to the user in a useful and understandable way. The goal of this paper is to propose a solution to provide the user with an intelligible description of emerging applications.

The paper is organized as follows. Section II describes in more details the problem and lists the main requirements. Section III analyzes the related work on service description and shows that the solutions are very limited in relation to our problem. Section IV presents and illustrates our approach to meet the requirements. Section V describes an experiment based on a prototype we have developed. It shows the feasibility of our approach and assesses whether it meets the requirements. Finally, a conclusion is given in Section VI as well as the perspectives of this work.

II. PROBLEM STATEMENT

In the absence of prior specification, emerging applications are unknown a priori and possibly surprising. They result from local interactions between distributed agents that constitute the engine. Composition relies on learned user preferences and a matching between required and provided services.

The user must be aware of the emerging application, its function and how to use it, to consider if she/he could benefit from. Therefore, applications must be presented in an intelligible way. Here, we target average users that are not familiar to programming and computer science. For instance, the user may be the inhabitant of a smart house or a public transport traveller in a smart city.

Consider a simple assembly consisting of a switch and a lamp. In that case, we would ideally like to tell the user something like “if you click on the switch, the lamp will turn ON/OFF”. Therefore, the problem lies in the construction of the understandable description of an application defined by an assembly of software components, and to compute the description from the participating components, their services and bindings.

A. Previous work

In [4], we have proposed an architecture that puts the user in the loop (see Fig. 1). An editor presents the emerging application, allows the user to accept it, then it is deployed, or to reject it, then it is cancelled, or to modify it (that is add, remove or change bindings between services). Acceptance, rejection, and modifications are notified back to the engine for learning.

Fig. 1. Overall solution architecture

For that, the editor exposes a structural description of the application (see Fig. 2) that is an editable graph of software components that are connected through their respective services, as well as other available components that may be useful. This is achieved using model transformation techniques that transform the output of the engine (set of components, services and bindings) into a model (conforming to a metamodel we have defined for this purpose) that is presented for the user.

In the state of our work, the solution is limited to the presentation of an editable structure of the application. On one hand, this allows the user to build of a tailor-made ambient environment. On the other hand, this requires to understand component-based architecture, at least the meaning of an assembly of components. Therefore, structural presentation is not understandable by an average user,

Fig. 2. Structural presentation via the editor

who needs to know the function rendered by the application (in other words its semantics), and how to use it.

The next section lists the requirements we have identified for an efficient presentation of an emerging application.

B. Requirements

1) **Semantics:** The function (*i.e.*, the semantics) of the application must be exhibited. For example, “the application allows to light up the lamp”.

2) **Usage:** The instructions on how to use the application must be exhibited. For example, “press the switch to turn ON/OFF the light”.

3) **Intelligibility:** The description must be understandable by an average user, without programming skills.

4) **Presentation scalability:** The description should remain useful and intelligible even when the application has about ten or more components.

5) **Automated processing:** The description must be automatically built by combining unit descriptions of components without human support.

6) **Expressiveness:** The description language must be expressive enough for software engineers with standard skills to make descriptions of the components they provide.

III. RELATED WORK

Fundamentally, software components and services are developed and documented for composition and reuse. In practice, they are built from scratch or from existing ones. In service-oriented engineering, service discovery and selection are fundamental operations. Selection generally aims to choose a service on a qualitative basis among several ones that have been previously discovered. Discovery and selection are performed either manually or more or less automatically, at design or runtime, from service descriptions.

In this section, we examine the related work in the field of service description. We first study the questions related to the target and objective of the description, then the questions of content and tools of description.

A. For whom and why describing a service?

Designers use service descriptions as documentation. They likewise describe the intent and use of the services they develop. When engineers specify business processes to be realized through the composition of existing services,

they describe (composite) services too. For example, composition of Web services are first explicitly specified by the service requester, then processed more or less automatically [5]. Thus, in that top-down mode, the demanded composite service is specified a priori, so no more description is necessary.

In [6], authors propose a user-centric service composition platform that assists end-users without skills in service-oriented engineering. End-users first enter their goals using a few keywords. Then an editor presents the available services and suggests possible and modifiable processes.

Most of the existing solutions use service description to support automated service discovery, selection and composition. Services are described to be processed by a program. Description allows service location and use, as is the case for WSDL [7] in the field of Web Services.

Semantic description of Web services first targets interoperability [8]. Relying on semantics also has a positive impact on the quality of the composition [9], in particular when Quality of Service (QoS) attributes are considered [10], [11]. In [12], authors propose semantic enhancement of software components with their properties and functionality to support matching between candidate components.

B. How to describe a service?

Service description can take more or less advanced forms depending on the requirements for discovery, selection and composition. In [13], authors overview and classify service description approaches used in automated service composition research.

In a basic way, descriptions may be limited to a syntactic level. For example, in object-oriented middleware like Java RMI [14], remote objects that provide services are registered and located only through a name. Services (resources in general terms) may be described more precisely using keywords in order to be retrieved by their characteristics rather than a simple identifier.

The semantic description of a service can be functional. It can take the form of a signature with inputs and outputs, possibly completed by preconditions and effects [15]. Authors of [11] explain that signature is not enough because different functions may have the same signature on the one hand, and that two services rendering the same function may differ fundamentally in their performances on the other hand. Therefore, service description may include extrafunctional properties that is QoS-related properties.

In [16], authors have proposed different techniques to create descriptions of services using the DAML-S language that was proposed to bridge the gap between the Web services infrastructure and the Semantic Web [17]. According to [13], OWL-S that succeeded to DAML-S has become a standard for industrial service composition. OWL-S [18] is an ontology for describing Semantic Web services that enables their automated discovery, composition and use. Ontology-driven description of services proved to be efficient for selection and composition [6].

C. Analysis

There are many solutions for functional and extrafunctional service description. Most of them focus on service discovery, selection, and top-down composition in order to build a complex service from unit ones. In our bottom-up approach, as the complex service to be built is unknown, there exists no solution which aims at combining descriptions. In most cases, service description supports automation, for example when based on ontologies. But in that case, descriptions are little or not at all intelligible by average human users. In addition, when extrafunctional properties are considered, they mainly concern the quality of services, but not their usage. In conclusion, to the best of our knowledge, there is no work that meets our requirements, mainly those concerning usage, intelligibility, and automated processing, in the context of bottom-up and goal-free application construction. Nevertheless, a functional description of services using signatures with preconditions and effects [15] may help in extracting the semantic information about the components' behavior and their interactions, that should be useful for the entire application description.

IV. PROPOSITION

This section presents our approach to describe components and their services, and to compute user-oriented descriptions of emerging composite ambient applications (assemblies of software components). Descriptions mainly consist of rules that explain the components and the applications. Composite application descriptions are generated from the unit descriptions of the components that are given at component design time, and the bindings between services that are supplied by the engine. Generation is achieved by combining the descriptions together, precisely the rules that belong to each unit description. At the end, the combination process aims at building a rule or a set of rules that describes the application, that can be then transformed into a text readable by the user. Our contributions are: (i) a language for the description of components' services and (ii) a combination method.

In the following, our proposition is explained in details.

A. Component and Service Description

A component description (CD) is a tuple that expresses how the component and its services work and interact with other connected components.

$$CD = \langle \text{ComponentName}, \text{Role}, \text{States}, \text{ProvidedServices}, \text{RequiredServices} \rangle$$

ComponentName and *Role* are strings: the name of the component and a free text (e.g., *ComponentName* = "Switch", *Role* = "Send a signal when pressed"). As components may have an internal state, such as a lamp that is ON/OFF, *States* is the (possibly empty) set of possible states (e.g., *States* = {"ON", "OFF"}). Last, the component's

required and provided service descriptions are gathered in the *ProvidedServices* and *RequiredServices* sets.

A service, whether provided or required, is also described by a tuple (SD).

$$SD = \langle \text{ServiceName}, \text{IOAction}, \text{Launcher}, \text{ServiceDescription}, \text{BoundTo}, \text{Rules} \rangle$$

ServiceName is a string (e.g., *ServiceName* = "Command").

IOAction represents how the service interacts with other services. It may have the following forms: *VAL@OUTPUT* or *TRIGGER ServiceName*. The first form refers to the emission of a message on the output interface of a required service. *VAL* covers all possible data types that the service handles (as the services have previously been composed by the engine, the type matching problem has been already resolved; thus types are useless for our descriptions), and may even be omitted. The second form refers to the transfer of control between services inside a component. Furthermore, *IOAction* can be empty for a provided service handling only the evolution of the component's state, without any output (e.g., the *OnOff* provided service of the lamp that changes the state to ON/OFF).

Launcher is a key defining what activates the service. It covers two cases. The first refers to an external interaction coming from another component (*onRequired*) or to an internal one coming from the component itself (*onTriggered*). The second case refers to an interaction coming from the user and can have multiple values such as *onButtonPressed*, *onSliderDragged*, *onCheckBoxChecked*...

ServiceDescription describes the service in a free text (e.g., *ServiceDescription* = "Turn ON/OFF the lamp"). This attribute is used by our combination algorithm to generate a textual form of the description (see section IV-B).

BoundTo is a set of services within their component (C-S) described as follows.

$$C - S = \text{ComponentName.ServiceName}$$

For example, $C - S = \text{Switch.Command}$.

Rules is a set of logic rules of the form "*Condition* \Rightarrow *Consequence*" that describes the service behavior. It is written as follows in BNF notation [19] where $\langle cp \rangle$ is a comparator, $S \in \text{States}$ and V is a value. Note that *IOAction* and *Launcher* have been put out of the rules for expressiveness and separation of concerns purpose.

$$\begin{aligned} & \text{Launcher} \\ & [\wedge (\text{STATE} < cp > S)] \\ & [\wedge (\text{VAL@INPUT} < cp > V)] \\ & \Rightarrow \\ & \text{IOAction} \mid \\ & \text{STATE} = S \mid \\ & \text{IOAction} \wedge (\text{STATE} = S) \mid \\ & \text{NOP} \end{aligned}$$

The common case is "*Launcher* \Rightarrow *IOAction*". Premises concerning the component's state and the inputted value are optional. It is usually the case for services that have no condition to check, other than their *Launcher*, before triggering their action. For example, for a switch to issue a command, it is only necessary that the button is pressed by the user.

In the general case, the condition part of a rule may contain a test on the component's state or on an inputted value. For the consequence part of the rule, several forms are possible. In particular, it may contain a state changing operation. Furthermore, *NOP* is a special key used if the service does not carry out any operation.

Here are examples of service descriptions of the *Command* service required by a switch and the *OnOff* service provided by a lamp, that have been connected by the assembly engine. Component and service descriptions have initially been written by the designer. They are completed by the engine by filling the *BoundTo* attribute according to the emerging assembly.

$$\begin{aligned} & \langle (\text{ServiceName}) \text{Command}, \\ & \quad (\text{IOAction}) @\text{OUTPUT}, \\ & \quad (\text{Launcher}) \text{onButtonPressed}, \\ & \quad (\text{ServiceDescription}) \text{Send a signal}, \\ & \quad (\text{BoundTo}) \{\text{Lamp.OnOff}\}, \\ & \quad (\text{Rules}) \{\text{Launcher} \Rightarrow \text{IOAction}\} \rangle \end{aligned}$$

$$\begin{aligned} & \langle (\text{ServiceName}) \text{OnOff}, \\ & \quad (\text{IOAction}), \\ & \quad (\text{Launcher}) \text{onRequired}, \\ & \quad (\text{ServiceDescription}) \text{Turn ON/OFF the lamp}, \\ & \quad (\text{BoundTo}) \{\text{Switch.Command}\}, \\ & \quad (\text{Rules}) \{\text{Launcher} \wedge (\text{STATE} == \text{OFF}) \\ & \quad \quad \Rightarrow \text{STATE} = \text{ON}, \\ & \quad \quad \text{Launcher} \wedge (\text{STATE} == \text{ON}) \\ & \quad \quad \Rightarrow \text{STATE} = \text{OFF}\} \rangle \end{aligned}$$

The next section presents the method for combining descriptions.

B. Combination of descriptions

Application descriptions are generated mainly from the rules that describe the services, and then from the remaining attributes (if used by the rules). If a service S1 is connected to a service S2 then the rules of S1 are combined with the rules of S2 to generate the rules that describe the composition.

The combination algorithm first finds matching keys available in each possible pair of rules which belong to S1 and S2 descriptions. For example: *VAL@OUTPUT* matches *onRequired* and *VAL@INPUT*; *TRIGGER Service-Name* matches *onTriggered*. Then, the algorithm infers the combined rules by transitivity. For example:

```
* R1: A  $\Rightarrow$  B  $\wedge$  C
* R2: C  $\Rightarrow$  D
R1 and R2 are combined into:
* R: A  $\Rightarrow$  B  $\wedge$  D
```

Note that there might be several combined rules at the same time, for example:

```
* R1: A  $\Rightarrow$  B
* R2: B  $\wedge$  B'  $\Rightarrow$  C
* R3: B  $\wedge$  B''  $\Rightarrow$  D
R1, R2 and R3 are combined into:
* R': A  $\wedge$  B'  $\Rightarrow$  C
* R'': A  $\wedge$  B''  $\Rightarrow$  D
```

Here is an example for the Switch-Lamp application:

```
* R': LauncherCommand  $\wedge$  (STATE == ON)  $\Rightarrow$  STATE = OFF
* R'': LauncherCommand  $\wedge$  (STATE == OFF)  $\Rightarrow$  STATE = ON
```

The combined rules are transformed into a textual form to be presented to the user. An attribute is linked to its component and the label is replaced by its content (*Launcher_{Command}* becomes *OnButtonPressed of Switch*). The *ServiceDescription* content is used to make the elements of the rule more explicit (the *STATE* element and *Turn ON/OFF the lamp* are compared). Finally, the \Rightarrow is translated in a verbal form (*IMPLIES ... IF*). In addition, the algorithm is able to group rules that have the same launcher. The textual presentation of the Switch-Lamp application is:

```
onButtonPressed of Switch IMPLIES
  Turn OFF the lamp IF Lamp is ON
  Turn ON the lamp IF Lamp is OFF
```

Note that the generated textual description may sometimes not be grammatically correct. At this point, syntax improvement is left for future work.

The above example has the simplest topology, but the solution targets more complex ones: pipeline, star... Our description language can easily be extended. For example in order to cover the case of a component that requires several services sequentially, a sequence operator could be added to the description language and handled by the combination algorithm.

The next section shows the experimentation we have carried out and analyzes our solution in relation to the requirements.

V. EXPERIMENTATION AND ANALYSIS

A. Proof of concept

In order to demonstrate the feasibility of our approach, we have developed a prototype in Java, where each component and its services XML-like descriptions are stored in a separate file. It was tested on different composite applications built by our assembly engine.

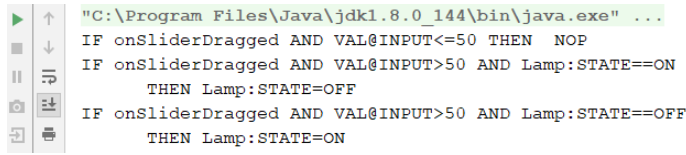

Here is an example with three components assembled in pipeline mode: a slider, a converter and a lamp. The slider acts as a switch. It requires the *ProcessVal* service. The converter provides the *Transform* service: it receives a value and, if greater than 50, transforms it into an order for the lamp through the *Order* required service. As in the previous section, the lamp provides the *OnOff* service. The descriptions of the services are given below (see Section IV-A for *OnOff*).

```
< (ServiceName) ProcessVal,
  (IOAction) VAL@OUTPUT,
  (Launcher) onSliderDragged,
  (ServiceDescription) Send a value  $\in$  [0,100],
  (BoundTo) {Converter.Transform},
  (Rules) {Launcher  $\Rightarrow$  IOAction} >
```

```
< (ServiceName) Transform,
  (IOAction) TRIGGER Order,
  (Launcher) onRequired,
  (ServiceDescription) Change value into signal,
  (BoundTo) {Slider.ProcessVal}
  (Rules) {Launcher  $\wedge$  (VAL@INPUT > 50)
     $\Rightarrow$  IOAction,
    Launcher  $\wedge$  (VAL@INPUT  $\leq$  50)  $\Rightarrow$  NOP} >
```

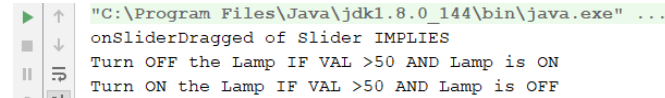

```
< (ServiceName) Order,
  (IOAction) @OUTPUT,
  (Launcher) onTriggered,
  (ServiceDescription) Send a signal,
  (BoundTo) {Lamp.OnOff},
  (Rules) {Launcher  $\Rightarrow$  IOAction} >
```

Fig. 3 shows the rules resulting from the combination algorithm. Then, the rules are transformed into a more intelligible textual version to describe the emerging application (Fig. 4).

```
"C:\Program Files\Java\jdk1.8.0_144\bin\java.exe" ...
IF onSliderDragged AND VAL@INPUT<=50 THEN NOP
IF onSliderDragged AND VAL@INPUT>50 AND Lamp:STATE==ON
    THEN Lamp:STATE=OFF
IF onSliderDragged AND VAL@INPUT>50 AND Lamp:STATE==OFF
    THEN Lamp:STATE=ON
```

Fig. 3. Description's rules of the emerging application

```
"C:\Program Files\Java\jdk1.8.0_144\bin\java.exe" ...
onSliderDragged of Slider IMPLIES
Turn OFF the Lamp IF VAL >50 AND Lamp is ON
Turn ON the Lamp IF VAL >50 AND Lamp is OFF
```

Fig. 4. User-oriented description of the emerging application

B. Analysis

Rules describing the composite application are actually inferred. They provide the information about both the function of the application and how the user can interact with it. Thus, the rule-based description of the components and their services in an assembly makes possible to satisfy the main requirements we have defined (see Section II-B) concerning *semantics*, *usage*, and *automated processing*. By transforming rules into text, the understanding is made easier. Nevertheless, no real users have yet assessed the *intelligibility*. User assessment experiments could help us in improving the description language and the rule combination process. Concerning *expressiveness*, we consider that the rule-based language is expressive enough for software engineers. Moreover many elements of CD and SD could be automatically extracted from the code of components, in particular from the signatures of methods. *Presentation scalability* requirement has yet to be improved. We would like to allow the folding and unfolding of descriptions when a number of components are involved, and therefore offer a kind of "responsive" presentation of applications with different levels of abstraction.

VI. CONCLUSION

In this paper, we have exposed an approach that aims to answer the requirements to generate user-oriented intelligible descriptions of emerging assemblies of software components. We have presented the limitations of the current solutions and highlighted the benefits of our one. We have developed a proof of concept that shows that our approach can meet the requirements. Further experiments must now be carried out on more complex composite applications and topologies in order to consolidate our solution and enrich the description language. Real users should be involved in the experiments to improve and validate intelligibility and scalability of the presentation.

Our next step towards addressing the scalability issue will be to fully use the power of Model-Driven Engineering

(MDE) approaches and tools to support the automatic generation of combination algorithms from the description language definition itself. Our description language being a domain-specific language (DSL), and our input assembly being a model, MDE which has been proved useful in this particular case [20] will allow us to define transformation between assemblies and their descriptions.

Abstract— Background: The use of chatbots has increased considerably in recent years. These are used in different areas and by a wide variety of users. Due to this fact, it is essential to incorporate usability in their development. Aim: Our objective is to identify the state of the art in chatbot usability and applied human-computer interaction techniques, to analyze how to evaluate chatbots usability. Method: A systematic mapping study has been conducted, searching the main scientific databases. The search retrieved 170 citations and 19 articles were retained as primary studies. Results: The works were categorized according to four criteria: usability techniques, usability characteristics, research methods and type of chatbots. Conclusions: Chatbot usability is a very incipient field of research, where the published studies are mainly surveys, usability tests, and rather informal experimental studies. Hence, it becomes necessary to perform more formal experiments to measure user experience, and exploit these results to provide usability-aware design guidelines.

Keywords—Usability; chatbots; systematic mapping study

I. INTRODUCTION

Chatbots are computer programs with a textual or voice interface, based on natural language [1]. They are specifically designed to make user interaction as natural as possible, and have received extensive attention from academia and industry in recent years. Chatbots not only enable a faster and more natural way to access information, but they will become a key factor in the process of humanizing machines in the near future.

Usability is defined as the degree to which a program can be used to achieve quantified objectives with effectiveness, efficiency, and satisfaction in a specified context of use [2]. Usability is a critical aspect in interactive software systems and so it is essential to incorporate usability in chatbots, to improve user experience. Chatbots are become pervasive and are used in many areas, such as bookings of all sorts of services, to obtain medical advice and for online shopping [1][3][4]. The multiple uses and benefits of chatbots explain their strong growth in terms of users, satisfaction and saving resources. It is expected that the number of users will grow in the US by 23.1% [5]. Although the market is still beginning to take shape (compared to the number of websites, the number of bots is still not large) it is estimated that the market size will expand massively [4].

Many universities and commercial companies have put into use chatbots interacting with mature systems. At the commercial level, Facebook messenger already has more than 300,000 chatbots in use [5]. This makes downloading and installing new apps unnecessary, and the use of smartphones allows for personalization possibilities [6]. Further, the use of

chatbots can be more cost-effective than human-assisted support [7]. Some companies are building chatbots independently (e.g., Microsoft is promoting the idea of “*conversation as a Platform*”) to support a variety of media, from Skype to search [8]. Chatbots are not an emerging concept. Research on dialogue systems can be traced back to the 50s, where Alan M. Turing posed the question “*can machines think?*” proposing the Turing test as a criterion for judging whether the machine has intelligence [9]. Weizenbaum’s development of ELIZA at MIT in the 60s can be considered the first dialogue system [1]. Lately, the advances in natural language processing (NLP) have boosted the raise of many chatbot development frameworks (e.g. DialogFlow (<http://dialogflow.com>)).

However, there are currently few works that discuss the usability of chatbots in an integrated and formalized manner. The objectives of our research are to identify the state of the art in chatbots usability and the applied Human-Computer Interaction (HCI) techniques by a Systematic Mapping Study (SMS) and to analyze how to evaluate the usability of chatbots. The contribution of this research is a picture of the current state of usability in chatbots. For this purpose, we present a SMS where we classify the types of chatbots, the measured usability characteristics, the applied usability techniques and the research methods used to evaluate chatbot usability.

Paper organization. In Sec. 2, we present related work. In Sec. 3, we describe the research method of the SMS. Sec. 4 presents the results of the SMS. In Sec. 5, we discuss the results and threats to validity, and finally Sec. 6 concludes.

II. RELATED WORKS

We found only three systematic reviews related to chatbots [9][10][11]. The one by Klopfenstein et al. [9] surveys conversational interfaces, patterns, and paradigms. However, they do not detail the literature retrieval process, and hence it may be potentially incomplete. The survey traces the history of chatbots, from ELIZA to modern chatbots for MOOCs. They conclude that only a subset of chatbots are designed for communicating in natural language, which sometimes makes users disappointed. Then they compare features of major messaging platforms that support bots, like Messenger, WeChat, Line and Skype. Most of them already support a variety of message types, pictures, videos, and sounds. However, none of them have comprehensive enough features. For example Line has groups, buttons and carousel features, but no payment and quick message reply. They detail advantages of bots for users and developers, and conclude

stressing the benefits of chatbots as a new software platform to provide services and data to users.

The work by Ramesh et al. [10] surveys design techniques for conversational agents. The paper presents various solutions for building chatbots, including AIML, NLP and Natural Language Understanding (NLU). The authors describe the general structure of a chatbot, which consists of a responder, classifier and graph master. Then, they list several design techniques for chatbots, from pattern matching, to recurrent neural networks. They stress that NLP techniques are increasingly being used in recent years. The paper presents a classification of chatbots, which includes retrieval-based and generative-based, long and short conversations and open/closed domain. Retrieval-based chatbots pick responses from a pool of predefined ones. The third work, by Laranjo et al. [11] makes a systematic review of conversational agents in health. This review retrieved 1,513 research papers, and identified 17 primary studies. The search was performed in April 2017 and updated in February 2018. They describe 14 different conversational agents distinguishing type of communication technology, dialogue management, dialogue initiative, input modality and task-oriented aspects. The evaluation measures were divided into three main types: technical performance, user experience and health-related measures.

Overall, these works do not focus on usability techniques or usability characteristics of chatbots. Therefore, to the best of our knowledge, there is no SMS on the status of the chatbot usability. Our work covers this gap.

III. RESEACH METHOD

We aim to answer the following research questions: (RQ1) *What is the state of the art of usability in the development of chatbots?* and (RQ2) *How to evaluate the usability of chatbots using HCI principles?* To answer both questions, we have executed an SMS to identify and classify these issues in the published literature [12].

Search String Selection

The first step is identifying search strings and relevant keywords. For this purpose, several options were tried and the best one chosen. In particular, we first read some initial articles, obtaining keywords and basic knowledge related to the topic. After combining the opinions of two experts in HCI, we opted for the search string: (usability OR “usability technique” OR “usability practice” OR “user interaction” OR “user experience”) AND (chatbots OR “chatbots development” OR “conversational agents” OR chatterbot OR “artificial conversational entity” OR “mobile chatbots”).

Databases and Search Protocol

The search was performed in sequence from Scopus, ACM Digital Library, IEEE Xplorer, SpringerLink and Science Direct. The search fields used were determined by the options provided by each database. Considering that the concept of chatbots is still relatively new, the search range is from January 2014 to October 2018. We ordered the search considering the data base that returned most results. The search fields were selected to assure that searches were similar across data bases.

The criteria used to retrieve the fundamental studies are summarized below.

- *Inclusion criteria:* The paper is written in English; AND The abstract or title mentions an issue regarding the chatbots and usability; OR The abstract mentions an issue related to usability engineering or HCI techniques; OR The abstract mentions an issue related to the user experience.
- *Exclusion criteria:* The paper does not present any issue related to the chatbots and usability; OR The paper does not present any issue related to the chatbots and user interaction; OR The paper does not present any issue related to the chatbots and user experience.

Paper Selection

The searches were run using the search string defined. The number of papers returned by the first search was 170, which are called *Retrieved Papers*. Then by inspecting the title, keywords and abstract of each retrieved paper, 41 papers were filtered to the group of *Candidate Papers*. The whole group of Candidate Papers was screened for duplicates. When duplicates were found, only the first occurrence of the paper was counted and maintained, the others were deleted. The final group has 39 papers, which is called *Non-Duplicate Candidate Papers*. Each paper of the Non-Duplicate Candidate Papers group was read, to determine if they described any sort of usability of chatbots. The results were cross-checked by two experts in the HCI area, and any disagreement was discussed and resolved in our meetings. Finally, 19 papers were identified as primary studies.

IV. SYNTHESIS OF THE RESULTS

Figure 1 provides an overview of the primary studies retrieved by the SMS. It is made of three categories, determined by the year of publication, type of paper (conference, journal, chapter) and usability characteristics. The left-hand side is composed of two scatter (XY) charts with bubbles at the intersections of each category. The size of each bubble is determined by the number of primary studies that have been classified as belonging to the respective categories at the bubble coordinates.

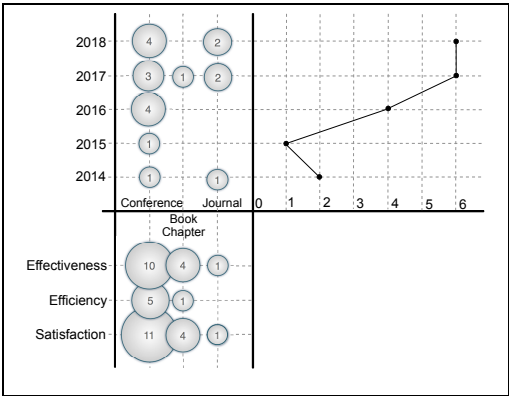

Figure 1. Overview of the Primary Studies

The right-hand side of the Figure shows the number of primary studies by publication year. Publications started to grow from 2015, and many articles (mainly in conferences)

have been published each year since then, confirming the interest in the field. It can be noted that most interest in chatbot usability is on *effectiveness* and *satisfaction*.

After conducting the SMS and analyzing the literature with respect to the usability of chatbots, the primary studies were classified from four different perspectives: usability techniques, usability characteristics, research methods and type of chatbots. These categories are reviewed next.

A. Usability Techniques

The primary studies in this category identify the adoption of usability techniques from HCI. This is the second-most studied group in the literature. The usability techniques are shown in Table I. From the analysis of the papers, we found that *questionnaires* and *interviews* are most commonly used.

TABLE I. USABILITY TECHNIQUES

Usability Techniques	Primary studies
Questionnaire (SUS/ad-hoc)	[1][3][13][14][15][16][17][18][19][20][21][22][23][24][25][26]
Interview	[15][21][22][23][24][26][27][28][29]
Think-aloud	[15][19][22]
Direct observation	[20]
Cognitive walkthrough	[22]

In most cases, two or more techniques are combined for the usability evaluation. Each of these methods has its own characteristics, and cannot fully meet all requirements of the usability test in isolation. Hence, it is necessary to combine various methods. For example, in [20], direct observation and the *System Usability Scale* (SUS) questionnaire are jointly used. In [21], questionnaires and interviews are used together in every research phase. In [22] the authors conduct a usability test to compare the usability of three chatbot platforms by using a SUS questionnaire, think-aloud and interview to rate the feedback from participants. A post-task questionnaire and an open-ended interview were used together in [26]. In [15], they video-recorded the experiment process for a retrospective think-aloud, and then conducted an interview and a questionnaire after accomplishing the tasks. In [24], user testing is combined with questionnaires and interview. In [23], they conducted semi-structured interviews and used different standard questionnaires together in the first and last evaluation period. In the middle period, to gather more comprehensive information, they used the SUS questionnaire. In [13], they developed a pre-study questionnaire to illustrate the types of interactions perceived to be the most frequent with an Alexa chatbot. In [1], participants were asked to fill the metrics to measure their user experience, and also were asked to compare two different interfaces and justify their responses.

In some cases, the authors used just one single technique to measure usability. In [14], they conducted a survey using a questionnaire. In [16], though they mainly used questionnaires to measure usability, they track user experience through different questionnaires from different periods with open questions. In [27], they used structured interviews. In [17], different questionnaires were used in three different periods of

the experiment. In [18], the authors used questionnaires to measure quantitative and qualitative evaluations of the new NLP method used by the chatbot. In [29], during the interview, participants had to explain the difficulties they had. In [28] to avoid excessive verbosity and to use verbal instead of text feedback, they used interview with open questions. In [25], to evaluate their web client, the authors used a questionnaire related to reliability, usability, and functionality of the system. Overall, we can conclude that the technique used depends on the specific conditions, while there is no standard proposal.

B. Usability Characteristics

According to the primary studies, usability characteristics are mainly identified in three aspects: Effectiveness, Efficiency and Satisfaction.

1) *Effectiveness*: Effectiveness is defined as the accuracy and completeness with which users achieve specified goals in HCI [30][31]. From Figure 1, most papers consider effectiveness as an essential factor when evaluating the usability of chatbots. Table II shows more details on the used effectiveness criteria.

TABLE II. EFFECTIVENESS

Measures of Effectiveness	Primary studies
Task completion	[1][13][22][25][27]
Accuracy	[17][18][24][25][26][28]
Recall	[18][25]
Experts and Users' assessment	[14][15][21][24]

We have identified task completion, accuracy of chatbot reply, comparison with recall and expert assessment as the main means to assess effectiveness. In [14] by gathering feedback from experts and potential users, they evaluate grading of the perceived quality of effectiveness of the chatbot [31] and find some shortcomings and possible solutions that will enhance the application's usability for its intended audience. In these works, the number of correct responses or interventions indicates the accuracy (to measure if user achieve specified goal [30]) and recall (users' ability to recall information from the interface [31]). The result shows that most chatbots achieve the required accuracy and recall of response [25][26]. For example, through comparing with other chatbots with similar functionality for completing the task, the authors in [1] proved their e-commerce chatbot performs better than the default chatbot. In [18], according to the result of the questionnaire, 80% participants claimed that the content of the retrieved information is clear and useful. In [27], the authors measure the number of users who complete the task (interview) through two different tools, showing that the chatbot has higher acceptability. To identify the measures of characteristics accuracy and recall, the works [30][31] have been followed.

However, there are still problems to achieve a high level of task completion and accuracy of the chatbot reply. In [13], 19 incomplete tasks were reported, because of an ill-defined system design. In [17], during the evaluation, there were some problems with the DBpedia semantic entry point, which

affected the accuracy of some of the users. In [28], 46 entries were negotiated, of which 7 (15.2 %) did not correspond correctly to the user's original wishes, but when a participant use more lengthy sentences, he produced noticeably more utterances compared to the average of the others. This problem mainly resulted from the inability of the system to process long, convoluted utterances properly and lacking the ability to guide the user during the interaction. In [24], the chatbot generated unnecessary information in response to highly structured conversations. In [25], the factor affecting the accuracy of chatbot reply is the need to handle one or more user conversation turns before providing the answer.

2) *Efficiency*: Efficiency relates to the resources expended in relation to the accuracy and completeness with which the users achieve their goals [30][31]. Most papers discuss *task completion time*, *mental effort* and *communication effort* to use the chatbot, as shown in Table III.

TABLE III. EFFICIENCY

Measures of Efficiency	Primary studies
Task completion time	[1][29]
Mental effort	[1][3]
Communication effort	[17][20][21]

In [1], the authors compare the number of views and average time the participants took in completing a task with the Convey chatbot, and a default one. The results showed they spent more effort and time with Convey in performing the task.

Perceived autonomy and competence are factors favoring efficiency in chatbot usability [3]. In [17], it was noted that, since the chatbot can correct erroneous inputs, users do not need to spend much communication effort when talking to the chatbot. In addition, less communication effort makes the chatbot easier to operate. In [20] the authors count the number of participants' cumulative assertions to measure the communication effort. Its steady increase demonstrates that users can use the chatbot efficiently in short time. Finally, users spend more communication effort when the chatbot has limited conversational ability, as discussed in [21].

3) *Satisfaction*: This is the largest group of papers within the primary studies. Satisfaction is defined as the degree to which user needs are satisfied when a product or system is used in a specified context of use [30][31]. The measures of satisfaction include *ease-of-use*, *context-dependent questions*, *satisfaction before* and *during use*, *complexity control*, *physical discomfort* of the interface, *pleasure*, the *willing of use* the chatbot *again*, and enjoyment and *learnability*. From Table IV, the ease-of-use, willing to use the chatbot again and user experience are the main measures of satisfaction used. Emotional aspects such as perceived utility, pleasure, comfort, are also considered in [24], and are related to the user experience. Among the primary studies, works have been found measuring the user experience mainly considering the physical discomfort and pleasure. These works are highlighted with a rectangle in the Table IV.

It must be noted that chatbots have more exploration space for interaction with users. A physical chatbot was proposed in

[16] to support self-management of diabetes by children. The usability evaluation included capabilities, social presence, and the quantity of speech and movements. Children stated that physical chatbots were more (inter)active, more present and capable of doing different things, such as dancing. Chatbots with actual images or entities are more likely to establish relationships with users, improving their experience. In [29], a combination of speech-and-gesture makes users get well better with the chatbot. In [22], the authors compared Pandorobot with two other chatbots. Overall, Pandorobot's voice sounded less robotic, entertaining users better.

TABLE IV. SATISFACTION

Measures of Satisfaction	Primary studies
Ease-of-use	[1][14][16][17][18][19][22][23][24][26]
Context-dependent question	[22][23][29]
Before use	[14][21][23]
During use	[3][21]
Complexity control	[14][18][23][25]
Physical discomfort	[14][18][21]
Pleasure	[1][13][16][17][21][22][26][29]
Want to use again	[1][14][16][17][21]
Learnability	[15][16][22]

Besides, more flexibility and speech commands context-dependent are required for better usability. In [1] participants mentioned that a shopping chatbot was easy to use since it tracked their search history. In [17] some users did not consider they needed an affective enhanced semantic chatbot at home. In [23] the authors observed that the acceptance of the chatbot decreases since its response mismatched the users' initial expectations. Potential explanations for such inconsistencies might include fundamental differences in user expectations for the chatbot and the emphasis on the interactive and entertaining qualities of the system over its informational value. The user background should be considered a key point in evaluating satisfaction. Cultural, socio-economical and personal preferences can influence the opinions towards the chatbot. In [23], the authors noticed that users in the Netherlands were more experienced with technology than in the other two countries of the study, therefore their expectations towards the novel technology were higher. In [15] users with higher technical knowledge learned quicker to use the chatbot.

C. Research Methods

The research methods used by the authors of the primary studies within this group include surveys of chatbots users' experience, experiments of using chatbots to realize some given tasks, usability tests, case studies and quasi-experiments. The research methods are detailed in Table V. The most common research methods include *survey*, *experiment* and *usability test*. In most experiments, very simple tasks are proposed. For example, using Apple Siri to find an inexpensive hotel in Osaka [15], search a flight ticket and hotel [3], whether

a simple chatbot can be appropriately used as a delivery mechanism [24], buying shoes [1], measuring the quality and quantity of the information retrieved [18], taking a structured interview with chatbot [27], or playing a game [29]. However, real-life situations are more complicated.

TABLE V. RESEARCH METHODS

Research methods	Primary studies
Survey	[13][16][19][22][24][25][26]
Experiment	[1][3][13][14][15][16][17][19]
Usability test	[18][19][22][25][27][28]
Case study	[14][20][23][29]
Quasi-experiment	[20][21][25]

Rather than aiming to fully recreate the real-world task, simulation-based assessment should incorporate psychologically relevant aspects and situations from the real-world task and the environment, such as time-pressure, or high uncertainty. In [17], the authors show that when the chatbot has visual appearance and emotions, users do not notice small changes in voice and facial expressions. The experiment concludes that it is not necessary to use extremely accurate facial expressions for realistic use. In [21], the authors deployed a digital pet avatar in the participants' home for 3 months to simulate real-life situations as much as possible. In [20], experiments were designed in a complex way, to simulate real-world situations. This is sometimes necessary, because if we were unable to use the chatbot effectively with a design as realistic as possible (but nonetheless simplified), it would be unlikely to be effective under more challenging conditions for the military, law enforcement and others in safety-critical real-world environments.

In most cases, researchers make comparisons. For example, in [14], the authors compare a chatbot with a similar one or with a similar application. Research methods can also be combined, which typically yields better results. In [13], a pre-survey questionnaire was performed to assess the usability of an Alexa chatbot. Then, an experiment was conducted to investigate specific problems. Machine learning (ML) algorithms, in combination with cloud-based databases can be used to solve some current shortcomings of handling natural language (e.g., chatbots can't recognize the words that they haven't been programmed for, and some chatbots speak unnatural language [24][26]).

D. Type of Chatbots

The AIML technology is still widely used in the design of chatbots [24][25]. However, the use of chatbots using NLP is growing [20]. For example, the PAL project [16] can generate reasonable feedback through user-entered information. In [13], the authors show that the chatbot can be used via natural language phonic control, to perform search, entertainment, and to control other devices. In [14], more users are satisfied with the chatbot, due to its speaker functionality and natural conversation flow. In [18], the authors used Object Relational Mapping (ORM) frameworks to improve the process of

generating SQL statements from NL queries. Many chatbots are built as Embodied Conversational Agents (ECA), and there are increasing number of chatbots with image, sound and personality [17][21][23][29]. However, sometimes chatbots have negative emotions. When the ECA has a negative personality, it tends to ignore or blame the user [17]. In addition, the chatbot is required to have the ability to learn and adapt to its user context to be useful [23]. Therefore, complete evaluations should be carried out to obtain a better comprehension of these issues.

V. DISCUSSION AND VALIDITY THREATS

The analysis reveals that the incorporation of usability techniques in the chatbot development process in a formalized manner is not strongly reflected in the primary studies. We found three papers reviewing the chatbot literature: one discussing the conversational interfaces, patterns, and paradigms [9], one investigating design techniques for conversational agents [10], and a systematic review of conversational agents in healthcare [11]. None of them does a SMS in chatbots usability, which proves our work is original. Judging by the increase in publications since 2015, the integration of usability of chatbots is of notable interest. However, there is no agreement on what would be a formalized and more systematic integration yet. Therefore, it is an open problem that requires more research effort. Even though the literature retrieved by the SMS provides a picture of chatbot usability, no paper provides generally applicable guidelines for chatbots usability. On one hand, the validity of our SMS is threatened by including only papers written in English. On the other, the authors of an SMS may make errors of judgement when analyzing the relevant publications. This is a horizontal rather than a vertical analysis, on which ground relevant publications may have been overlooked. Additionally, although the terms used in the search string were the most commonly accepted by other authors, other terms used describing relevant publications may have been overlooked. Finally, the publications were evaluated and classified based on the judgment and experience of the authors, and other researchers may have evaluated the publications differently.

VI. CONCLUSIONS

This paper has described an SMS study conducted to answer two research questions: **RQ1.** *What is the state of the art of usability in the development of chatbots?* We retrieved 19 primary studies dealing with integration from four different perspectives: usability techniques, usability characteristics, research methods and types of chatbots. The usability techniques are applied to evaluate the usability of the developed chatbot, but not in the analysis and design activities of the chatbot. The procedure more frequently followed to evaluate the usability of chatbot is to select a group of subjects to use the chatbot freely or perform certain tasks and then measure satisfaction with a SUS survey.

RQ2. *How to evaluate the usability of chatbots using HCI principles?* The evaluation of the usability of chatbots must be done considering the context of use, i.e. the environment where the chatbot will be used, and with representative subjects to whom the chatbot is directed. The most commonly used

methods are surveys, experiments and usability tests. The experimentation and replication of experiments is key within HCI. Achieving successful replicas in a discipline allows its results to be added to previous ones, making the body of knowledge grow. However, there is an absence of controlled experiments and replicas measuring chatbots usability.

There are many ways for practitioners to apply the usability material in this paper: (i) The chatbot implementation team can use usability characteristics (Tables II-IV) as checklists to help them solve critical problems, and (ii) comparing the test results of the same system at different times can check whether the usability characteristics is improved or decreased.

The real-life application of a chatbot will save time to companies, leading to financial gain because of the tasks it is able to take on. As the intelligence and technology of chatbots evolve, they will take on more responsibilities. The chatbot industry is very much interested in the adoption of usability techniques in its development process. On this ground, there is a need for usability-aware design guidelines.

Abstract — This paper presents a scenario-based approach to specify requirements and tests by extending Behavior-Driven Development (BDD) with the aim of ensuring the consistency between user requirements and user interface design artifacts. The approach has been evaluated by exploiting user requirements specified by a group of potential Product Owners (POs) for a web system to book business trips. Such requirements gave rise to a set of User Stories that have been refined and used to automatically check the consistency of task models, user interface (UI) prototypes, and final UIs of the system. The results have shown our approach was able to identify different types of inconsistencies in the set of analyzed artifacts and consistently keep the semantic traces between them.

Index Terms — Behavior-Driven Development (BDD); User Interface Design Artifacts; Automated Requirements Assessment.

I. INTRODUCTION

Modeling is recognized as a crucial activity to manage the abstraction and the inherent complexity of developing software systems. As a consequence, software systems tend to be designed based on several requirements artifacts which model different aspects and different points of view about the system. Considering that different phases of development require distinct information, resultant artifacts from modeling tend to be very diverse throughout the development, and ensuring their consistency is quite challenging [1]. To face this challenge, extra effort should be put on getting requirements described in a consistent way across the multiple artifacts. Requirements specifications should not, for example, describe a given requirement in a user interface (UI) prototype which is conflicting with its representation in a task model.

Behavior-Driven Development (BDD) [2] has aroused interest from both academic and industrial communities as a method allowing specifying testable user requirements in natural language using a single textual artifact. BDD describes User Stories (US) [3] and scenarios in a easily understandable way for both technical and non-technical stakeholders. In addition, BDD scenarios allow specifying “executable requirements”, i.e. requirements that can be directly tested from their textual specification. Despite providing support to automated testing of user requirements, BDD and other testing approaches essentially focus on assessing fully interactive artifacts such as full-fledged (final) versions of user interfaces. Automated assessment of model-based artifacts such as task models, UI prototypes, etc. is not supported.

Motivated by such a gap, we have researched and developed an approach based on BDD and User Stories to support the specification and the automated assessment of functional aspects of user requirements on user interface design artifacts such as task models, UI prototypes, and final UIs [4]–[8]. This paper presents a refined version of this approach and summarizes the new results we got in a case study exploiting User Stories specified by potential Product Owners (POs) to automatically assess user interface design artifacts for a web system to book business trips. The following sections present the foundations of this work as well as the refined version of our approach and a brief discussion of the results obtained with this case study.

II. FOUNDATIONS

A. Behavior-Driven Development (BDD)

According to Smart [9], BDD is a set of software engineering practices designed to help teams focus their efforts on identifying, understanding, and building valuable features that matter to businesses. BDD practitioners use conversations around concrete examples of system behavior to help understand how features will provide value to the business. BDD encourages business analysts, software developers, and testers to collaborate more closely by enabling them to express requirements in a more testable way, in a form that both the development team and business stakeholders can easily understand. BDD tools can help turn these requirements into automated tests that help guide the developer, verify the feature, and document the application.

BDD specification is based on User Stories and scenarios which allow to specify executable requirements and test specifications by means of a Domain-Specific Language (DSL) provided by Gherkin. User Stories were firstly proposed by Cohn [3]. North [10] has proposed a particular template to specify them in BDD and named it as “BDD story”:

Title (one line describing the story) Narrative: As a [role], I want [feature], So that [benefit] Scenario 1: Title Given [context], When [event], Then [outcome]
--

In this template, BDD stories are described with a *title*, a *narrative* and a set of *scenarios* representing the acceptance criteria. The *title* provides a general description of the story, referring to a feature this story represents. The *narrative* describes the referred feature in terms of the role that will benefit from the feature (“*As a*”), the feature itself (“*I want*”), and the

benefit it will bring to the business (“*So that*”). The acceptance criteria are defined through a set of *scenarios*, each one with a title and three main clauses: “*Given*” to provide the context in which the scenario will be actioned, “*When*” to describe events that will trigger the scenario and “*Then*” to present outcomes that might be checked to verify the proper behavior of the system. Each one of these clauses can include an “*And*” statement to provide multiple contexts, events and/or outcomes. Each statement in this representation is called a *step*.

B. User Interface Design Artifacts

1) *Task Models*: Task models provide a goal-oriented description of interactive systems but avoiding the need of detail required for a full description of the user interface. Each task can be specified at various abstraction levels, describing an activity that has to be carried out to fulfill the user’s goals. By modeling tasks, designers are able to describe activities in a fine granularity, for example, covering the temporal sequence of tasks to be carried out by the user or system, as well as any preconditions for each task [11]. The use of task models serves multiple purposes, such as better understanding the application under development, being a “record” of multidisciplinary discussions between multiple stakeholders, helping the design, the usability evaluation, the performance evaluation, and the user when performing the tasks. Task models are also useful as documentation of requirements both related with content and structure. HAMSTERS [12] is a tool-supported graphical task modeling notation for task modeling. In HAMSTERS, tasks can be of several types such as abstract, system, user, and interactive tasks. Temporal relationships between tasks are represented by means of operators. Operators can also be of several types such as enable, concurrent, choice, and order independent operators. The temporal operators allow extracting usage scenarios for the system. This is done by following the multiple achievable paths in the model, with each combination of them generating an executable scenario that can be performed in the system.

2) *User Interface (UI) Prototypes and Final UIs*: A UI prototype is an early representation of an interactive system. They encourage communication, helping designers, engineers, managers, software developers, customers and users to discuss design options and interact with each other. Prototypes are often used in an iterative design process where they are refined and become more and more close to the final UI through the identification of user needs and constraints. While the beginning of the project requires a low-level of formality with UI prototypes being hand-sketched in order to explore design solutions and clarify user requirements, the development phase requires more refined versions frequently describing presentation and dialog aspects of the interaction. By running simulations on prototypes, we can determine and evaluate potential scenarios that users can perform in the system [13]. The presentation aspect of full-fledged user interfaces frequently corresponds to how the user “see” the system. From the user’s point of view, the presentation of a user interface actually is the system, so if some feature is not available there, then it does not exist at all. Mature UI versions are the source for acceptance testing and will be used by users and other stakeholders to assert whether or not features can be considered as done.

III. THE PROPOSED APPROACH

Our proposed approach for assessing the considered artifacts is illustrated in Figure 1, where User Story scenarios are used to ensure consistency in our target artifacts (task models, UI prototypes and final UIs). Therein are exemplified five steps of scenarios being tested against equivalent tasks in task model scenarios, and the equivalent interaction elements in UI prototypes and final UIs. In the first example, the step “*When I select ‘<field>’*” corresponds to the task “*Select <field>*” in the task model scenario. Such a correspondence is due to the fact that the step and the task represent the same behavior, i.e. selecting something, and both of them are placed at the first position in their respective scenario artifacts. The interaction element “*field*” that will be affected by such a behavior will be assessed on the UI prototype and on the final UI. In both artifacts, such a field has been designed with a *CheckBox* as interaction element. The semantics of the interaction in *CheckBoxes* is compatible with selections, i.e. we are able to select *CheckBoxes*, so the consistency is assured.

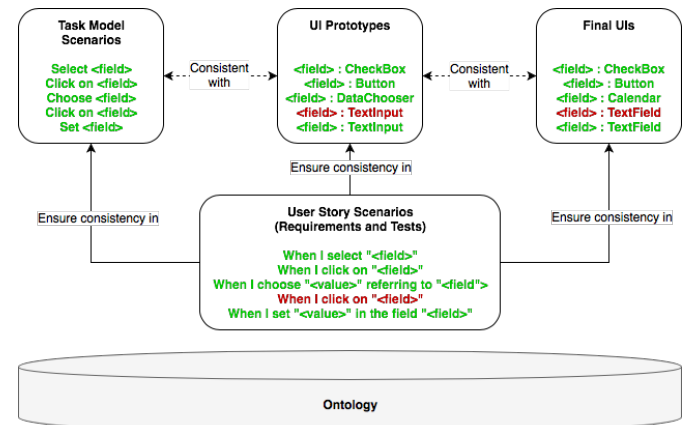

Figure 1. The approach for assessing the different UI artifacts.

The same is true in the example with the second step (“*When I click on ‘<field>’*”). There is a corresponding task “*Click on <field>*” at the same second position in the task model scenario, and the interaction element “*Button*”, that has been chosen to address this behavior in both the UI prototype and the final UI, is semantically compatible with the action of clicking, thus the consistency is assured as well. In the third example, the step “*When I choose ‘value’ referring to ‘field’*” is also compatible with the task “*Choose <field>*” in the task model, and with the interaction elements *DataChooser* and *Calendar*, respectively in the UI prototype and in the final UI. Notice that, despite being two different interaction elements, *DataChooser* and *Calendar* support a similar behavior, i.e. both of them support the behavior of choosing values referring to a field.

The example provided with the fourth step (“*When I click on ‘<field>’*”) illustrates an inconsistency being identified. Even though there exists a corresponding task in the task model scenario, the interaction elements that have been chosen to address this behavior (*TextInput* in the UI prototype and *TextField* in the final UI) are not compatible with the action of clicking, i.e. such kind of interaction element does not semantically support such an action. The semantics of *TextInputs* (or *TextFields*) is receiving values, not being clicked. Such an example is provided with the fifth step (“*When I set*

'value' in the field '<field>'''). For this step, the consistency is assured because *TextInputs* and *TextFields* support the behavior of having values being set on them. All this semantic analysis is supported by the use of an ontology that models the interaction elements and the interactive behaviors they support [14], [15].

The present strategy for assessment allows tracking some key elements in the UI design artifacts and check whether they are consistent with the user requirements. The solution has been implemented in Java integrating multiple frameworks such as JBehave, JDOM, JUnit, and Selenium WebDriver.

A. Alternatives for Performing the Approach

Depending on the project phase, our approach can be applied in two ways. The first one is applied when the project is running, and artifacts have already been designed. In such a case, our approach can be used to assess such artifacts, indicating where they are not in accordance with the specified requirements. The second one refers to a project in the beginning, where no artifacts have been designed yet. In this case, by using the ontology, they can be modeled in a consistent way from the beginning, taking into account the possible interactions supported by each interaction element on the UI.

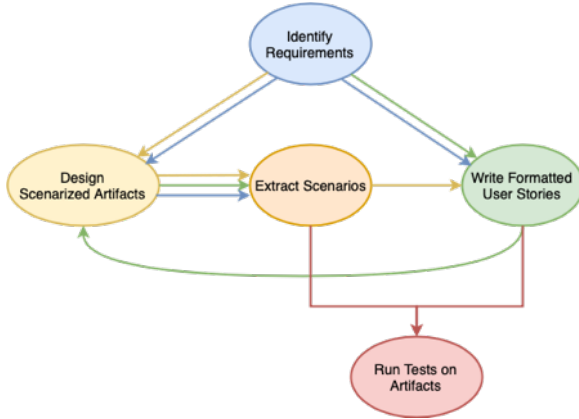

Figure 2. The graph of options for performing our approach (colors are used to visually identify the different paths).

Figure 2 illustrates the resultant graph of options considered. The colored lines indicate the possible paths to be taken in the workflow. The yellow path indicates the design of scenarized artifacts before writing formatted User Stories. The green path indicates the opposite, while the blue path indicates both activities in parallel. Notice that regardless the path chosen, the extraction of scenarios is only possible after having designed the scenarized artifacts, and the identification of requirements is a precondition for all the other activities. Finally, to run tests on the artifacts, it is required to have extracted scenarios and written the User Stories. The approach benefits from the independence for testing artifacts, i.e. tests can run on a single artifact or on a set of scenarized artifacts which will be targeted at a given time.

IV. CASE STUDY

To investigate the potential of the approach, we have conducted a case study with an existing web system for booking business trips. We have studied the current implementation of user requirements in this system, and by applying a manual reverse engineering, we redesigned the appropriate task models

and UI prototypes for the system. Based on a set of User Stories collected in a previous study [16], we refined it to simulate the assessment of the resultant user interface design artifacts. The aim of this present study is to provide a preliminary evaluation regarding the extent of inconsistencies our approach is able to identify in the targeted artifacts.

We started the study by setting up an initial version of User Stories before reengineering initial versions of task models (in HAMSTERS) and UI prototypes (in Balsamiq) from the existing web system. After getting a first version of task models, we extracted a representative set of scenarios from them. By following our strategy for testing, we parsed and ran the initial version of User Stories against the initial set of extracted scenarios. As the strategy we follow for testing scenarios in task models parses all the steps of each scenario at once, the first round of results was obtained with a single battery of tests. Following this step, we ran the same initial version of User Stories against initial versions of Balsamiq prototypes. Unlike the strategy for testing task models, the strategy we follow for testing UI prototypes and final UIs parses each step of each scenario at a time, so if an error is found out, the test stops until the error is fixed. That requires to run several batteries of tests until having the entire set of scenarios tested. Consequently, at the end of running, the tested scenarios are fully consistent with the UIs. Finally, we analyzed the testing results and the main types of inconsistencies identified in each artifact.

In total, we set up for assessment 3 User Stories with 15 different scenarios, reengineered 3 task models (and extracted 10 scenarios from them), reengineered 11 UI prototypes, and tested 7 different final UIs. For scenarios extracted from task models, testing results return the equivalent position of each task in the US scenarios. For UI prototypes and final UIs, the expected result for each step is the presence on the UI of one and only one of the supported interaction elements designed to address a given interactive behavior.

TABLE I. RESULTS AFTER ASSESSING THE ARTIFACTS

Artifact	Total (Steps Analyzed)	Results	
		Consistent	Inconsistent
Task Models	147	5	142
UI Prototypes	36	21	15
Final UIs	288	276	12

Table 1 summarizes the results obtained. For task models, the most common source of the 142 inconsistencies identified concerned the task gaps present in the beginning of the scenario. As the assessment is performed in the extracted scenarios which represent a sequential instance of the tasks in the task model, a task gap in the beginning causes a domino effect in the forthcoming tasks in the scenario. So even if the remaining tasks in the scenario are semantically equivalent to the respective steps, they will be shown as inconsistent once they will be found in wrong positions due to this gap. For UI prototypes, from the 15 inconsistencies identified, we noticed they were mainly due to interaction elements specified with different names in the step and in the prototype. For final UIs, the high number of consistent steps (276 out of 288) in the set of scenarios analyzed is due to the need of fixing the inconsistency found before moving forward to the next steps. This makes that the scenarios which

call previous ones, in order to reuse steps and reach a given state of the system, already have these steps fully consistent during the test. Most part of the inconsistencies on final UIs was due to interaction elements that do not carry a unique and single identifier (or carry a dynamically generated one) and, as such, cannot be reached during the test.

We could also remark that some of the inconsistencies identified showed to be more critical than others. While simple inconsistencies such as differences in names of tasks and fields, conflicts between expected and actual elements, and messages and elements not found are easy to solve, conflicts between specification and modeling, and different specification strategies for task models represent more critical problems. On UI prototypes, the presence of semantically inconsistent elements as well as more than one element to represent the same field are also critical problems. On final UIs, fields already filled-in denotes inconsistencies that exposes important design errors. During the test, we also noticed that some inconsistencies were due to a wrong specification of the step in the US scenario, and not to a problem in the design of the artifact itself. So, to fix these inconsistencies, steps of US scenarios needed to be modified during the battery of tests to obtain a consistent specification of user requirements and artifacts. An immediate consequence of this fact is that scenarios used to test a given version of an artifact may be different than the ones which were used to test another artifact previously. This makes regression tests essential to ensure that a given modification in the set of US scenarios did not break the consistency of other artifacts and ended up making some artifact (that so far was consistent with the requirements) inconsistent again.

As limitations of the approach, it is worthwhile to mention that its current version covers only the assessment of HAMSTERS task models, Balsamiq UI prototypes and web final UIs. The need of extracting scenarios from task models to perform testing in such artifacts, and tools that do not support yet the automatic classification of errors are other limitations.

V. CONCLUSION AND FUTURE WORKS

This paper summarizes the new results we got by applying our approach for specifying and checking the consistency of user requirements on core user interface design artifacts. Compared to plain-vanilla BDD, this approach benefits from (i) an extension to assess other software artifacts than final UIs, and (ii) a common vocabulary to be reused for specifying interactive scenarios without requiring developers to implement the mentioned behaviors. Compared to other approaches for assessing requirements and artifacts, the term “test” is usually not employed under the argument that such artifacts cannot be “run”, i.e. executed for testing purposes, so in practice they are just manually reviewed or inspected in a process called verification. Manual verification of the software outcomes is highly time-consuming, error-prone and even impracticable for large software systems. Fully interactive artifacts such as final UIs can in addition be validated by users who can interact with the artifact and assess whether its behavior is aligned with their actual needs. As within our approach we succeed automatically running User Stories on software artifacts for assessing their consistency with user requirements, we actually provide the “test” component for both verification and validation of artifacts in the software development. We consider this a big step towards

the automated testing (and not only the manual verification) of software artifacts by means of a consistent approach allowing fully verification, validation, and testing (VV&T).

Future works include evaluating the impact of maintaining and successively evolving the mentioned artifacts throughout a real software development process, besides investigating the suitability of the approach for assessing a wider group of artifacts, especially those related to conceptual aspects of software modeling such as class diagrams. Concerning the tools, the development of a plugin to suggest and autocomplete steps in the User Story scenarios based on the interactive behaviors of the ontology is also envisioned.

Abstract— The software development workflow typically involves developers executing tasks and manipulating artifacts. When developers receive a new task they typically envision a task context with the artifacts they intend to manipulate based on their past experiences. Given software projects may last several months, accumulating a vast amount of tasks, artifacts and developers, envisioning this initial task context may be difficult and error-prone. Developers have to walk-through months of past experiences or examine the experience of other developers, select similar tasks and then define the initial context. This paper introduces a method that helps developers defining the initial task context by combining interaction information over artifacts with text information of tasks. First, the Method uses the Clustering technique to organize project tasks into similar groups by interaction in artifacts. Then, the Method uses the Natural Language Processing technique to associate a new task with groups of similar tasks by interaction. The evaluation shows that the clustering of similar tasks by interaction produces similar tasks assigned with artifacts that will be edited by new tasks. The association of new tasks with similar groups by interaction indicates correlation between textual similarity and interaction similarity.

Keywords—component; interaction; task context; recommendation

I. INTRODUCTION

Software development projects last for months or years, where developers interact with each other and manipulate many artifacts. A typical task context in software development is formed by a set of artifacts that the developer uses to perform a task [1], [2]. Another widely explored context variable is the identification of task experts [3], as well as by experts in similar tasks to the new task [4].

When the developer receives a task to correct an error or add new functionality to the software, the developer usually starts by searching for artifacts that he needs to change to accomplish the task. This search is based on the developer's experience and the human capacity to remember of the artifacts already used in previous similar tasks [5]. In addition, the search is time-consuming, even when using the traditional navigation and

textual search tools available in development environments, e.g., Eclipse Project Explorer.

In this scenario, recommending an initial task context can help developers in performing new tasks. The recommendation tools in Software Engineering aim to reduce the uncertainties of the future through the analysis of project history, and in a more specific way, according to Robillard et al. [6], these tools are software applications that provides information items estimated as valuable to a software engineering task in a given context.

Aiming at inferring new task context, some works focus on the recommendation of artifacts, i.e., source code, files, classes, packages [1], [7]–[11], others in the recommendation of artifact experts [12], [13]. Proposals [14], [15] and [16] recommend experts to new tasks. Malheiros et al. [17] and Ashok et al. [18] recommend similar tasks to new task, while Wang et al. [4] and Ashok et al. [18] also recommend experts on similar tasks to new task.

This paper presents part of the Tacin method (Task Context based on Interactions) to recommend a new task context in software development projects. First, we defined that two tasks are similar by interaction if the developers edited at least one common artifact while performing the tasks. The weight of similarity is equal to the number of artifacts in common. After, the Method uses the Clustering technique to organize project tasks into similar groups by interaction in artifacts [19]. Then, the Method uses the Natural Language Processing technique to associate a new task with groups of similar tasks by interaction [20]. In this article, the edit interaction values are captured by Mylyn, an interaction model [28].

In the evaluation, the clustering of similar tasks by interaction indicated the production of task groups that had only 6% of the artifacts available in the project, but containing 77% of the artifacts that will be edited by new tasks. The association of new tasks with similar groups by interaction reduced by 90% the available artifacts and produced a recall of 52%. Therefore, the evaluation indicates success in Clustering and need for improvement in Natural Language Processing technique, i.e., improve the recall to a percentage closer to 77%.

This paper is organized as follows. Section II defines Clustering and Natural Language Processing. Section III presents the Method to recommend artifacts to new tasks in software projects. Section IV assesses the Method based on

average hits on recommending artifacts to new tasks. Section VI reviews related work and Section VI concludes our paper with a brief description of future work.

II. BACKGROUND

Developers interact with artifacts and collaborate among them to perform tasks in software development projects. The task objective is generally expressed by text. For example, the Mylyn Docs project uses a *short description* in natural language (English) to express an error. So, developer uses this textual information to search artifacts from the project's artifact database to correct it.

Table 1. Short description of task 245759 from the Mylyn Docs project.

	TaskId 245759 ^a
Short Description	cannot run the HtmlViewer or MarkupViewer in a stand-alone GUI

a. Available in https://bugs.eclipse.org/bugs/show_bug.cgi?id=245759.

The project task history is large since the projects last months, but for each performed task is possible to have the artifacts that were edited and by whom. Our method uses Clustering technique to organize the software project history database in clusters using edit interaction information. After, our method uses Natural Language Processing technique to identify the cluster that best fits the new task using textual information [20]. In this section we briefly introduce these two techniques.

Clustering is a computational technique for organizing data objects (elements) into groups (clusters) in order to provide an organization to support the human being in understanding information. Most similar elements tend to stay in the same group, while less similar or non-similar elements tend to stay in different groups [21], [22]. Similar groups do not have an identification according to the content of the groups, so this technique is also known as unsupervised learning.

The Natural Language Processing (NLP) is formed by a set of computational techniques motivated by theory for the automatic analysis and representation of human language [20]. The techniques and models designed for one language are not easily generalized to other languages in most cases [23]. According to Cambria and White [20], NLP research began with the word analysis paradigm, evolved to the analysis of concepts, and it is expected that models can understand narratives in the future.

III. METHOD TO RECOMMEND ARTIFACTS TO NEW TASKS

The Tacin method recommends a new task context defined as: 1- artifacts that will probably be edited by developers to perform a new task; 2- performed tasks similar to the new task; 3- experts in the new task. This paper presents the part of Tacin to recommends artifacts to new tasks in software projects.

In software projects, developers create or change artifacts to perform tasks. So, Tacin defines that the similarity weight between two tasks is equal to the number of artifacts edited in common between them. First, Tacin organizes task history into groups of similar tasks by edit interaction. Figure 1 shows the task representation of the Mylyn Docs project. Tasks are represented by green triangles; artifacts by blue squares;

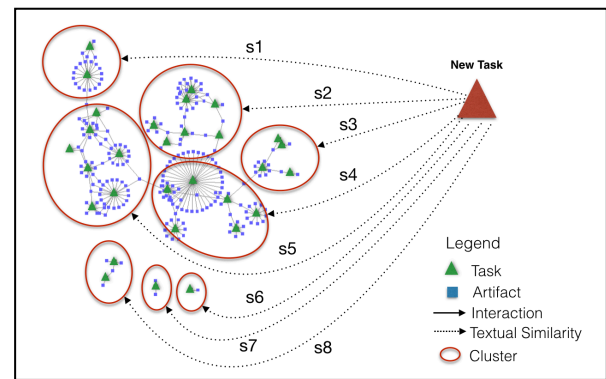

Figure 1. Illustration of the method to recommend artifacts to compose the context of a new task in software development project.

interactions by black lines linking tasks to their artifacts. A black line can represent one or more edit interactions on artifact.

The automatic determination of similar groups from a dataset is extensively studied in the literature [21]. Tacin uses LNS_SMC (Large Neighborhood Search - Software Module Clustering) heuristic based on the large neighborhood search metaheuristic. The LNS_SMC algorithm was chosen because presented a good efficiency using the Modularization Quality (MQ) measure applied to the clustering problem of software modules [20].

Figure 1 illustrates the association of a new task with the project task history organized in clusters. Each cluster can be seen as a single task where its *short description* is defined as the concatenation of the short descriptions of all tasks belonging to the cluster. Thus, the textual similarity between the new task and the clusters can be calculated.

Figure 1 also illustrates the recommendation of artifacts with Tacin. The first three groups (clusters) that present the greatest textual similarity to the new task are selected for the recommendation. Tacin recommends artifacts that belong to the group(s) considering three options: 1 - only the group most similar textually to the new task; 2 - the two groups most similar textually to the new task; 3 - and the three groups most similar textually to the new task. Tacin chooses a option according with the effectiveness of past recommendations. For this, the harmonic average between Reduction and Recall (Rc-measure) for three options is calculated for each new task, equations defined in (1-3). The option that has the highest Rc-measure receives 1 point. Then Tacin can recommend artifacts to developers using the highest scoring option. If there is a tie, Tacin recommends the option of a smaller number of selected groups.

$$\text{Reduction} = 1 - \frac{|\text{Recommended Artifacts}|}{|\text{Project Artifacts}|} \quad (1)$$

$$\text{Recall} = \frac{|\text{Recommended Artifacts} \cap \text{Relevant Artifacts}|}{|\text{Relevant Artifacts}|} \quad (2)$$

$$\text{Rc-measure} = 2 \times \frac{(\text{Recall} \times \text{Reduction})}{(\text{Recall} + \text{Reduction})} \quad (3)$$

IV. ASSESSMENT

The planning of the study includes objective, case, research questions and method according to the guide to conduct and report case study in Software Engineering [24]. The objective is described in the format indicated by GQM [25]: *Analyze the Tacin method to recommend artifacts for the purpose of evaluating their effectiveness from the perspective of the developer in the context of a software development project.* According to this objective following the RQ1 research question: Is the Tacin method effective in recommending artifacts at the beginning of a new software development task?

The effectiveness of Tacin depends on the effectiveness of task clustering by edit interaction and the correlation between textual similarity and similarity by edit interaction between tasks. Then two research sub-questions were defined: RQ1.A: Is task clustering by edit interaction effective for recommending artifacts? RQ1.B: Is there evidence on the existence of correlation between textual similarity and similarity by edit interaction among tasks?

Tacin reduces the number of artifacts available at the beginning of a new task, trying not to omit the artifacts that will be edited by developers. Equation 1 present Reduction measure. Equation 2 show Recall measure. So, Equation 3 combines these two measures in a harmonic way. Therefore, the Rc-measure metric was chosen to measure the efficacy of the Method.

The Mylyn Docs project was the case selected to evaluate the artifacts recommendation because it has the textual information of the tasks and developer interactions on the artifacts. The data collected from Mylyn Docs project was generated by the Mylyn, Git and Bugzilla tools. The Mylyn plugin logs developer's interactions about artifacts as interaction event with kind='edit'. The parameters for the query were Classification = Mylyn and Product = "Mylyn Docs" and Component = EPUB or Framework or HtmlText or Wikitext and Status = RESOLVE and Resolution = FIXED and Match ALL of the following separately → Attachment Description → contains the string → mylyn/context/zip. The query was executed in the site <https://bugs.eclipse.org/bugs/query.cgi> at April 05, 2017 and returned 334 tasks with 49906 edit interactions performed by 6 developers over 1538 artifacts. We have identified many performed tasks in the Mylyn Docs project that do not have Mylyn logging. So, committing actions were collected to infer editing actions, usually, a committing action submits edited files to code repository. Commits extraction resulted in 918 commits performed by 33 developers over 5407 artifacts.

The study generated artifact recommendations to new task in 20 trials, simulating a new task on each first day of the month from 09/01/2008 to 04/01/2010 to evaluate a long time period. The artifacts that were associated with tasks up to the date of the trial and were also associated with the new task after their completion form the set of relevant artifacts of the new task. Tacin tries find these relevant artifacts using only edit interactions finished before the start of each new task. Each trial generates groups of similar tasks by edit interaction. For each trial, 30 trials using the LNS_SMC were performed and the cluster with the highest MQ was chosen to be used to make recommendation.

Tacin calculates all textual similarities between the new task and the calculated clusters. The *short description* field of the new task was used with concatenation of all the *short description* fields of the tasks in each cluster. RapidMiner Studio was used to calculate textual similarity. The text processing used the functions Replace Tokens, Transform Cases, Tokenize, Filter Stopwords, Filter Tokens (by Length) and Stem (Porter). Then the texts were represented in vectors using the occurrence of terms. Finally, the similarities between the vectors (texts) were calculated using the cosine similarity function.

The evaluation contemplates three options of recommendation according to textual similarity among new task and tasks clustered by edit interaction. The first option evaluates the recommendation of the artifacts to the group that presents greater similarity. The second recommends the task artifacts of the two groups that present the greatest similarities. Likewise, the third one recommends the task artifacts of the first 3 groups. These 3 options are rated according to Recall, Reduction and Rc-measure for each trial.

A. Results

The average Recall of the first option was 37%, with Reduction equal to 97% and Rc-measure of 41%. The second option presented Recall equal to 45%, Reduction of 93% and 48% of Rc-measure. The third one obtained average Recall of 52%, Reduction of 90% and 57% of Rc-measure. Accordingly, we observed that the third option is the best according to the average values of Rc-measure.

The result of this study shows that clustering of similar tasks by interaction (RQ1.A) built at least one cluster that had only 6% (94% of Reduction) of the artifacts available in the project, but that had 77% of relevant artifacts (Recall) for a new task. The conclusion is that the answer is yes to RQ1.A when combined LNS_SMC with MQ. In 8 rounds, the first cluster more similar textually with the new task also presented the highest Recall. However, in 10 trials, the 3 clusters most similar textually to the new task did not present maximum Recall, among these, in 4 trials (20%) there are no correlation between similarity by interaction and textual. The conclusion is that the answer is yes also for RQ1.B, the study showed that there is evidence of correlation between textual similarity and similarity by interaction in software development tasks.

V. RELATED WORK

Hipikat uses a large number of documents available in the project such as source code, documentation, communications between developers (e-mail, discussion forums), error reporting and test plans. The Hipikat evaluation presented an average Recall of 65% [1]. Antunes et al. [8] proposed a recommendation system to recommend a list of relevant artifacts. The System uses developer interactions in real time and artifact access time to list the most relevant artifacts. Then it uses the relations of the language structure (Java) and textual associations to order the recommended artifacts in a decreasing way of relevance. The evaluation showed an average Recall of 42,7%.

The proposal of Ye et al. [9] lists a classification of relevant artifacts (top 10) to correct an error in the software considering the information of the project history. The evaluation indicates

that the proposal can recommend relevant artifacts in 70% of the recommendations. CodeRants is a recommendation method for recommending artifacts. This Method is based on the repetition of the textual searches performed by the programmers and on the metaphor of the ant colony [10]. The evaluation was performed in a simulated environment, in this environment CodeRants obtained an average Recall of 71%. Almhana et al. [11] have shown that to recommend relevant artifacts to support the developer in the correction of an error can be mitigated as a multi-objective problem, maximizing the relevance of the recommended artifacts and minimizing the number of recommended artifacts. The evaluation showed strong evidence that the proposal may recommend lists with relevant artifacts: Recall @ 5 = 72%; Recall 10 = 81%; Recall 15 = 87%; Recall 20 = 94%.

VI. CONCLUSION

This paper presents part of Tacin method to recommend artifacts to compose the context of new tasks in software projects. Tacin makes use of Clustering and Natural Language Processing techniques. The clustering of task history in similar tasks by interaction presented a Recall of 77%. The next study will consider the degree of relevance between artifact and task. The textual association of the new task with the similar task groups to produce artifacts recommendation with 52% of Recall. This study uses only task *short description* field. The next study should consider other text information from task history, e.g., comments from developers while performing tasks. In addition, other techniques such as dw-cosine [26], an extension of the cosine of similarity, and also techniques for small texts with grammatical errors need to be evaluated.

Abstract—There is an ever increasing growth in the use of Q&A websites such as Stack Overflow (SO), so are the number of posts on them. These websites serve as knowledge sharing platforms where Subject Matter Experts (SMEs) and developers answer questions posted by other users. It is effort intensive for developers to navigate to right posts because of the large volume of posts on the platform, despite the presence of existing tags, that are based on technologies. Tagging these posts based on their context and purpose might help developers and SMEs in easily identifying questions they wish to answer and also in identifying contextually similar posts. To support this idea, we propose *SOTagger* as a prototype plug-in for Stack Overflow to tag questions contextually. We have considered SO data provided on *SOTorrent* and automated the identification of 6 categories of questions using Latent Dirichlet Allocation. We have also manually verified relevance of these categories. Using these categories and dataset, we have built a classification model to classify a post into one of these six categories using Support Vector Machine. We have evaluated *SOTagger* by conducting a user survey with 32 developers. The preliminary results are promising with about 80% developers recommending the plugin to others.

Index Terms—Stack Overflow, Contextual Tagging, LDA

I. INTRODUCTION

Stack Overflow (SO) is one of the most frequently used websites with about 11M visits every day. With a user base of 10M users, about 7.3K questions are posted per day. It comprises of about 18 million questions, of which 71% are answered¹. These questions correspond to various technical categories, tools, libraries and are tagged into atmost 5 of 54K tags² present on the website. This tagging is done based on their technical relevance with the posted content and is used to organize posts and thus help users to browse for questions and answers concerning to particular topics such as *javascript*, *jquery*, *python* and so on [1]. However, these tags don't classify questions based on the context in which they are asked. The context would capture situations pertaining to conceptual understanding, issue resolving and so on.

Recent studies have aimed at classifying questions on SO based on their context and arrived at almost similar

taxonomies of categories. They have used various techniques such as K-NN clustering [2], automatic categorization by topic modeling using LDA and MALLET [3] and manual categorizations [1], [4]. Some of these studies have aimed to contextually categorize technology-specific questions such as questions related to Android application development [2] and mobile operating systems like *Android*, *Apple* and *Microsoft Windows*. However, existing tools do not categorize posts on SO platform based on context. To this end, the contributions of this paper are as follows:

- *SOTagger*³ - a prototype plug-in that classifies posts on SO into six categories: *Conceptual*, *Discrepancy*, *Implementation*, *Error*, *Learning* and *MWE (Minimum Working Example)*.
- Application of NLP techniques - Latent Dirichlet Allocation(LDA) and Machine learning (ML) classifier - Support Vector Classifier (SVC) to classify SO posts.
- Evaluation of *SOTagger* with 32 professional developers and manual cross-verification of 100 posts.

II. RELATED WORK

In the recent years, several studies have been done to analyze posts on SO, which include analyzing developers' area of interest based on questions asked [5], analyzing and suggesting tags of the questions [2] [1] [6] [7], identifying difficulties faced by developers [8], identifying trending technological topics [9], and so on. Researchers have classified posts on SO based on the context by manually interviewing software developers. In a survey conducted by Latoza et al., 179 professional software developers were asked to identify hard-to-answer questions pertaining to code that they solicit wherein 371 questions were reported. They have manually categorized them into 21 categories with 94 distinct questions, of which the 5 most frequently reported categories were - *Rationale*, *Intent* and *Implementation*, *Debugging*, *Refactoring* and *History of code* [10].

Studies have been conducted to investigate various question categories based on the context in which they

DOI reference number: 10.18293/SEKE2019-067

¹<https://stackexchange.com/sites?view=list#traffic>

²<http://bit.ly/SONumTags>

³<https://github.com/chaitanya-lakkundi/SOTagger>

were asked. Rosen et al. manually categorized 380 posts on SO into 3 question categories based on the three interrogative words- *How, What and Why*, corresponding to three mobile operating system categories - *Android, Apple and Microsoft Windows* [4]. Treude et al. have manually classified 385 questions on SO into 10 categories - *How to, Decision Help, Discrepancy, Environment, Error, Conceptual, Review, Non-Functional, Novice, Noise* [1]. Although methods involving manual effort are necessary to capture ground truth, we see a need to find better ways to scale this approach such that automation is possible.

Elucidating further studies, Beyer et al. have proposed 7 question categories - *API Change, API Usage, Conceptual, Discrepancy, Learning, Errors, Review* by manually classifying 500 SO Android posts and performed automatic classification using supervised machine learning algorithms with a precision of 88% [2]. Allamanis et al. found 5 major question categories using LDA and unsupervised machine learning algorithm [3].

Insofar as the development in methods of classification is concerned, the research community has progressed from significant manual studies to automating them using machine learning algorithms and NLP techniques. Contemporary tools such as EnTAGREC++ [6], TagCombine [7] have been developed to provide tag suggestions to users when they post questions on SO. These tools suggest tags based on technologies involved in the post content. The prototype plug-in we propose, *SOTagger*, tags posts on SO based on their purpose or intent rather than considering the technologies involved. Based on the existing work on classifying posts [2] [1] [4] [3], we propose a taxonomy to tag posts contextually.

III. PROPOSED TAXONOMY

Posts can be classified using several NLP techniques such as LDA, LSA, TF-IDF. However, inline with the existing work, we followed LDA technique.

We present six question categories that we have derived from existing studies and results obtained from LDA topic modeling. As a result of LDA topic modeling configured for 6 topics, we obtained 6 topics characterized by keywords for each topic, along with the weightage of keywords in every topic. Omitting the technical terms and considering interrogatives, it has been observed that *Topic 0* comprises of *discrepancy*, *Topic 1* contains *error*, *Topic 2* contains *how-to or implementation*, *Topic 3* contains *learning*, *Topic 4* contains *conceptual* and *Topic 5* contains *MWE* keywords respectively, as shown in Table I. These results obtained by applying LDA on SO posts indicate the presence of contextual categories in SO data. Comparing these results with the existing taxonomy discussed by Beyer et al. in [2] and other taxonomies presented in [1] [4] [3], we reorganize few categories in the existing literature and arrive at labelling five of these six topics as *conceptual, discrepancy, implementation, error and learning* respectively. We

TABLE I
TAXONOMY OF QUESTION CATEGORIES

S.No.	Topics	Keywords
1	Conceptual	What is use/difference, Is there a way, Is it possible[2]
2	Discrepancy	doesn't work, tried to, have/facing problem, before upgrade previous version [2]
3	Implementation	How to implement [4] [3] [1]
4	Error	Exception, error [2]
5	Learning	suggest, tutorial, where can I find [2]
6	MWE	for this code, code tags

observed that many of the posts on SO contained code snippets, which could indicate that users post questions containing code to reproduce the bug they are facing. Such code snippets serve as *Minimum Working Examples (MWE)*⁴, which is proposed as another category *MWE*. We observe this naming to be inline with work proposed by Allamanis et al. [3]. Each post can be classified into one or more of these six categories.

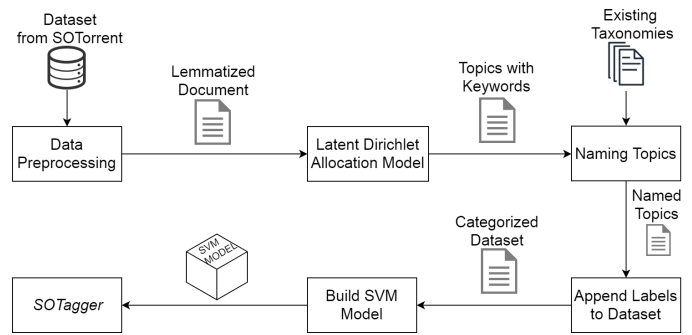

Fig. 1. Overview of Approach for *SOTagger*

IV. DESIGN METHODOLOGY

We followed a six step approach in designing a contextual classification model as shown in Fig 1.

Step 1 - Extract DataSet. To perform categorization of SO posts, we downloaded *Posts.xml* file available on *SOTorrent*⁵. We considered a subset of this file that constituted 100K Stack Overflow posts under *Body* column and filtered out questions based on *PostTypeId* column that resulted in a dataset of 20K posts.

Step 2 - Data Preprocessing. Data present in *Body* column whose *PostTypeId* = 1 was considered for pre-processing. We considered English stop words provided by NLTK library and omitted interrogative words from the list of stop words keeping in view, the taxonomy proposed. We processed the data for stop word, punctuation removal and lemmatization using *spaCy*.

⁴<https://stackoverflow.com/help/mcve>

⁵<https://zenodo.org/record/2273117>

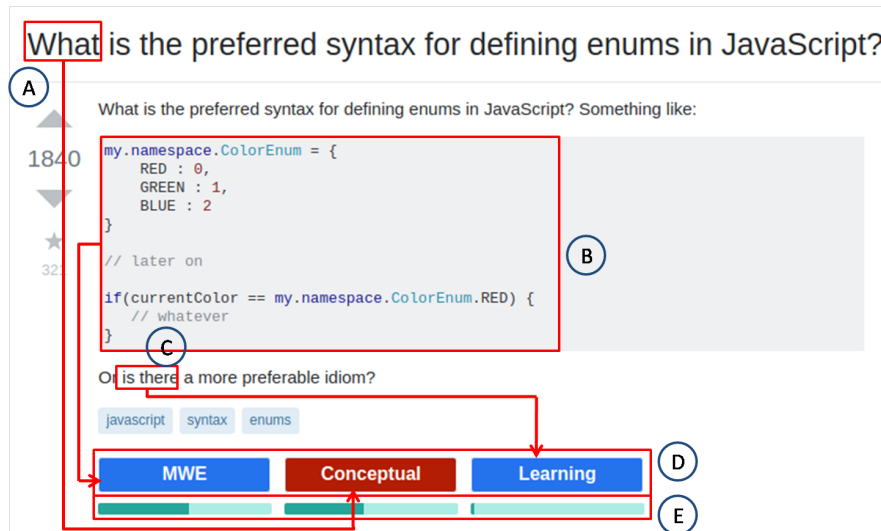

Fig. 2. A Snapshot of *SOTagger*

Step 3 - Latent Dirichlet Allocation Model. We applied LDA to perform topic modeling. We primarily created a dictionary of lemmatized words and then created a corpus of these words with their frequency of occurrence. Considering this corpus, we generated an LDA model that categorizes given data into 6 topics.

Step 4 - Naming Topics. Based on existing taxonomies in the literature [2] [1] [4] [3], we identified contextually useful keywords in each of the 6 topics, and used them to identify and name topics.

Step 5 - Append Labels to Dataset. The LDA model provided us with a topic-document correlation matrix, where document refers to content of one post. This matrix contained probabilities of every identified topic for each document. We then classified posts in the dataset into topics based on the dominant topic from correlation matrix which had the highest probability.

Step 6 - Prepare a Machine Learning model - Build SVM Model. We applied various machine learning classification algorithms such as *Linear SVC*, *Logistic Regression*, *Multinomial Naive Bayes*, *Random Forest Classifier* to arrive at the best classification model on available dataset with 75% train and 25% test data. We observed that SVC was able to classify the given data set with higher accuracy (78.5%) than other models. Based on this, we designed SVC model and pipelined to *CalibratedClassifierCV* to get prediction probabilities.

V. DEVELOPMENT OF *SOTagger*

This plug-in has been developed as an extension to *Google Chrome* to support classification of posts on SO. It tags posts on SO based on their context. *SOTagger* reads SO posts on the page and extracts questions from these posts which are fed into previously developed ML classification models using SVM classification. This model outputs the categories of specific posts along

with associated probabilities which are presented as tags below the posts on SO platform.

A snapshot of *SOTagger* is shown in Fig 2 for a sample post on SO. Tags corresponding to context of the question are displayed below the post as shown in [D] of Fig 2 and are arranged in decreasing order of probability. The probability with which a post is tagged into each of the displayed categories is represented by a bar as depicted in [E] of Fig 2. According to *SOTagger*, this post is classified as *MWE* category with highest probability. As pointed in [B] of Fig 2, presence of code segment justifies classification of the post into *MWE* category. Presence of *What* keyword as highlighted in [A] of Fig 2, contributes to *Conceptual* tag, with a lesser probability than *MWE* tag. *is there* phrase represented by [C] of Fig 2 contributes to *Learning* category, with least probability.

However, the keywords or phrases demonstrated in Fig 2, are for the purpose of analyzing the correctness of *SOTagger*, but are not the only basis for classification. Actual classification was based on NLP and ML techniques that have been used in development of *SOTagger*.

VI. EVALUATION AND RESULTS

We evaluated *SOTagger* by conducting a user survey with 32 professional developers with a development experience ranging from 2 years to 19 years.

The participants were asked to use *SOTagger*, navigate to SO website and analyze the contextual tags added by *SOTagger*. A user survey was conducted with the help of five point Likert scale, containing a questionnaire as provided in Table II.

Apart from user survey, we manually evaluated⁶ contextual tags of about 100 random posts on SO tagged by *SOTagger* and obtained an accuracy of 77%. The

⁶<https://git.io/fjC83>

results of our survey indicate, *SOTagger* had a good user-friendly interface (82% in Q1). In Q2, about 85% of participants have agreed that *SOTagger* has appropriately tagged the posts. The ratings in Q3 and Q4 indicate that *SOTagger* has helped about 80% of participants in faster browsing of posts on SO and that the experiment has been considerably interesting (81% in Q4). In Q5, most of the participants have agreed that they would recommend *SOTagger* to their peers (83%).

TABLE II
QUESTIONS IN SURVEY USING A 5-POINT LIKERT SCALE.

Q1: How easy was it to use <i>SOTagger</i> interface?
Q2: <i>SOTagger</i> has tagged SO posts correctly based on their context.
Q3: <i>SOTagger</i> has helped me in quick browsing of posts based on context.
Q4: <i>SOTagger</i> has kept the whole experiment interesting and informative.
Q5: I will recommend <i>SOTagger</i> to my peers.

VII. THREATS TO VALIDITY

We have manually examined top 20 posts based on probability values in each of the 6 topics generated by LDA technique to assign topic name. This could be inaccurate considering limited number of posts examined.

To understand the accuracy of classification, we randomly browsed 100 posts on SO. We realize that examination of 100 posts in total is not enough to get an overall idea about the accuracy of classification. During the creation of LDA model, we tweaked a few parameters such as chunk size and number of passes which resulted in different statistical distribution of topics. Some of the distributions were imbalanced and biased towards one particular topic. We selected those parameters which resulted in a nearly Gaussian distribution. We assume that LDA model which classifies data in Gaussian distribution performs better than other models. However, initial results show that accuracy of trained LDA model is around 70%, but with scope for experimenting with other distributions. The machine learning model has been trained on a dataset of 20K questions, however we should consider a larger number of posts from SO to improve our approach.

VIII. CONCLUSION AND FUTURE WORK

In this paper, we presented *SOTagger*, a prototype plug-in to SO that tags questions on SO based on the purpose for which they are asked. We performed LDA topic modeling on data set available on *SOTorrent* to identify categories. We labelled the resultant LDA topics by harmonizing the existing taxonomies. We presented 6

question categories, independent of technical aspects involved in the questions. We then labelled question posts in the dataset into one or more of the 6 categories. We applied SVC on the labelled dataset to obtain machine learning classification model which was integrated into the plug-in to support tagging of posts on SO.

As a part of future work, we plan to extend *SOTagger* to display contextual tags of posts on SO landing page by training machine learning model only over titles of questions. We plan to work in the direction to improve levels of taxonomy from single level presented in the paper to multiple levels and display the same as a part of detailed contextual tagging. We could conduct an experiment to check whether we get better results by considering the opening and closing statements of SO posts.

Questions tagged with MWE could be of greater use for future research. Researchers interested to understand and analyze code provided by users when posing questions can easily find questions with this tag. We envision that future work based on this paper may include clustering posts classified as MWE to automatically find bugs, combine co-occurring tags to formulate new tags and so on. Also, several empirical studies on SO posts such as understanding code quality, misuse of code snippets and automatic bug reporting could be conducted.

Abstract—Currently, there is the need for systems to manage repositories of MATLAB code bases capable of supporting global queries and feed their results to analyses components. Such features are not directly supported in current platforms. This paper presents a repository management system that supports queries over semi-automatically annotated code files and are able to associate them to higher level concepts. To meet this need, this paper proposes an approach that equips the repository with support for sophisticated queries over its stored code base and allows patterns to emerge from such queries, namely for visualisation and further analysis. This is achieved through the synergistic combination of a token-based metrics extraction component and a relational model fed by an ubiquitous data mining process. The code base is represented by means of relational knowledge, enabling intelligent queries that can be extended with new code metrics. Presently, query results are being used for the detection of concerns, including those whose code is scattered over multiple modular units. This paper outlines the proposed system's architecture and presents a proof-of-concept implementation developed for MATLAB programs. It is evaluated by means of a set of illustrative queries over a seed repository of MATLAB systems.

Index Terms—MATLAB, Concern, Self Organizing Map, UbiSOM, Advanced Data Exploration, Software Repository Management System

I. INTRODUCTION

The MATLAB language is known to lack support for fully fledged modules capable of enclosing most concerns typically present in MATLAB systems [1] [2]. Its basic units of modularity are *m-files* (MATLAB code files) and *toolboxes*, comprising folders of *m-files* and optionally sub-folders. The latter often correspond to standalone programs or libraries made available for the user community. Lack of modularity makes it hard to obtain well-organised code that is easy to read and reuse [1] [3]–[5]. These shortcomings motivated ongoing research to study the symptoms induced by the lack of modularity [3] and use of that knowledge for the detection of unmodularised concerns in existing systems [6] [5].

The above research on concern detection techniques is centred on the idea of decomposing *m-files* into its low-level elements [3] and derive a number of metrics based on that information [6] [5]. A number of analysis components can subsequently be plugged into the system to derive higher-level information. Further details are given in section II.

Developing and maturing the concern detection techniques entailed the assembling of repositories of many MATLAB

systems in order to exercise and test functionalities. A number of metrics were derived, which were extracted from the code base by means of a tool that includes a lexical analyser for MATLAB [3] [6] [5]. Activities on the code repository included the performing of many kinds of search, e.g., to find new patterns, perform studies, check results. Initially, it was carried out by the metrics extraction tool. As search patterns tended to become increasingly elaborate and structured, the motivation for mounting the entire repository in a more intelligent system arose. This paper presents the outcome of that effort.

This paper presents a repository management system that exposes low-level data and allows the plugging of new analysis and visualisation components, which can be added over time. The repository management system could compute many of the queries previously supported by the lexical analyser tool and much else besides. It supports queries over automatically added annotations received from a data mining process and related annotations made by humans. Among other things, the system is able to expose associations between *m-files* based on higher level concepts.

Past work illustrated one potential use of the proposed repository through the implementation of a high level knowledge from a *Self Organizing Map* (SOM) data mining model that derives patterns from the code to enable the semi-automatic detection of (possibly unmodularised) concerns [6] [5]. By *semi-automatic*, we mean a process that starts with a machine learning classification phase, whose output can be corrected by a human or enriched by new annotations. We implemented a relational database and an associated web interface through which query results produced by the UbiSOM algorithm [7] are made available for further processing.

The rest of this paper is organised as follows. Section II describes the token-based technique used to decompose *m-files*. Next, section III describes the system's architecture and the relational model that enables a wide variety of queries over the code. Section IV illustrates how an external concern mining model can be used to automatically provide concern relevant tagging for all *m-files* in the repository. Section V presents a number of queries that illustrate the repository's capabilities. Section VI provides a short discussion of this work and section VII concludes the paper.

II. USE CASE: CONCERN DETECTION

This section relates to past research on the detection of concerns in MATLAB code bases [3] [5] and describes an use case for the annotated repository.

A *concern* is any abstraction, concept or cohesive set of functionalities that would ideally be enclosed in its own module, for the sake of comprehensibility and ease of maintenance and evolution [8]. Ideally, each individual concern would map to a different unit of modularity (e.g., an m-file or a function in MATLAB), with each unit having a single, *primary* concern. However, several factors contribute to this not being so in practice. The limited and incipient nature of MATLAB's modules and limited programming experience from many users, among other issues, contribute to many concerns remaining unmodularised. As a consequence, potentially useful and reusable pieces of code are left *scattered* throughout a system's m-files and functions, and *tangled* with conceptually unrelated code. Scattering and tangling are the two dual symptoms usually observed in the code when modularity support is deficient [9] [8]. Tangling is particularly harmful to the comprehensibility of all concerns found in the modular unit, including the primary concern [1] [4] [3].

The concern detection technique explored in this paper bases the representation of an entire code base of a repository, comprising all systems stored in it, on the decomposition of each and every code file into *tokens*, i.e., the lexical elements extracted by means of the lexical analyser. The subset of tokens that are *words* (keywords and identifiers) plays an important role in the concern detection approach. It is based on the idea that specific groups of word tokens can be associated to specific concerns, with individual tokens being associated to one concern at most. Patterns of occurrence of such tokens can be used to identify the presence of the associated concern in the code unit.

Presently, this approach is focused on function names, particularly names of functions from standard MATLAB libraries, because they are deemed more intention-revealing and are common to many MATLAB systems. Such names provide a measure of guarantee that the technique will operate uniformly in most systems. Programmer defined variable names are not currently considered because they are more variable across a repository of systems developed by many different teams.

The examples shown in section V serve as an illustration of the technique. They are focused on concern *verification of function arguments*, which relates to the processing that many MATLAB functions must carry out at the beginning to determine in which "mode" they were called (e.g., by finding out how many arguments it received). It is associated to a group of tokens that include `nargin`, `varargin` and `varargout`.

III. THE RELATIONAL MODEL

This section describes a relational model for a MATLAB seed code repository. It is important to note that although the system presented in this paper was developed as a proof of concept focused on MATLAB systems, its design – described

here – was created in view of covering a broader range of systems and programming languages.

The annotated repository was developed with the purpose of accommodating in one place all the data needed to perform exploratory analyses on MATLAB code, by means of advanced analysis components. The diversity and quantity of data being generated called for a powerful solution for data storage and query support. For this reason, a relational data model was adopted (e.g., [10]). It represents all data as *tuples*, grouped into relations. Note that *all* tokens are stored into the model: not just word tokens but also symbolic tokens, literals, etc. Such a model can easily be implemented in a relational database management system. A MySQL solution proved to be sufficient for the Web component of the system, while data analysis is based on snapshots of the systems in the repository, taken at the time of analysis of relevant information stored in a SQLite database.

The relational model represents the toolboxes, m-files and their complete contents (including comments, though presently they are not used). New systems, toolboxes and m-files can be added and similarly represented, including new versions of existing elements. Two main entities represent the organisation of all the systems into toolboxes and m-files and taking into account the possibility of multiple versions of these elements. Each m-file is in turn decomposed into code lines containing MATLAB code and thus stored. To reconstruct the original file (e.g., for visualisation or for some other subsequent processing), the model provides a separate entity to represent lines with comments only.

Tokens are the main subject of the analysis in this paper. Figure 1 depicts the main entities and relations for modeling the relation of MATLAB tokens and annotations within the repository according to the notation used by Silberschatz et. al. [11]. *Blocks* are intermediate entities grouping one or several lines and that are part of an m-file. Relations between toolboxes, m-files, code blocks, lines and tokens are simple one-to-many relations. For instance, a given line is always part of a block, which is always part of some m-file. Though an m-file is not necessarily organized into functions, we are mainly interested in that set of m-files since our focus is on MATLAB modularity. Under that view, blocks will always belong to some function, which in turn always belongs to some m-file. Decomposition of the entire code base along these lines requires just some basic parsing functionality added to the lexical analyser tool. Each block ends either with the `end` keyword or when another clearly defined block (e.g., a new function or control structure) begins. During design, we chose to also model each line of code in the repository as a tuple of the entity `Lines_mfiles` identified by its unique `line_id` identification code. The line number within the m-file and the block unique id are also unique identifiers for each line in the repository.

A token *instance* refers to individual occurrences of a given token. For instance, the various occurrences in the code of the `while` keyword can be said to be instances of the `while` token. The present token-based approach requires the

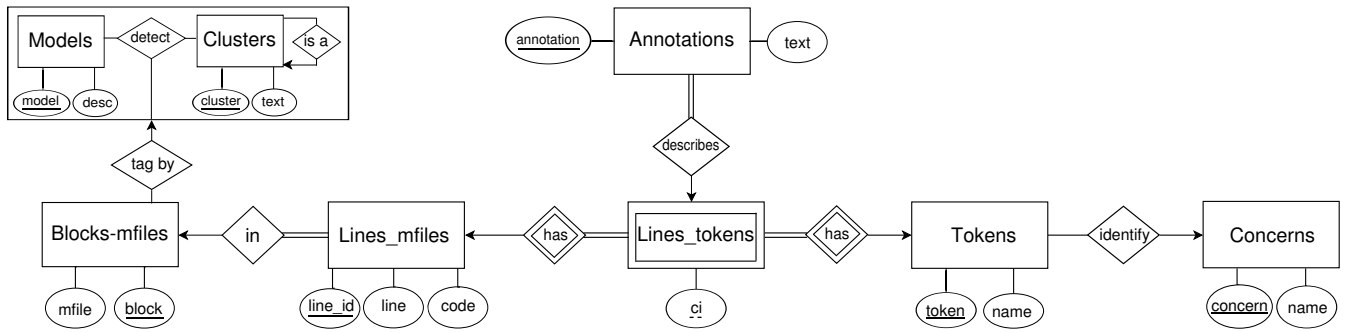

Fig. 1. Part of the system ER diagram for token related entities.

identification of each token instance, which is done by the lexical analyser tool. Each line comprises a *sequence* of token instances (order and position are important). Each non-empty line comprises at least one token instance or is a pure comment line in Fig. 1. Since a line can contain more than one instance of a given token, a weak entity (*Lines_tokens* in Fig. 1) is used to represent it. That weak entity is identified by the *line_id* of the *Lines_mfiles* entity and token position within the line (attribute *ic*). So, it is possible to know the line containing the token instance (attribute *line* from entity *Lines_mfiles*). This way, an indirect relation is made where each token instance is associated to its code or name. A token can also be associated to a given concern and a concern can be associated to several tokens — represented by the *identify* relation in Fig. 1. The design takes into account that future analyses may approach the code repository based on many different selection criteria. Annotations are also easily added using the *Lines_tokens* weak entity. This way a new entity *Annotations* is used so that users can add annotations when relevant *Lines_tokens* are found in Fig. 1. A simple annotation revision process is already supported: only accepted annotations will be shown in the final user interface.

During tool tests there was often a need to look for different combinations of two or more tokens or token-concern combinations. For instance, it was useful to find and visualize in what context some combinations occur in different m-files. The query can be done directly with a regular expression on the *code* field of entity *Lines_mfiles*, but this search is slow and slow to write. Besides, it will always be ineffective because limited to a single code line. As an alternative, the web interface performs a quick generation of queries in SQL (over the relational model). To obtain results quickly, the search is done on a first token after which an inner join is added for each additional token, of the resulting relation with itself. This way, it is possible to identify a sequence of elements (tokens or concerns) that are associated in the same m-file (through entity *Lines_tokens*). If they are relevant, extra constraints can be added to the query. For example, it is possible to specify a limit on the number of rows (or tokens) between the occurrences of both search tokens (the *ic* field of entity

Lines_tokens is essential for a correct result).

The code base used as testing material for the present research originates from a repository of MATLAB programs and toolboxes originally assembled to test a compiler for MATLAB [12]. It comprises 35 193 m-files organised by toolboxes and covering various application domains, downloaded from *Sourceforge* and *GitHub* [12]. The repository was already used in previous work for concern mining [6] [5].

The output of a fully automatic concern mining component can be easily related with this system. The relational model aims to be generic and should support hierarchical unsupervised machine learning methods. The simultaneous reference to several concern mining models is supported by means of an aggregation between entities *Models* and its detected *Clusters*. Such aggregation can be used for tagging *Blocks-mfiles* entries with the cluster assigned by a model, resulting from a data mining process over the repository. Also some unsupervised learning methods discover models where clusters can be related with other clusters (e.g. in hierarchical clustering methods). This way, each block in the repository can be assigned to a cluster derived from the concern mining model and the resulting cluster can be a sub-cluster of another related cluster. Moreover, no restriction is made regarding sharing of clusters among models (this could be useful in situations where related models identify the same kind of clusters). Finally, *Block-mfiles* tagging can be continuously updated by a ubiquitous data mining process (such as illustrated in section IV) or can be directly assigned/revised by means of a human made model (which probably entails laborious manual m-file cluster identification and correction tasks). The concern mining model presented in previous work [5] is used in the illustrative results presented in section V.

IV. VALIDATION USING UBISOM OUTPUT MODELS FOR CONCERN MINING

The system's design should provide for a continuous incoming stream and storage of MATLAB code files. Analysis and mining of its contents can be done based on ubiquitous data mining algorithms [13]. The UbiSOM algorithm was selected as an illustrative validation of this approach [5]. Appropriate support was developed for the continuous analysis

of data, approached as a data stream in which new m-files and toolboxes can be continuously added. The use of metrics to characterize the relevant blocks of code in the various m-files makes it possible to represent those blocks as a set of measures for different concerns, i.e., a set of feature-value pairs that is also stored in the database in a `patterns` entity. Each new set of such value pairs can be analyzed by means of the UbiSOM algorithm [7]. Note that each concern gives rise to its own specific value for each metric considered.

The UbiSOM component performs a continuous analysis of the data stream and maintains a SOM summarising all m-files in the repository and its contents, updating it whenever new contents are added. The relational model can deal with multiple SOM instances, all of which are represented in the database. This opens the way for (suitably trained) users to specify queries over the repository (using SQL) that also use SOM information to perform selections based on higher-level concepts. Note that each resulting SOM model and related query results can immediately become internally accessible to the system for subsequent processing.

The SOM model used consists of a fixed rectangular grid of units. Each unit can be seen as a generalisation of representations of sets of m-files with similar metric values – also called a *prototype* [14]. In the relational model, the `patterns` entity can also represent the various units of the SOM – again as sets of feature-value pairs. This way, for a given SOM model it is possible to associate each m-file to the SOM unit whose vector of metric values is closer to it (Euclidean distance is used for this purpose). The SOM community would call this unit the *best matching unit* (BMU) for that m-file. Various sub-sets of units in contiguous areas of the SOM, are also aggregated into *regions* of similar units in the SOM, whose information is stored as tuples in the database. Regions and units are represented in the entity `Clusters`.

V. ILLUSTRATIVE QUERIES

This section presents results that can be derived from mining the seed code base for higher level concepts. We call these *intelligent queries*. To facilitate comparison of results, we use an already published set of metrics and corresponding SOM model as an illustrative example [5] and which is copied into the database.

The set of concerns and related metric values are used as different dimensions or positions in the pattern vector fed to UbiSOM. The study refers to two disjoint clusters of m-files that were labelled as regions A_1 and A_3 in the original dataset [6] [5]. We retain the A_1 and A_3 labels in the database mainly to facilitate the task of readers wanting to make the connection with previous work [6] [5]. The description that follows does not depend on details from the other study. Though no m-file can belong to two clusters simultaneously, the previous analysis revealed the simultaneous presence of two or more concerns in those clusters [5]. This is a clear indicator of code tangling, which in turn is a clear indicator of deficient modularity [3] [6] [5]. From this, it can be concluded that the situation in which multiple concerns are found in the

Fig. 2. Code view in the web system.

same m-file arises often. Several such cases are reported in that study [6] [5]. In it, A_1 and A_3 correspond to two SOM regions that represent two disjoint sets of m-files.

One of the concerns detected in m-files from the A_1 and A_3 clusters is *verification of function arguments*. It relates to functions that were prepared to be called in several different "modes", which are selected on the basis of the number of arguments that were passed upon its call. The previous study calls them *schizophrenic functions* [6] [5]. Typically, such functions use the `nargin` function from the MATLAB standard library and/or related functions. `nargin` returns the number of input arguments given in the call. A glimpse of code pattern based on calls to `nargin` is provided in Fig. 2 and Table II. In many cases, these `nargin` calls are made in a considerable number of points at the start of the code's schizophrenic function.

To illustrate the use of queries that join the relational representation of the SOM model with the data in the repository, a query is next shown, which returns the number of tokens associated to a given concern for each m-file covered any of the two regions A_1 and A_3 , i.e., A_1 or A_3 [6] [5]. These regions represent the set of m-files that also give rise to high metric values relative to the concern *verification of function arguments*. Restricting the query to the set of m-files from regions A_1 or A_3 , facilitates the analysis. Note that the restriction could be specified on the basis of *other* concerns (also restricted to A_1 or A_3 in this case). These are an examples of high-level restrictions that would be hard to express without the intelligent assistant for an annotated repository presented in the current paper.

TABLE I
CONTENT (TOP 5 COUNTS) HIGHER LEVEL CONCEPTS QUERY

Cluster	Sub-cluster	m-file	linesCount per m-file	VFAccount per m-file
A_3	19	31424	779	202
A_3	19	12311	480	67
A_3	79	9252	950	49
A_1	739	30854	452	45
A_1	799	24100	162	40

Table I shows an output example of this query. It represents the dataset restricted to clusters A_3 or A_1 (column Cluster), SOM unit identifications (column Sub-cluster), the respective m-file id (column m-file), the number of lines of code of each m-file (column linesCount) and the number of tokens associated to concern *verification of function arguments* (column VFACount). After the query, we learn that the m-file with $id = 31424$ has 202 tokens associated to the concern under analysis (a significantly high value, with 26 occurrences per 100 lines of code). Table II shows a few code lines where token `nargin` occurs, in some cases complemented with the following lines for clarity. It is used in lines 185-189 and again in 195-200. In the second example, `nargin` checks whether the function receives zero arguments. In the third example, an error is issued in case the number of arguments equals 1.

TABLE II
SQL CODE PATTERN '%ARGIN%' IN M-FILE=31324

line	code
1	<code>functionargout = spm_sp(varargin)</code>
	<code>if nargin == 0</code> <code>error('Do what? no arguments given...')</code> <code>else</code> <code>action = varargin{1};</code> <code>end</code>
185-189	<code>otherwise,</code> <code>if nargin==1, error('No space : can't do much!'), end</code> <code>[ok,str] = spm_sp('issetspc',varargin{2});</code> <code>if ~ok, error(str), else, sX = varargin{2}; end;</code> <code>end;</code>
195-200	

The system's current implementation is a web prototype that pays special attention to code visualization. The code view enables token highlighting and provides pop-overs for various kinds of information as illustrated in Fig. 2. A frame is also available for searching *non-contiguous token sequences* in repositories as illustrated in Fig. 3. It also provides a *TreeMap* view (not shown) suitable for the visualisation of hierarchical data, e.g., *toolboxes > m-files > concern* [15], [16]. A visualization of the SOM model is also provided, which allows the selection of elements to derive a database relation of m-files belonging to specific SOM units and their regions.

VI. DISCUSSION

One may ask why a relational model was used instead of say a noSQL-type model. Granted, noSQL-type and graph databases may offer specific advantages in some cases. However, we opted for a relational model because token-based data comprises a significantly structured domain. The relational model facilitates integration with additional components and transaction support to cope with the addition of new annotations on the part of different users. It also facilitates efficiency gains for some queries, which are left for future work.

Mathworks¹ maintains the MATLAB Central website, which aims to provide the best support for MATLAB. It

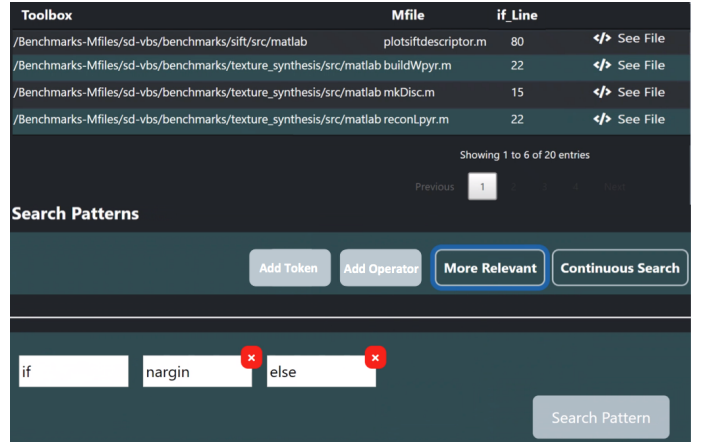

Fig. 3. Example of the web interface frame for token sequences.

has a forum that is claimed to contain 110,000 answered questions and a *File Exchange toolbox repository* for sharing code, where developers can easily import their toolboxes from GitHub [17]. As in every other software repository that we are aware of, the focus is on the toolbox. All toolboxes can be tagged and some of those toolboxes have online tutorials or even Webinars. There is also an area for MATLAB code examples, conveniently indexed by main topics in the language (e.g. matrixes and arrays) and highlighting to toolsets with example code. Each function also points to code examples. Unfortunately, MATLAB developers do not seem to have direct query access to that huge repository of code. We searched many repositories in several other major programming languages but failed to find a system managing a repository of MATLAB programs and toolboxes that supports global analyses and enables extraction of higher-level concepts. By contrast, this paper proposes a software repository enabling searches down to the level of tokens and which are still able to link results to the enclosing toolbox.

Tokens are usually defined as the smallest individual elements of any program. Queries over tokens allow the search of all the information in the repository. As token usages are also very diverse and case specific, there is a need for higher level searches, namely over concerns. However, there are too many possible types of tokens and token combinations. The use of concerns in queries allow for a more direct representation of the concepts involved in the reasoning of software developers when working on the code, thus bridging an important conceptual gap. To search for concerns, we need to resort to their manifestation in the code, by means of metrics on code patterns [5]. The present work is based on *concern metrics* and also relates to past research work on that category of metrics [18] [19].

It should be noted that the higher level concepts used in the illustrative queries are the combinations of concerns used in section V, which refers to our recent work on this front [5]. Presently, the database contains just the clusters and regions explained in that model [5]. Searches over the higher

level concepts with combinations of concerns proved very promising for several kinds of search regarding the concerns present in the code. However, the database and supporting site are more general. It is a relevant subject for this research to find other UbiSOM models (possibly with new metrics) that may answer different questions. The system is general enough to frame and annotate results from new knowledge discovery models and we are available to collaborate with the community to add new models to the system.

Past work used the UbiSOM algorithm to explore the related set of concern metrics [5], through which manual analyses of SOM results led to the detection of many cases of the joint occurrence of multiple concerns in a single m-file. However that method was still based on a generic data mining tool and unable to query a software repository. The repository here described uses the SOM as a data-mining tool to identify clusters of m-files having similar patterns regarding possible distinct sets of concern metrics. The SQL queries that can be devised over such clusters provide the advanced user with higher level concepts. Such queries result in sets of m-files available in the repository. A visual web interface allows end-users (namely MATLAB programmers) to search over relevant higher level concepts, such as the illustrative *schizophrenic functions* concept described in V.

VII. CONCLUSION

This paper proposes a software repository management system supporting intelligent queries over MATLAB code files and able to associate them to higher level concepts. This is achieved by the synergistic combination of a token extraction tool, a relational database and the advanced exploratory capabilities of a Self-Organizing Map. A web interface supports queries over the resulting knowledge stored in a relational model. The latter supports a token-based advanced exploration of the repository. Higher level concepts from SOMs – based on software concerns – can be used by programmers, by means of the web interface. A demonstration web site with full illustrative examples of such higher level concepts and supplementary material is available ². In addition, direct access to the repository database is freely available for research purposes.

Regarding future work, SOMs can be used for tackling problems other than those covered in this paper. SOM models are already available in our database, which opens the way for extending the present annotation with additional data mining processes. For instance, WEBSOM [20] is a classical use of SOM to document clustering. Line comments provide another interesting opportunity: if we approach them as documents, the joint inclusion of such a SOM in our database comprises a promising topic for future work on mining.

Abstract—Access control is a ubiquitous feature in almost all computer systems, and as data becomes more and more of an important asset for organizations, so do the associated access control policies. However, with the increase in the amount of data being produced, e.g. in IoT and social networks, the interest in simpler access control is increasing as well since more subjects (public, researchers, etc.) are now requesting access to it. Defining the exact conditions to allow each subject to access the data can be difficult, especially when vaguely defined conditions such as "expertise of a researcher" come into play. Fuzzy Inference Systems (FIS) allow to process these vague conditions and enables access control mechanisms to be more easily applied. The contribution of this paper lies in showing how a FIS can be used to output binary access control decisions (grant/deny) and what are the differences in the inference process that stems from restricting the output to these two output values.

Keywords—fuzzy systems, vague knowledge, information security, access control.

I. INTRODUCTION

Access control has always been an important feature in any system, be it physical or digital, as it restricts access to a resource in a controlled and selective manner [1]. The most successful access control models are usually those that mimic real-world ways of managing permissions within the context of their application, of which the Role-based Access Control (RBAC) [2] model is a key reference. RBAC is a classical model that maps subjects trying to access some resource to a role, a meaningful category within the context of the system being protected, and crisp access control rules define the resources a subject playing a given role may access to successfully complete its tasks. Other classical access control models operate in a similar manner, using crisp rules that clearly define which resources each subject may access.

However, with the advent of big data and social networks, the quantity and complexity of data available that needs to be stored and processed have increased considerably. Classical access control models are ill-suited to handle these scenarios, as they require tight mappings between subjects, objects, and permissions. This means new subjects must be manually assigned to their permissions before they can access the data, which introduces delays and adds security management loads.

Additionally, the real world is not always as unambiguous as

the classical access control models require it to be in their policies. For example, some documentation from European projects may not be publicly available but could be disclosed to experts researching in some area related to a project. There is no hard definition of what makes someone an expert, so normally it would have to be checked manually on a case-by-case basis. In such situations, the fuzzy set theory is an appropriate solution since it can handle vague concepts, such as expertise of the subject, without requiring crisp values within its rules. Thus, allowing policy rules to be richer in meaning and flexibility.

The theory of fuzzy logic [3] aims to capture how human perception and cognition interpret the world, which is not unambiguous all the time. To this end, it uses relative graded memberships between a subject and a vague concept. Thus, fuzzy logic permits the inclusion of vague human assessments in computing problems, which proved to be an effective way to deal with multi-criteria problems [4]. Solutions known as fuzzy inference systems (FIS) were then designed to map a set of inputs to outputs, using fuzzy logic and fuzzy sets to define vague conditions. These characteristics allowed fuzzy logic and fuzzy set theory to find a lot of uses in various areas, such as medicine [5]–[7], computer security [8]–[14], networking [15], [16], aeronautics [17], stock trading [18], and many others [4], [19]–[22].

Consider a community managed public data, like a wiki, where only subjects that are experts (to some degree) on the contents of a page would be able to modify it. Since wiki pages are generally given categories related to their contents and other related tags, the access control system could access services such as Scopus to retrieve the number of publications, their keywords, citations, etc. This information could then be fed into a fuzzy inference system to determine the level of expertise of the user and help the access control system to make its access control decisions. Thus, leading to fewer modifications by users with malicious intents and more modifications with quality content.

Thus, the contribution of this paper lies in proposing an access control model that uses a FIS to make binary access control decisions, herein known as BDFIS; the presentation of application scenarios where such a system could be useful; and what are its benefits/issues when compared to other access control mechanisms.

The rest of this paper is organized as follows: section II will

This work is funded by FCT/MEC through national funds and when applicable co-funded by FEDER – PT2020 partnership agreement under the project UID/EEA/50008/2019 and SFRH/BD/109911/2015.

provide some of the state of the art in regards to the application of fuzzy set theory in access control; section III will provide the analysis made to each step made during the output generation process of the BDFIS; section IV will present a proof of concept of the proposed model; and section V will provide a short discussion while addressing the issues found.

II. RELATED WORK

The fuzzy set theory is a topic that has been researched in recent years to tackle scenarios where the information that needs to be processed is vague, which can include management science, politics, social psychology, artificial intelligence, and access control, among others [4]. This capability to handle vague information is what enables it to be useful in scenarios where binary decisions must be made and the decision rules are difficult to define in a crisp manner.

Surprisingly, it was found that there is very little research done in terms of the application of fuzzy set theory in access control systems. The issue is suspected to come from the fact that by using vague conditions in the form of fuzzy sets, a fuzzy-based access control system does not explicitly state which input values would grant access to some resource which would not. This paper is focused on exploring these limitations and where fuzzy systems can be improved for this area of intervention.

In [23], the authors introduce Fuzzy Role-based Access Control (FRBAC), which uses fuzzy relations between users-roles and roles-permissions:

- $USERS \times ROLES \rightarrow [0, 1]$
- $ROLES \times PERMISSIONS \rightarrow [0, 1]$

This approach allows for users to have partial permission assignments, which are then used to calculate the access degree they have to each resource. Then, if the access degree is used directly to control access to a resource, the resource itself must have fractional access, defined using the following access function where $USERS$ is the set of users, OPS the set of operations and OBS the set of objects:

- access: $USERS \times OPS \times OBS \rightarrow [0, 1]$

Martínez-García et al. define a function that takes a threshold variable δ (i.e. a value between 0 and 1) and returns *grant* if the access degree is greater than δ or *deny* if not. However, this approach still restricts the fuzzy sets to roles. Therefore, it limits the type of access control logic that can be used. BDFIS, in contrast, does not require subjects to be mapped to the protected resources through any specific model, such as roles, allowing to abstract any mapping between them.

Another work was found where the trust level of devices is measured, so a fuzzy approach to trust-based access control could be achieved (FTBAC) [11]. This is done by capturing information about the devices to determine the vague concepts *Experience (EX)*, *Knowledge (KN)* and *Recommendation (RC)*, and several fuzzy sets (linguistic terms) were defined for each one. The following values for each concept are calculated for a context c between two devices A and B , used as inputs for the membership functions of the linguistic terms.

EX depends on the history of interactions v_k between A and

B , where $k \in [0, n]$, incrementing or decrementing when a positive or negative interaction occurs, as shown in (1).

$$(EX)^c = \frac{\sum_{k=1}^n v_k}{\sum_{k=1}^n |v_k|} \quad (1)$$

KN is calculated with the help of direct knowledge d , indirect knowledge r , and their respective weights (W_d, W_r), where $d, r \in [-1, 1]$, $W_d, W_r \in [0, 1]$, and $W_d + W_r = 1$, as shown in (2).

$$(KN)^c = W_d * d + W_r * r \quad (2)$$

The RC is calculated by device A based on the summation of the RC values from n other devices about device B . W_i and $(r_c)_i$ are weights assigned by device A to the recommendation of the i^{th} device and its RC value respectively, where $r_c \in [-1, 1]$ and $W_i \in [0, 1]$, as shown in (3).

$$(RC)^c = \frac{\sum_{i=1}^n W_i * (r_c)_i}{\sum_{i=1}^n (r_c)_i} \quad (3)$$

Different permissions can be mapped to different levels of trust, so depending on the level of trust the granted permissions change. This the access decisions solely based on the level of trust. If there are other access conditions, they need to be considered separately. Since BDFIS can abstract any mapping rule between subjects and resources, the level of trust can be used in the same manner. However, unlike FTBAC, other access requirements can be added without issue to the inference system.

Another work was carried out that uses fuzzy set theory to calculate a measure of risk and applies it to enhance the access security of eHealth cloud applications [10]. To achieve this, three different inputs are used: *data sensitivity*; *action severity*; and *risk history*. Next, a set of rules is applied to calculate the level of risk associated. A crisp output value is then determined by applying a defuzzification technique, which indicates the overall level of risk as a percentage. However, the process to determine whether the access should be granted given a risk level is not detailed. Moreover, this approach is specific to the measurement of the level of risk with a given access attempt. This limits the applicability of this approach when compared to BDFIS, which can use most concepts in its policies.

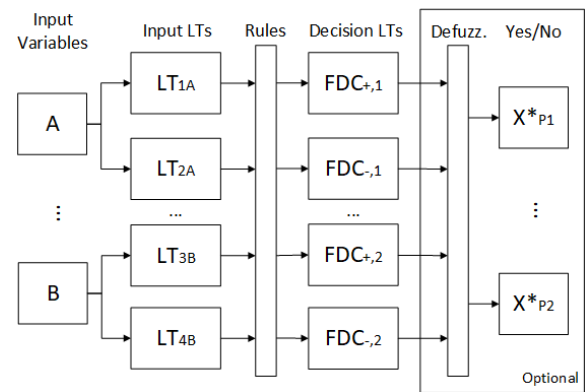

Figure 1. Conceptual BDFIS block diagram.

III. BINARY DECISION FIS ANALYSIS

In this section, a FIS is analyzed regarding its applicability to binary decision making (access control grant/deny decisions) in each of its processing steps.

There are many different types of FIS [24]–[28]. However, the Mamdani-type FIS [28] was chosen for analysis since it is a type of system that is commonly available on most FIS implementation tools, has widespread use and it was found to be easily adaptable to support binary decisions. The Sugano-type FIS [27] is also commonly available in such tools, but it falls short as it has less expressive power and interpretability than the Mamdani-type FIS [29]. Fig. (1) shows the conceptual BDFIS that will emerge from the analysis made in this section and will serve as an illustrative guide to the proposed modifications.

The standard Mamdani-type FIS goes through the following set of steps during processing:

1. The determination of the set of fuzzy rules by an expert in the application context (i.e. the rules block);
2. The fuzzification of the input variable values into the input linguistic terms (LTs) using the associated membership functions;
3. The application of the fuzzy rules to establish the rule strengths to the output LTs, known as the fuzzy decision components (FDC) in the BDFIS;
4. The combination of the rule strength and the output LTs membership functions to determine the consequence functions for each output variable;
5. The combination of the consequence functions to get an output distribution function for each output variable;
6. The defuzzification step, which outputs a single crisp value for each output variable (a decision in the context of the BDFIS) given an output distribution function (required only if a crisp output is needed).

These steps will be detailed in the following subsections and how they were modified for the BDFIS.

A. Fuzzy Rule Determination

The fuzzy rule determination process involves deciding which linguistic terms are going to be used within the FIS, both for input and output variables, and how they influence each other using predefined rules.

The input linguistic terms should stay effectively the same as they still qualify the attributes available in the application context. The input linguistic terms and their membership functions are still required to be written by an expert.

The output variables and linguistic terms, however, are dependent on the decisions must be made. In the case of an access control system, the decisions are either to grant or deny a subject some permission to a resource. Thus, permissions can be declared as the output variables according to Def. (1).

Definition 1. Access permissions in a BDFIS are output variables associated with exactly two FDC linguistic terms: one for a positive decision FDC_+ (yes/grant); and one for a negative decision FDC_- (no/deny).

The rules can then take input linguistic terms from one or more input variables and establish a relation to one of the FDCs. To illustrate, consider two input variables A and B , with the linguistic terms LT_A and LT_B , and an output variable Z . A rule can take the form "if A is LT_A and/or B is LT_B then Z is FDC_{\pm} ". For example, "if *Expertise* is *High* and *Activity* is *Moderate* then *Read* is *Granted*."

This shows how a FIS can be used to easily encode vague access conditions: given a set of vague concepts about a subject (e.g. *Expertise*, level of *Activity*, etc.), the permissions (*Read*, *Write*, etc.) to the resource are output variables that are defined by either being granted (FDC_+) or denied (FDC_-). Furthermore, the permission and decision pair are easily identifiable.

B. Input Fuzzification And Rule Strength

The input fuzzification process and rule strength determination are steps that qualify the input variables in terms of the defined linguistic terms. Given a set of linguistic terms T_i for an input variable i , the membership degree of a subject s to each linguistic term $t \in T_i$ is obtained by applying that linguistic term membership function μ_t , as shown in (4).

$$\mu_t(s): t \rightarrow [0,1], t \in T_i \quad (4)$$

To illustrate, if $\mu_t(x) = x/20, 0 \leq x \leq 20$ is used to define the "high" linguistic term for the "number of publications" input variable, then if a subject has 15 publications it has a membership degree of $15/20 = 0.75$ to that linguistic term. The membership functions μ are defined by an expert in the application context the BDFIS is to be deployed on, since vague concepts like *Expertise* can change slightly depending on the context. After a membership degree is calculated for each input linguistic term, the rule strength for each output FDC can be determined. This is usually done by applying the fuzzy logic operators as dictated by the rules (AND, OR, and NOT). If more than one rule applies to the same FDC, the rule strength of each such rule is unified by typically applying the OR operator. These operators have several different implementations for fuzzy logic that can be used, but they always satisfy the De Morgan's Laws.

To reiterate, there are only two possible output linguistic terms: the FDC_- and the FDC_+ . This makes it clear for which outcome a rule is being used for instead of having something more abstract, such as the user expertise level, and lets the system make access control decisions based on it.

C. Consequence Determination

The next step is to determine the consequence of the rules and to do so it is necessary to think about what the output is intended to be.

The goal is to have a FIS that can make a binary access control decision for each permission (i.e. grant or deny). As such, each decision is defined by two linguistic terms, the FDC_+ and FDC_- output linguistic terms previously introduced. These represent the positive and negative decisions for a single output, respectively. This way, a subject attempting to access some piece of information or service is mapped automatically through rule strengths to each FDC.

Since each FDC is also a fuzzy set, each can have any

membership function that the security expert chooses. However, a simpler approach is proposed to reduce the complexity of the calculations and the potential performance bottleneck that running a FIS can introduce. Instead of a user-defined output membership function, each FDC will have a predefined singleton function (see Def. (2)) instead.

Definition 2. A given function $f(x)$ is a singleton function if its output is always 0 except for a single input value x_0 , for which its output is 1 as shown in (5).

$$f(x) = \begin{cases} 1, & \text{if } x = x_0 \\ 0, & \text{if } x \neq x_0 \end{cases} \quad (5)$$

Since it is expected for the BDFIS to output a decision, it makes sense that they are each associated with a single value. This is partially the reason why the membership function for each FDC is proposed to be a singleton function. This is done by setting the single function x_0 value to 0 for the FDC_- and to the value 1 for the FDC_+ . These values were carefully chosen since they simplify the defuzzification step considerably, which will be shown in section III.D.

Thus, the membership functions of the FDC_- ($\mu_-(x)$) and FDC_+ ($\mu_+(x)$) are singletons that are defined as shown in (6) and (7), respectively.

$$\mu_-(x) = \begin{cases} 1, & \text{if } x = 0 \\ 0, & \text{if } x \neq 0 \end{cases} \quad (6)$$

$$\mu_+(x) = \begin{cases} 1, & \text{if } x = 1 \\ 0, & \text{if } x \neq 1 \end{cases} \quad (7)$$

Finally, the process of determining the consequence consists of truncating the output membership function, i.e. both $\mu_-(x)$ and $\mu_+(x)$. Def. (3) shows how this process is accomplished.

Definition 3. The process of truncating a given function f at the value $y = y_0$ generates a new function g that has the same output as f except that any output value greater than y_0 becomes y_0 , as shown in (8).

$$g(x) = \min(f(x), y_0) \quad (8)$$

Determining the consequence from these singleton functions also becomes easier for the following reasons:

1. Singleton functions only have one input value ($x = x_0$) for which the output is not 0, thus only one value may have to be truncated;
2. The FDC singleton membership functions always output 1 for the value $x = x_0$;
3. The rule strength applicable to each FDC always lies within the range $[0,1]$ since it is the result of the application of fuzzy logic.

Since the output membership function of each FDC is either 0 or 1 as stated in reasons (1) and (2) and the rule strength is a value within the range $[0,1]$ as stated in reason (3), the consequence function C is determined by simply replacing the output value 1 with the rule strength RS for that FDC , as shown

in (9) for FDC_- and (10) for FDC_+ .

$$C_-(x) = \begin{cases} RS_-, & \text{if } x = 0 \\ 0, & \text{if } x \neq 0 \end{cases} \quad (9)$$

$$C_+(x) = \begin{cases} RS_+, & \text{if } x = 1 \\ 0, & \text{if } x \neq 1 \end{cases} \quad (10)$$

These consequence functions can then be used in the defuzzification step to generate a single, crisp output value. This explains in part how using singleton functions simplifies the computation of the final decisions. However, further benefits from this approach will be explored in the following subsection.

D. Consequence Combination And Defuzzification

The next step in the process involves combining the consequence functions of both FDCs (C_- and C_+) into an output distribution function for each output decision. This allows to apply a defuzzification method, an inverse transformation to the fuzzification step, that outputs a crisp output value for each output decision.

These steps are optional and depend on the level of information the system requires to reach a decision. If the system requires more than a crisp output value, it can use the rule strengths given to each FDC and make a more informed decision this way. For example, a use case could require an access control system to ask a human to manually grant or deny access if the rule strengths of both FDCs are close to one another.

However, if the system requires a crisp value between 0 and 1, then the consequence functions can be combined into an output distribution function (Def. (4)) and a defuzzification step may be used.

Definition 4. Given the consequence functions C_- and C_+ of an output variable O , the output distribution function θ associated with O is the result of applying an accumulative function S , as shown in (11).

$$\theta(x) = S(C_-, C_+) \quad (11)$$

The approach used in this paper uses the maximum accumulative function. Consider that both FDC_- and FDC_+ have RS_- and RS_+ rule strengths respectively. The resulting output distribution function for each output decision Z (θ_Z) is shown in (12).

$$\theta_Z(x) = \begin{cases} RS_-, & \text{if } x = 0 \\ RS_+, & \text{if } x = 1 \\ 0, & \text{if } x \neq 0 \wedge x \neq 1 \end{cases} \quad (12)$$

Therefore, all output distribution functions are the combination of two singleton functions, one for the FDC_- on the x value 0 and the other for the FDC_+ on the x value 1.

A defuzzification method can then be applied to each output distribution function generated this way for each output variable. To show why the selected x values for each singleton were chosen, the commonly used center of gravity for singletons (COGS) defuzzification technique will be applied to θ_Z . The general COGS formula for a given output distribution function

θ_z is given in (13).

$$\text{COGS}(\theta_z) = \frac{\sum_x x * \theta_z(x)}{\sum_x \theta_z(x)} \quad (13)$$

Note that if the output distribution function θ_z is not generated from singleton membership functions then the formula for the center of gravity is a division of two primitives. Fortunately, since the proposed output distribution functions are always the combination of two singletons, which are also always defined on the x values 0 and 1, the formula (14) follows:

$$\text{COGS}(\theta_z) = \frac{0 * \theta_z(0) + 1 * \theta_z(1)}{\theta_z(0) + \theta_z(1)} = \frac{\theta_z(1)}{\theta_z(0) + \theta_z(1)} \quad (14)$$

As it can be seen, the COGS formula was simplified to a simple fraction of the rule strength of the FDC_+ to the sum of the rule strengths of the FDC_- and FDC_+ , reducing its complexity.

The application of the COGS defuzzification method to each output distribution function results in a crisp output value, which can be used to arrive at a final decision. The simplest way to achieve this is to set a fixed threshold, such as 0.5, and if the crisp output is lower than the threshold then the decision is negative (*deny*, in the access control context), otherwise, it is positive (*grant*, in the access control context). The threshold value can be increased or decreased to fine-tune the system as required by an expert. Any other method to arrive at a decision is valid, such as the maximum method which takes the x value that maximizes the output distribution function and depends only on the use case.

E. BDFIS Analysis

A modified Mamdani-type FIS called BDFIS has been proposed and detailed in this paper. However, upon further analysis, it was found that the consequence determination lacks some of its former expressibility. The reason behind this comes from the fact that the output linguistic terms and distribution functions are now fixed, i.e. FDCs and singleton functions respectively, while these functions could be defined freely in a standard FIS. This forces the rule strengths for the FDCs to be calculated directly from the input linguistic terms, where abstract concepts such as *Expertise* could be defined in a standard FIS instead. Thus, the ability to define abstract concepts is hindered to some degree.

While this fact may not impact use cases with simpler access control policies, it can impact the interpretability of the defined rules in others. Consider a rule that defines the vague concept of *Expertise*, such as “**if** *Number_of_Publications* is *High* **then** *Expertise* is *High*”. If someone is newly hired to manage a system that uses this rule, it is clear what it is expressing: the expertise of the subject.

As is, the BDFIS would need the input variables to be mapped directly to the output decision variables, meaning that the *Expertise* vague concept cannot be explicitly defined or used in the mapping to the FDCs. Thus, a new security expert would need more detailed external documentation to understand what the rules are meant to represent to master the system, to write new rules, etc. However, it is possible to add a second layer of rules and intermediate variables to allow this (or more for additional abstraction). The input linguistic terms are mapped to

these intermediate variables, which can include vague concepts like *Expertise*, and then these variables are mapped to the FDCs. This approach allows for rules to remain easily interpretable by humans at the cost of some processing.

IV. PROOF OF CONCEPT

In this section, a proof of concept of the BDFIS will be shown. The prototype of the BDFIS used for this proof of concept uses JFuzzyLogic[30][31] and is available at github.com/Regateiro/FuzzyAC/tree/master/java/BDFIS. The *academic.fcl* file defines a BDFIS that makes access control decisions based on the expertise of a subject, using the Fuzzy Control Language (FCL)[32]. The BDFIS also comprises of two blocks of variables and rules, the first calculates the degree of expertise of the subject and the second the access control permissions. Fig. (2) shows the output of the proof of concept BDFIS implementation using the provided FCL file.

```

Figure 2. Sample BDFIS implementation output.

The defined BDFIS takes two input variables: the *number of publications* (omitted); and the *number of citations* (lines 1-4). These are used to determine the *Expertise* of the subject in the first set of rules (lines 6-10). The *Expertise* is then applied in the second set of rules to calculate the FDCs for a *Read* and *Write* permissions (lines 12-18). These are necessary to calculate whether the subject is granted each permission, by checking if the final defuzzified value is greater than 0.5 (grant) or not (deny). This value can be modified by an expert to require subjects to have lower or higher membership degrees to be granted access.

The numbers to the right of the input and output variables denote the crisp value associated with them (either provided as input or calculated from defuzzification). The number to the right of the terms denote their associated membership degrees. These are calculated from piecewise linear membership functions and rules defined by an expert in the *academic.fcl* file using the steps and methods explained in this paper. The BDFIS implementation automatically passes the *Expertise* value calculated by the first set of rules to the second set of rules as an input. Finally, since the *Read* permission has the output value $1.0 > 0.5$, it is granted, and the *Write* permission with the output value $0.275862 < 0.5$ is denied.

V. DISCUSSION

In this paper, a FIS that can make binary access control decisions was proposed. Through the analysis made to each processing step, several changes were introduced that allowed a Mamdani-type FIS to specialize in the output of binary decisions. Furthermore, some proposed modifications optimized the output generation process, making this type of systems to have the potential for deployment in access control scenarios that deal with vague knowledge. Given the broad spectrum of areas where FIS are used, it shows that they are useful if correctly defined. By creating the BDFIS as closely as possible to a standard FIS, it is expected that it can be just as effective in access control scenarios.

One might question the appropriateness of applying fuzzy set theory to model access control since its inherent vagueness prevents an expert from easily knowing if a subject can access the protected data or not. Furthermore, auditing such a system is not easy given that new subjects may request access at any time.

Due to the vague nature of the fuzzy access control rules, the exact ranges of input values that grant access to the data is not clear. Thus, the possibility that an unexpected combination of input values granting access to the data may exist. It is important to note, however, that such a fuzzy access control model would still be deterministic. Furthermore, since vague conditions are applicable to a range of input values (with varying membership degrees), fewer rules are needed when compared to classic models, which generally requires each combination of input values to be written down as a separate rule. Nonetheless, fuzzy-based access control models are not easily accepted to manage sensitive data (e.g. hospital patient data), understandably due to the issues related to its inherent vagueness.

For future work, it is intended to build a system that can audit a BDFIS for correctness, an important feature for any access control system to have, and the calibration of the threshold values. Since the subject parameters used as input values are fuzzified, it is hard to determine from the fuzzy rules if they have access to a resource or not. Thus, being able to determine which input values grant or deny access is an important step towards making BDFIS a viable part of an access control system.

Abstract—In search-based software engineering (SBSE), software engineers usually have to select one among many quasi-optimal solutions with different values for the objectives of interest for a particular problem domain. Because of this, a metaheuristic algorithm is needed to explore a larger extension of the Pareto optimal front to provide a bigger set of possible solutions. In this regard the Fuzzy Multi-Objective Particle Swarm Optimization (FMOPSO), a novel *a posteriori* algorithm, is proposed in this paper and compared with other state-of-the-art algorithms. The results show that FMOPSO is adequate for finding very detailed Pareto Fronts.

Index Terms—Search-Based Software Engineering; Multi-Objective Optimization; Particle Swarm Optimization; Next Release Problem; Fuzzy Logic.

I. INTRODUCTION

Search-Based Software Engineering (SBSE) is a discipline that aims to help software engineers build high quality software through the application of search methods. The main strategy is to change the focus from describing how to develop the software to describing what the software characteristics are. This description has to be codified to be understood by a search algorithm capable of generating new possible products and evaluate their quality using a set of rules provided by the engineer [1].

The problems to be solved using this type of approach are formulated as optimization problems that have, in the majority of the cases, a combinatorial search space and multiple objectives. Because of this, metaheuristics are generally used, discarding classical methods for optimization such as mathematical programming.

This paper introduces a first version of a novel metaheuristic algorithm named Fuzzy Multi-Objective Particle Swarm Optimization (FMOPSO), designed to deal with this kind of problems by creating a fitness function of multiple objectives using fuzzy weight factors. Different configurations of this fitness function are used to guide the method in the approximation of the Pareto-optimal front. This new algorithm has been tested on two instances of a well-known Search-Based Software Engineering problem, the Next Release Problem (NRP).

This problem, first proposed by [2], is aimed at finding a requirement subset to be implemented that satisfy the stakeholders' needs, looking for the maximization of the profit and minimization of the implementation cost [3]. In addition, it may also be restricted by dependencies between requirements such as precedence and simultaneity, among others.

The rest of this paper is organized as follows. In Section II the multi-objective optimization is introduced. Section III describes the Fuzzy Bi-Objective Particle Swarm Optimization algorithm proposed in this paper. Section IV explores the behavior of this proposal and compares it with another well known state-of-the-art algorithms. Finally, Section V contains the conclusions and future work.

II. MULTI-OBJECTIVE OPTIMIZATION

A commonly used optimization approach consists on selecting as objective function one of the system's attributes and using it to define the (total) order of preferences of the feasible solutions, resulting a *mono-objective* problem. The rest of the attributes modeled as constraints.

On the other hand, the *multi-objective* optimization approach uses several attributes as objective function. These objectives compete against each other defining a partial order on the solution space where there are solutions that are not comparable *a priori*. This partial order is called *Dominance Relation*. The set of all the non-dominated solutions is called *Pareto Front*, and is the result of an optimization method that makes no assumptions about the preferences of the decision-maker.

It is important for the Pareto Front to be as detailed as possible so the decision-maker can select the solution that best fits their needs. Additionally, the Pareto Front provides valuable information about the relation between the competing objectives to use to analyze "What if..." questions.

III. FUZZY MULTI-OBJECTIVE PARTICLE SWARM OPTIMIZATION

Particle Swarm Optimization (PSO) is a population-based metaheuristic, which means that in each iteration there is a set (swarm) of possible solutions called particles that move through the search space to find new solutions.

The movement or change in the position of each particle is computed using a movement equation. This equation specifies the way in which the solution is perturbed. Thus, this is a perturbative metaheuristic.

Each particle has access to a fitness function that evaluates the efficiency of the particle's position. This function is the objective function to be optimized. Then, each particle i in the iteration $k+1$ change its position $X_i^{[k+1]}$ according to the particle's velocity $V_i^{[k+1]}$, computed using the movement rule:

$$V_i^{[k+1]} = V_i^{[k]} + w_C \times r_1^{[k+1]} \times [b_i^{[k]} - X_i^{[k]}] + w_S \times r_2^{[k+1]} \times [b_G^{[k]} - X_i^{[k]}] \quad (1)$$

where $b_i^{[k]}$ is the best position reached by the particle in previous iterations, $b_G^{[k]}$ is the best position reached by the swarm in previous iterations, r_1 and r_2 are random numbers uniformly distributed in the interval $[0,1]$, and w_C and w_S are prefixed constants. These three terms from the movement equation are, in that order, the inertia term, the memory term, and the cooperation term. Consequently, the position $X_i^{[k+1]}$ is modified as follow:

$$X_i^{[k+1]} = X_i^{[k]} + V_i^{[k+1]} \quad (2)$$

A. Canonical PSO Implementation

PSO is an algorithm that was originally designed to work with continuous variables. However, in order to approach combinatorial optimization problems, it can be reformulated to take into account the combinatorial aspects of the problem into the movement equation. It is because of this that the Canonical PSO model comes up [4], specifying the necessary and sufficient conditions to use PSO in any domain. According to it, the representation of the following items has to be defined: (a) the position and velocity of a particle; (b) a scalar-valued or vector-valued fitness function; (c) a total or partial order relation on the fitness function codomain; (d) the binary operations:

- $\text{subtraction}(\text{position}, \text{position}) \xrightarrow{-} \text{velocity}$
- $\text{external_product}(\text{real_number}, \text{velocity}) \xrightarrow{\cdot} \text{velocity}$
- $\text{addition}(\text{velocity}, \text{velocity}) \xrightarrow{+} \text{velocity}$
- $\text{displacement}(\text{position}, \text{velocity}) \xrightarrow{+} \text{position}$

For the Next Release Problem, binary vectors are used to represent the position and velocity of a particle [5]. Each vector has a length equal to the number of requirements. In the position vector, each component x_j represents the decision of including (1) or excluding (0) requirement j . In the velocity vector instead, the value 1 in the position v_j means the value in x_j has to change to its complement.

The binary operations are described in the following sections.

B. Fuzzy Single-Objectivization

It is possible to compose a single objective function of multiple objectives using fuzzy sets [6]. A fuzzy decision set \tilde{D} can be built from nO objectives $\tilde{O}_1, \tilde{O}_2, \dots, \tilde{O}_{nO}$ using the intersection according to the triangular norm t , that represents the objectives *confluence*. Thus, \tilde{D} is defined as follow:

$$\tilde{D} = \tilde{O}_1 \cap_t \tilde{O}_2 \cap_t \dots \cap_t \tilde{O}_{nO} \quad (3)$$

then, using an in-order notation:

$$\mu_{\tilde{D}}(x) = \mu_{\tilde{O}_1}(x) t \mu_{\tilde{O}_2}(x) t \dots t \mu_{\tilde{O}_{nO}}(x) \quad (4)$$

It is reasonable in the majority of the cases to choose the option x with the maximum membership degree to the fuzzy decision set.

Furthermore, [7] presents a mechanism to give to each objective differentiated preferences by affecting the membership function using an exponential weighting factor ρ in order to contract (increase), with $\rho > 1$, or dilate (decrease), with $\rho < 1$, the relevance of each objective.

Let $\rho_1, \rho_2, \dots, \rho_{nO}$ be the exponential weighting factors associated with each objective such that $\sum_{i=1}^{nO} \rho_i = nO$. In consequence, \tilde{D} is defined as follows:

$$\mu_{\tilde{D}}(x) = \mu_{\tilde{O}_1}^{\rho_1}(x) t \mu_{\tilde{O}_2}^{\rho_2}(x) t \dots t \mu_{\tilde{O}_{nO}}^{\rho_{nO}}(x) \quad (5)$$

The problem addressed in this paper contemplates two objectives: the implementation cost C , and the profit B given by the stakeholders' satisfaction. The membership function of the fuzzy number associated to the cost is:

$$\mu_C(X, \rho_C) = \begin{cases} 1 & \text{if } C(X) \leq C_{min} \\ \left(\frac{C(X) - C_{max}}{C_{min} - C_{max}} \right)^{\rho_C} & \text{if } C_{min} < C(X) < C_{max} \\ 0 & \text{if } C(X) \geq C_{max} \end{cases} \quad (6)$$

where $C(X)$ is the cost of implementing the solution X , C_{min} and C_{max} are the minimum and maximum values of reference for the cost variable, and ρ_C is the prefixed weighting factor.

In the same way, the membership function of the fuzzy number associated to the profit is:

$$\mu_B(X, \rho_B) = \begin{cases} 1 & \text{if } B(X) \geq B_{max} \\ \left(\frac{B(X) - B_{min}}{B_{max} - B_{min}} \right)^{\rho_B} & \text{if } B_{min} < B(X) < B_{max} \\ 0 & \text{if } B(X) \leq B_{min} \end{cases} \quad (7)$$

where $B(X)$ is the profit given by the solution X , B_{min} and B_{max} are the minimum and maximum values of reference for the profit variable, and ρ_B is the prefixed weighting factor.

If the stakeholders' preferences are not known and it is required to find the whole Pareto Front, this method is still suitable by using multiple weighting factor values to specialize the search in multiple regions of the search space at the same time.

This strategy may be implemented by assigning different values for the weighting factors to distinct groups of particles, so each group explores a different region of the space (Fig.

Fig. 1: Configurations of the fuzzy numbers for different groups (by column) with two objectives: Profit (blue): $\bar{\rho} = (0, 0.5, 1, 1.5, 2)$ and Cost (red): $\bar{\rho} = (2, 1.5, 1, 0.5, 0)$.

1). Therefore, the fitness function evaluated for a position X in group j is:

$$\mu_D(X, j) = \min \left(\mu_C \left(X, \frac{2(j-1)}{(n-1)} \right), \mu_B \left(X, 2 - \frac{2(j-1)}{(n-1)} \right) \right) \quad (8)$$

C. Topology and individual best updates

A key aspect to consider when using PSO is to define how the particles communicate with each other. The component that rules this communication is called *topology*.

Assuming that there are n different weighting factors values or, in other words, n groups into the swarm, the particles assigned to the j^{th} group share a single best group position denoted b_j that is used into the memory term of the movement equation. If each group has the same number of particles, say m , the swarm is thus arranged in a matrix $M^{m \times n}$. Consequently, each particle can be denoted with a double subindex (i, j) , with $1 \leq i \leq m$ and $1 \leq j \leq n$.

Additionally, each particle has access to the best position reached by its adjacent groups b_{j-1} and b_{j+1} , if they exist. In order to determine the position to be used in the cooperation term, the one with the highest value is selected.

Furthermore, an additional rule has to be taken into account to update the best group solutions b_j . When a new position $X_{ij}^{[k+1]}$ is computed, it is evaluated according to at most three version of the fitness function: $\mu_D(X_{ij}^{[k+1]}, j-1)$, $\mu_D(X_{ij}^{[k+1]}, j)$ and $\mu_D(X_{ij}^{[k+1]}, j+1)$.

As each particle is affected by its neighbours, this particle can find a good solution to its own fitness function version or to the version of its neighbors. Thus, when it is time to update the best group positions, b_j , the new position to be evaluated are $X_{il}^{[k+1]}$, with $i \in \{1, \dots, m\}$ and $l \in \{\max(1, j-1), \dots, \min(j+1, n)\}$.

D. Binary Operators

The binary operations used in the FMOPSO implementation are Xor, And & Or from Boole's Algebra, denoted by \oplus , \cdot , $+$, respectively. In this approach, the movement equation leave aside the inertia term:

$$V_{ij}^{[k+1]} = r_1^{[k+1]} \cdot (b_j^{[k]} \oplus X_{ij}^{[k]}) + r_2^{[k+1]} \cdot (b_{Vj}^{[k]} \oplus X_{ij}^{[k]}) \quad (9)$$

This rule can compute an unfeasible position, thus, the Xor operation related to the movement is performed in increasing order adding predecessors or removing successors, as appropriate.

Finally, if the particle does not change its position in two consecutive iterations, a mutation is applied on a random component to invert its value, adding predecessors or removing successors too.

IV. EXPERIMENTAL DESIGN

A study on two NRP instances obtained from the *classic* set of instances of [8] were performed. The first one, named *nrp1* has 140 requirements and 100 stakeholders. The second one, named *nrp2*, has 620 requirements and 500 stakeholders. Both instances have precedence relations between requirements. The reference values B_{min} and C_{min} were set to 0 for both

instances. The values for B_{max} were 2909 for *nrp1* and 14708 for *nrp2*. The values for C_{max} were 787 for *nrp1* and 4758 for *nrp2*. These values were found through an exact mono-objective optimization using Branch & Bound.

Several tests were conducted on the aforementioned instances using the proposed FMOPSO algorithm. The results were compared with two widely used state-of-the-art algorithms: NSGA-II (Non-Dominated Sorting Genetic Algorithm) [9] and IBEA (Indicator-Based Evolutionary Algorithm) [10].

The metrics used for the comparison were the Hypervolume (HV), to evaluate the quality of the solution, and the Pareto Front Size (PFS), to assess the population diversity [11].

The parameters were tuned ad-hoc by executing each algorithm 5 times with many different configurations to find the best set of values. The best configurations were selected according to the median of the Hypervolume. With this best setting for each algorithm, 10 more executions were performed to obtain a representative value distribution of the selected metrics. All the partial results can be found in [12].

The software used for the experiment was written in C++ using and extending the ParadisEO library [13]. FMOPSO was implemented by the authors. The ParadisEO's versions of NSGA-II and IBEA were used. The crossover operator used to produce two new individuals is equivalent to the boolean operators $+$ and \cdot . The mutation operator is the same used in the FMOPSO, as mentioned before. The code can be found in <https://github.com/casanovac/FMOPSO>.

The running time was the same for all the algorithms: 30 seconds for *nrp1* and 60 seconds for *nrp2*.

A. Results

The results (Table I) show that FMOPSO is a better option regarding diversity, this is, the values for the PFS metric, obtained using this algorithm, are higher than those obtained using the state-of-the-art alternatives. However, FMOPSO is overtaken by IBEA for the Hypervolume, but shows a better performance than NSGA-II, a widely used algorithm in Search-Based Software Engineering (Fig. 2).

Additionally, Figure 3 shows that NSGA-II does not cover the Pareto Front uniformly: there are many regions that were not explored. IBEA, on the other hand, generates the best non-dominated solutions, but with many gaps too. FMOPSO, however, scans the whole front in a uniform way, with a low

TABLE I: Result Descriptors

Metric	Problem Algorithm	FMOPSO	NRP1 IBEA	NSGAII	FMOPSO	NRP2 IBEA	NSGAII

Fig. 2: Box plots with the distribution of the HV (Top) and the PFS (Bottom) on two instances of the Next Release Problem.

quality loss, as can be seen in the scatterplot related to the second instance of the problem.

According to this study, FMOPSO is an adequate alternative when the purpose is to obtain a very detailed Pareto Front, with a very good level of quality.

V. CONCLUSIONS AND FUTURE WORK

In this paper, the Bi-Objective Next Release Problem has been presented at a conceptual level. A novel *a posteriori* metaheuristic algorithm that approximates the Pareto Front for the aforementioned bi-objective NRP was also presented: FMOPSO. This algorithm composes a fitness function by using mixed weights for different groups of particles from the swarm.

Technical and theoretical aspects on this algorithm have been presented. A comparative study was performed comparing this proposal with two different state-of-the-art algorithms. The obtained results are promising and encourage to keep looking forward to the study of many yet unexplored aspects of this new algorithm.

It is necessary to adapt FMOPSO to be used in an interactive way. Extending the FMOPSO to deal with other SBSE problems that include more than two objectives should also be a goal.

Abstract

This paper proposes a method to predict word grammatical classes using automatically generated discrete-time Markov chains to model typical sentences. Such method advantage relies on the availability of input resources needed to build an efficient and effective solution to virtually any language, dialect, or domain lingo. One of the main advantages of the proposed method is its simplicity when compared to other sophisticated approaches based on Hidden Markov Models or even more complex formalisms. The proposed method is instantiated to an example and we show that the achieved efficiency and effectiveness bring advantages to traditional similar solutions.

1 Introduction

Part-Of-Speech (POS) tagging is a very basic task for all Natural Language Processing (NLP) techniques based on linguistic approach. However, only well resourced languages have very effective solution for POS tagging [14]. This fact makes statistical approaches very popular to less resourced languages [6, 13] or even domain lingo [17]. Acquiring information on informal texts, as social networks chats and comments, the use of a tool independent of formal language definition is even more interesting, since it can help to tackle an open NLP problem.

In contrast with the difficulty to find out structured knowledge for less resourced and informal languages, the Internet offers abundant unstructured material (texts) in every language and dialect. Consequently, a procedure capable to produce structured knowledge from textual sources would cope with such limitations.

As for software tools, the basic modules needed for a POS-tagger are a dictionary retriever (to identify possible grammatical classes for known words) and a predictor (to disambiguate words that can be employed with more than one role, or guess the role for unknown words). The dictionary retrieving task for any language can be solved

very efficiently by the use of decision diagrams [12], and even multilingual dictionary retrievers can be implemented very efficiently [3].

The gap between a dictionary retriever and a POS-tagger is essentially the syntactic disambiguation task. In the context of this paper we limit ourselves to consider only a shallow POS-tagger assigning a word class to each word, but the methods and techniques discussed in this paper can be applied to even more sophisticated POS-tagger without any loss of generalization.

Our goal is to provide an effective grammatical class predictor to words inside a sentence previously tagged with an efficient dictionary retriever. In order to do so, we propose the construction of Markov chains [16] to describe typical phrases and use the transient analysis of such chains to predict the grammatical class of each word. These typical phrases can be viewed as a training set for the POS-tagger. Consequently, the produced Markov chains can be viewed as a model of the language patterns, *i.e.*, the structured knowledge of the target language. The enlargement of scope of POS-taggers would benefit several NLP tasks like term extraction [9, 10], ontology processing [5], and textual data mining [1], to cite a few.

Our proposed method fits into a POS-tagging landscape as simpler than sophisticated approaches based on Data mining approaches as Support Vector Machines - SVM [4], or inference models as Conditional Random Fields - CRF [8]. Nevertheless, our method is more flexible than traditional linguistic approaches heavily anchored in specific languages [2, 15].

2 Basic Tools

To better understand this paper proposed method, this section presents brief descriptions of Markov chains and Decision Diagrams-based dictionary retrievers.

2.1 Markov Chains Markov chains is a formalism to represent discrete state models as, in our case, a finite

—*DOI reference number: 10.18293/SEKE2019-097

automaton where the transitions are fired by the occurrence of a stochastic process [16]. Although there is a very large variety of Markovian models the plain discrete-time Markov chains are sufficient to express a model as a set of states and transitions among them associated to known probabilities. To exemplify such chains, as will be used in the context of this paper, Figure 1 depicts a simple chain with three states: Sunny, Cloudy, and Rainy.

Figure 1: Simple Markov chain example.

Formally, we denote a DTMC by a matrix P where the element $p_{(i,j)}$ corresponds to the probability of leaving state i towards state j , e.g., in the chain of Fig. 1, $p_{(\text{Rainy}, \text{Cloudy})} = 0.7$ and $p_{(\text{Sunny}, \text{Rainy})} = 0.0$. For a model like this it is possible to make simple predictions, as for example, if a unknown day was preceded by a Sunny day and succeeded by a another Sunny day, it is possible to analyze all three possible intermediate states: Sunny-Sunny-Sunny ($0.5 \times 0.5 = 0.25$); Sunny-Cloudy-Sunny ($0.5 \times 0.3 = 0.15$); and Sunny-Rainy-Sunny ($0.0 \times 0.1 = 0.0$). Since all three possibilities sums up 0.4, it is possible to say that the intermediate day was: Sunny with probability 0.625 ($\frac{0.25}{0.4}$) or Cloudy with probability 0.375 ($\frac{0.15}{0.4}$).

2.2 Diagram Decision-based Dictionary Retriever The use of decision diagrams to recognize words, and associate its word class (or possible classes), can be very efficient and very effective as proposed in the WAGGER software tool [3]. According to this work, a decision diagram structure holding a multilingual dictionary with English and Portuguese words (a little more than one million words) can be used to tag possible word classes to large corpora (for instance, two million words) in less than three seconds using a personal machine. Such performance leads us to employ WAGGER for all experiments in our paper.

The technology behind such a dictionary retriever are Multi-Terminal Multi-valued Decision Diagrams [7]. Such structures are not only very effective to provide a fast recovery using small amounts of memory, but they also provide flexible structures that can be enhanced, for instance, by including new dictionary words.

The input of WAGGER is a dictionary in textual format, i.e., a list of words with their possible word classes. Then, it generates a MTMDD structure that can acts as dictionary retriever for a list of sentences that are annotated with the

possible word classes of each sentences' word.

I	believe	what	I	see	.	but
pronoun noun	verb	pronoun adverb	pronoun noun	verb	punctuation	conjunction preposition adverb noun
I	see	what	I	look	and	I
pronoun adverb	verb	pronoun adverb	pronoun noun	verb noun	conjunction noun	pronoun noun
look	what	I	want	to	look	.
verb noun	pronoun adverb	pronoun noun	verb noun	preposition adverb	verb noun	punctuation

Figure 2: WAGGER output for an example sentence.

The WAGGER output is all words of each sentence followed by the possible word classes. For example, Figure 2 presents the output of WAGGER using our English dictionary [3] for the sentence “I believe what I see, but I see what I look and I look what I want to look”. In this figure, the correct word class is indicated in bold. For instance, word “and” plays the role of conjunction in this sentence, but according to the dictionary “and” can also be employed as a noun.

In order to formalize the WAGGER output we will denote by w_i^s the i -th word in sentence s , and $C(w_i^s)$ the set of all possible word classes of word w_i^s . Note that the set $C(w_i^s)$ of a given word is independent of the sentence in which the word is (s). For instance, the word “and” (the thirteenth word of the example sentence) is formally defined by:

$$w_{13}^s = \text{“and”} \quad C(w_{13}^s) = \{\text{conjunction, noun}\}$$

3 Proposed Method

The proposed method follows the general idea of train and test, since it starts with a set of sentences manually tagged (training set), and only after we attempt to disambiguate word tags for sentences tagged by WAGGER (testing set). Figure 3 depicts the proposed method with the training task to construct the Markov chains, and the testing task to disambiguate WAGGER multiple or absent tags. It is important to notice that the training task needs a supervised action: a human made annotation, required according to the language of the target corpus.. All other tasks, including the annotation made by WAGGER, are fully automated, and, as exemplified in Section 4, memory and time efficient.

Figure 3: Proposed method.

3.1 Training Task Giving annotated sentences as the example in Figure 4, we construct a Markov chain for each sentence considering the sequences of word classes found in the sentence. This process corresponds to the capturing of an approximative model of the patterns of word class sequences, having each example sentence as an instance of the language usage.

Stochastic	models	will	save	the	world	.
adjective	noun	verb	verb	article	noun	punctuation
but	not	everything	in	our	imperfect	and
conjunction	adverb	pronoun	preposition	pronoun	adjective	conjunction
beautiful	world	deserves	to	be	saved	.
adjective	noun	verb	preposition	verb	verb	punctuation

Figure 4: Manually annotated sentence used as training.

Basically, the Markov chain created has all word classes as the chain states, and every exiting arc represents a possible succession of words classes. For instance, the adjectives (*adj*) are succeeded twice by a noun (*n*) and once by a conjunction (*conj*). Hence, the *adj* state has transition towards *n* with probability $\frac{2}{3}$ and a transition towards *conj* with probability $\frac{1}{3}$. Repeating the same procedure for all word classes creates the Markov chain depicted in Figure 5.

Figure 5: Markov chain for sentence in Figure 4.

This same process of creation of Markov chain is repeated for a certain number of sentences. For example, Figure 2 sentence correctly annotated would produce the Markov chain depicted in Figure 6.

3.2 Disambiguation using Markov Chains The disambiguation process is made through the estimation of probabilities of neighbors words according to the constructed chains. Every word that needs disambiguation is analyzed to all possible word classes, *i.e.*, we compute the probability of its immediate predecessor and successors according to each chain.

Figure 6: Markov chain for sentence in Figure 2.

Formally, a word w_i in sentence s , has its probability of being of word class c computed according its predecessor (Eq. 3.1) and successor (Eq. 3.2) to chain m respectively by:

$$(3.1) \quad \leftarrow c_{w_i^s}^{(m)} = \frac{\sum_{k \in C(w_{i-1}^s)} P_{[k(w_{i-1}^s), c(w_i^s)]}^{(m)}}{|C(w_{i-1}^s)|}$$

$$(3.2) \quad \rightarrow c_{w_i^s}^{(m)} = \frac{\sum_{k \in C(w_{i+1}^s)} P_{[c(w_i^s), k(w_{i+1}^s)]}^{(m)}}{|C(w_{i+1}^s)|}$$

where $P_{[x,y]}^{(m)}$ is the probability of leaving state x and going to state y in the Markov chain m .

The overall probability of a word w_i in sentence s be of class c according to all training chains of a set M is given by:

$$(3.3) \quad \hat{c}_{w_i^s} = \frac{\sum_{m \in M} \left(\leftarrow c_{w_i^s}^{(m)} + \rightarrow c_{w_i^s}^{(m)} \right)}{2 |M|}$$

Hence, the disambiguation of a word w_i^s will be made by choosing the word class $c \in C(w_i^s)$ with the maximum value $\hat{c}_{w_i^s}$.

For example, considering the sentence “*The old book is dusty and black.*”, the WAGGER annotation is depicted in Figure 7. In this sentence the words “*book*” - w_3^s (either a noun or a verb) and “*black*” - w_7^s (either an adjective, a noun or a verb) need disambiguation.

The	old	book	is
article	adjective	noun verb	verb
dusty	and	black	.
adjective	conjunction	adjective noun verb	punctuation

Figure 7: Example sentence to disambiguate.

Using the first chain (Figure 5), let us call it m_1 , we observe that the probability of a noun be preceded by an adjective (“*old*” precedes “*book*”) is equal to $\frac{2}{3}$, and since “*old*” can only be an adjective, *i.e.*, $C(\text{“old”}) = \{\text{adjective}\}$,

we express formally:

$$\overleftarrow{n}^{(m_1)}_{\text{"book"}} = \frac{P_{[adj,n]}^{(m_1)}}{|C(\text{"old"})|} = \frac{0.6667}{1} = 0.6667$$

We also observe that the probability of a noun to precede a verb ("book" precedes "is") is also equal to $\frac{2}{3}$, and since "is" can only be a verb, *i.e.*, $C(\text{"is"}) = \{\text{verb}\}$, we express formally:

$$\overrightarrow{n}^{(m_1)}_{\text{"book"}} = \frac{P_{[n,verb]}^{(m_1)}}{|C(\text{"is"})|} = \frac{0.6667}{1} = 0.6667$$

Analogously, repeating the computations for the second chain (Figure 6), let us call it m_2 , we obtain zero values, since there is no word class noun in it, formally:

$$\overleftarrow{n}^{(m_2)}_{\text{"book"}} = \frac{P_{[adj,n]}^{(m_2)}}{|C(\text{"old"})|} = \frac{0.0}{1} = 0.0$$

$$\overrightarrow{n}^{(m_2)}_{\text{"book"}} = \frac{P_{[n,verb]}^{(m_2)}}{|C(\text{"is"})|} = \frac{0.0}{1} = 0.0$$

Computing the overall probability for "book" be a noun considering the two Markov chains ($M = \{m_1, m_2\}$) will be formally:

$$\hat{n}_{\text{"book"}} = \frac{\overleftarrow{n}^{(m_1)}_{\text{"book"}} + \overrightarrow{n}^{(m_1)}_{\text{"book"}} + \overleftarrow{n}^{(m_2)}_{\text{"book"}} + \overrightarrow{n}^{(m_2)}_{\text{"book"}}}{2 |M|}$$

$$\hat{n}_{\text{"book"}} = 0.3333$$

Analogously, computing the probability of "book" being a verb in the sentence of Figure 7, we formally obtain:

$$\widehat{verb}_{\text{"book"}} = \frac{0.4}{4} = 0.1$$

As result, we conclude (correctly) that "book" must be tagged as a noun (probability 0.33), and not a verb (probability 0.1). Analogously, we conclude (also correctly) that "black" must be considered an adjective, since:

$$\widehat{adj}_{w_7^s} = 0.13 \quad \hat{n}_{w_7^s} = 0.08 \quad \widehat{verb}_{w_7^s} = 0.12$$

4 Application Example

We employ the proposed method in a larger scale to illustrate the efficiency and effectiveness benefits of our approach. To do so, we choose the following test bed:

- Two POS-tagger to Portuguese: PALAVRAS [2] and LX-Center Suite [15];
- A Portuguese dictionary and the WAGGER dictionary retriever [3];

- Fifty Brazilian Portuguese manually annotated sentences to be used as training set;

- One hundred and twenty eight Brazilian Portuguese manually annotated sentences to be used as test set.

Applying our proposed method to the sentences of the training set has produced 50 discrete-time Markov chains. As mentioned, these chains can be considered an approximative model of Brazilian language usage in terms of word class sequences. The choice of these sentences is not particularly planed, since these sentences were randomly taken from domain corpora composed of articles and other academic texts of several scientific domains [11].

After that, 128 sentences were also randomly chosen from the same corpora in order to test our proposed method. The only concern choosing these 128 test sentences were not to choose a sentence that was already used as training set. For both training and testing sets, the manual annotation was performed by two linguist specialists.

The application of our method to the training set delivered 2,455 correctly classified words from a total of 2,958 words from the testing set. This result corresponds to a 83.0% precision, which is comparable to the precision of word class tagging made by PALAVRAS (86.1%) and LX-Center (88.8%).

In terms of efficiency, however, our proposed method is far more impressive, while the time spent for PALAVRAS and LX-Center were measured in terms of minutes, the performance of our method took less than one second. Table 1 summarizes the effectiveness (precision) and efficiency (time to tag) of the prototype implementing our proposed method in comparison with PALAVRAS and LX-Center running on a portable machine with i7 2.2 GHz processor, 8 Gbytes memory. This table results indicate a reasonable effectiveness and an extraordinary efficiency improvement. Such performance let us believe that the proposed method is a worthy option for real-time POS-tagger.

Table 1: Overall comparative performance of the proposed method prototype.

	correct words	precision	time to tag
our method	2,455	83.0%	<1 sec.
PALAVRAS	2,548	86.1%	2.3 min.
LX-Center	2,627	88.8%	1.5 min.

Finally, it is important to remember that unlike PALAVRAS and LX-Center rigid approaches, our method is based on train and test phases. Therefore, a careful choice of a training set may improve the effectiveness of our method.

5 Final Considerations

This work lays down the basic ideas to a novel approach to predict grammatical classes from corpora. This novel idea is much simpler than sophisticated HMM, CRF or SVM. Nevertheless, our method is more prone to evolution than traditional rigid approaches available at existing POS-taggers like PALAVRAS and LX-Center Suite.

The examples presented here embody the core concept of our technique, yet the results delivered a reasonable precision and very impressive efficiency. We believe that a trusted Markov chain database can make a difference in this kind of scenario. Thus, we are currently working on the construction of a solid training databases for several formal and informal languages in order to promote a broader test. For instance, we are building an additional lexicon of informal words and abbreviations usually employed in informal chats to try to grasp a reasonable POS-tagging for such a complex dialect.

We also expect to refine the disambiguation phase by considering more information than just the predecessor and successor of the target word. It is important to call the reader attention that the number of Markov chains is not an obstacle to the efficiency, since the weight computed according to each Markov chain may be computed independently, *i.e.*, a parallel implementation of the proposed method would scale very well to a very large number of Markov chains.

Despite those promising future works, the initial results encourage this line of research. In fact, our approach seems to gather the flexibility of sophisticated learning methods, the easiness of development, and computational efficiency. Therefore, our proposed method can bring effective and efficient POS-tagging to virtually any language, dialect or domain lingo.

Abstract—NL2SQL advocates an idea of helping engineers and/or end users generate SQL statements from natural language queries. However, it still remains a strong challenge in improving its precision and scalability. This paper introduces MultiSQL, a multitask deep learning approach to performing NL2SQL. MultiSQL unifies the task representations and trains a model in parallel on multiple tasks, including NL2SQL, machine translation, etc. It employs a multitask question-answering network for jointly learning all tasks and transferring knowledge among tasks. We have evaluated MultiSQL on two query datasets: WikiSQL (an open sourced dataset) and CnSQL (a Chinese dataset we created). The evaluation results clearly show the effectiveness of MultiSQL. In particular, the accuracies achieved by MultiSQL approximate those achieved by the state-of-the-art NL2SQL methods on WikiSQL, and its accuracy is 78%, which is 17% higher than the “Chinese2English + NL2SQL” method on CnSQL.

Index Terms—NL2SQL, SQL statement generation, deep learning, multitask learning

I. INTRODUCTION

With the rapid development of data engineering, industry engineers frequently perform data queries for data analyses and/or obtaining online reports. SQL is a popular and flexible language for querying data. In order to facilitate end users to perform data queries, some studies on NL2SQL, i.e., translating natural language queries into SQL statements, have been conducted.

So far two mainstreams of NL2SQL methods do exist. One mainstream is to use a *seq2seq* (sequence to sequence) model with neural networks for query generation [1], [2]. In particular, training a *seq2seq* model requires a standard format [2]. Meanwhile, a query result can have different logical forms, which reduces the effectiveness of the training process. *Seq2set* (sequence to set) is another mainstream, which divides a query into parts and generates them individually [3], [4]. A *seq2set* method is capable of processing the disorders of filtering conditions effectively, but it may miss internal dependencies in the input sequences.

The existing efforts have achieved remarkable results. However, they are still facing two main difficulties when applied in practice.

First, many NL2SQL methods are only evaluated on the machine-generated datasets, making their effectiveness unclearly shown. Indeed, most of the methods are evaluated on WikiSQL*—an open sourced dataset automatically extracted from Wikipedia. An NL2SQL method should be evaluated on both the machine- and the human-generated datasets [5].

Second, many NL2SQL methods are not scalable, as they only focus on translating queries in English into SQL statements. In case that queries in other languages are raised, they must at first be translated into descriptions in English, and then to SQL statements. The imprecision occurred during the translation stage can be propagated.

One solution to this is combining the language translation task with NL2SQL to seize the latent information in the queries and datasets. This paper presents MultiSQL, a multitask learning approach to NL2SQL. MultiSQL learns one model for multiple NLP tasks, including NL2SQL, machine comprehension, machine translation, etc. MultiSQL uses a TCR (Task-Content-Result) template to unify all tasks, and builds a multitask deep learning network for jointly learning all tasks and transferring knowledge among them.

This paper makes the next contributions:

- 1) **A deep learning approach.** We propose a general, scalable multitask deep learning approach, MultiSQL, to NL2SQL. MultiSQL trains a model for multiple NLP tasks, and takes three training strategies for accelerating sample efficient learnings and supporting knowledge transfers among tasks.
- 2) **A multitasking neural network.** We design a multitasking neural network with an encoder and a decoder. The encoder adopts dual coattention to represent the task and its content sequences, compressing all of this information with two BiLSTMs. The decoder with multi-pointer-generator utilizes attention over the content, task and previously output tokens to make decisions.
- 3) **Dataset and evaluation.** We have evaluated MultiSQL on WikiSQL and CnSQL. CnSQL is a Chinese SQL dataset we collected from real-world applications. Through transfer learning, the performance of NL2SQL is enhanced, achieving the logical form accuracy of 78.7% and the database execution accuracy of 86.1%. Furthermore, MultiSQL achieves logical form accuracy

of 78%, which is 17% higher than the “Chinese2English + NL2SQL” method.

II. RELATED WORK

A. Code Generation and NL2SQL

Code generation is becoming a promising approach to improve the productivity of software development. At present, there are three mainstream technologies: generation from models using templates [6], program synthesis by logic specification, and code generation and recommendation via machine learning or information retrieval [7]. NL2SQL is one of its research hotspots in recent decades, and in particular, neural-network-based NL2SQL has achieved remarkable results.

Dong and Lapata [1] have introduced a seq2seq approach that uses the augmented pointer network to convert textual queries to logical forms. Zhong et al. [2] have published the WikiSQL dataset and proposed a seq2seq model with reinforcement learning. Xu et al. [3] have further improved the results by taking a seq2set model and an attentional model. Similarly, Guo and Gao [8] have developed tailored modules to process three components in SQL queries. A parallel work [4] obtained a high execution accuracy on WikiSQL for SQL statements belongs to the “select-aggregator-where” type. External knowledge bases are also employed for tagging question words. Sun et al. [9] have presented a generative learning model to replicate contents in column names, cells, or SQL keywords. They have also improved the generation of the WHERE clauses by leveraging the column-cell relations.

B. Multitask Learning

Multitask learning is a machine learning paradigm. It aims to improve the generalization performance of a task using many other related tasks. Multitask learning has been successfully applied in the domain of natural language processing.

Collobert et al. [10] have proposed a unified framework for processing multiple natural language tasks, including chunking and part-of-speech tagging. Hashimoto et al. [11] have presented a neural network for dependency analysis, semantic correlation, and natural language reasoning. Zero-shot translation can be achieved by multitasking in language translations [12], where seq2seq models use two or more encoders and decoders for translation, parsing, and image subtitles [13]. Through model modularization, the above approaches can be applied to image classification and speech recognition [14]. Learning this modularity can further alleviate task interruptions [15]. Through multitask learning, the model can be used to learn some generally purposed expressions, since simultaneous learning of relevant tasks can provide inductive bias. Performance can be improved due to knowledge transfers across tasks.

III. APPROACH

MultiSQL is a multitask-learning-based approach to NL2SQL. As Fig. 1 shows, it takes a deep learning model to learn multiple tasks simultaneously. The deep learning model consists of a dual coattention encoder and a multi-pointer-generator decoder.

A. A Multitask QA Network

In MultiSQL, every task is formulated as a QA (Question Answering) task. Multiple tasks are trained jointly using a deep learning model, and knowledge is shared among tasks.

Task Unification. We design a TCR (Task-Content-Result) template to unify all the tasks. Each task instance is described with a *task*, *content*, and *result*, as Fig. 2 shows. During training, MultiSQL takes three sequences as its inputs: a content C with l tokens, a task Q with m tokens, and a result A with n tokens. Each token is represented by a d_{emb} -dimensional embedding.

Dual Coattention and Multi-Pointer. A task formed by the TCR template often contains key information that constrains the search space. MultiSQL uses dual coattention [16] for presenting conditions for both sequences, compresses the information with two BiLSTMs, applies self-attention [17] to collect long-distance dependencies, and then uses two BiLSTMs to get representations of the task and its content. The multi-pointer-generator [18] decoder uses attentions over the content, task, and previously output tokens to make a decision: copying from the content, copying from the task, or generating from a limited vocabulary.

Cross-task Transfer. MultiSQL facilitates sample-efficient learning and knowledge transfers among tasks. Three multitask collaborative training strategies can be used: *joint learning* (training all tasks jointly), *curriculum learning* (training simple tasks first), and *anti-curriculum learning* (training hard tasks first).

B. Encoder

MultiSQL adopts a deep stack-based recurrent neural network with a collaborative- and self-attention mechanism to generate the content embedding and the task embedding. The encoder takes six steps in the encoding process:

Step 1. Independent Encoding. A linear layer projects the input matrices onto a common d -dimensional space:

$$CW_1 = C_{proj} \in \mathbb{R}^{l \times d} \quad QW_1 = Q_{proj} \in \mathbb{R}^{m \times d}$$

The projected representations are fed into a shared BiLSTM $BILSTM_{ind}$ to get the independent encoded representations $C_{ind} \in \mathbb{R}^{l \times d}$ and $Q_{ind} \in \mathbb{R}^{m \times d}$.

Step 2. Alignment. The encoder obtains the coattended representations by aligning encoded representations of each sequence. The alignments are obtained by normalizing dot-product similarity scores between the content sequence and the task sequence:

$$\text{softmax}(C_{ind}Q_{ind}^\top) = S_{cq} \quad \text{softmax}(Q_{ind}C_{ind}^\top) = S_{qc}$$

Step 3. Dual Coattention. These alignments are used to compute weighted summations of a token in one sequence and a relevant token in another sequence:

$$S_{cq}^\top C_{ind} = C_{sum} \quad S_{qc}^\top Q_{ind} = Q_{sum}$$

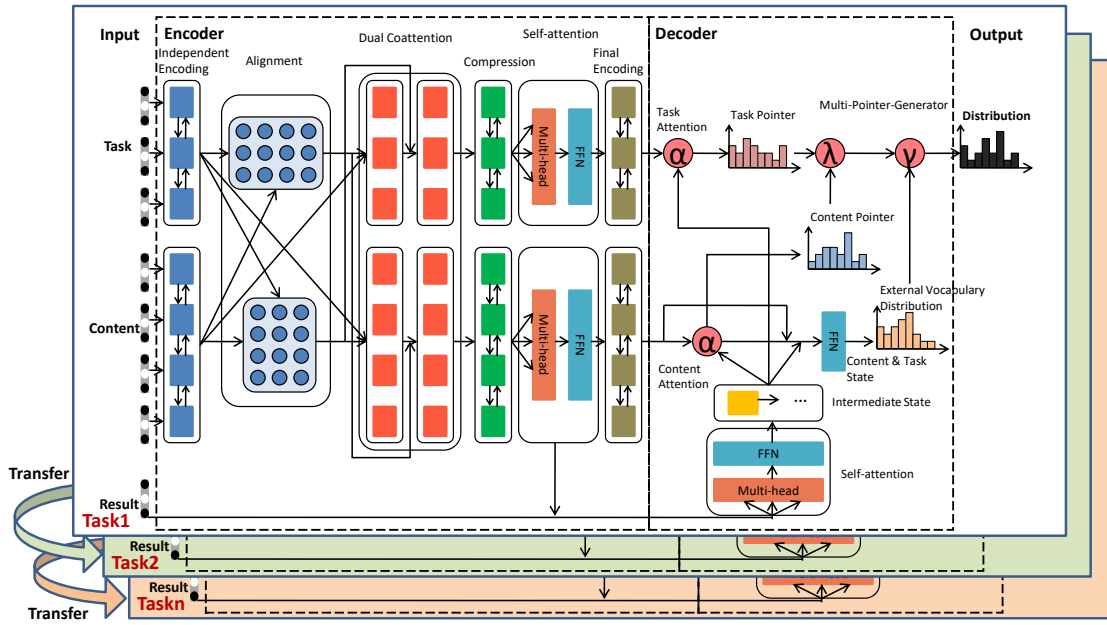

Fig. 1: An overview of the MultiSQL approach.

Task	Content	Result
Translate Chinese to English	告诉我南澳有哪些注意要点	Tell me what the notes are for South Australia
Generate SQL statements from neural text in English	The table has column names... Tell me what the notes are for South Australia	SELECT notes from table WHERE 'Current Slogan' = 'South Australia'

Fig. 2: Some TCR examples.

The coattended representations use the same weights to transfer information gained from alignments back to the original sequences:

$$S_{qc}^T C_{sum} = C_{coa} \quad S_{cq}^T Q_{sum} = Q_{coa}$$

Step 4. Compression. In order to compress embeddings from dual coattention back to the more manageable dimension d , we concatenate all of the four representations and feed them into separate BiLSTMs:

$$BiLSTM_{comC}([C_{proj}; C_{ind}; Q_{sum}; C_{coa}]) = C_{com}$$

$$BiLSTM_{comQ}([Q_{proj}; Q_{ind}; C_{sum}; Q_{coa}]) = Q_{com}$$

Step 5. Self-attention. We use multi-head, scaled dot-product attention [17] to capture long distance dependencies within each sequence.

$$Attention(\tilde{X}, \tilde{Y}, \tilde{Z}) = softmax\{\frac{\tilde{X}\tilde{Y}^T}{\sqrt{d}}\}\tilde{Z}$$

$$MultiHead(\tilde{X}, \tilde{Y}, \tilde{Z}) = [h_1; \dots; h_p]W^o,$$

where $h_j = Attention(\tilde{X}W_j^{\tilde{X}}, \tilde{Y}W_j^{\tilde{Y}}, \tilde{Z}W_j^{\tilde{Z}})$

All transformations in the above equations are linear such that the multi-head attention representations maintain dimensionality as d .

$$MultiHead_C(C_{com}, C_{com}, C_{com}) = C_{mha}$$

$$MultiHead_Q(Q_{com}, Q_{com}, Q_{com}) = Q_{mha}$$

We then use the projected, residual feedforward networks (FFNs). The FFNs are equipped with ReLU activations and layer normalization on the inputs and outputs (with parameters $U \in \mathbb{R}^{d \times f}$, $V \in \mathbb{R}^{f \times d}$):

$$FFN(X) = \max(0, XU)V + X$$

$$FFN_C(C_{com} + C_{mha}) = C_{self} \in \mathbb{R}^{l \times d}$$

$$FFN_Q(Q_{com} + Q_{mha}) = Q_{self} \in \mathbb{R}^{m \times d}$$

Step 6. Encoding. Finally, we feed C_{self} and Q_{self} into two BiLSTMs $BiLSTM_{finC}$ and $BiLSTM_{finQ}$ to get the representations $C_{fin} \in \mathbb{R}^{l \times d}$ and $Q_{fin} \in \mathbb{R}^{m \times d}$, respectively.

C. Decoder

MultiSQL's decoder takes four steps in decoding:

Step 1. Self-attention. The decoder starts by projecting the answer embeddings onto a d -dimensional space:

$$AW_2 = A_{proj} \in \mathbb{R}^{n \times d}$$

Since recurrence and convolution are not contained in this step, we add positional encodings to A_{proj} :

$$A_{proj} + PE = A_{ppr} \in \mathbb{R}^{n \times d},$$

$$\text{where } PE[t, k] = \begin{cases} \sin(\frac{t}{10000^{\frac{k}{2d}}}) & k \text{ is even;} \\ \cos(\frac{t}{10000^{\frac{k-1}{2d}}}) & \text{Otherwise.} \end{cases}$$

We use self-attention so that the decoder is aware of previous outputs and the content to prepare for the next output. A residual FFN layer is applied to the content:

$$\begin{aligned} MultiHead_A(A_{ppr}, A_{ppr}, A_{ppr}) &= A_{mha} \in \mathbb{R}^{n \times d} \\ MultiHead_{AC}((A_{mha} + A_{ppr}), C_{fin}, C_{fin}) &= A_{ac} \in \mathbb{R}^{n \times d} \\ FFN_A(A_{ac} + A_{mha} + A_{ppr}) &= A_{self} \in \mathbb{R}^{n \times d} \end{aligned}$$

Step 2. Getting Intermediate Decoder State. We next apply a standard LSTM with attention to get a recurrent content state \tilde{c}_t for time-step t . The LSTM produces an intermediate state h_t using the previous answer word A_{self}^{t-1} and recurrent content state:

$$LSTM([A_{self}^{t-1}; \tilde{c}_{t-1}], h_{t-1}) = h_t \in \mathbb{R}^d$$

Step 3. Task and Content Attention. This intermediate state is used to get attention weights α_t^C and α_t^Q , allowing the decoder to focus on encoded information of the time step t :

$$\begin{aligned} softmax(C_{fin}(W_2 h_t)) &= \alpha_t^C \in \mathbb{R}^l \\ softmax(Q_{fin}(W_3 h_t)) &= \alpha_t^Q \in \mathbb{R}^m \end{aligned}$$

Content representations are combined with these weights and fed through an FFN with \tanh activation to form the content state and the task state:

$$\begin{aligned} \tanh(W_4[C_{fin}^\top \alpha_t^C; h_t]) &= \tilde{c}_t \in \mathbb{R}^d \\ \tanh(W_5[Q_{fin}^\top \alpha_t^Q; h_t]) &= \tilde{q}_t \in \mathbb{R}^d \end{aligned}$$

Step 4. Multi-Pointer-Generator. The model may generate tokens that are not in the task or the content. Thus additional vocabulary tokens v are accessed. We obtain distributions over tokens in the task, content, and the external vocabulary:

$$\begin{aligned} \sum_{i: c_i = w_t} (\alpha_t^C)_i &= p_c(w_t) \in \mathbb{R}^n \\ \sum_{i: q_i = w_t} (\alpha_t^Q)_i &= p_q(w_t) \in \mathbb{R}^m \\ softmax(W_v \tilde{c}_t) &= p_v(w_t) \in \mathbb{R}^v \end{aligned}$$

Two scalar tune the importance of each distribution in determining the output distribution:

$$\begin{aligned} \sigma(W_{pv}[\tilde{c}_t; h_t; (A_{self})_{t-1}]) &= \gamma \in [0, 1] \\ \sigma(W_{cq}[\tilde{q}_t; h_t; (A_{self})_{t-1}]) &= \lambda \in [0, 1] \\ \gamma p_v(w_t) + (1 - \gamma)[\lambda p_c(w_t) + (1 - \lambda)p_q(w_t)] &= p(w_t) \end{aligned}$$

A token-level negative log-likelihood loss is used throughout the training process: $\mathcal{L} = -\sum_t \log p(a_t)$.

IV. EXPERIMENTS

We have implemented MultiSQL and evaluated it on several datasets. The evaluation is designed to answer the following research questions:

- **RQ1.** Is MultiSQL more effective than singletask learning methods?
- **RQ2.** Can MultiSQL be used to generate SQL statements from queries in other languages (Chinese in this study)?

A. Setup

The experiment contains ten NLP tasks, each of which is evaluated using one dataset. The ten datasets used in the evaluation are listed in Table I. In particular, NL2SQL was evaluated on WikiSQL (an open sourced dataset) and CnSQL (a Chinese dataset we created). CnSQL[†] includes 1534 pairs of Chinese queries and SQL statements. It was collected by the human engineers from end-user queries in a Chinese HR outsourcing platform (ezhiyang.com).

Several commonly used metrics are chosen: logical form accuracy [2] for NL2SQL, BLEU [19] for Chinese-English translation, and F1-Score for machine comprehension.

B. Results for RQ1

The pointer-generator seq2seq (S2S) model [18] is selected for comparison. The results for comparing the singletask and the multitask learnings are shown in Table I. Here, (w/SAtt), (+CAtt), (+QPtr), and (+ACurr) represent the S2S model with an adjunction of the self-attention mechanism, the dual co-attention mechanism, the task pointer, and the anti-curriculum learning strategy, respectively.

1) Singletask Learning

The self-attentive (w/SAtt) mechanism [17] increases the capacity of the S2S model of integrating information from the task and the content. It improves the performance on most of the tasks. For WikiSQL, this model approximates the state-of-the-art (72.4%), but it does not use a structured approach.

We supplement the model with a coattention mechanism (+CAtt) next. The performances on part of the tasks are improved while decrease on the others and significantly reduce on MNLI and MWSC. For these two tasks, since the S2S baselines have the content concatenated to the task, the pointer generator mechanism can copy words directly from the input. In case that the task and the content are separated, the effectiveness of the model may be reduced.

Thereafter, we add a task pointer (+QPtr) to the network, which boosts the performance on MNLI and MWS. It also improves performance on SQuAD to 75.5% in nF1, which matches the performance of the first wave of SQuAD models that utilize direct span supervision [16].

When tested on WikiSQL, the final model achieves logical form accuracy of 72.6% and database execution accuracy of 80.4%.

2) Multitask Learning

During multitask learning, the S2S model performs worse on many tasks than the singletask model, with a total score of 483.6 points. However, the performance of the model is getting better and better after the combination of (w/SAtt), (+CAtt), and (+QPtr) sequentially. The score finally reaches to 584.7 points.

Performances on tasks requiring heavy use of the external vocabulary drop more than 50% from the S2S baselines until (+QPtr) is added. In addition to a coattended content, the task pointer utilizes a coattended task, allowing task information

to flow directly into the decoder. The main reason is that it is easy for the model to decide, if it can directly access the task, whether generating output tokens is more appropriate than copying.

By multitask joint learning with anti-curriculum strategy, the logical form accuracy of NL2SQL reaches 78.7%, and the database execution accuracy gets 86.1%.

C. Results for RQ2

The baseline for comparison is NL2SQL with Google’s translator. The results show that MultiSQL obtains logical form accuracy of 78% on CnSQL. It is 17% higher than that of the baseline. The results also indicate that MultiSQL performs well both on the human- and the machine-generated datasets.

V. CONCLUSION

MultiSQL is a multitask learning approach to generating SQL statements from natural language queries. MultiSQL leverages a deep learning model for jointly learning multiple tasks such that the performance of NL2SQL can get improved. The evaluation results show the effectiveness of MultiSQL. It achieves accuracies that approximate those of the state-of-the-art methods and outperforms the existing methods for translating Chinese queries into SQL statements.

In the future, we will improve MultiSQL by introducing other state-of-the-art language models. We also plan to feed domain knowledge into MultiSQL, expecting that the deep learning model can be further enhanced.

Abstract—In software development environment, software companies usually ignore the user requirements validation process in requirement gathering phase, which results in large number of modifications being required in the software maintenance phase to fulfill the customer requirements. Identification of accurate requirements from user stories and determining the effectiveness of work deliverable of software industry has always been a challenging task. In this paper, a new measurement approach for forward engineering completeness for software was introduced by using requirements validation framework. The forward engineering completeness for software was measured in two steps. In the first step, software component structure was developed in order to find the functional and non-functional requirements rejected by the customers in the requirement validation framework. In the second step, completeness of software from component-based development was determined in which the following parameters, such as functional, non-functional completeness attributes, were considered in the measurement process, and the unadopted attributes of the reuse code were also considered. Quality level for the attributes were assigned based upon the valuation of interior quality of the source code. Therefore, it resulted in the reduction of development time required for the software and the cost required for the software development was also reduced. A case study was incorporated in this research to explain the measurement process of forward engineering completeness. If the forward engineering code is satisfying the quality standards, then the code is in the completeness form. The attributes of code that negates to be used were considered as unadopted attributes.

Keywords—completeness; forward engineering; functional requirements; non-functional requirements; requirements engineering; validation

I. INTRODUCTION

It has been observed that software industries that abused the Requirement Engineering (RE) in the software development process resulted in the project failures [1-6]. Ana-Maria et al. [7] argued that business analysts needed to focus on requirement gathering techniques in a technically responsible way. Question had been raised as to the

relationship between the functional and non-functional requirements, with some, such as Vishal and Xiaoqing [8], argued that there was reciprocal relationship. Software quality measurement is one of the most complicated tasks in software design methodology [9]. Quality of the software can be determined by the success of software system for this various parameters, framework and methodologies has been proposed [10]. Forward Engineering as defined by Pressman [11] “In most cases, forward engineering does not simply create a modern equivalent of an older program. Rather, new user and technology requirements are integrated into the reengineering effort. The redeveloped program extends the capabilities of the older application”. Reverse and forward engineering are practiced in the legacy systems to extend the system usable lifespan [12].

Requirements are client’s invariant statements related to sub system or system [13]. Functional requirement describes the complete functionality of software components that should be required in the software. Non-functional requirement describes the requirements of software with respect to security, usability, portability, availability, capacity, efficiency and reliability [14]. In past lot of work has been done by the researchers on functional and non-functional requirements. But illustrating the graphical user interface for user requirements in the software specification, in order to validate the user requirements has always been ignored in the requirement gathering phase. This research focus on the importance of validation of user requirements so that time and budget wasted in the modification of software in the maintenance phase can be saved. Thalheim [15] suggested the design quality parameters which include completeness, naturalness, minimality and flexibility. The software after the development process is said to be in the completeness form, if it satisfies all the functional and non-functional requirements. Component is a reusable visible interface, which is the factored form of any software or sub system. Software architecture is a static structure that represents arrangement of components [13]. This research was conducted with the collaboration of software company. In this new template is introduced by the authors that demonstrates the requirements of software components, which is illustrated in Table 1. In

order to identify the adjusted and unadopted requirements Table 1 was discussed in the requirements validation framework.

In this research authors defines the two types of requirements unadopted and adjusted requirements. The functional or non-functional requirements rejected by Chief Executive Officer (CEO) of software users/customers are called unadopted requirements. Business analyst gathers the software requirements from software users/customers in natural language, after this these requirements were illustrated in Table 1, i.e. if software users/customers identifies that user login should not be by user name and password, but it must be by any of the followings: thumb scan, scan of Quick Response (QR) code or scanning the bar code of employee card etc. in the requirement validation framework then the rejected requirements are called unadopted requirements. Adjusted requirements are new requirements (functional or non-functional requirements) which are added in the software according to users demand or when any existing software components are replaced with new software components, then new functional and non-functional requirements are incorporated into the software. Examples includes: replacement of software component of login (email address and password) with QR code. In addition, as existing functionality of software was to calculate percentile of student result and now the customer of software has demanded that the software must also calculate Cumulative Grade Point Average (CGPA) of the student. Completeness is defined as “the state or condition of having all the necessary or appropriate parts” [16]. Whereas requirements completeness is defined as “a quality demanded to the set of software requirements and to each requirement itself, in order to ensure that there is no information left aside” [17].

In order to adapt the complete customer requirements in the software, software industries are developing the software globally [18]. The purpose of global software development is to gather the adjusted requirements of the software. As different countries use different social network software, such as Instagram, Twitter, Reddit, and Facebook etc., according to their requirements, therefore different regions in the world has different adjusted requirements. These differences are due to cultural difference, language difference, platform difference, business process difference and how the organization interpret with manual work. Different countries have different cultural and business-related problems so there is need to develop the software that captures the complete organization processing tasks. For this adjusted requirement must be incorporated in the requirement gathering phase, so that the developed software must be in the complete form.

II. METHODOLOGY

In this research authors develops the software by using forward engineering completeness approach. The methodology structure is illustrated in the Fig. 1. The developed system is said to be in forward engineering completeness, if it is developed with complete conditions or states of new business procedures and rules according to software engineering philosophies. In System Specification (SyS) information related to functional requirements, data

requirements, quality requirements and constraints for software was determined. Problem definition, objectives, goals, context and major capabilities of the software was determined.

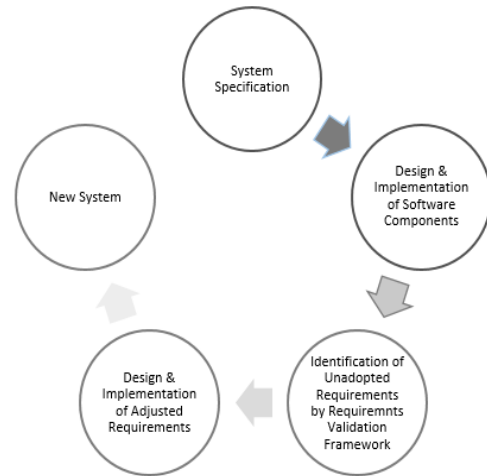

Figure 1. Forward Engineering Completeness

The purpose of requirement validation framework was to identify unadopted requirements as illustrated in the Fig. 2. In this business requirements were gathered from the users in which user identifies the goal and objectives of the system.

Figure 1. Requirements Validation Framework

The business analyst specifies the functional and non-functional requirements of the system. The business analyst and software engineer completed the task of software specification as shown in Table 1. The Software Quality Assurance (SQA) team members performed testing on the software to identify the errors in the software components. The basic purpose of this Table 1 was to present it in the framework meeting so the different categories of end-users from different regions can present their views. Scribe writes the report of the meeting. Chief executive officer attended the meeting along with end-users. Project manager and development team leader monitored the complete working process from requirement gathering to validation process. Software developer delivers the presentation of software requirements. The advantage of using this requirement validation framework showed the successful completion of software because after this process software modifications were not required in the software maintenance phase.

Rules & Definitions

Where S stands for Software, R_i , FR_j , NFR_k stands for n number of Requirements, Functional Requirements and Non-Functional Requirements respectively. Where $1 \leq i \leq n$, $1 \leq j \leq n$ and $1 \leq k \leq n$.

$$S(R_1, R_2, R_3, \dots R_n)$$

whereas

$$FR_j \& NFR_k \in R_i$$

As defined by Sommerville [19]

S ("what a software should do" & "how the system will do so")

Therefore

$$S(FR_1 \& NFR_1, FR_2 \& NFR_2, FR_3 \& NFR_3, \dots FR_n \& NFR_n)$$

Unadopted and adjusted requirements can be functional or non-functional requirements. Unadopted functional, unadopted non-functional, adjusted functional and adjusted non-functional requirements are represented by UFR_i , $UNFR_m$, AFR_p and $ANFR_q$ respectively. $SFEC$ stands for software developed by forward engineering completeness approach. Where $1 \leq l < n$, $1 \leq m < n$, $1 \leq p < n$ and $1 \leq q < n$.

$$FR_j \& NFR_k \in S \text{ and}$$

also

$$UFR_l \& UNFR_m \in S$$

but

$$AFR_p \& ANFR_q \notin S$$

whereas

$$AFR_p \& ANFR_q \in SFEC$$

In order to measure the Forward Engineering Completeness for the software this research incorporates case study and two steps were considered in the measurement process. In the first step, unadopted requirements were identified in the requirement validation framework and for adjusted requirements, structure of software component was also discussed. In the second step, software completeness was calculated by using following parameters. *i-First parameter* was functional and non-functional requirements attributes. These attributes determine the completeness of the forward engineering. In this integration among the attributes was also determined, which increases the completeness value. More completeness scales the forward engineering process closer to the actual budget and development schedule of the software and vice versa. *ii-Second parameter* was unadopted attributes. In which authors identified those attributes that were not required in the software by requirement validation framework. The identification of unadopted attributes helps in budget and time saving. The time spent on developing the software components that were not required in the developed software, was saved by identifying the unadopted attribute in the initial phase.

As clarified by Sommerville [19] "the non-functional requirements should define the usability, security, availability and performance requirements of the service". Therefore, usability and security were important for each component in non-functional requirements. The introduced technique was helpful for software engineers to measure the forward engineering completeness for software. In forward

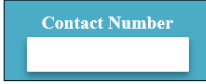

engineering, the software changes can be in terms of technology or adding new functionality e.g. if software was developed in old technology it can be changed to new technology for this, functional, non-functional and unadopted requirements were identified according to plate form difference.

III. CASE STUDY

Table 1 consists of three columns, first column describes the functional requirements of software, second column describes the system response and the third column illustrates the software components structure. Table 1 was discussed in the requirement validation framework. The non-functional requirements where were applicable, were explained by using software component structures in the requirement validation framework. In the pre-condition, user login the system by using organization email address. The organization email addresses and default password were issued by the organization for their employees.

TABLE I. REQUIREMENTS OF SOFTWARE COMPONENTS

Functional Requirements	System Response	Software Components
FR₁: The system shall display text box to enter the email address	The system displays a message asking the user to enter organization email address	
FR₂: The system shall display text box to enter the password	The system displays a message asking the user to enter the password	
	The system displays a message of "Successful Login"	
	The system displays the user Employee Number (EN) and name after the login	
FR₃: The system shall display options (yes/no) to change the password	The system asks the user if he/she wants to change the password	
	If the user clicks on the yes option, the system displays a message asking the user to enter current password, new password and confirm new password	
	The system displays the message "Password Changed Please login again with new Password"	
FR₄: The system shall display drop-down list for the selection of department	The system displays a message asking the user to select the department from the drop-down list	

FR₅: The system shall display drop-down list for the selection of employee title	The system displays a message asking the user to select employee title from the drop-down list	
FR₆: The system shall display calendar control for the selection of date of joining	The system displays a message asking the user to select date of joining the organization from the calendar control	
FR₇: The system shall display drop-down list for the selection of bank title	The system displays a message asking the user to select bank title from the drop-down list	
FR₈: The system shall display text box to enter bank account number	The system displays a message asking the user to enter bank account number	
FR₉: The system shall display text box to enter home address	The system displays a message asking the user to enter home address	
FR₁₀: The system shall display text box to enter contact number	The system displays a message asking the user to enter contact number	
FR₁₁: The system shall display options (yes/no) to save the changes	The system displays a message asking the user whether he/she wants to save the required data in the software or not	
	The system displays the message "Changes Saved" if user clicks on the yes option	

A. Condition 1

Customer₁ from organization₁, requested the modification in the software, functional and non-functional requirements for user login were by scanning the bar code of employee card with the bar code reader instead of login by email address and password. The bar code reader will be connected with the system through serial port or interface device called wedge or keyboard port. The bar code of the card will be matched with the repository of the user saved in the software in order to find the user matching text (identification).

According to Table 1, Functional Requirement Attributes (*FRA*) are those that defines the system behavior under precise circumstances. *FRA* (*email_address*, *password*, *change_password*, *current_password*, *new_password*, *confirm_new_password*, *department*, *employee_title*, *date_of_joining*, *bank_title*, *bank_account_number*, *home_address*, *contact_number*, *save_changes*). Non-functional Requirement Attributes (*NFRA*) are those that defines in what way a system must act and create restraints on its functionality. *NFRA* (*security*, *usability*, *portability*, *availability*, *capacity*, *efficiency*, *reliability*, *performance*, *integrity*, *recovery*, *compatibility*, *maintainability*). Unadopted Attributes, Total functional and non-functional requirements Attributes are represented by *UA* and *TA* respectively. In this following were the unadopted attributes *email_address*, *password*, *change_password*,

current_password, *new_password*, *confirm_new_password*. *FRA* = 14, *NFRA* = 12, *UA* = 6, *TA* = 26.

Functional Requirement Attributes Completeness

$$(FRAC) = FRA/TA = 14/26 = 0.54$$

Non-Functional Requirements Attributes Completeness

$$(NFRAC) = NFRA/TA = 12/26 = 0.46$$

Unadopted Attributes Completeness

$$(UAC) = UA/TA = 6/26 = 0.23$$

Software Completeness = *FRAC* + *NFRAC* - *UAC*

$$= 0.54 + 0.46 - 0.23 = 0.77$$

As the value are represented in unit interval (0, 1).

B. Condition 2

Customer₂ from organization₂, whose functional and non-functional requirement were: when the user login the system by email address and password. The system shall send PIN at the user cellphone for further authentication of user. So, there was requirement of new functionality by the user to be added in the software. The new functionality was required to be integrated with email software component. According to Table 1, *FRA* = 14, *NFRA* = 12, *UA* = 1, *TA* = 26.

Functional Requirement Attributes Completeness

$$(FRAC) = FRA/TA = 14/26 = 0.54$$

Non-Functional Requirements Attributes Completeness

$$(NFRAC) = NFRA/TA = 12/26 = 0.46$$

Unadopted Attributes Completeness

$$(UAC) = UA/TA = 1/26 = 0.04$$

Software Completeness = *FRAC* + *NFRAC* - *UAC*

$$= 0.54 + 0.46 - 0.04 = 0.96$$

C. Condition 3

Customer₃ from organization₃, functional and non-functional requirements for user login were by thumb scan or by scanning the Quick Response (QR) code instead of login by email address and password. QR code functionalities are represented in the Fig. 3 [10].

Figure 3. QR Code

According to Table 1, the value of *FRA*, *NFRA*, *UA* and *TA* were same as for condition 1, because unadopted attributes in both conditions were same.

Software Completeness = *FRAC* + *NFRAC* - *UAC*

$$= 0.54 + 0.46 - 0.23 = 0.77$$

D. Condition 4

Customer₄ from organization₄, functional and non-functional requirements were by selecting images for the password. The images must be available in the software. According to Table 1, $FRA = 14$, $NFRA = 12$, $UA = 4$, $TA = 26$. In this unadopted attribute were *password*, *current_password*, *new_password*, *confirm_new_password*.

Functional Requirement Attributes Completeness

$$(FRAC) = FRA/TA = 14/26 = 0.54$$

Non-Functional Requirements Attributes Completeness

$$(NFRAC) = NFRA/TA = 12/26 = 0.46$$

Unadopted Attributes Completeness

$$(UAC) = UA/TA = 4/26 = 0.15$$

$$\text{Software Completeness} = FRAC + NFRAC - UAC \\ = 0.54 + 0.46 - 0.15 = 0.85$$

Figure 4. Images Displayed for Password

In this user selects six images for password according to his/her order.

Figure 5. Images Selected for Password

In this research, complete software was developed in which team A used Forward Engineering (FE) approach. Team B developed the software by using Forward Engineering Completeness (FEC) approach. Both approaches were evaluated by monitoring following types of errors/defects [11]: Incomplete or Erroneous Specification (IES), Misinterpretation of Customer Communication (MCC), Intentional Deviation from Specification (IDS), Inconsistent Component Interface (ICI), Miscellaneous (MIS). Total number of Correct Functionalities (CF) in the software were also counted. In this research only IES, MCC, IDS, ICI, MIS, were monitored, because these errors/defects were related to the introduced technique. Total number of functional and non-functional requirements in the software were 1398. Table 1 represents the basic software components. During the evaluation process following errors in the software were identified: $IES = 173$, $MCC = 122$, $IDS = 27$, $ICI = 42$, $MIS = 301$, $CF = 733$ as shown in Fig. 6. All other errors/defects that does not belong to IES, MCC, IDS, ICI, were considered in the MIS. One value was assigned for one error/defect whether that error/defect belongs to functional or non-functional requirements of 1398 total requirements.

Figure 6. Errors & Correct Functionalities in FE Approach

In forward engineering completeness same type of errors/defects were monitored in the development process in order to determine the importance of requirement validation framework. Total number of functional and non-functional requirements were in the range of 1398 to 1430. The range in requirements were due to modifications in the unadopted requirements in order to fulfill different customer needs. Maximum value of requirements was assigned to the total requirements. During the evaluation process total number of errors in the software were as: $IES = 11$, $MCC = 14$, $IDS = 9$, $ICI = 21$, $MIS = 39$, $CF = 1336$ as shown in Fig. 7.

Figure 7. Errors & Correct Functionalities in FEC Approach

Team A developed the software without following the introduced techniques whereas team B followed the template of table for software requirements. After this these requirements were validated in the requirement validation framework before the actual development of software. Team A software development duration was more than the prescribed duration whereas team B developed the software in less than the prescribed duration. Total percentage of errors in software requirements was about 48% in forward engineering approach. In forward engineering completeness approach total percentage of errors in software requirements was about 7%. The decrease in errors was due to the validation of requirements before the software development. It has been observed that if development time of software increase, budget allocated for that software becomes less. As team A completed the software two months more than prescribed duration, so for these two months extra budget was

used in order to fulfill the salaries requirements of employees and other expenses of software company. Software development time increases due to identification of errors and defects in software, if these are found in last phases of system development life cycle than more time is required to remove them. As team B developed the software by using requirement validation framework therefore the defects found in this were nearly negligible. From the Fig. 7 it has been observed that whenever unadopted requirements are identified at the start of software development, there was reduction in budget and time duration for development also reduces. Forty-five days were required by Team A to perform corrective, adaptive, perfective and preventive maintenance whereas Team B completed all maintenance types in one day.

IV. CONCLUSIONS

This research supported the convincing evidence that, whenever requirement validation framework was used in the forward engineering, then surplus budget allocated for the maintenance phase was saved. The suitability of attributes allows illustrating conclusion about how suitable software component was for a specific problem. The time required to develop the software was also reduced. The time spends on corrective, adaptive, perfective and preventive maintenance reduces approximately 1 to 2 months for one-year projects, whereas in normal routine it takes 2 to 3 times more than scheduled time. It has been observed that software size is increasing day by day due to change in technology and new requirements of end-users. As software size increases ultimately the software complexity also increases. In the final phase the software, size becomes like a pyramid so if user stories are ignored in the requirement gathering phase then large number of errors and defects are identified in the software. The requirement validation framework identified the unadopted requirement in the software and new requirement were also identified in the face to face meeting which resulted the software in completeness form. The identification of unadopted requirement saved the software engineers from complexity of errors and defects.

Abstract—In current era, smart devices play vital role in social connectivity and performing routinely activities. The motor and non-motor (rigidity, tremor at rest, dysarthria, slowness of movement, and depression) symptoms of Parkinson's disease (PD) have definite negative impacts on patients' interaction with smart devices. An adaptable interface named PD-Helper is designed and developed to meet the physical capabilities as well as social needs of patients and to improve the accessibility via smart devices. Single touch interaction is provided via scanning selection technique, video and web user controls and input method editor (IME) application allows PD patients to access web browsing, entertainment like watching videos, typing text and contacting medical stuff. 40 users with PD, participated in the evaluation process of the PD-Helper. Preliminary results are promising and satisfactory. Further studies are in progress to attest the PD helper potential, such as improving the quality of life of people with other Neurological disorders.

Keywords—component; Parkinson's Disease, Mobile Interaction, Accessibility, Single touch interaction, interaction with smart devices

I. INTRODUCTION

In current society, Parkinson's disease (PD) is a progressive degenerative disorder that affects the nervous system and consequently decreases the quality of life (QOL) effecting more than 1% of the patients worldwide and in China [8,13]. As smart devices becoming an indispensable part of human life, PD also inevitably need to use modern communication products. Smart technology has evolved the ways of interaction such as input becomes based on tiny touch screens, on screen keyboards, on gesture and finger input [1]. But the physiology and psychology of the patients with PD are very different from the target customers of smart phones [1,8,22]. Cardinal symptoms of PD like rigidity and tremor, neurological disorders like insomnia and severe fatigue, undermined speech and voice capabilities are likely to reduce the individual's mobility and autonomy and thus affect the way they interact with smart devices [8].

At present, the smart device with less functions can solve the basic needs of the special groups, but cannot meet the fashion need of the special groups for health, recreation and social demand [1]. The problems of existing smart devices and computers are divided into three sectors: user interface, interaction design, physical capabilities. As for user interface, decorative fonts prevent patients with visual problems reading text easily [5], patients with visual problems find it hard to adapt

to the brightness changes between screens [1,4], elder patients may have problems with perception of the application and the devices itself and verbiage in system requires an understanding of smart devices basics to make sense [10]. In terms of interaction design, for smart devices, the interaction is mainly implemented by gestures on the screen. And the problem lies in that motor-impaired PD patients cannot accurately tap on a small icon on the screen or perform those interaction gestures well, like sliding or scrolling. Buttons of touch screens react too fast and this is a problem for the elderly [4]. Audio interaction is also not feasible as PD has strong effects in patients' language competence, which result in their lack of clarity and loudness and make it hard for ASR to recognize what they are saying [22]. What's more, spreading information across screens or forcing scrolling may be problematic due to working memory decline [2] and decline in ability to coordinate multiple tasks using attention switching [3]. Screens which present too many options or buttons may become confusing due to patients scanning the whole screen towards their goal rather than zeroing in, by visual cues, on what they are looking for [10]. Considering physical capabilities, smartphones usual keypad is not good for elderly and the physical buttons from mobile phones are too small. Design of the size should consider the trade-off between the screen size and handset size for patients to hold. As for the volume of audio interaction, when some instructions of a UI want to be given by voice, patients with audio impairment cannot receive the signal in some frequencies range [1]. Consider whether to listen carefully to the elderly, but also need to consider the impact of the size of the sound on vision [12].

To provide an optimal design to the intended audience, we designed and developed PD-Helper to satisfy the patients' need of communication, entertainment and requirement for medical care. With consideration of usability, accessibility and customization, application is developed based on scanning technique to provide single touch interaction over entire screen of smart devices. Personalization feature allows patients to adjust the font size, background color and scanning speed according to one's individual pace. 40 users with PD, participated in the evaluation process of the prototype. Preliminary results are promising and indicate a good level of acceptance. The contributions of this study are that 1) an easy and feasible solution that helps PD patients to enhance their interaction with smart devices 2) A single platform that provides access to four major daily life utilities to satisfy the fundamental needs of PD patients 3) To accommodate the variant conditions

of PD Patients, they can choose controllable speed, and entire screen as touch keypad helps to improve the accuracy, single touch interaction smoothly fits to their physical limitations and helps to reduce physical fatigue. 4) This research also insights that by improving the accessibility and usability of interaction design of smart devices, they can be really helpful to provide a more productive, independent, social and fulfilling life to elder society.

II. RELATED WORK

Assistive technology is trying to assist the elderly society and motor impaired by providing a variety of applications to cope with interaction challenges in web search, text input as well as for health care. Keyboard is an essential modularity to interact with mobile phones. Researchers tried to optimize the QWERTY keyboard for a high efficiency by changing the layout [21], changing the key size, width or color [17,18] and different kinds of gestures such as swipe [19], shake [14] and other hand gestures [16] are used to promote typing efficiency. For web browsing, [11] developed a browser allowed patients to choose the links by presenting a series of brain responses within limited time. Web Accessibility Initiative provides bigger text with larger clicking areas and patients can order a special mouse to deal with the problem of shaking hands. For patients' Health care system, [7] did a survey to determine participants' perceptions of whether PROME would facilitate patient-physician communication. For multimedia, [23] created a Brain-Computer-Interaction system based on electroencephalography (EEG) signals to meet the recreation need of people with severe disability.

Though the development of the IME seems highly improved the efficiency of typing for healthy people, but the number of keys and the complexity of gestures increase difficulty for patients whose hands are shaky to tap or follow the gestures that is why systems [14-21] are not suitable for PD patients.

The browsers which have been developed [9, 11, 23, 24] have a strong limitation due to precise use of mouse control movement, hence is not adaptable to PD patients. It is more important for doctors to get patients feedback to decide whether the medicine is suitable or not [6,7]. But the need to access medical services directly by expressing patient feeling is still need to pay attention.

Multimedia and recreation content access is really helpful to change the mind state of patients especially when they feel depressed. PD patients are incapable to use most of them [23]. All above mentioned problems highlight the need of our proposed PD-Helper system that can help PD patients to interact with smart device applications according to their physical capabilities. The details are given below in the design section.

III. APPLICATION DESIGN

To make our design in accordance with PD patients' needs and physical capabilities, we have considered following aspects: *accessibility*, simple design without intervention of wearable sensors and additional hardware and interaction technique should be feasible for PD patients; *usability*, the system is easy to learn and use; *customization*, users are allowed to make adjustment to the system settings according to their own

controllability. We carefully considered and applied the three aspects in user interface design, interaction design and physical capabilities adaptation.

A. User interface design

- Main interface: PD-Helper provides four modules, namely website browsing, multimedia access, notebook and health care. As for the layout of the four modules and main interface, we adopted a neutral color scheme as background color and highlighting colors as icons' color, in order to ease the visual burden for PD patients to distinguish the flashing icons. The layout is concise and consistent in the whole system. Each icon and graphic representing modules or functions are easy to identify and are displayed with a larger size than that of the traditional mobile systems.
- IME interface: The layout is designed with 7 keys and one large size touch pad to make the interaction easier and efficient for motor impaired patients. First the initial alphabet (consonant) of pinyin is displayed. After that the system will show the possible pinyin combination. By selecting desiring combination, system will display the Chinese characters. The desired choices in each step are displayed within 7 keys.

B. Interaction design: Single touch and menu selection

PD-Helper provides a single touch interaction and whole screen as input area for users. Considering the trembling or rigidity symptoms, single touch allows users to touch the screen for a very short time to realize input and the application sets a large touch pad for them to touch and decrease the probability of error. Users do not click over individual keys and alphabets to select, they can tap over the entire area to make a selection. Menu selection is realized using scanning technique rather than touching on the small area of an icon. When the target items start to flash in turn, users can touch anywhere on the screen to select them.

C. Input technique: IME and shortcut menu

Consonant Character Input Method [25] is used in the IME application. To control the interaction via single touch, scanning ambiguous keyboard concept is used, because this is an efficient way to implement the system with reduced size and control the output via single key [23]. Sequence of typing one word is as follows. First look up for the initial alphabet (consonant) of pinyin. After that system will show the possible pinyin combination. By selecting desiring combination, system will display the Chinese characters. A small offline database connects the IME application to retrieve the Chinese characters efficiently. To maintain the efficiency during whole typing process, an online database is connected. So that if user does not find desired character, he just need to select the "x", system will type pinyin directly in the textbox. After user finished one sentence, system will replace pinyin with corresponding Chinese character.

D. Physical capabilities adaptation

A design should meet the patients' physical capabilities to make it adaptable at user level. Fig.1 shows the difference between device interaction and user capabilities to interact with

them. As interaction techniques based on precise target selection are out of questions for the patients, so it is really challenge for them to cope with these devices.

PD-Helper uses *scanning technique* to make selection, Icons flash in turn and users can touch on the entire screen to realize their input. *Single tap input* allows users to input with least physical effort. In this way, these applications accessible to more people with physical disabilities. *Personalization settings* are provided to change the scanning speed (4s, 3s, 2s), and color theme to facilitate the diverse conditions of PD. The web user controls with scanning technique and video easy control help patients to access the applications.

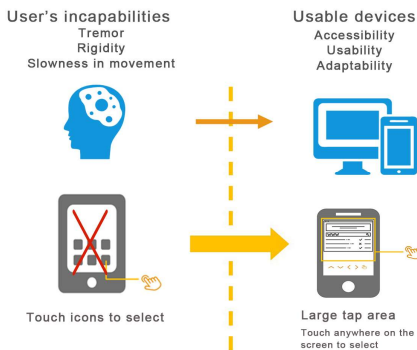

Figure 1. Physical capabilities adaptation

IV. APPLICATION IMPLEMENTATION

To implement the proposed design, we developed PD-Helper for Android platform. PD-Helper is composite of four modules, namely web browsing, multimedia, notebook and healthcare and provide patients with social connectivity, medical care and entertainment. The detailed implementation of each module in the application is listed below:

A. Main menu

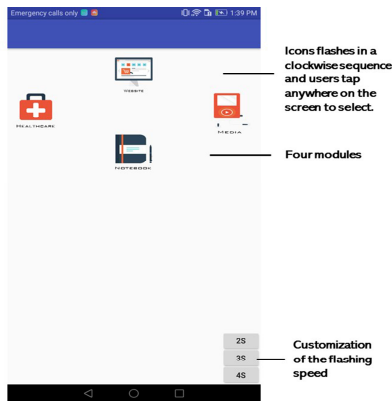

Figure 2. Main menu of PD-Helper

Main page displays four modules and their icons flash clockwise from website to multimedia, then notebook and the lastly healthcare (see Fig.2). Lower most right settings help to change the scan interval speed of the entire application. The

selection in PD-Helper can be made by single tap anywhere on the entire screen.

B. Web browsing

This module allows patients to browse the internet. When user opens browser, internet browser page divides into 2 parts: *page control area* and *web control area* (see Fig.3). *Web page control area* consists of web controls that start to scan in turn and helps to increase and decrease the font, refresh the current page, open new page and return to main menu by single tapping over the screen.

Figure 3. Web-Browsing PD-Helper

C. Multimedia

Video source: Multimedia Access provides a list of videos for users to watch, including some classic movies and rehabilitation treatment videos (see Fig.4).

Easy control: users touch the screen to select the video, and it plays automatically. Users can pause and play by single tapping for a short time, and then tap it again to continue to play. Touching the screen for a bit long time can exit the video and return to the video list. This mechanism is easy for PD patients to control videos.

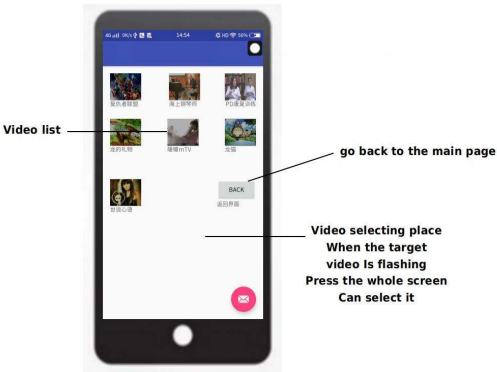

Figure 4. Multimedia module of PD-Helper

D. Notebook

This module provides an IME application that designed specifically for PD patients to type Chinese character in the text input area via single touch. Notebook application helps to type text, save notes, record notes and view the previous records. Users can also browse some relevant articles by typing keyword via “search” function. It provides many motivational cards with pictures and some motivational words to encourage users to change their mood. The content of the cards will be changed with tapping on the screen. Patients often have trouble in sleeping well due to physical therapy and psychological stress. The subsection “Sleep” provides many hypnotic music to improve PD patients’ sleep quality (see Fig.5).

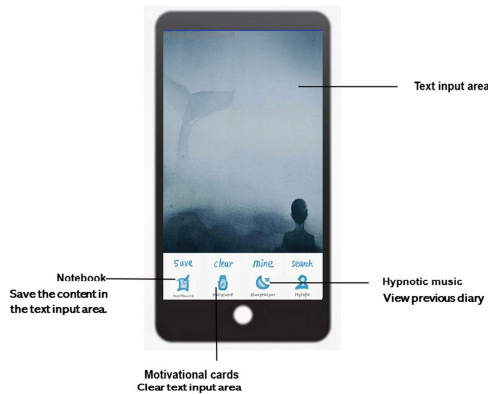

Figure 5. Notebook module of PD-Helper

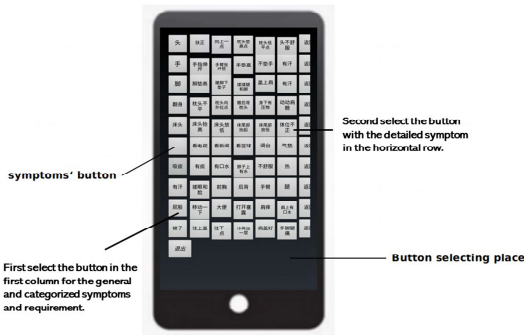

Figure 6. Health care connectivity

E. Healthcare

PD patients may suffer from speech impairment and are unable to express their need. This module provides common possible symptoms and needs for patients to express their feelings to the medical care staff automatically via the message system (see Fig. 6). The system helps to select the category of symptoms from the column via scanning technique and then pick the detailed symptoms in the corresponding row via single tap over the entire screen. The message will be sent to the contact number of care taker staff.

V. USER STUDIES

We conducted user studies to test the usability and to determine the effects of PD-Helper with PD patients. 40

recruited patients (18 males, 22 females) with age ranging from 43 to 89 (mean=69; SD=11.03) have been divided into two group according to their PD symptoms, namely tremor (T) and rigidity(R). Neurologist helped us to make selection of patients based on information from hospital records and nursing staff. Patient inclusion criteria includes 1) Parkinson’s disease symptoms (Rigidity, Tremor), 2) off state. Neurologist helped to motivate the patients to take part in the user study voluntarily. Neurologists helped to collect UDPRS data of participants. We divided the patient’s disease degree of severity into 3 levels only (using UDPRD data). All the patients signed informed patient consent form willingly and voluntarily participated to test the system.

To test the adaptability and accessibility of PD-helper with patients an experiment with 30 min time span is conducted. Keeping in view patient physical condition, it was tiring for a patient to test all the modules of PD helper. To test each module, we have divided patients into groups based on their capability to test the different modules. 22 Patients who were familiar with pinyin helped to test the notebook /IME module. The 18 patients with no or little knowledge of smart devices helped to test the web browsing and multimedia module. During the test sessions, participants had to perform the following tasks with three different scanning speeds.

Task 1: play the third video from the multimedia module, and check the play, pause and close functions.

Task 2: Patient has to open SOHU website and used the all available web user controls to increase, decrease font, refresh the page, open new page, and back to main menu.

Task3: Type a random sentence (selected from the old Chinese poem and daily life sentences) with the note book module (see Table III).

Test was conducted on Tablet (7.5 inches screen, android OS). Patients performed the test while holding the tablet in assistant hand, in their own hand and over the table as well.

A. Results and data of Task 1

18 participants took part to complete the video test. During test session, patient has to play a video, then use play, pause and close features of the application that are specifically designed to assist the diverse conditions of PD. The aim of the test is to measure the accuracy rate of users’ operation with different speed interval on video task. Before the test, we estimated the time required to complete the task without error and the estimated time (ET) for 2-4s speed interval is respectively 71.6s, 73.6s and 75.2s. We then measured the actual time (AT) participants took to complete the task in the test. Accuracy rate calculated in the following way:

$$R (\text{Accuracy rate}) = 1 - 100\% * (AT - ET) / AT \quad (1)$$

TABLE I. ACCURACY AND ERROR RATE OF TASK 1

Speed Interval	Accuracy Rate		Error Rate	
	T	R	T	R
4s	95.4	91.9	4.6	8.1
3s	88.0	89.9	12.0	10.1

Speed Interval	Accuracy Rate		Error Rate	
	<i>T</i>	<i>R</i>	<i>T</i>	<i>R</i>
2s	78.7	80.5	11.3	19.5

B. Results and data of Task 2

18 participants took test in web browsing module and all of them have completed the test. The test aims at testing the usability of web browsing mechanism and measuring the accuracy rate of users' operation with different speed interval. Before the test, we estimated the time required to complete the task without error and the estimated time (ET) for 2-4s speed interval is respectively 30s, 40s and 50s. We then measured the actual time (AT) participants took to complete the task in the test. Accuracy rate calculated by equation (1).

TABLE II. ACCURACY AND ERROR RATE OF TASK 2

Speed Interval	Accuracy Rate		Error Rate	
	<i>T</i>	<i>R</i>	<i>T</i>	<i>R</i>
4s	92.2	98.7	7.8	1.3
3s	85.3	90.4	14.7	9.6
2s	77.6	79.9	22.4	20.1

C. Results and data of Task 3

22 Participants overall have been divided according to their degree of severity to test the correlation between degree of severity, different speed interval (1s, 2s, 3s) and typing speed.

Patient used Table III sentences to complete the task 3. By keeping in view patients' physical condition short random sentences are preferably selected to avoid from tiredness and physical fatigue. In 1s speed interval test, the numbers of people with degree of severity from 1 to 3 are respectively 4, 13, 5. In 2s speed interval test, there are 19 people with 2 degrees of severity and 3 people with 3 degrees of severity. In 3s speed interval test, 10 people are with 2 degrees of severity and 12 people are with 3 degrees of severity.

Figure 7. Interval Plot of w/m speed

In terms of speed interval in relation to typing speed (Fig. 7), people have an approximately average typing speed of 2

words/minute with 1s interval, 1.1 words/minute with 2s interval, 0.65 word/minute with 3s interval. There's negative linear relationship between degree of severity and speed of typing. People have an approximately average typing speed of 2.3 words/minute with 1 degree of severity, 1.5 words/minute with 2-degree of severity, 0.7 word/minute with 3-degree of severity.

TABLE III. TEST SENTENCES FOR TASK 3

Sentence	Pinyin	Meaning
谢谢	xie xie	Thanks
没问题	Mei wen ti	No problem
我在北京	Wo zai bei jing	I'm in Beijing.
妈妈有三个孩子	Ma ma you san ge hai zi	Mom has three children
欢迎使用这个系统	Huan ying shi yong zhe ge xi tong.	Welcome to use this system

VI. DISCUSSION

From above data results section, it is proved that single touch PD-Helper is effective for patients to access the four major daily life utilities with more ease and accuracy via smart devices. The reason was that touch interaction technique was based on user experience and it was easy for the patients to adapt the one touch interaction technique as they were already familiar with it rather than learning novice and complex gestures. All patients used the three flash speeds to complete the test irrespective of their severity. During task 1 tremor patients showed more accuracy 95% with 4s as compared to rigidity patients 91%. During task 2 the lowest rate for accuracy was 77 % and 79 % of tremor and rigidity respectively. That shows really good acceptance especially in case of PD patients. It showed that patients adapt only those features that are in accordance with their capabilities. User's questionnaire feedback shows that IME is easy to use due to simple consonant vowel structure and personalized features make it suitable for diverse severity patients. The proposed system is best combination of accessibility, accuracy and usability.

Accessibility: Different scanning speed level can be adjustable according to patient physical condition, so patients with diverse conditions can access PD-Helper without any discomfort

Accuracy: large size icons, font size and color theme provide more clarity and visibility to the patients. A fatigue of exact target selection is also eliminated. To make selection of target they can touch anywhere of the screen. It helped to increase the accuracy for patients.

Usability: single tap selection along with large touch area reduce their motoric interaction and hence physical fatigue for them.

Fig.8 shows the user study performed with patients. This user study has made major relevant contributions in minimizing the motoric interaction for PD patients to access the smart devices. The idea of PD-Helper via single tap interaction over smart

devices is introduced for the first time for PD patients that is why the comparative study was not possible. All users appreciate the idea and practical worth of this system

Figure 8. User Study with PD-Helper Patients in Xuan Wu Hospital

VII. CONCLUSION

Parkinson's disease (PD) Patients with diverse physical conditions exhibit challenges in interacting with smart devices due to motor impairment. To enhance their interaction, and accessibility with smart devices, PD-Helper is designed and developed with single touch interaction as well as a large touch pad area to improve tactile experience for intended audience. Scanning technique is used to control input via single tap to minimize the physical fatigue for patients. By virtue of personalization features 40 participants (PD patients) were able to access the web, multimedia content and input Chinese text with more accuracy. The IME application, Web user controls, video easy controls, and connectivity with health care staff helps PD patient to improve their social connectivity via smart devices. Further studies are in progress to attest the PD helper potential, such as improving the quality of life of people with other Neurological disorders. Current limitation of the system is that it is developed for Chinese language. As a future work, a multilingual PD-Helper solution will be offered to support the patients around the globe.

Abstract—For dilated cardiomyopathy (DCM) patients, immediate emergency diagnosis and treatment are critical for life saving and later recovery. T1 mapping is a non-invasive and effective diagnostic imaging approach to detect DCM. However, it is a demanding and time-consuming approach. In this paper, we propose an attention-based network structure, which can automatically identify DCM patients in a speedy manner to prioritize their treatment. In the proposed method, we adopt attention modules to generate attention-aware features. Inside each attention module, a bottom-up top-down feed-forward structure is used to unfold the feed-forward and feed-back attention processes into a single feed-forward process. It allows the network to focus more on determining useful information about the current output that is significant in the input data. Moreover, inspired by the residual network idea, we make full use of the characteristics of the original data. Combined residual block, we design down-residual modules for classification tasks. It consists of seven convolution layers and three layers of residual blocks. Our network achieves the most advanced recognition performance on cardiac datasets. We evaluated our approach on CMR(cardiac magnetic resonance) T1 mapping images with lower PSNR(peak signal to noise ratio), and the results demonstrate that our architecture outperforms previous approaches.

Index Terms—medical image classification, attention, classification, myocardial

I. INTRODUCTION

Image classification is one of the most important tasks in computer vision tasks [1], and it is also the basis of other high-level visual tasks such as object tracking and behavior analysis [2] [3]. Particularly in medical image tasks, medical image classification is the key issue to determining whether medical images can provide a reliable basis for clinical diagnosis and treatment [4]. The development of medical classification technology plays an extremely important role in biomedical image analysis. In recent years, classification technology has made significant progress because of the application of deep learning algorithms in medical image classification. This is more challenging than classification tasks on natural images. The highly cluttered background and the particularity of medical images pose major challenges to classification accuracy [5] [6].

Dilated cardiomyopathy (DCM) is a common myocardial disease [7] [8] [9]. The disease can lead to ventricular systolic dysfunction, congestive heart failure and arrhythmia. The disease is progressively aggravated, and death can occur at any stage of the disease. Therefore, the use of DCM data as a dataset is of great significance [10] [11] [12] [13].

At present, many methods use medical image classification, such as, the SVM-based(Support Vector Machine) classification method [14] [15] and texture-based method [16] [17]. However, on comparing various methods, the method based on an artificial neural network achieves better results. It is found that the artificial neural network has learning and recognition abilities similar to the human brain. Moreover, it can model human organs, and independently learn the determined

DOI reference number: 10.18293/SEKE2019-155

diagnostic information and diseased tissue. Additionally, it can improve the reliability and effectiveness of diagnosing a patient's condition. Therefore, in this paper, we use an attention-based neural network method to effectively classify medical images.

Inspired by the residual attention network and recent advances in deep neural networks [18] [19], we propose a new network based on attention. It is composed of two attention modules that generate attention-aware features. Additionally, we design the down-residual module. It is capable of extracting the high-level features of the input data without causing a loss of the original features. As the number of layers increases, the attention-aware features from different modules are adaptively changed.

In addition to the additional discriminating features acquired by the attention module, our network has the following advantages: 1) Before the attention module, we design a down-residual module, which enables the extraction of high-level features of the input data without causing a loss of the original features. 2) Because of the scalability of the attention module, our network can be easily extended to hundreds of layers. Our network outperforms state-of-the-art residual attention networks. Experimental results show that the performance of our proposed network is better than that of residual attention network.

II. ATTENTION MODULE

The visual attention mechanism is a brain signal processing mechanism that is unique to human vision [20] [21]. Human vision scans the global image quickly to identify the focus area, which is generally called the focus of attention, and then invests a large amount of attention resources in this area to obtain more details of the target and suppress other useless information. The attention mechanism in deep learning is essentially similar to the human selective visual attention mechanism. The core goal is to also select more information from the many information that is of vital importance to the current mission objectives [22]. In recent years, the attention model has been widely used in various types of deep learning tasks, such as natural language processing, image recognition and speech recognition [23] [24] [18]. It is a core technologies that deserves the most attention and insight. In this paper, the attention model used is based on the attention module of residual attention network.

To improve the classification accuracy, Wang fei et al. proposed a residual attention network [25]. Compared with ResNet-200 [26], the residual attention net achieves 0.6% top-1 accuracy improvement and has good robustness. Based on the above advantages, we adopt an attention module in a residual attention network. As shown in Figure 1, each attention module is divided into two branches: the mask branch and trunk branch. The trunk branch performs feature processing and can be adapted to any state-of-the-art network structure. For the mask, first, through a series of convolution and pooling, it gradually extracts high-level features and increases the receptive field of the model. Then the size of

the feature map is enlarged to the same size as the original input by the same number of up samples. Thus, it maps the area of attention to each pixel.

Given input x , $T(x)$ denotes the trunk branch output, and the mask branch uses a bottom-up top-down structure to learn the same size of mask $M(x)$ that softly weights output features $T(x)$. The output mask is used as control gate for neurons of the trunk branch that are similar to the highway network. The output of attention module $H(x)$ is:

$$H_{i,c}(x) = (1 + M_{i,c}(x)) * T_{i,c}(x), \quad (1)$$

where i ranges over all spatial positions, c is the index of the channel ($c \in \{1, \dots, c\}$), $M(x)$ is the output of Soft Mask Branch and $T(x)$ is the output of the Trunk Branch. The entire structure can be trained end-to-end. Each pixel value in the attention map output by the mask branch is equivalent to the weight of each pixel value in the original feature map, which enhances meaningful features and suppresses meaningless information. Therefore, the weighted attention map is obtained by element-wise multiplication of the output of the mask branch and the output of the trunk branch. However, this weighted attention map cannot be directly input into the next layer because the activation function of the mask branch is sigmoid and the output value is in the range $(0, 1)$, so the author performs an element-wise operation on the weighted attention map and the feature map of the trunk branch.

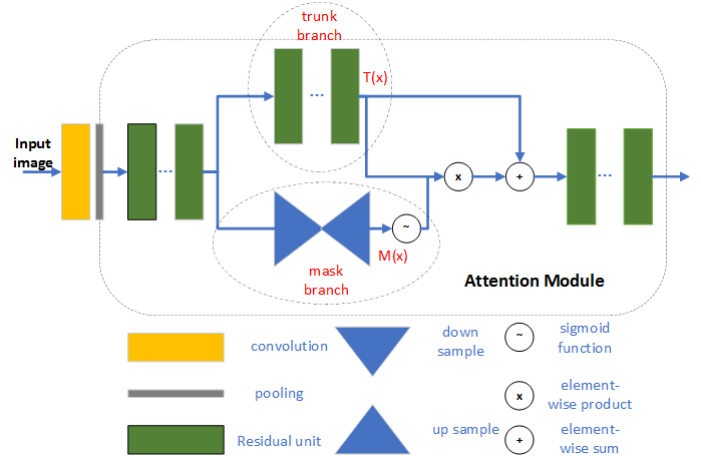

Fig. 1. Network structure of the attention module.

The attention module has the following advantages: 1) The attention module is similar to the residual learning mode, so a very deep model can be easily optimized and learned, and has very good performance. 2) The forward attention mechanism of bottom-up top-down. Other networks that use attention often need to add a branch to the original network to extract attention, and the author's model can extract the attention of the model in a forward process, thereby making the model training easier.

III. METHOD

In this paper, we construct a down-residual module and combine it with the attention module to construct an attention-based convolution network(ACNet). The network combines the advantages of the down-residual module with the advantages of the attention module to deliver outstanding performance and robustness.

A. Attention-based Network

We construct an attention-based convolution network based on attention. The overall network architecture and hyperparameter settings are shown in Figure 2. The network consists of three modules: the first module consists of seven convolutional layers and three residual blocks, and then two attention modules are connected. The former operation quickly collects the global information of the entire image and the latter operation extracts high-level distinguishable feature information.

From input x , convolution are firstly performed several times to increase the receptive field rapidly. After achieving the high-level features, they are used as input into the three residual layers. The residual layer can fully extract the useful advanced feature information and combine it with the input information of the upper layer. The useful feature information is fully used and missing useful feature information is avoided. Finally, the features are put into two attention layers.

B. Loss Function

Cross entropy describes the distance between two probability distributions. The smaller the cross entropy, the closer the two are. It is often used for the classification loss function of deep neural networks. In this paper, we use cross entropy as the loss function of the myocardial classification.

$$H(y, y') = - \sum_i^n y'_i \log y_i, \quad (2)$$

where H is a representation of the loss value, y indicates the predicted probability distribution, y' denotes the true probability, and n suggests the number of samples. Furthermore, the cross entropy loss function is put to a frequent use in classification networks.

Learning rate strategy: We conducted several trials with different learning rates, and the results showed that the learning rate of 0.001 was the most appropriate. If the learning rate is too high, it will lead to over-fitting, and the network cannot learn the feature information correctly. If the learning rate is too low, the network fitting speed is very slow. Therefore we set the learning rate to 0.001 .

Experiment configurations: To ensure the consistency of the experiment, we use accuracy as the quantization metric, 100 epochs are trained for each experiment ($batch_size = 3$). All experiments are implemented in python2.7 by using Tensorflow and Keras framework. We train the networks on a NVIDIA Tesla M40 GPU and the model that performs the best on test data set are saved for further analysis.

IV. EXPERIMENT AND RESULTS

A. Dataset, Pre-processing and Evaluation Metrics

CMR T1-mapping images of 485 myocardial sections from the same hospital were both trained and tested. The ground truth of the training and the testing samples of images with the myocardial were manually annotated by an experienced cardiologist. The pixel size of each CMR image amounts was 1.406×1.406 mm with a size ranging between 192×256 and 224×256 . Considering the fact that the size of the myocardium is small and surrounded by a substantial amount of noise, we first resampled the resolution of the image to $1 \times 1 \times 1$, and each image was cut to a fixed image size of 128×128 . Finally, the intensity range of the T1-mapping images was normalized to $[0 - 255]$.

To improve the classification performance of ACNet, three groups of experiments were constructed. In experiment 1, we increased the dataset size by using 485 images with a size of 128×128 (included 36 normal people and 449 patients), 388 training images, and 97 test images. In experiment 2, because the ratio of the positive and negative samples of the above dataset was very unbalanced (the negative sample contained only 36 cases), the dataset may have caused the classification performance to decrease. To solve this problem, we used data enhancement methods such as image rotation and random increase of noise to increase the number of samples of normal people from 36 cases to 191 cases, a total of 640 datasets of size 128×128 [27]. A residual attention network, which is a broadly applied state-of-the-art network structure, was used as a baseline method. To conduct a fair comparison, we used most of the settings same as Residual Attention Network paper. We adopted the same weight initialization method as the previous study and trained residual attention network using nesterov SGD with a mini-batch size of 3.

We used four indicators to assess the performance of the network, which includes accuracy, sensitivity and specificity. The accuracy is the average of the accuracy of in each group of experiments. In the medical field, sensitivity is the probability of correctly predicting positive samples, and specificity is the probability of correctly predicting negative samples. Sensitivity is computed using a closed-form formula:

$$sensitivity = \frac{A}{A + B}, \quad (3)$$

where A is the number of positive samples that are correctly predicted and B is the number of positive samples with incorrect prediction results. Similarly, specificity is computed using a closed-form formula:

$$specificity = \frac{D}{C + D}, \quad (4)$$

where D is the number of negative samples that are correctly predicted and C is the number of negative samples with incorrect prediction results. Generally, the higher the above four indicators, the better the performance of the experimental method.

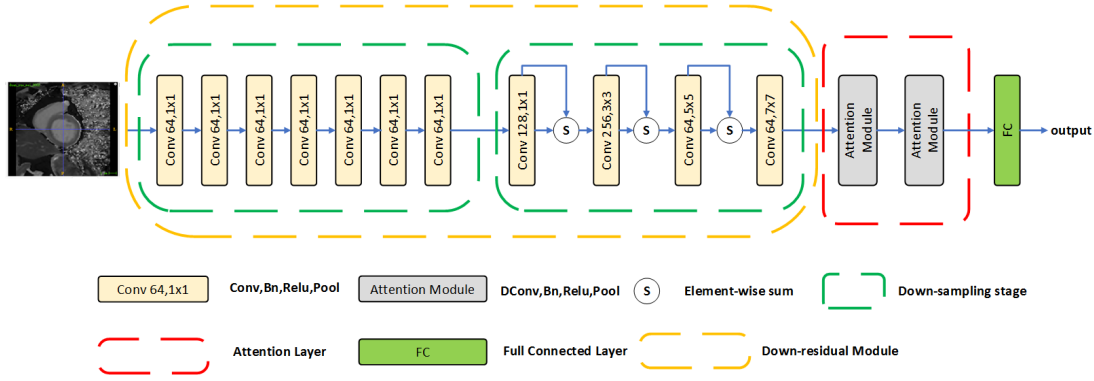

Fig. 2. The attention-based network structure proposed in this paper.

B. Results and Discussion

In this paper, we evaluated the performance of the residual attention network, VGG16, ResNet50, ResNet101 and our proposed network on the myocardial dataset. Two groups of experiments were constructed, and each group experiment was divided into two parts. In the first part, we used the myocardial dataset to perform multiple experiments on the residual attention network, VGG16, ResNet50 and ResNet101 to observe changes in the indicator. In the second part, we performed multiple experiments on the proposed attention-based network(ACNet) using the myocardial dataset to obtain the values of each indicator. Finally, the accuracy, sensitivity and specificity were compared to obtain the performance difference between the two methods.

For experiment 1, as shown in Table I, in the case of the same amount of myocardial data, the classification accuracy of the residual attention network was only 0.4179, the accuracy of VGG16 was only 0.8593, the accuracy of resnet50 is only 0.6251, and the accuracy of resnet101 is only 0.8347, however, the accuracy of our proposed network can reached 0.9277. Our approach is far superior to the other four comparison networks in terms of accuracy. Additionally, for the two indicators of sensitivity and specificity, our proposed network was also superior to the residual attention network, VGG16, ResNet50 and ResNet101. Unfortunately, the sensitivity of all methods in Table I was very low, whereas the specificity was close to 1. This phenomenon was caused by the imbalance between the number of positive samples and the number of negative samples. Therefore, to solve this problem in experiment 2, we used the data enhancement method to increase the number of negative samples, so that the difference between the positive and negative samples was reduced.

Figure 3 shows the attention features of two different samples in the residual attention network and ACNet. The myocardial instance mask highlighting the area surrounding of the myocardial. As can be observed from the figure, the myocardial mask highlighted the area around the myocardium and inhibited the middle area. The surrounding area of the myocardium is just the main feature area for assessing whether the heart muscle is normal. Therefore, we can know that the

TABLE I

EXPERIMENT 1 RESULTS FOR BOTH NETWORKS. IN THIS EXPERIMENT, A 5-FOLD CROSS-VALIDATION METHOD WAS USED. THE AVERAGE ACCURACY WAS THE AVERAGE OF FIVE EXPERIMENTAL PRECISIONS. THE SENSITIVITY AND SPECIFICITY WERE THE AVERAGE RESULTS OF FIVE EXPERIMENTS.

Network	Accuracy	sensitivity	specificity
Residual attention network	0.4179	0.1067	0.9571
VGG16	0.8593	0.3642	0.9142
ResNet50	0.6251	0.1753	0.8327
ResNet101	0.8347	0.3162	0.9059
Ours	0.9277	0.5305	0.9901

attention mechanism can highlighted useful feature information while suppressing the useless feature information, thereby improving the classification performance. Additionally, by comparing the feature maps of the two methods, we can clearly observe that ACNet's ability to highlight useful information and the ability to suppress useless information was stronger than that of the residual attention network. It essentially shows that ACNet outperformed the residual attention network.

For experiment 2, as shown in Table II, we used the data enhancement method to increase the number of negative samples. This method can reduce the difference in the number of between positive and negative samples, the number of positive samples and the number of negative samples remained relatively balanced. From Table II, we can observe that ACNet's three indicators were much higher than those of residual attention network, VGG16, ResNet50 and ResNet101. This result once again demonstrates that the performance of our proposed method is the most outstanding.

Figure 4 shows the comparison of the accuracy results of the residual attention network, VGG16, ResNet50, ResNet101 and ours ACNet. From the figure, we can clearly observe that, in the case of the same DCM dataset, the ACNet classification accuracy was always much higher than that of remaining four networks. From Figure 5, we can observe that the specificity of ACNet was much larger than that of remaining four networks, indicating that ACNet's ability to predict correct negative

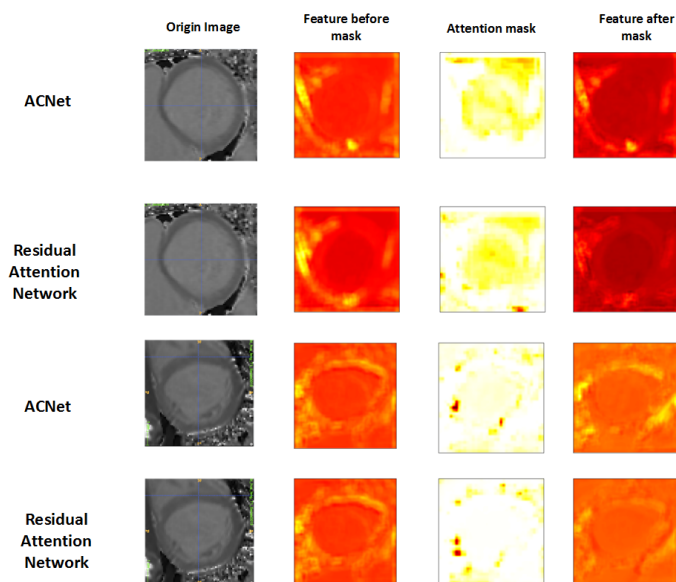

Fig. 3. Example images illustrating that different features have different corresponding attention masks in attention module. The myocardium instance mask highlights high-level myocardium surrounding part features.

Fig. 4. Distribution of accuracy results in experiment 2.

samples was significantly higher than that of remaining four networks. The difference in sensitivity results between the residual attention network, VGG16, ResNet50, ResNet101 and ACNet is shown in Figure 6. From the figure we can observe that the sensitivity result of the residual attention network, VGG16, ResNet50 and ResNet101 was much lower than that of ACNet. This demonstrates that the ability of remaining four comparison networks to predict correct positive samples was far lower than that of ACNet.

In general, from a comprehensive analysis of the results of the above methods, we can clearly observe that the advantages

Fig. 5. Distribution of specificity results in experiment 2.

Fig. 6. Distribution of sensitivity results in experiment 2.

of ACNet proposed in this paper were very prominent. Our method is much higher than the four comparison methods in terms of accuracy, sensitivity and specificity. From Figure 4 6 5, we can see that the three indicators of our method are very stable. It can be seen that our method is very robust. In the medical image classification task, the performance of ACNet was far stronger than that of the residual attention network, VGG16, ResNet50 and ResNet101. From the many experimental results, we can observe that the experimental results of ACNet were very prominent and stable, the robustness of ACNet was also strong.

To summarize, in the two groups of experiments, the four indicators of ACNet were much larger than those of the remaining four comparison networks. Thus, we can clearly observe that ACNet outperformed the residual attention network, VGG16, ResNet50 and ResNet101. Furthermore, the three indicators of experiment 2 were much higher than those of experiment 1, in particular, the results of ACNet in experiment

TABLE II

EXPERIMENT 2 RESULTS OF BOTH NETWORKS. IN THIS EXPERIMENT, THE UP-SAMPLING METHOD WAS USED TO INCREASE THE NUMBER OF NEGATIVE SAMPLES.

Network	Accuracy	Sensitivity	Specificity
Residual attention network	0.4718	0.6890	0.3510
VGG16	0.9452	0.7891	0.9405
ResNet50	0.7859	0.7132	0.8327
ResNet101	0.9274	0.7672	0.9361
Ours	0.97152	0.9582	0.9761

2 were significantly higher than the results of experiment 1. Therefore, we found that after using the data enhance method, performance was greatly improved. Similarly, in the field of medical imaging, there are often problems such as small datasets, and unbalanced proportions of positive and negative samples. We can use the method of data enhance to appropriately increase the number of samples, so that the number of positive and negative samples is basically the same. This can greatly improve the classification performance of the network.

V. CONCLUSION

In this paper, we proposed an attention-based convolution network. It combines attention module and down-residual module designed that we designed. The down-residual module can acquire high-level features without losing the original features, and the attention module highlights useful features and suppresses useless features. To prove the effectiveness of our framework, we compared it with residual attention network, VGG16, ResNet50 and ResNet101. We found that the proposed method was superior to remaining four comparison networks in terms of three indicators. The experimental results show that this method is obviously superior to the most advanced classification methods, with the highest accuracy, sensitivity and specificity. Additionally, the framework that we used is generally applicable to the classification tasks of other medical images or natural images. We plan to conduct further research in the future.

Discovering Indicators for Classifying Wikipedia Articles in a Domain

A Case Study on Software Languages

Abstract

Wikipedia is a rich source of information across many knowledge domains. Yet, recovering articles relevant to a specific domain is a difficult problem since such articles may be rare and tend to cover multiple topics. Furthermore, Wikipedia's categories provide an ambiguous classification of articles as they relate to all topics and thus are of limited use. In this paper, we develop a new methodology to isolate Wikipedia's articles that describe a specific topic within the scope of relevant categories; the methodology uses supervised machine learning to retrieve a decision tree classifier based on articles' features (URL patterns, summary text, infoboxes, links from list articles). In a case study, we retrieve 3000+ articles that describe software (computer) languages. Available fragments of ground truths serve as an essential part of the training set to detect relevant articles. The results of the classification are thoroughly evaluated through a survey, in which 31 domain experts participated.

1 INTRODUCTION

Wikipedia is a very large-scale, continuous community effort to collect and organize (informal) knowledge in almost all domains. In general, the quality of the articles and the mere principles of collection and organization challenge automated procedures in the quest of extracting and structuring Wikipedia knowledge [1–4]. Recovering articles describing topics in a certain domain is a reoccurring problem [5–7]. This paper presents a supervised machine learning approach for recovering Wikipedia articles relevant to an ontological class.

We conduct a case study on *software languages* defined as a set of digital artifacts, for which syntax, type system, semantics, and pragmatics can be (in)formally defined, documented, and implemented [8]. For the purpose of this research, we assume that Wikipedia's notion of "computer

language" – a notion that is used all across computer science and beyond – is essentially equivalent to the notion of "software language"; see also [9] for a discussion.

An important barrier is that, in a large number of cases, a *single Wikipedia article covers multiple subjects*. Looking at the very first sentences of the article about MATLAB (see Figure 1), several topics are mixed together (e.g., user interfaces, numerical computing, and software languages). The category graph is impacted as well (e.g., linear algebra and array-programming languages are both mentioned). There are also two infoboxes—one about MATLAB the *language*, the other about MATLAB the *software*.

Moreover, Wikipedia's category graph cannot be directly used for classification within the domain [10]; categories serve purposes other than classification, for example, collecting articles related to a common topic; see [https://en.wikipedia.org/wiki/Category:Java_\(programming_language\)](https://en.wikipedia.org/wiki/Category:Java_(programming_language)). Wikipedia's guidelines partly explain why multiple topics appear in an article: there should not be a new article, when the description benefits from explaining two or more subjects in the context of an existing article¹. Such rules and editing practices, though reasonable, complicate *classification*, i.e., automated identification of articles (instances) and underlying categories (classifiers). For some domains, like animals [5], categories that represent scientific classification are consistently used and provide a decision ground for still identifying relevant articles. In the domain of software languages such crucial features do not exist for articles or are used inconsistently. Alas, the recovery of relevant articles becomes looking for needles in a hay stack.

Significance of the multiple-subject problem. We initially explored articles that link to (subcategories of) the category 'Computer languages' and search for the top ten frequent nouns ('NN' tag recovered with part-of-speech tagger). We noticed that nouns from the music and astronomy domain are dominant. Fig. 2 reports the number of articles for the top ten most frequent nouns in the category

DOI reference number: 10.18293/SEKE2019-126

¹https://en.wikipedia.org/wiki/Wikipedia:Notability#Whether_to_create_standalone_pages

Figure 1. General structure of a Wikipedia article and some indicators.

tree of 'Computer languages' tree that we cut off at a depth of seven. Within the category tree, we observed subjects that belong to other domains, such as 'songs', 'stars', 'album' and 'music'. Except for the minority that describes domain specific languages in the respective domains, most of the article are obviously irrelevant to software languages. Fig. 2 also provides evidence that relatedness-based sub-categorization connect to irrelevant subjects.

Figure 2. Top 10 most frequent nouns in articles below 'Formal languages' category.

Research question and contributions. Overall, our case study is an instance of the problem of extracting domain-specific knowledge from Wikipedia [7, 10, 11]: *How can we classify Wikipedia articles by their relevance to a given domain when relevant articles are rare and multiple main topics are covered by articles?* Our objective is essentially to detect members (here: Wikipedia articles) of a certain class (here: software languages).

We develop a seed-based learning methodology for identifying articles relevant to a domain-specific class while leveraging the available limited ground truth (based on

Github and TIOBE) and identifying indicators by inspecting a learnt decision tree that include URL patterns, summary text, infoboxes, list articles and category graph. We then present a case study which, in itself, results in the most comprehensive corpus on software languages available today. The results are evaluated by domain experts through a survey.

2 SEED-BASED LEARNING

We now detail how we exploit fragments of ground truths and instrument a decision tree classifier. The datasets including plotted decision trees are available online². Figure 3 provides an overview of our approach. i.) For training, we recover articles describing elements that appear in trustworthy external resources. ii.) Based on such seed, we define the scope in which we want to isolate relevant articles and label 4000 randomly sampled articles from this scope for additional training data. iii.) From the training data, we build a feature matrix with categorical values that state whether a structural feature, such as the programming language infobox template, is present. iv.) We configure a binary classifier that decides whether an article is relevant.

2.1 Seed Matching

As first step, we have identified and reused two trustworthy external data sets: both act as *seeds* for recognizing relevant articles. *GitHub* presents statistics on which languages

²<https://github.com/softlang/wikionto/>

Figure 3. The ingredients of the approach. The seed in the training data influences decisions.

are used for any repository. The complete list of languages that are recognized can be extracted³. The *TIOBE* index presents statistics on how often software languages (mainly programming languages) are mentioned on the web. The list includes variations of names⁴.

Identifying each language on Wikipedia from the lists is challenging. We encountered favorable and problematic cases. To our favor, most names can be matched with article titles by leaving out annotations (e.g. '(programming language)') or by using Wikipedia redirects. However, manual reviewing remains crucial to make sure that languages are matched correctly, e.g., 'Red' is matched with 'Red (programming language)' and not with the color. In some cases, we succeeded by varying the writing style for the name, e.g., by unfolding acronyms, such as EBNF. In less favorable cases, we had to rely on Wikipedia's search engine to detect mentions in the text of existing articles. Only if the existing article describes the seed language as its main topic in the summary, we take it as the recalled article. To ensure availability of the necessary features for classification, we exclude stub articles from further analysis.

The resulting merged seed contains 327 *recalled seed languages* where 110 *overlap*. 158 seed languages are only casually mentioned in articles and 99 seed languages remain unrecognized.

2.2 Category Scope Exploration

We narrow the scope of our analysis to articles that are reachable by links to (subcategories of) chosen upper categories. Technically, we have manually identified common upper categories so that the seed is linked to them. At first, we hypothesized that all relevant languages link to 'Computer languages', but we found 'Augmented BackusNaur form' as a seed member that links to 'Formal languages', where 'Computer languages' is a subcategory. Moreover, for seed articles such as 'CSV', we noticed the upper category 'Computer file formats' that is disconnected from 'Formal languages'. Such formats are categorized in a different manner, but they do conform to the definition of software language. Our experiments show that all seed articles are

Table 1. Number of seed articles per depth.

	0	1	2	3	4	5	6-8
Formal languages	2	6	85	136	70	16	7
Computer file formats	8	22	11	7	0	0	3

linked to (subcategories of) two disconnected roots in the category tree at a maximum depth of eight. Table 1 illustrates at what depth from the chosen root categories seed articles exist.

2.3 Feature Extraction

Next, we describe which features we extract from the content types discussed in Section 1. To counter lack of decisive features and to reduce dimensionality, we exclude stub articles and only consider features that appear in at least ten articles. For now, we also exclude articles at a distance to the upper categories that is higher than 8. As a resulting dataset, the extraction returns an article-feature matrix with $104,186 \times 46,173$ entries with label '1' for present and '0' otherwise. Then, the set of 4000 randomly sampled articles and the seed form the training set. To avoid memory issues and enable loading the whole article-feature matrix, we use sparse matrices.

In the evaluation, we discuss that irrelevant articles in the training set are actually members of many other domain classes and have many different features. Hence, the resulting decision tree decides by features present in seed articles. In fact, GitHub and TIOBE seeds have a more general interest: **Seed articles provide representative features for recognizing relevant articles.** We show which features of seed articles provide a representative positive indication and hence may be found in a fit decision tree.

Infobox Templates. In the scope, there exist 864 distinct infobox template names. 263 seed articles use an infobox template. We found the templates on 'programming language' (215), 'file format' (32), 'technology standard' (3) and 'software license' (1). Especially, the templates 'programming language' and 'file format' provide a strong positive indication, but they do not exist for every relevant article.

URL Pattern. We extract all words separately in braces from every article's title as they provide a semantic anno-

³<https://github.com/github/linguist/blob/master/lib/linguist/languages.yml>

⁴<https://www.tiobe.com/tiobe-index/programming-languages-definition/#instances>

tation for disambiguation. Only around a third of the seed articles has such an annotation. The words in braces appearing more than once with their frequency are: 'language' (125), 'programming' (114), 'software' (6), 'stylesheet' (3) and 'markup' (2). 'programming' always appears together with 'language'.

Lemmas in Summary. From the summary, we extract all words, filter them by a stop word list and apply lemmatization on the remainder. We recovered 5449 lemmas from seed articles while 457, 164 distinct lemmas can be recovered from all articles. We enumerate the top five lemmas from the seed: 'language' (301), 'programming' (253), 'use' (216), 'develop' (120), 'design' (117). Lemmas are often used for topic models [12]. They are essential to distinguish the domain of software languages and co-occurring topics in articles from other unrelated domains such as natural languages.

Dependency Pattern. Following [10], we identified multiple kinds of relationships that can be extracted from the first sentence. Hypernyms provide a reliable feature as most articles on Wikipedia begin with a sentence containing 'is a'. Based on the dependency graph, we extract the hypernym [13], if the sentence does not start with 'A'. This allows us to ignore subset relationships as in 'A programming language is a formal language[...]'. To reach higher coverage, we infer instantiation from relationships such as part-of as in 'Perl 6 (also known as Raku[5]) is a member of the Perl family of programming languages', where 'languages' is the extracted hypernym. In the seed, we found 'language' (235), 'format' (16) and 'dialect' (10) as the most frequent hypernyms. The hypernym 'language' and 'dialect' are also recovered when analyzing articles on natural languages.

Wikipedia List Entries. As an internal resource, we consider Wikipedia lists of things [14]. Such lists collect names of entities of a certain kind and optionally provide additional information, e.g., 'List of dog breeds'. First, we recover the list of lists by searching for 'list of' in the title of articles in the scope. Binary Features state in which lists an article is linked. In the seed, we found 267 articles linked in such lists, such as the 'List of programming languages'.

3 EVALUATION

We investigate the results from evaluating a classifier based on labels by experts (RQ1). Since we chose to use a decision tree classifier, we can present technical insights on how decisions are made and explain the effects of using a representative seed (RQ2). We conclude with presenting how many software language articles and categories are estimated in the scope (RQ3).

3.1 Precision & Recall (RQ1)

We provide qualitative insights on **How well does the classifier perform beyond the seed?**

To gain an evaluation set that is as objective as possible, we conducted a survey in which 31 domain experts from our research groups and external collaborators participated. In each question in the survey, participants decided whether a presented article explicitly describes a software language as one primary topic. We received 990 articles labelled by at least two experts. In order to gain additional insights on problems with decision making, we emphasized the possibility of commenting on each question. For 43 articles, experts did not agree. The articles present border cases, for which experts are not sure. For example, articles do not directly refer to logic formulae as a software language, but such formulae are often digitally encoded, follow a syntax, well-formedness rules (thus, a type system) and have semantics and pragmatics. For the future of SLEBOK [8], such border cases can be used to further investigate on the borders of the term software language. A refinement of definitions would then again lead to better expert labels to, for now, problematic articles. Such refinement hopefully leads to a better categorization on Wikipedia itself.

As long as experts cannot reliably decide for an article whether a software language is described, a machine cannot as well. As a consequence, we exclude these articles. Since only ~4% is excluded, the threat to validity is reasonably low. We took the remaining expert labels as the evaluation set and explored several configurations with a k-best feature selection and synthetic oversampling with SMOTE [15].

With $k = 23$, the learned classifier performs with an *f1-score* of 0.7, *balanced accuracy* of 0.9, *recall* of 0.81 and *specificity* of 0.99.

3.2 Indicator Discovery (RQ2)

For imbalanced datasets, a classifier usually overfits towards the major class unless countermeasures are taken [15]. This problem is countered in two ways. i.) By adding the seed as an addition to the random sample to our training set, the rate of relevant articles in it is not representative which can be seen as a form of manual oversampling. ii.) Actually, we isolate articles relevant to a single class from articles relevant to many other classes (e.g., songs, stars, software). Feature selection based on *Gini index* or *entropy* pick features according to their score in discriminating classes, in our case relevant versus not relevant. Consequently, the features frequently appearing in seed articles are preferred, since the irrelevant articles have a huge amount of different features and thus single features recall a lesser percentage. At last, synthetic oversampling with SMOTE further improves results. This peculiarity mo-

Table 2. How many articles and categories exist in *total*, identified by the *seed*, and classified as *relevant*.

	Articles			Categories		
	<i>Total</i>	<i>Seed</i>	<i>Relevant</i>	<i>Total</i>	<i>Seed</i>	<i>Relevant</i>
Formal Languages	101641	301	2897	21822	353	1339
Computer File Formats	6116	46	745	235	18	79

tivates further inspection of the learned decision tree as an answer to **what features indicate articles on software languages**.

The templates ‘programming language’ and ‘file format’ provide a strong positive indication, but they do not exist for every relevant article. While the hypernym ‘language’ also provides strong indication, it cannot be used alone. Otherwise, natural language related articles are confused to be relevant. Lemmas, lists and URL pattern help in discriminating relevant articles from articles with overlapping features. Below, we list the most important indicators in the decision tree categorized by their source (see Section 2.3).

Infobox Templates: file format, programming language; **URL Pattern:** programming, language; **Lemmas:** syntax, code, programming, compiler, design, general-purpose, language, support, compile, object-oriented, use; **Dependency Pattern:** language; **Wikipedia List Entries:** List of programming languages, List of programming languages by type, List of file formats, List of C-family programming languages, List of object-oriented programming languages.

3.3 Article and Category Relevance (RQ3)

We give quantitative insights as an answer to the question: **How many articles and categories remain relevant for the domain of software languages?** Table 2 summarizes the degree of the reduction per root category based on the configuration from Section 3.1. **Based on the predicted reduction, we find 2797 more articles in the scope than there are already in the seed.** That is, we significantly augment the identification of software languages.

For the root category ‘Computer file formats’, the classifier predicts a lot of irrelevant articles. When inspecting infobox templates used in these articles, we observe a topic mix with, for example, software, websites and companies. Here, a threat remains that the articles do not directly address formats in several articles in a recognizable way. In comparison to ‘Formal languages’, a higher percentage of categories is estimated as relevant. Accordingly, we observe that the subcategory tree is more consistently maintained.

Inspecting single categories backs up subjective hypotheses based on manual inspection of the usefulness of specific categories. For example, out of 22546 articles that are (transitive) members ‘Statistical data types’, only 52 are classified as relevant. The number of articles indicated to be

relevant in a category becomes a more objective estimation for its usefulness.

Table 2 provides a summary when inspecting all categories based on the assumption that the number of relevant articles hints at the relevance of categories. Out of 21822 categories below ‘Formal languages’, 353 categories contain seed members and 1339 categories remain relevant. **Only 6% of transitive subcategories under ‘Formal languages’ are estimated to be useful within the scope.**

4 RELATED WORK

Previous attempt: In [16], the category graph is pruned by manually excluding categories not serving for classification of software languages in a common sense, subject to a small suite of criteria. In contrast to our work, the approach relies on manual selection of categories instead of automatically classifying articles by combining several indicators.

Domain ontology: Wikipedia is a frequent target for knowledge discovery. *To the best of our knowledge, no approach tries to detect articles describing a class from an inconsistently maintained domain, where relevant articles are rare and require to combine multiple indicators.* For deriving domain ontologies, various distinct approaches can be found. The approaches range from supporting manual crafting [17, 18] to unsupervised crafting from text [12]. Wang et al [5] extract a domain ontology for animals from Wikipedia based on the category graph, article graph and section structure in articles. For the animals domain, most pages are maintained well and describe exactly one concept in a consistent order. Mirylenka et al [10] extract subset, membership, part-of, sub-topic and other relationships by analyzing the varying nature of subcategorization. Dong et al [6] learn subsumptions from articles describing domain concepts based on Hearst pattern. In a related approach [7], the concept set is learned by matching articles with Stackoverflow tags. Based on the article- and category graph, the concept set is expanded and further relationships are learned. Related works discover knowledge from different structural features, such as the title [10, 19], text [13, 20], an article’s section structure [5], links to other articles [7, 20], infoboxes [3], lists [14], etc.

External knowledge: The usefulness of WordNet varies depending on the coverage of terms in a domain. While WordNet is a known assistant in more common knowl-

edge domains, low coverage is reported in more specific domains [2, 5]. Our experience confirms it for software languages. Various knowledge graphs exist. *DBpedia Live* [21] mirrors Wikipedia while refining it with more ontological knowledge. YAGO [4] is a knowledge graph derived from Wikipedia, WordNet and Geonames that explicitly focuses only on structured knowledge aspect that is then again linked by Dbpedia as well. Wikidata [18] is widely manually crafted and tries to reach a clean knowledge graph from scratch. A type encompassing the term software language is not maintained by any of the mentioned resources.

5 CONCLUSION

In a domain where only a small set of positively labeled articles can be used as a ground truth, we did find strong indicators for classifying 3000+ articles as relevant for software languages. We showed that a learned decision tree classifier provides reasonably high recall and low false-positive-rate and allows one to inspect isolated articles inside Wikipedia. While learned random forests might provide higher accuracy, we are specifically interested in higher interpretability of decision trees. 31 domain experts thoroughly evaluated our classifier by labelling over 990 Wikipedia articles.

A natural follow up of this work is a collaborative engagement with experts to further extract and improve fine-grained classification knowledge into a high-quality domain ontology that will help students and professional developers to better understand software languages. We are in the process of repeating the experiments for the domain of software (in a broad sense). The general problem is the same: We are confident that our learning methodology can identify the body of domain knowledge within Wikipedia. There are also specific challenges ahead due to particularities of the domains (for example, 'Computing platforms' as a category is disconnected from 'Software').

Model View Controller in iOS mobile applications development

Dragoş Dobrean and Laura Dioşan

Faculty of Mathematics and Computer Science, Babes Bolyai University

Cluj Napoca, Romania

{dobrean,lauras}@cs.ubbcluj.ro

Abstract—Due to the increased number of mobile applications and their popularity, many software developers have begun to focus on mobile platforms. While this focus has positive effects (e.g. a larger developer community, new open source projects, new tools), it also has a down side. With the migration of developers from different software development areas, where they have used other programming paradigms or architectural approaches, the topic of software architecture on mobile platforms become more trending and hype in the mobile development communities. Even though several new architectural solution were proposed for solving some of the issues which arise from using the classical architectural patterns popularised by the creators of the mobile platforms, we want to emphasise the principles of software architecture in mobile computing, why they have to be respected and how their adoption impacts the development process. Therefore, this paper focuses on showing that the Model View Controller (MVC) — one of the most common classical architectural patterns — can be used successfully for building mobile applications and the problems which might arise are by products of the wrong usage of the pattern rather than pattern issues. We show that by analysing the most common architectural misuses of the MVC pattern in both open-source and private projects and offers solutions to those problems.

Index Terms—Apple's Model View Controller (MVC), Mobile Software Architecture, Architectural Smell, iOS.

I. INTRODUCTION

Mobile applications have become an important part in the life of the modern man. The involved devices have become indispensable companions in our lives. We use them for social interactions as well as for business activities, for increasing our productivity or for self improving and entertainment. According to GSMA Intelligence two thirds of the world are connected by mobile devices [1]. In order to be able to sustain this high rate of adoption and popularity of the mobile applications, many developers migrated from building other types of software to building mobile applications.

This blend of domains has brought many new trends to the mobile platforms (for instance, functional programming which has become used in large mobile projects [2], [3]). However, this union of domains has also had downsides: new or inexperienced developers of those who have migrated from other platforms did not understand fully how all the mobile development concepts work, how are they supposed to be used, and there were not many places in which they could learn how

to properly use those. Mobile software architecture has become greatly affected by this phenomena [4]–[6].

It is an established fact that a good software architecture and design could increase the system quality: performance, evolvability, maintainability and reliability [7]. When weak design decisions affect the software properties, the architecture is often subject to various problems (code smells, design smells or architectural smells). Related work regarding software architectural smells can be found in [8] where the authors showcase 11 architectural smells grouped in 4 different categories (Interface-Based Smells, Change-Based Smells, Concern-Based Smells and Dependency-Based Smells). All of issues can also apply to mobile platforms software applications. In [9] and [10] 4 of the architectural smells are analysed in depth and shown on 2 industrial software systems. Other work has been done in [11] where the authors have analysed the architectural erosion of Open-Source Software projects.

Although the drawbacks of architectural erosion have been already recognized [9], [10], [12], [13], the authors of these studies have focused on classical systems, rather than mobile ones: Velasco et al. [14] presented several architectural smells that are relevant to MVC, while Aniche et al. [15] identified six classes in the context of web applications constructed on MVC pattern.

Our initial effort drives to identify the possible MVC problems in the context of mobile applications, to characterise them and to describe how they can be fixed. In this paper, we aim to answer the following research questions:

- RQ1: What are the problems of MVC in the context of mobile applications?
- RQ2: Is there a classification for the MVC architectural problems?
- RQ3: How can the problems be fixed?

To the best of our knowledge, an MVC analysis in the iOS context was not been performed until now. Previous works [14], [15] are focused on web or classic flavours of MVC and on the problems caused only by the violation of constraints which MVC style defines between its components or layers. In the mobile context, the weaknesses of Android's design have been analysed and a passive flavour of MVC was proposed in [16].

The rest of the paper will focus on the iOS platform on its architectural pattern encouraged by Apple, Model View Controller (MVC) [17]. Architectural issues explained in this

Fig. 1. Apple's Model-View-Controller architectural overview

paper also apply to other platforms which use MVC for building applications (macOS, Windows, etc.), while the naming conventions might be different the concepts and issues are the same. MVC was chosen as is one of the most know presentation architectural pattern while being present on all the mobile applications platforms in various flavours. In addition, MVC is highly versatile, having different flavours as Model-View-View-Model (MVVM) [18], Model View Presenter (MVP) [19], etc.

The following section talks about MVC and Apple's flavour of it. Section

II. APPLE'S MVC

Model View Controller is one of the most widespread presentational architectural patterns, being used to create desktop, mobile and web applications [20]–[22]. The purpose of MVC is to provide a simple separation of concerns for an application that embeds a user interaction component. One of the most important aspects of this pattern is that the application should work, and fulfil all its requirements even if we remove the View and Controller layers. The data manipulation and the business logic should reside the Model and it should not be affected in any way by those other layers.

Apple's version of MVC [17] is different from the conceptual, generic one [23]. The classic MVC [23] was coined when there did not exist the concept of mobile applications; in order to compensate for this fact, Apple promoted a flavour of MVC, which is better suited for mobile and desktop applications.

It is composed from the same three layers (Model, View, Controllers) and the only thing changed is their way of interaction and the data flow. The layers are more decoupled and it does not rely so heavily on the Observer/Delegate pattern; it is still being used, but it is not as used as intensively as on the classical pattern. In Apple's flavour, the Observer/Delegate pattern is more aimed to provide callbacks from one layer to another than to observe Model layer properties.

The accent in the Apple's flavour of MVC is on the Controller, as can be seen in Fig.

This emphasis shift can also be seen in the way they have named their framework components. At the centre of every iOS application, we find the View Controllers which act as bridges between the data of the application (Model) and the user interfaces (View).

In Fig.

Advantages This flavour of MVC simplifies (from the classic MVC) the data flow between the layers, making the data flow clearer. In addition, it also reduces the coupling

between the layers; the link between the Model and The View (from the classic MVC) no longer exists, making the components more isolated.

Disadvantages The Controller layer becomes the central piece of the architecture; it needs to ensure the proper communication between the Model and the View layer and vice-versa. This task makes the Controller layer to grow to be quite complex, which can lead to architectural issues (massive view controllers) as well as OOP issues (violation of single responsibility principle).

III. ANALYSIS

As instances of poor design decision, the architectural smells originate in the improper use of a design solution or of software architecture-level abstractions. In what follows we attempt to facilitate the identification of such problems in the context of mobile applications involving the MVC pattern. We provide a short description of each problem and its causes (trying to answer RQ1), the architectural smell's class it belongs to (as answer to RQ2) and one or more possible solutions (answer to RQ3).

In order to be able to answer those questions we needed to inspect different sized codebases, we have chosen 5 codebases, with different variations of MVC that added architectural layers from: MVVM [18], MVP [19] VIPER [24].

- Wikipedia – education and information app [25]
- Firefox – a mobile web-browser [26]
- Trust – cryptocurrency wallet [27]
- E-Commerce — private
- Game – private

TABLE I
CODEBASES SIZE

Application	Blank	Comment	Code	Source
Firefox	23392	18648	100111	open-source
Wikipedia	6933	1473	35640	open-source
Trust	4772	3809	23919	open-source
E-Commerce	7861	3169	20525	private
Game	839	331	2113	private

As can be seen in Table

A. Complexity

1) *Issues:* Mobile applications have grown to be complex software systems where they do much more than just fetching some data from a web service and displaying them on the screen. While for a simple application the MVC pattern would be sufficient, if we add extra complexity, such as working with databases, caching, virtual reality, audio, photo or video manipulation, we might ran into some issues.

Although using another presentational pattern (e.g. MVVM [18] or MVP [19]) might solve some of the problems, if the application becomes more complex, even these patterns will not be sufficient to maintain it flexible to change, testable and easy to be understood and worked on.

2) *Solutions:* MVC is an architecture to be used on small-medium sized applications. If we talk about a complex application then an architectural approach needs to be designed in order to fulfil its use-case. MVC provides the basis for this new architecture and its three degree of separation should definitely be implemented. But, in addition and in order to make the codebase maintainable, we might introduce additional layers, such as Presenters from MVP, View - Models from MVVM or Routing objects from VIPER [19], [24], [28], [29].

3) *Findings:* Trust, E-Commerce and the Game had the clearest defined architecture. Analysing the codebase is easy to get a grasp on how the app works and the codebases were consistent in both naming and design pattern used. Firefox, being the largest codebase and given its functionality, is a more complex one and it is the hardest from the codebases to understand and uses multiple layers. Wikipedia relies on multiple open source libraries and internal UI libraries which introduce extra obfuscation and makes the codebase harder to comprehend.

B. Misunderstandings

1) *Issues:* Another common problem we encounter when talking about MVC is that people usually have different concepts of what MVC is and how should it be used. People coming from ASP.net MVC [30] development might have a total different idea of how the MVC components should communicate from those who are developing mobile applications. As we have already seen, different companies have different definitions for what MVC is and how it should be used with their frameworks. This problem has a real impact when developers migrate from one platform to another and try to use the same MVC definitions on a new framework.

Almost all people with some knowledge about the MVC agree that the Model should contain data useful for application [31], the View is responsible with presenting the data to the user and the Controller layer acts as a mediator of some sort between the other two layers. Those are very vague definitions of MVC and 2 people can disagree on what should be put in the Model and what should reside in the View or Controller layer.

Developers of MVC frameworks usually give their definition of what MVC meant for them or how should this be used; however, those definitions usually are vague as well. The reason of this ambiguity can be rooted in the generality of the frameworks, which should adapt to many types of applications. A constrained architecture, which would fulfil all potential use-cases is not feasible and it is considered redundant for applications that do not need a high level of architectural complexity.

2) *Solutions:* The first step into ensuring that an architectural pattern is correctly implemented is to have clear definitions of its elements and everyone involved in the project to be well aware of. In order for this to happen, it is important that the lead developer or the system architect to understand clearly the scope of the product and to be able to draw architectural guidelines which would fit the project.

3) *Findings:* From the analysed projects, Trust, Firefox and the E-Commerce app were the ones in which there was a clear defined architecture which could be inferred from the codebase and it was consistently used. The Game app was the smallest and its architecture didn't require any specific guidelines given its complexity. In the case of Wikipedia, the code was not consistent, and the guidelines were not clear.

C. Model

1) *Issues:* Most of the problems which appear in this layer are design pattern issues; the usage of too many singleton objects and the violation of SOLID principles [32] are the root cause of the problems which can appear at this level. The result will be a damaged architecture at a micro level — high coupling between items in the same layer.

Among the common mistakes in the model are the fact that objects which interact with a database or a web backend service have reference to the ones using those (usually View Controllers). These references can create retain cycles — Dependency-Based Smells [8] — and also impact the MVC architecture by making the Model layer have knowledge about the Controller layer.

The problems which appear at this level are usually from the Interface-Based Smells category as defined in [8], [11]. Is not uncommon to find Ambiguous Interfaces or Concern Overload where a component performs a large amount of tasks and have a scarce number of interfaces. For instance, the objects which communicate with the backend for fetching data are most of the time responsible for creating the connection, converting the input parameters to what types of information does the backend service expect, parsing of the response it receives and mapping it to a codebase defined entity.

2) *Solutions:* This issue can be solved using the Observer/Delegate pattern, where the Model layer provides callbacks for its events and the Controller layer takes various actions based on those events.

3) *Findings:* All the analysed codebases presented issue on the Model layer as each one of them has wrong, direct dependencies between the Model layer and the View or Controller layer. The most problematic ones were the E-commerce and Firefox. In all the codebases excepting the Game, we find the Concern Overload and the Ambiguous Interfaces smells [8], [11].

D. View

1) *Issues:* In large projects, which do not have major architectural issues, the Controller objects configure the Views by directly passing the Model item as an argument. This common practice creates a dependency between the View and the Model, which is not presented in the Apple's way of defining the MVC (Fig.

An example would be a list of new movies in a booking application: the cell that is responsible for displaying a new movie will usually receive from the Model, a Movie entity, which contains much more data then what is needed to be displayed (the ID from the database, a list of actors, number

of people who already booked it, etc.). This is an overlooked issue with MVC and usually the developers accept it, even if this is an architectural mistake nevertheless.

The mentioned problem belongs to Co-change Coupling smells [11], an architectural issue which occurs frequently at this level. The coupling is predominantly done between the View and the Model layer. However, this can also appear in the View and Controller layer.

2) *Solutions*: In order to overcome this difficulty, new objects can be defined for keeping the configuration of the view (when the view needs a lot of configuration information from the model), or this information can be passed as parameters to the view using primitive types.

The new defined items for the configuration of the View rise another problem: where should those items reside? They know nothing about the View so is not in the View layer; however, they are only used and have meaning in a context in which those Views exist. An approach to solve this problem would be to treat these items as belonging to the Model as they handle the business logic display part, they can be seen as mappers between entities and views or data transfer objects.

Another approach, if the developed application needs this kind of complexity, is to use another architectural pattern namely MVP [31], which inherits from MVC; basically, it is a variation of MVC, where there is a new layer for configuration objects, called Presenter. The Presenter, however, is a more specialised object: besides configuration information, it also contains information regarding the state of the View (selected, unselected, highlighted, whether or not some of the fields should be pre-filled etc.).

3) *Findings*: All the analysed codebases have shown Co-change Coupling smells, the most severe ones was the E-commerce one. The open-source apps also exhibited this issue, however at a much lower degree.

E. Coordinating Controllers

1) *Issues*: Just like in the case of Apple's MVC, there are different flavours of MVC where there is a combination of roles (View and Controller) into a single entity called View Controller. This entity owns the View and it responds to its events. The View Controller is responsible for responding to input received from the View and for displaying and moving those Views on the screen. Those kind of controlling objects usually derive from a superclass. For instance, on the iOS SDK, the superclass is `UIViewController`, on Android we have the `Activity` superclass.

There are cases where the complexity of the application requires another kind of controller objects — Coordinating Controllers. Coordinating type of controllers are simple objects that manage the application; they usually decide when a certain action should happen and keep track of the state of the application [33]. Those kinds of objects are responsible for deciding on what state (flow) of the application to go next (when a certain event occurred) based on the current state, for setting up the initial state and managing the lifecycle of contained objects.

By flow and state we mean what use case scenario is presented on the screen at a certain moment in time; flow is a broad term and in the context of this paper we are using it to describe a use case (e.g. sign up), if we were to have a higher granularity, the flow can be split in multiple sub-flows (e.g. the forgot password of the sign up flow).

Therefore, the Controller layer can be split into two categories: View Controllers and Coordinating Controllers. The View Controller objects have come to be generally accepted as the Controller objects by most of the practitioners in this field. However, this is not always the case and there is an important distinction between Coordinating Controller objects and View Controllers [17].

Unfortunately, this degree of separation in the context of Controller layer is not so well understood on the iOS platform. All these concepts appear in AppKit development scene (desktop application for macOS), as this platform is older and more evolved. Usually this form of separation within the Controller layer is not needed, as the applications are not complex enough to justify it. The problems start arising when the application becomes complex and the people working have a lack of architectural knowledge on how to scale it or the architectural state in which they need to arrive is unknown or insufficiently defined.

Frequently, the responsibilities of Coordinating Controllers get stuffed in the View Controller objects increasing their complexity and changing their purpose as now, they also have to take care of knowing the state of the application and correctly transitioning between the states in every possible configuration. By taking this responsibility in other custom objects (Coordinating Controllers), the View Controller object become slimmer and they are no longer depending on each-other.

This practice is fairly popular or familiar and is usually implemented in applications where a clear architectural guideline is not defined or not sufficiently described and defined for all the potential corner cases. A lighter common version of this coordination is to have an object which all the View Controllers inherit from, where all the common navigation flows are stacked in.

This sort of behaviour (merging responsibilities) is common for small applications where the UI is quite simple (one-three screens), where the extra Coordinating Controller objects would not provide real value, or for beginner developers. Most of the applications which are fairly complex have multiple flows (sign up, sing in, browse items, add to cart, checkout, previous orders, feedback, settings, profile, etc.). These applications are the ones which suffer massively from the lack of coordinating layer as their View Controller objects become bloated with navigation and configuration logic. This kind of complexity creates architectural issues especially when the application needs to be changed because many components fulfil the same functionality, for instance the correct navigation from one screen to another (Scattered parasitic functionality [8]).

Fig. 2. Firefox iOS application screenshot [26]

2) *Solution*: The solution to this problem (complex application with multiple use-cases and flows) is to have multiple Coordinating Controller objects for every flow of the application or for every sub-flow of the application; each of these flows will have a single, well defined use case (login in the user, uploading a picture, making a payment, etc.). All the application's flows and navigation will be then expressed via those building blocks (Coordinating Controller objects for certain flows or sub-flows). By using this approach, we reduce the complexity of View Controller objects. They become concerned only with displaying the data and mediating between View and Model layers. All the navigation and configuration logic now resides in the Coordinating Controller objects. In addition, we can easily change the flows of the application even at runtime, we can Unit Test the navigation from one screen to another and the correct configuration of the View Controller objects, which, in the case of massive view controllers, is rather hard.

3) *Findings*: Firefox, Trust and the E-commerce apps were the ones in which the Coordinating Controllers were correctly used. Wikipedia was the worst analysed app from the Coordinating controllers point of view, the Scattered parasitic functionality [8] is predominantly present in the codebase.

F. View Controllers

1) *Issues*: Another issue which is overlooked is that developers usually use one view controller per screen (the UI elements shown on the full size of the screen). While this is the right approach for simple screens such as a "Terms and conditions" screens or even a "Login" screen, if we talk about complex UI interfaces (e.g. the browse screen from Firefox) this is totally wrong.

The browse screen from the Firefox application (see Fig.

A large amount of the problems which we encounter in the MVC approach on iOS deals with the View Controller.

In fact, it has access to both View and Model layers and acts like a binder between them; an example would be if the data obtained from the Model is not well formatted, the View Controller will format it for the View and this is not clearly its responsibility. A View Controller should only be concerned with presentational aspects of a certain part of the application and for handling the user input received from the View. Obviously problems can appear at other levels, as well on Coordinating Controllers or Model level, but these usually, like in the case of View Controllers, have the root cause the low granularity of the architectural components and can be solved by increasing the granularity of the elements (splitting a certain item in multiple others and use the Composition design pattern).

In addition, the View Controller objects are also bloated with handling View logic and states. By view logic and state we mean keeping the internal state of the view which cannot be inherited from the Model. For instance, knowing which items were selected on the screen, what slider is enabled etc., before applying these changes to the Model. This sort of logic should be implemented in custom objects; most of the times the MVP pattern is used for solving this issue, but as a workaround in MVC, these can reside in subclasses of View components or in custom objects defined in the Model layer.

At this level, the major architectural smell is Concern Overloading [11], as like previously shown, the View Controller object become bloated with an excessive amount of responsibilities.

2) *Solutions*: The solution to this problem is to use multiple view controllers for the UI elements; for instance, we could have a View Controller object responsible for the turn by turn navigation advices, we could have another one for the map and so on. Furthermore, if these elements are complex by their own, they could be split further in more View Controller objects which should respect the single responsibility principle. By using this approach we would obtain view controllers that respect the single principle responsibility ensures a good separation of concerns, they contain less code, and they become testable.

As in the case of Coordinating Controllers where we could have Coordinating Controller objects, which depend on other Coordinating Controller objects we can apply the same logic to creating user interfaces and using multiple child View Controller objects to construct a single screen of the application. By using this approach, each View Controller object will have single responsibility and purpose.

3) *Findings*: All the codebases shown signs of Concern Overloading [11], the issues are however bigger as the codebase increased. In the case of the apps which were using Coordinating Controllers (E-Commerce, Trust, Firefox) the issues were lower than in the case of Wikipedia where the View Controller classes were way more complex as they also had to handle navigation logic.

IV. CONCLUSIONS

By our study we have tried to provide interesting insights about several common problems of MVC for both mobile developers and scientific community which are commonly found in open-source or private projects. We describe these problems in detail as well as their corresponding architectural smells. Furthermore, several solutions to those problems have been proposed which shed some light on architectural corner cases which were less explored by practitioners.

As we have shown previously in this paper, MVC can be used as the presentational software architecture for a mobile application. If the concepts are implemented correctly this does not produce any of the popular issues, neither massive view controllers nor the violation of the single responsibility principle.

What is important to be understood is that based on the complexity of the application the entities in the MVC architecture should be more granular, in order to be flexible, testable and maintainable. Based on this complexity, new types of layers or sublayers can appear which are close related to the requirements of the application.

Based on the observations made throughout many years of developing commercially those kinds of applications, the presentational architectural concept used was never an issue for the flexibility, extensibility and testability of the application; the issue always came from its bad implementation, or the misuse of programming language features.

Our further work will continue on developing tools for ensuring that a certain architectural pattern or certain architectural rules are respected with every commit made by a developer. By following this direction we can educate developers regarding the architectural aspects of a mobile software application, we will help them produce cheaper and cleaner code.

Abstract

The improper use of GPS and location-related APIs may result in abnormal battery drain in Android applications. Over the last few years, the developers' discussions on improving energy efficiency have been increased. In this paper, we mine StackOverflow to analyze and summarize the characteristics of developers' discussions of managing energy and accuracy-related requirements of location-based Android applications. We extracted 11,911 questions from StackOverflow and filtered 320 relevant questions to answer four research questions. We conducted a manual thematic analysis on relevant questions. Our study shows that the developers are concerned about energy consumption, but are unclear about their preferences as energy and accuracy evolved as conflicting requirements.

1 Introduction

In Location Based Applications (LBAs), the improper use of location-related APIs may result in abnormal battery drain [1]. There has been an increasing amount of research efforts [2, 3] made by researchers to reduce the energy consumption of location sensing in Android smartphones. These studies have less information on the programming knowledge required to manage the energy and accuracy-related issues of LBAs. In recent years, mining StackOverflow [4, 5] to summarize the knowledge on energy consumption of Android applications proved to be a successful technique. However, these studies are not specifically focusing on location-based Android applications. Hence, in this paper, we aim to summarize the characteristics of developers' discussion of managing energy and accuracy-related requirements of location-based Android applications. More specifically, this paper aims to explore and answer the following questions:

- **RQ1:** Do developers ask questions to improve energy and accuracy requirements?
- **RQ2:** Which developer goal yield more successful answers?
- **RQ3:** Which developer goal is popular among the developer community?
- **RQ4:** How have the developers' goals changed over time?

We followed the methodology suggested by Braun et al. [6] to conduct a thematic analysis of the selected questions. We extracted 11,911 questions from StackOverflow and through semi-automated filtering and manual validation process, we identified 320 relevant questions for further analysis. We identify 3 main categorizations, namely: Status of question (*successful, unsuccessful, ordinary*), Goals of developers (*energy saving, improving accuracy, balancing both*) and Type of question (*implicit, explicit, fundamental*). The important finding of this study is that the developers are facing problem in balancing energy and accuracy-related requirements. In addition to this, the study found that several developers are unclear about their preference for selecting energy saving or improving accuracy as their primary goal.

The rest of the paper is structured as follows: Section 2 presents related works, Section 3 describes the empirical study methodology, Section 4 presents the answers to the research questions, Section 5 briefs the validity threats and Section 6 concludes the paper with possible future works.

2 Related Works

In recent years, there has been an increasing amount of empirical studies on the energy consumption of Android applications [7, 8, 4, 5]. The first empirical study on categorizing the energy-related issues of smartphones was published by Pathak et al. [8] by mining four online forums and presented a comprehensive study of energy-related issues in smartphones. Pinto et al. [4] mined StackOverflow for software energy consumption-related questions and answers and identified seven causes for energy consumption problems. Malik et al. [5] explored the quantitative and qualitative aspects of energy-related questions specific to the Android platform on StackOverflow. The authors have summarized energy-related issues into four main categories and explore the APIs that are significantly discussed in the energy-related posts. Though there have been several studies on energy consumption in Android applications, none of the studies have explicitly focused on location-based Android applications. In this paper, we aim at summarizing the developers' discussion on energy and accuracy-related issues of location-based Android applications.

3 Study Methodology

We collected the energy and accuracy-related questions of location-based Android applications using suitable SQL Queries on StackExchange Data Explorer¹. We used the keywords *android*, *location*, *gps* on the *tag* field of StackOverflow questions. The SQL query returned a total of 11,911 questions in the form of *.csv* file. This file was our raw data set which was used for the further filtering process. The dataset contains information about *Title*, *Body*, *Accepted Answer*, *Score*, *Views Count*, *Favorites Count*, *Created Date* and other relevant information. The second step is a semi-automated method to filter the questions that are specific to energy and accuracy-related issues of location-based Android applications. During this filtering process, we used keyword matching on the *Body* field of the questions and obtained 651 relevant questions². We further categorized the questions under three different categories: *successful*, *ordinary* and *unsuccessful*. The questions with negative and zero scores were removed from successful and ordinary categories as they were insignificant to our study. This reduced the dataset to 399 relevant questions. We manually read the title and body fields of the questions to verify its relevance to energy and accuracy-related requirements during which 79 false positives were found and removed resulting in 320 questions being considered for thematic analysis. We followed the guidelines given by Braun et al. [6], to conduct the thematic analysis. We defined three major themes based on the codes that we created during our reading. The first category of theme is about the type of questions asked (*Implicit*, *Explicit* and *Fundamental*), the second category of theme is based on the developers' goal (*Energy Saving*, *Improving Accuracy* and *Balancing Both*), and the third category of theme is based on the status of the question (*Successful*, *Ordinary*, *Unsuccessful*). Each question's title and body field was read and marked by the first author and verified by the second and third author. During the discussion sessions, we resolved the conflicts in the coding process. Due to space restriction, more details on the data analysis have been discussed in Section 4.

4 Answers and Discussions

In this section, we describe the analysis method and answers to the mentioned research questions.

4.1 RQ1: Do developers ask questions to improve energy and accuracy requirements?

The purpose of this research question is to know how clear the developers are with energy and accuracy-related requirements. We conducted a manual thematic analysis on the title and body field of the relevant questions. We identified the following themes:

- **Explicit:** We categorized the questions under this category, if the developers can clearly specify their requirements in terms of energy, or accuracy, or balancing both. Ex: "*Battery dies quickly when GPS or Wi-Fi is used. How can I save battery life? Is it right to request location updates every 5 seconds in the code?*" (PostID: 28407944).
- **Implicit:** We categorized questions under this category if the developers are unsure about the solutions and mentioned only the issue they are facing rather than their specific requirements or goals. Ex: "*How to keep an application running in the background? Keep collecting data?*" (PostID: 6291729)
- **Fundamental:** We categorize the questions under this category if the developer wants to gain knowledge about the topic. Ex: "*Does anyone know whether the Android addProximityAlert on the LocationManager is battery intensive?*" (PostID: 1113606).

As a result of quantitative analysis, we found 35% questions under *Explicit* category, 16% questions under *Implicit* category, and 49% questions under *fundamental* category. From the results, we can infer that the developers do ask questions to improve energy and accuracy requirements. To be more specific, 51% of the developers that ask questions about location-based Android applications strive to improve energy and accuracy requirements. Among this 51% of questions, 35% are explicit about their requirements, whereas, the rest 16% are implicit or indirect. We also infer that 49% of the developers asking fundamental questions are unaware of the best practices related to energy consumption and increasing accuracy.

4.2 RQ2: Which developer goal yield more successful answers?

The purpose of this question is to summarize which developers goals get more preference and consequently get more accepted answers. The fundamental questions (157) which were identified from the previous thematic analysis were removed as they were not contributing to either improving energy-efficiency or accuracy. The remaining 163 questions related to developers goals category were considered for thematic analysis. We identified the following themes: *Energy saving*, *Improving accuracy* and *Balancing both*. Table 1, describes the identified themes and few examples from StackOverflow. Further, we classified these 163 questions based on their status. Under the status category, we found the following themes: *successful*, *ordinary* and *unsuccessful*. The questions are classified under *successful* category if there is an *accepted* answer. The ordinary questions are categorized so if they have been answered, but none of the answers were *accepted* by the developer who posted the question. The questions with no

²<https://bit.ly/2E1kbID>

Table 1: Identified themes under developers' goals category and examples

Goal	Description	Percentage	Example
Energy Saving	Questions were categorized under this category, if they are about reducing the battery usage by ignoring accuracy	58.89%	"How to receive driving start and stop activity with Android in an energy efficient manner which works even offline?" (PostID:45739938).
Improving Accuracy	Questions were categorized under this category, if they are about increasing the accuracy by ignoring battery draining behaviour	28.83%	"How to get location updates while device is powered?" (PostID:45204188).
Balancing Both	Questions were categorized under this category, if they are about balancing energy and accuracy related requirements	12.26%	"Android best way to get location repeatedly in background considering battery as well?" (PostID:27313684).

Figure 1: Developer goal versus Status of questions

answers are categorized as *unsuccessful*. The categorized questions were grouped based on the status of the question and the developer's goal.

The result of thematic analysis is represented in Figure 1 where we observe that *energy saving* related questions yield the most successful answers, closely followed by questions related to *balancing both*. This shows that the developers are more interested in either energy saving or balancing both conflicting requirements (energy and accuracy). On the other hand, *improving accuracy* alone has not been given much preference as it yields 47% *unsuccessful* questions. This shows that improving accuracy by ignoring energy issues may not be feasible or not a best practice while developing location based Android applications. Therefore, to build a successful application we believe that balancing between both the conflicting requirements is the essential factor.

4.3 RQ3: Which developer goal is more popular among the developer community?

We followed the method suggested by Pinto et al. [4] to calculate the popularity of the questions. The formula for calculating the popularity of the questions is as follows:

$$P = S + A + C + F + V \quad (1)$$

Where, P is the calculated popularity of the question, S is the score of the question, A is the number of answers, C is the number of comments, F is the number of favoritizations, and V is the number of views. Here, we slightly deviated from the guidelines suggested by Pinto et al. [4] with respect to selecting StackOverflow views. Here, instead of selecting overall StackOverflow views, we used the average views of all questions related to location based android applications. Hence, the views of a question can be calculated

Table 2: Popularity of questions under each category

Developer Goal	Median (V)	Median (P)
Energy Saving	643.5	6.039
Improving Accuracy	373	5.047
Balancing Both	523	6.755

as follows:

$$\frac{\text{Views of question } (Q)}{\text{Avg. views of all LBAs related questions}} \quad (2)$$

As shown in Table 2, it is clear that the theme of *balancing both* energy and accuracy has gained more popularity than the rest. Although the number of questions related to balancing both requirements is the least, this category has scored the most popularity, reflecting the importance of giving equal priority to both types of requirements. Further, *energy saving* is observed as the next most popular requirement. Activities such as continuous background location updates and improper use of location APIs result in more abnormal battery drain, making it a higher concern of the developers to extend users battery life.

4.4 RQ4: How have the developers' goals changed over time?

The purpose of this question is to observe the trend in developers preference towards *energy saving*, or *improving accuracy*, or *balancing both*. The obtained information related to questions were grouped by the year and the occurrences of each goals category were tabulated. The data were quantitatively analyzed and the trend over the years is depicted in Figure 2. As shown in Figure 2, we observe that energy saving has been given a higher priority from the beginning in 2010 with a ratio of 3:0:0 questions in each category (EnergySaving:ImprovingAccuracy:BalancingBoth). But as the years passed the priority of saving energy rela-

Figure 2: Developers goals over time.

tively decreased, changing the ratio to 1:12:1 in 2018. Till 2014, Android-native APIs were used, making it the task of the developers to configure everything by themselves resulting in major energy consumption issues. However, in 2015, the introduction of Google Location APIs had decreased the energy consumption related issues, hence, decreasing the requirement of the developers to find solutions for abnormal energy consumption. In the perspective of accuracy-related questions, developers have never shown much concern until 2016. However, in the years of 2017 and 2018, the interest in accuracy-related questions drastically rose due to the introduction of Doze mode in higher versions of Android. Doze mode, in short, kills the background location updates when a smartphone enters sleep mode. Users on StackOverflow have complained about not being able to decrease the time between consecutive background service updates and receiving the following message, “In an effort to reduce power consumption, Android 8.0 (API level 26) limits how frequently background apps can retrieve the user’s current location. Apps can receive location updates only a few times each hour” (PostID: 47471600). This resulted in lesser accuracy as continuous location updates were not possible. Hence, developers were more interested in solving accuracy-related issues in recent years. As shown in Figure 2, we also observe that the questions related to *energy saving* decrease drastically to 1 in 2018 from a maximum of 19 in 2015 while there was an increase in accuracy-related questions. Hence, energy and accuracy evolve as two conflicting requirements, polarizing the interests of the developers.

5 Threats to Validity

This section presents the internal and external threats to validity.

Internal: As the scope of the study is narrowed down to location-based Android applications, we selected only 320 questions for thematic analysis. However, we believe that these manually selected questions may be a better candidate set for summarizing the characteristics of developers discussions. Second, the presence of false positives in the

dataset. To reduce the number of false-positives, we conducted manual in-depth reading on all filtered questions and carefully removed the false positives.

External: First, our results are only limited to Questions and Answers on StackOverflow. Other online forums, online surveys, and physical interviews have not been used to obtain information. Second, the solutions and results presented cannot be generalized to other software, domains or type of developers. They are only applicable to location-based Android applications.

6 Conclusion and Future Works

In this paper, we present the results of an empirical study summarizing the characteristics of developers’ discussions on StackOverflow about energy and accuracy requirements in location-based Android applications. We identify three main categorizations, namely: Status of the question, Goals of developers and Type of question. We applied quantitative and thematic analysis to answer four research questions based off 320 relevant StackOverflow questions. As a result of this study, we were able to infer that developers on StackOverflow are facing both energy and accuracy-related issues, however, are finding it difficult to balance both as energy and accuracy requirements have evolved as conflicting requirements. As future work, we aim to analyze the answers of relevant questions to provide more qualitative insights on balancing the energy and accuracy requirements of location-based Android applications.

Abstract— In recent years, Android has become one of the most popular mobile operating systems. Software testing of Android applications becomes a very important issue. In the past research, many studies focus on functional testing. Recently, some studies start to discuss the layout anomaly issue. However, these schemes investigate few types of layout anomalies. Moreover, there may exist underlying platform constraints. In this paper, a detection tool LAD (Layout Anomaly Detector) is proposed. LAD considers the anomaly types studied in the previous work with a newly proposed anomaly type for scale maladaptation of components and text. LAD also supports testing scripts. We have conducted empirical experiments with four real apps. The experimental results show that LAD can effectively detect the layout anomalies of these apps.

Keywords—Android; layout anomaly; GUI layout testing; automatic testing

I. INTRODUCTION

As shown in the statistics of AppBrain, the number of Android apps has exceeded 2.59 million on Google Play in March 2019 [1]. In the past, automatic Android software testing has received many attentions, such as [2-5]. However, most of the previous studies focus on functional testing. To our best knowledge, the number of research studies on detecting layout anomalies for Android apps is comparatively few [6-9]. Because Android devices have the severe fragmentation problem, layout anomalies become an important issue for user experience.

The layout anomaly problem occurs in an app if its layout design does not consider the diversity of different screen specifications. This problem can be very annoying for users and app developers. For example, the layout anomalies such as UI component overlap or cropped text may hamper the user operations. As reported in [8], some UI components may even disappear when the app is executed in a smaller screen size.

To tackle layout anomalies, app developers need to take a lot of time to inspect the layouts for many screen specifications. As illustrated in [8, 9], if there are m layouts in an app and n screen specifications, the time complexity of the inspection work is $O(m \times n)$. This workload is harmless if n is very small. However, a survey of OpenSignal shows that over 150 different screen sizes have existed for Android devices in 2014 [10]. If there are 100 different screen specifications to be inspected and the inspection time is 5 minutes per layout, the total inspection time will be 83 hours for an app of 10 layouts.

In recent years, studies have been conducted to deal with the problem of layout anomaly detection. Several tools like Galen Framework [6] and ITArray Automotion Framework [7] are developed to perform visual testing for Android apps. Their users need either to write scripts to specify the geometry relationships or to import the customized Java code into the app under testing (AUT). In 2017, Shih *et al.* proposed an automatic detection tool called UI-Explorer to detect two types of layout anomalies [8]. In UI-explorer, all layouts are traversed and inspected automatically. However, UI-explorer provides only click events to traverse the layouts. It lacks an approach to handle user inputs. Hasellknippe and Li also proposed a tool called the Layout Bug Hunter (LBH) to detect three different types of layout anomalies [9]. LBH does not need any user specification. However, LBH relies on the underlying Fuse platform [11] to implement the GUI analytical work.

In this paper, we propose a layout anomaly detection tool called LAD (Layout Anomaly Detector) to perform visual testing on Android app layouts. LAD is designed to detect six types of layout anomalies: *components missing*, *cropped text*, *component overlap*, *component overflow*, *component misalignment*, and *component/text scale maladaptation*. To automate the detection process, a procedural script language is devised to specify the navigation procedure and the detection operations. LAD also supports two inspection modes: the *standalone* mode and the *comparative* mode. In the comparative mode, users specify a designated resolution to get *gold standard layouts* (GSLs) as the inspection templates. LAD automatically inspects all *layouts under test* (LUTs) in the testing resolutions against the GSLs. In the standalone mode, LAD works only for one testing resolution. To operate in a contiguous integration (CI) testing process, LAD is designed as a native Java tool in a modular design.

The rest of this paper is organized as follows. Section 2 briefly reviews the related research work on the layout anomaly detection problem. Section 3 describes the layout anomalies detected in LAD and the LAD design. Section 4 presents the empirical study on LAD with four Android apps. Finally, Section 5 concludes this paper.

II. RELATED WORK

The layout anomaly detection problem is an important issue for traditional window-based interface design and Web application design [12-14]. For automatically detecting layout

anomalies, the detection approaches can be mainly classified into two categories: the image comparing approach [15, 16] and the layout analysis approach [6-9].

The image comparing approach inspects the layout anomalies by making comparisons between two captured screenshots to find their pixel differences. Since there is no layout structure information in the contrasting process, this approach may suffer from the challenge to decide whether two images presented in difference screen sizes/resolutions are identical [9].

For the layout analysis approach, the layout information is used to detect the anomalies. In Galen Framework [6], users can program the test cases using Galen Specs Language to describe the relationships between two objects. However, Galen is mainly designed for Web apps. In ITArray Automation Framework [7], a library is supported to perform visual testing on web and mobile pages. Users can describe the visual relationships using the library calls. As pointed in [9], however, these tools require users to provide detailed information about the placement of GUI objects and the validation parameters. If the GUI layouts are changed frequently, this scripting-in-detail approach may incur high maintenance costs.

In 2017, Shih *et al.* proposed a tool called UI-Explorer to automate the detection of layout anomalies [8]. UI-Explorer uses a GUI ripping engine to extract the layout information of all GUI components and automatically traverse all layouts under two different screen specifications. With UI-Explorer, users do not need to provide detailed visual information for testing. However, UI-Explorer considers only two types of layout anomalies: *components missing* and *cropped text*. Moreover, it provides only click events to traverse the layouts.

Hasellknippe and Li proposed a tool called the Layout Bug Hunter (LBH) for detecting three GUI layout anomalies: *component overlap*, *component overflow*, and *component misalignment* [9]. LBH employs a set of specified rules to detect layout anomalies. Therefore, LBH does not require any script for its visual testing. However, LBH does not consider the comparative approach. As discussed in [9], an intentional overlap design may be identified as an anomaly. Moreover, the current LBH design relies on the underlying Fuse platform [11].

III. DESIGN OF LAYOUT ANOMALY DETECTION MECHANISMS

This section first presents the layout anomalies considered in LAD. The design of the LAD architecture is described thereafter.

A. Layout Anomalies

In addition to the layout anomaly types discussed in the previous studies [8, 9], *components missing*, *cropped text*, *component overlap*, *component overflow*, and *component misalignment*, LAD considers one more type: *component/text scale maladaptation*. LAD supports two inspection modes for layout anomaly detection: the *standalone* mode and the *comparative* mode. In the *standalone* mode, LAD uses the pre-defined heuristic rules to decide the detection results. In the *comparative* mode, the layouts in a user-designated resolution are used as the inspection templates, which are the *gold standard*

layouts (GSLs). The *layouts under test* (LUTs) in different screen sizes/resolutions will be investigated against the GSLs.

1) Component Missing

A component missing anomaly happens when some GUI component disappears in a different LUT screen size/resolution. Generally, this anomaly occurs when the screen size/resolution becomes smaller. As shown in Figure 1, the gender symbol at the bottom of the app in the 768×1280 GSL disappears in the 480×800 LUT.

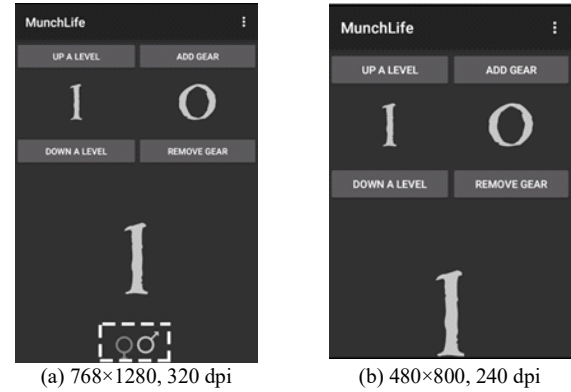

Figure 1: Component missing anomaly

To detect component missing anomalies, LAD first retrieves the XML dumps of GSLs and LUTs. From the XML dumps, LAD calculates the total numbers of components of each GSL and the corresponding LUT. If these two numbers are not equal, the LUT is regarded as having a component missing anomaly.

2) Cropped Text

The cropped text anomaly happens when some text string correctly appears in the GSL, but it is cropped in the corresponding LUT. Generally, this anomaly occurs because the GUI components are squeezed in the LUT of a smaller screen resolution. As shown in Figure 2, when the 768×1280 GSL resolution is shrunk to the 480×800 LUT resolution, the text in the red box of Figure 2(b) is cropped. In this case, the app user cannot read the complete text.

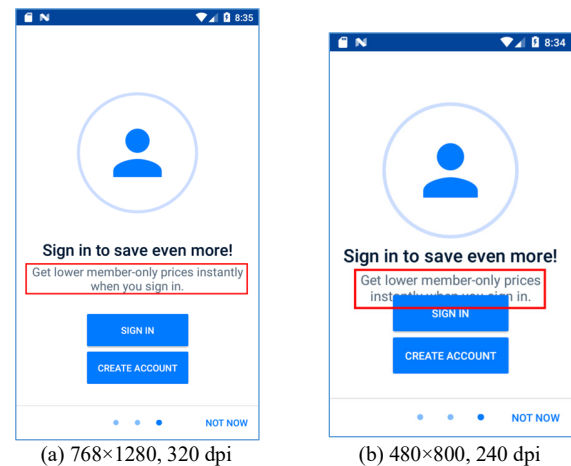

Figure 2: Cropped text anomaly.

LAD uses the same approach proposed in [8] to first obtain the coordinates of the text component C_1 in the GSL and invoke OpenCV (a computer vision library) to get a screenshot S_1 of C_1 . LAD then invokes Tesseract (an OCR text recognizer) to perform the OCR work and get the OCR text T_1 . Similarly, LAD gets the OCR text T_2 for the corresponding component C_2 in the LUT. For example, T_1 in the red box of Figure 2(a) is recognized as “Getlowermember-onlypricesinstantlywhenyousignin” and T_2 is recognized as “GetlowermemberonlypricesWMin-”.

Because the OCR results usually have errors, LAD calculates the Levenshtein distance (Ed_1) between T_1 and the original string $C_1.text$. LAD also calculates Ed_2 between T_2 and $C_1.text$. Therefore, if $|Ed_1 - Ed_2| \geq T_{ED}$ where T_{ED} is a predefined threshold, the LUT is regarded as having a cropped text anomaly.

3) Component Overlap

The component overlap anomaly happens when one GUI component covers a part of another GUI component. This may occur when a smaller screen size/resolution is used for LUTs. However, the original design may also contain this anomaly. Therefore, LAD detects it in both inspection modes.

Figure 3 shows an example in which Figure 3(a) is a correctly displayed GSL of a calculator app. In Figure 3(b), the dashed button area overlaps the background text area in the LUT. In this case, the app users cannot get the correct result.

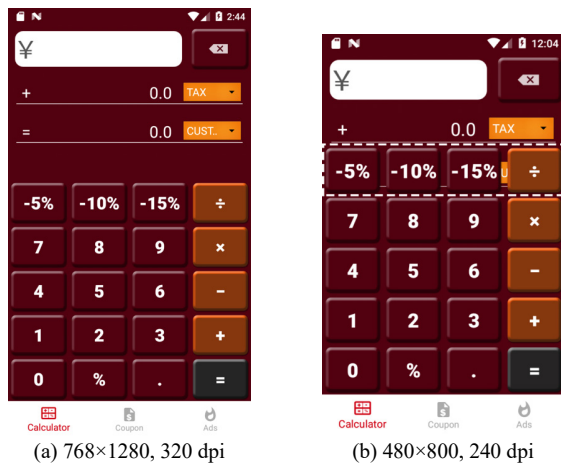

Figure 3: Component overlap anomaly.

To detect component overlap anomalies, LAD retrieves the XML dumps of LUTs and obtains the coordinates of the upper left corner and the lower right corner of each component C_i from the XML dumps. Then LAD calculates the areas of two components to see if these two areas are overlapped.

4) Component Overflow

When an app developer forgets to adjust the component size according to the new LUT resolution, a component overflow anomaly may occur in the LUT if the area of some component exceeds the screen boundary. In the worst case, users may not be able to correctly operate the component.

Figure 4 shows an example. In the 768x1280 GSL of Figure 4(a), both button components are completely displayed. In

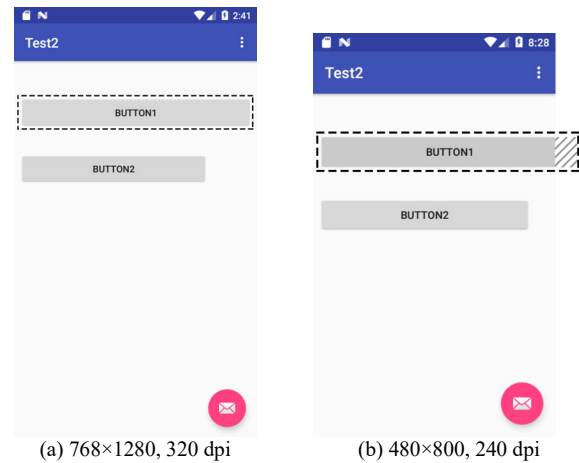

Figure 4: Component overflow anomaly.

Figure 4(b), however, the area of BUTTON1 exceeds the boundary of the 480x800 LUT layout.

LAD also analyzes the XML dumps of LUTs to obtain the coordinate (x_{i1}, y_{i1}) of the upper left corner of each component C_i and its coordinate (x_{i2}, y_{i2}) of the lower right corner. LAD also analyzes the component information to get the height H_i and the width W_i . LAD compares these values with the screen height S_h and the screen width S_w , respectively. If one of the following inequalities is satisfied, the LUT is regarded as having a component overflow anomaly.

- Horizontal boundary overflow

$$x_{i1} + W_i > S_w \parallel x_{i2} < W_i \parallel x_{i2} > S_w$$

- Vertical boundary overflow

$$y_{i1} + H_i > S_h \parallel y_{i2} < H_i \parallel y_{i2} > S_h$$

5) Misalignment

When a programmer designs a layout, the components are usually aligned in the layout. There are three kinds of vertical alignment: *Align Top*, *Align Middle*, and *Align Bottom*. Similarly, the horizontal alignment also has three kinds: *Align Left*, *Align Center*, and *Align Right*. When the component position is not properly adjusted with the resolution change, it is possible that a

Figure 5: Component misalignment anomaly.

component misalignment anomaly occurs in the LUT resolution. For example, the 768×1280 GSL in Figure 5(a) illustrates that the left sides of BUTTON3 and BUTTON4 are aligned with the right side of BUTTON1 along with the red line. However, the 480×800 LUT in Figure 5(b) demonstrates that BUTTON1 is not horizontally aligned with BUTTON3 and BUTTON4.

To detect component misalignment anomalies, LAD makes comparisons for each pair of two components C_i and C_j using their coordinates and centers. However, a strict alignment judgement may incur many false alarms for two cases:

- Some very minor misalignments can be allowable because it is very hard for users to find them by eyes.
- Some misalignments are intentionally designed.

Therefore, LAD has two thresholds D_S and D_L to control the misalignment detection. D_S is used to ignore the misalignments that are not easily recognized by users. In the current LAD design, the default value of D_S is 2 pixels. D_L is used to ignore the misalignments that are intentionally designed. In LAD, the default value of D_L is 8 pixels. For example, if the left upper corner of C_i is (x_{i1}, y_{i1}) and the left upper corner of C_j is (x_{j1}, y_{j1}) , the LUT is regarded as having a component misalignment anomaly when the following condition is satisfied.

$$D_S < |x_{i1} - x_{j1}| < D_L$$

6) Component/Text Scale Maladaptation

As the resolution of the screen changes, the sizes of the components and text characters may also change. If the size of a component is excessively reduced, users will have difficulty clicking the component or reading the text. The LUT is regarded as having a component/text scale maladaptation anomaly. LAD tackles this scale maladaptation problem separately for GUI components and text strings.

For GUI components, the size of an interactive component should be at least 44 pt × 44 pt according to the Apple User Interface Design Guide [17]. In [18], however, Zea suggests that the minimum target size of the component should be 5 mm × 5 mm = 30 px × 30 px. In the current LAD design, we use the size suggested by Zea as the threshold to determine the scale maladaptation anomaly for a component. If the size of a component is smaller than this threshold, a scale maladaptation

Figure 6: Component scale maladaptation anomaly in 768×1280 LUT.

Figure 7: Text scale maladaptation anomaly.

anomaly occurs on the component. For example, Figure 6 illustrates that the dashed area is smaller than 5 mm × 5 mm in the 768×1280 LUT.

For the text scale problem, Kahn and Lenk have pointed out that the font sizes of 12 and 14 points allow the user to read comfortably [19]. Tennant also points out that the 16-pixel font size is approximately equal to the 12-point font size which is suitable for reading [20]. Because the height of the 12-point font is approximately 0.42 cm, LAD use this as a default threshold to determine if the scale of a text string is maladapted in the LUT.

Figure 7 illustrates an example in which LAD first gets the coordinates of the dashed box containing a string “Return date” and then invokes OpenCV to get its screenshot. LAD then uses a text edge detection algorithm [21] to obtain the height H_T of the string as shown in Figure 7(b). If $H_T < 0.42$ cm, the LUT is regarded as having a text scale maladaptation anomaly.

B. LAD Architecture

1) Script Language

To automate the visual testing, a script language is devised in LAD for controlling the testing procedure. With the test scripts, LAD can automatically enter text inputs into the

Figure 8: Component marks and the list of their IDs.

```

1: #Username
2: LAD.input[@id='editText','User']
3: #Password
4: LAD.input[@id='editText2','1234']
5: LAD.testoverlap
6: button.click
7: LAD.testall

```

Figure 9: An example script.

components and navigate to different layouts. In order to let the script writer know the component IDs of each layout, LAD has a companion tool LADMark to extract the component IDs and mark each component on the layout screenshot as shown in Figure 8(a). Figure 8(b) is the component list.

Figure 9 shows a script example based on the list in Figure 8(b). A starting “#” is used to denote a comment. On the second line, “LAD.input[@id='editText','User']” is used to enter the text input “User” for the username. On line 4, “LAD.input[@id='editText2','1234']” is used to input the password “1234”. On line 5, LAD.testoverlap instructs LAD to perform anomaly detection for component overlap. On line 6, button.click tells LAD to click the LOGIN button such that the app moves to the next layout. Finally, LAD.testall instructs LAD to perform anomaly detection for all kinds of anomalies.

2) Architecture Design

Figure 10 shows the architecture of the LAD. The system reads the AUT, the LUT screen resolution, the GSL screen resolution, and the testing scripts. Then, LAD analyzes the testing scripts and automatically navigates the GSLs and LUTs for testing.

Finally, LAD collects the testing results and generates the detection report. To help the developer find the corresponding places of the detected anomalies, the report contains the

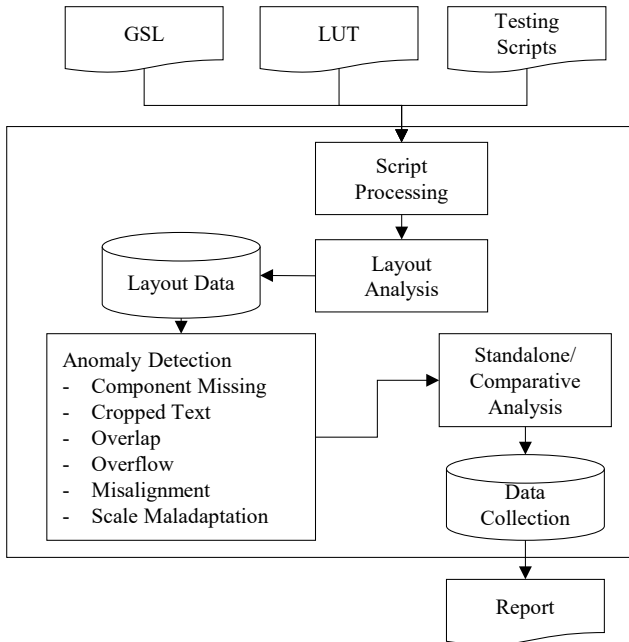

Figure 10: Detection system architecture.

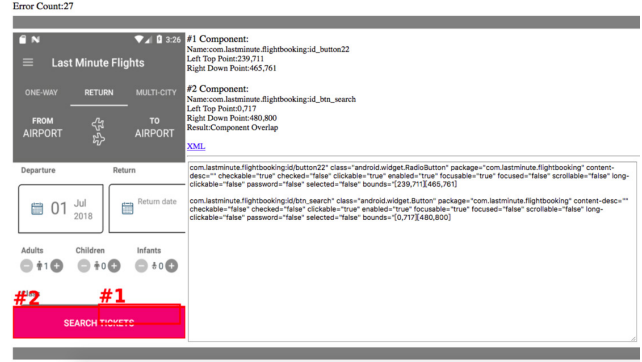

Figure 11: A detection report example.

screenshots, the detection results, and the XML information of the problematic components. Figure 11 illustrates a report example.

IV. EXPERIMENTS

To evaluate the effectiveness of the proposed anomaly detection mechanism, we have conducted experiments with four Android apps. This section describes the experimental results.

A. Experimental Environment

We have implemented a prototype for experiments. The LAD prototype was executed on a PC running with 16 GB RAM and an Intel i5-6500 3.20 GHz CPU. The operating system was Ubuntu 16.04 64bit. The Android emulator was the built-in emulator of Android Studio 3.1 emulating Google 7.0.0 API 24. The resolutions of GSL and LUT were 768×1280 and 480×800, respectively. Four investigated apps are as follows:

- **MunchLife** 1.4.4 (ML): This app is used to track the character level for a card game Munchkin.
- **Last Minute Flights Booking** 2.0 (LMFB): This app allows users to compare flight and hotel information provided by airlines and travel agencies. Users can use it to find the most suitable flights and hotels.
- **Priceline** 4.34.170 (PL): This app allows users to quickly plan their travel itineraries, including booking cheap flights, hotels and rental cars.
- **MyAir365** 1.06 (MA): This app allow users to easily order low-cost airlines.

The main reason for choosing these four apps is that they all have layout anomalies. Therefore, they can be used to demonstrate the detection performance. In order to clearly present the detection results, this paper shows the experimental results using only the first page of each app.

B. Experimental Results

As shown in Table 1, the numbers are the anomalies detected in the experiments. For anomalies of *components missing*, *cropped text*, *component overlap*, *component overflow*, and *component misalignment*, the results are obtained in the *comparative* mode. For scale maladaptation anomalies, the results are measured in the *standalone* mode with the 768×1280

TABLE I. DETECTION RESULTS OF LAD.

	ML	LMFB	PL	MA
Comp. missing	1	0	0	0
Cropped text	0	3	4	0
Overlap	2	10	0	7
Overflow	0	0	0	0
Misalignment	0	6	0	11
Comp. scale maladapt.	0	5	8	8
Text scale maladapt.	5	10	8	3

resolution. The manual inspections show that these detection results can effectively discover many anomalies which may be ignored by inspectors.

In the experiments, some false alarms were found in the standalone mode because the default heuristic thresholds are not appropriate for some apps and scree specifications. However, these false alarms can be eliminated in the comparative mode because the GSLs can filter out their detections in the LUTs.

V. CONCLUSION

Since Android has the severe fragmentation problem, visual testing has received considerable attentions in recent research. Traditionally, developers need to spend much time in manually checking layouts with different screen resolutions. This manual inspection process is time-consuming and error-prone.

In this paper, we present the design of an anomaly detection tool LAD which can be used to detect six types of layout anomalies. To automatically detect these anomalies in different layouts, a procedural script language is devised to specify the app navigation procedure and the detection operations. To operate in a contiguous integration (CI) testing environment, LAD is designed as a native Java tool in a modular design. Moreover, LAD supports two inspection modes: the *standalone* mode and the *comparative* mode. The *comparative* mode facilitates the avoidance of false alarms in the detection results.

In our future work, we plan to conduct comprehensive investigations with more apps to study the effectiveness of LAD. Human inspectors will also involve the experiments to make performance comparisons by measuring more metrics, such as accuracy, precision, and recall. Moreover, the functionality of LAD will be enhanced. The current design does not have a plug-in interface. Therefore, it is inflexible for users who want to add a new module for a new anomaly. The algorithms for anomaly detection will be also improved further and the practical applicability of the detection reports will be enhanced to help developers quickly detect the layout anomalies and improve the quality of Android apps.

ACKNOWLEDGEMENT

This work was supported in part by Ministry of Science and Technology, Taiwan under grant MOST 107-2221-E-155-012. The authors would also like to express many thanks to the anonymous reviewers for their precious suggestions.

Abstract—Autonomous driving systems are complex real-time mobile systems. To guarantee their safety and security, the mobile objects (agents) in these systems must be isolated from each other so that they do not collide with each other. Since isolation means two or more mobile objects cannot be located in the same area at the same time, a scheduling policy is required to control the movement of these mobile objects. However, traditional scheduling theories are based on task scheduling which is coarse-grained and cannot be directly used for fine-grained isolation controls. In this paper, we first propose an event-based formal model called a *time dependency structure* which is used to model and analyze real-time mobile systems. Then, an event-based schedule is defined. Finally, we analyze the schedulability of isolation—that is, checking whether a given schedule ensures the isolation relationship among mobile objects or not.

Index Terms—mobility, isolation, scheduling policy, ambient.

I. INTRODUCTION

Autonomous driving systems are complex mobile systems, which are a prominent subcategory of cyber-physical systems. In these complex mobile systems, safety and security, especially the isolation of mobile objects (agents), has become crucial issues. Isolation means two or more mobile objects cannot be located in the same area at the same time. The mobile objects in real-time mobile systems must be isolated from each other so that they do not collide with each other. Thus, we should have an effective mechanism for checking whether a given scheduling policy can ensure the isolation of mobile objects or not.

Existing scheduling theories, e.g., [2], [7], [8], [10]–[12], focus on task scheduling. Task scheduling mainly consider how to generate the optimal scheduling policies while the objective of the schedulability analysis is to verify that there are no violations of constraint conditions. However, as for the inherent complexity of scheduling, existing work is far from enough to solve these problems. Specifically, in the practical mobile systems, mobile objects and environments interact with each other, it is very difficult to separate a mobile system into independent tasks. We cannot directly use existing methods and techniques to obtain the scheduling policies for the isolation of mobile objects.

To solve the problem, it is necessary for a new scheduling policy to control the whole mobile system [1], [4]. Jiang et

al. [4] have proposed more fine-grained event-based scheduling instead of task scheduling. An event is generally the occurrence of an action or activity. A task, process or complex activity may consist of multiple events [6]. A complex scheduling problem cannot be decomposed into independent tasks, but it can be divided into sub-problems of event-based scheduling. Though Jiang et al. [4] have discussed event-based scheduling, such event-based scheduling does not consider real-time scheduling controls, especially the scheduling in real-time mobile systems.

To investigate the scheduling in real-time mobile systems, we must model real-time mobile systems. We extend the dependency structure model [4], [5] and add the time modeling power to it. Such a model is called a *time dependency structure*, which can conveniently specify the timing constraints and mobility of real-time mobile systems.

In this paper, we first introduce a time dependency structure. Then, an event-based schedule is defined. Finally, we investigate the schedulability analysis of isolation—that is, checking whether a given schedule ensures the isolation relationship among mobile objects or not in a real-time mobile system.

II. NOTATION AND RUNNING EXAMPLE

We will adopt the concept similar to the ambient calculus [3], where computation happens in an ambient that is a closed and bounded place and a mobile object (agent) can enter or exit an ambient.

Here, we first give some notations. Given a set X , the notations 2^X and $|X|$ denote the power set and the size of X , respectively. **Time** = $[0, \infty)$, the set of non-negative reals, denotes the domain of time. **A** and **M** denote the sets of ambients and mobile objects, respectively. The event of a mobile object $\mathcal{M} \in \mathbf{M}$ for entering an ambient $\mathcal{A} (\mathcal{A} \in \mathbf{A})$ is denoted by $en_{\mathcal{A}}^{\mathcal{M}}$ and the event of \mathcal{M} for exiting \mathcal{A} is done by $ex_{\mathcal{A}}^{\mathcal{M}}$. In fact, it is enough for us to only use the two movement events (entering and exiting events) for specifying the mobility in a mobile system. For more information, please refer to our previous work [4].

We present a running example, which is a simple yet typical mobile system where a passenger *John* needs to take a bus in a road intersection area. It is assumed that all the vehicles are equipped with Navigation Satellite System (GPS or BDS) devices and have access to a digital map database, which provide them with critical information such as position, heading, speed, road and lane details. The road area is represented as a

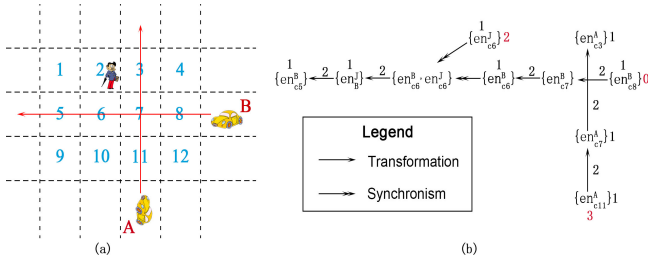

Fig. 1. A simple mobile system

grid which is divided into small cells in Figure 1.(a). Each cell in the grid is associated with a unique identifier. The buses A and B pass the intersection cell $c7$. John is located in the cell $c2$. The bus A moves along the cells $c11, c7, c3$ and the bus B does along the cells $c8, c7, c6, c5$.

John may enter the cell $c6$ and take the bus B . For simplification, we give some notations. John is denoted as J , and the event of John for entering the bus B (resp. the cell $c6$) is denoted as en_B^J (resp. en_{c6}^J). If a bus X enters a cell cx , the entering event is en_{cx}^X . To simplify modeling specification, we only consider the entering events because the event of exiting one cell in fact means the event of entering the next adjacent cell. Thus, there exist the following events: $en_{c6}^J, en_B^J, en_{c11}^A, en_{c7}^A, en_{c3}^A, en_{c8}^B, en_{c7}^B, en_{c6}^B, en_{c5}^B$.

Note that if there exist two or more vehicles in the same cell, they will collide. To avoid collision, when the buses A and B enter the cell $c7$, they must be scheduled so that they pass through the cell $c7$ in sequence. Additionally, John should enter the bus B in the cell $c6$ before B leaves.

Since a time dependency structure can represent a real-time mobile system, it is used to denote such a real-time mobile system. A real-time mobile system \mathcal{TDS} may contains multiple mobile objects and ambients. For convenience, the notation $\mathcal{TDS}_x \sqsubset \mathcal{TDS}$ is used to denote that \mathcal{TDS}_x is a mobile object or ambient of a real-time mobile system \mathcal{TDS} .

III. SYSTEM MODEL

An event is a core concept here, which means an occurrence of an activity or action. If an event occurs, such an event is said to be *available*; otherwise it is *unavailable*. The dependency structure model [4], [5] uses an *event set* (a set of events) as a basic element. If all the events in an event set are *available*, such an event set is said to be *available*; otherwise it is said to be *unavailable*. We equip events and the relationship among events with time attributes, and introduce the *time dependency structure*.

Definition III.1 A *time dependency structure* (\mathcal{TDS}) is a tuple $\langle \mathcal{E}, \mathbb{I}, \mathbb{T}, \mathbb{S}, \mathbb{C}, \mathbb{W}, \mathbb{F}, \mathcal{T}_i, \mathcal{T}_e, \mathcal{T}_t \rangle$ with

- \mathcal{E} , a finite set of events,
- $\mathbb{I} \subseteq 2^{\mathcal{E}}$, the set of initially available event sets,
- $\mathbb{T} \subseteq 2^{\mathcal{E}} \setminus \{\emptyset\} \times 2^{\mathcal{E}} \setminus \{\emptyset\}$, the (asymmetric) *transformation* relation,
- $\mathbb{S} \subseteq 2^{\mathcal{E}}$, the *synchronism* relation such that $\forall A \in \mathbb{S} : |A| > 1$,
- $\mathbb{C} \subseteq 2^{\mathcal{E}}$, the *choice* relation such that $\forall A \in \mathbb{C} : |A| > 1$,
- $\mathbb{W} : \mathcal{E} \rightarrow \{1, 2, 3, \dots\}$, the capacity function,
- $\mathbb{F} \subseteq 2^{\mathcal{E}}$, the set of finally available event sets,

- $\mathcal{T}_i : \bigcup_{X \in \mathbb{I}} X \rightarrow \mathbf{Time}$, the initial time function,
- $\mathcal{T}_e : \mathcal{E} \rightarrow \mathbf{Time}$, the event delay function, and
- $\mathcal{T}_t : \mathbb{T} \rightarrow \mathbf{Time}$, the transformation delay function.

Here, for all $A, B \in 2^{\mathcal{E}}$, $(A, B) \in \mathbb{T}$ is called a *transformation dependency*, denoted as $A \rightarrow B$, all read as B depending on A , and A, B are called the *pre-* and *post-dependency set* of the dependency (A, B) , respectively. The events in A, B are called the *pre-* and *post-events* of (A, B) , respectively.

Transformation is a binary relation between event sets where a transformation dependency $(A, B) \in \mathbb{T}$ is that the occurrences of all the events in B depends on the occurrences of all the events in A . A set $A \in \mathbb{S}$ and a set $B \in \mathbb{C}$ are called a *synchronism set* and a *choice set*, respectively. The capacity function \mathbb{W} restricts the available number of events, that is, if an event e may cause the occurrence of n events, then the capacity of such an event is n ($\mathbb{W}(e) = n$). The capacity function is similar to the token capacity function of places in a Petri net [9], which is used to control a loop.

To support multiple clock modeling, the initial time function is introduced. $\mathcal{T}_i(e)$ refers to the initial clock valuation of the initial available event e . The occurrence of an event may go on for some time. $\mathcal{T}_e(e)$ specifies the timing constraint of the event e . A transformation dependency expresses the dependency relationship between the two event sets and may have a time delay constraint. If a transformation dependency (A, B) has time delay t' , $\mathcal{T}_t((A, B)) = t'$.

In our running example (see Figure 1(b)), we can assume that it takes 1 time unit to enter an ambient and takes 2 time units to cross a ambient for vehicle A and B . we assume that the initial time of the vehicles A, B and passenger John are 3, 0, and 2, respectively. Therefore, the running example can be modeled as $\mathcal{TDS}_{run} = \langle \mathcal{E}, \mathbb{I}, \mathbb{T}, \mathbb{S}, \mathbb{C}, \mathbb{W}, \mathbb{F}, \mathcal{T}_i, \mathcal{T}_e, \mathcal{T}_t \rangle$ where

$\mathcal{E} = \{en_{c11}^A, en_{c7}^A, en_{c3}^A, en_{c8}^B, en_{c7}^B, en_{c6}^B, en_{c5}^B, en_{c6}^J, en_B^J\}$,
 $\mathbb{I} = \{\{en_{c11}^A\}, \{en_{c8}^B\}, \{en_{c6}^J\}\}$,
 $\mathbb{T} = \{(\{en_{c11}^A\}, \{en_{c7}^A\}), (\{en_{c7}^A\}, \{en_{c3}^A\}), (\{en_{c8}^B\}, \{en_{c7}^B\}), (\{en_{c7}^B\}, \{en_{c6}^B\}), (\{en_{c6}^B, en_{c6}^J\}, \{en_B^J\}), (\{en_B^J\}, \{en_{c5}^B\})\}$,
 $\mathbb{S} = \{\{en_{c6}^B, en_{c6}^J\}\}$, $\mathbb{C} = \emptyset$, $\forall e \in \mathcal{E}, \mathbb{W}(e) = \infty$, $\mathbb{F} = \{\{en_{c3}^A\}, \{en_{c5}^B\}\}$, and the timing constraints are as follows:

$\mathcal{T}_i(en_{c11}^A) = 3, \mathcal{T}_i(en_{c8}^B) = 0, \mathcal{T}_i(en_{c6}^J) = 2$,
 $\mathcal{T}_e(en_{c11}^A) = \mathcal{T}_e(en_{c7}^A) = \mathcal{T}_e(en_{c3}^A) = \mathcal{T}_e(en_{c8}^B) = \mathcal{T}_e(en_{c7}^B) = \mathcal{T}_e(en_{c6}^B) = \mathcal{T}_e(en_{c5}^B) = \mathcal{T}_e(en_{c6}^J) = \mathcal{T}_e(en_B^J) = 1$,
 $\mathcal{T}_t(\{en_{c11}^A\}, \{en_{c7}^A\}) = \mathcal{T}_t(\{en_{c7}^A\}, \{en_{c3}^A\}) = \mathcal{T}_t(\{en_{c8}^B\}, \{en_{c7}^B\}) = \mathcal{T}_t(\{en_{c7}^B\}, \{en_{c6}^B\}) = \mathcal{T}_t(\{en_{c6}^B, en_{c6}^J\}, \{en_B^J\}) = \mathcal{T}_t(\{en_B^J\}, \{en_{c5}^B\}) = 2$.

A system can just run along the path formed by its transformation dependencies. Synchronism, choice and timing constraints only control the execution of such a system. While a system runs, each of transformation dependencies may lead to the change of its states. With the passage of time, a transformation dependency may be *activated*. Only activated transformation dependencies will be possibly executed. Thus, a state includes the current possibly available events, the number of possibly activating transformation dependencies, the “absolute” time of the occurrence of every possibly available event, and currently activated transformation dependencies.

Definition III.2 Let $\mathcal{TDS} = \langle \mathcal{E}, \mathbb{I}, \mathbb{T}, \mathbb{S}, \mathbb{C}, \mathbb{W}, \mathbb{F}, \mathcal{T}_i, \mathcal{T}_e, \mathcal{T}_t \rangle$ be a time dependency structure. A *state* of \mathcal{TDS} is a tuple $\mathcal{S} = \langle \Delta, F, f_t, \Gamma \rangle$ where $\Delta \subseteq \mathcal{E}$ is the set of possibly available events, the *availability function* $F : \Delta \rightarrow \mathbb{Z}^*$ is a function from Δ to the set \mathbb{Z}^* of nonnegative integers, the time function $f_t : \Delta \rightarrow \mathbf{Time}$, and $\Gamma \subseteq \mathbb{T}$ is the set of activated transformation dependencies satisfying for all dependencies $(A, B) \in \Gamma \Rightarrow A \subseteq \Delta$. The *initial state* of \mathcal{TDS} is defined as $\mathcal{S}_0 = \langle \Delta_0, F_0, f_{t0}, \Gamma_0 \rangle$ such that $\Delta_0 = \bigcup_{X \in \mathbb{I}} X, \forall e \in \Delta_0 : F_0(e) = |\{(A, B) \in \mathbb{T} \mid e \in A\}|$, $\forall e \in \Delta_0 : f_{t0}(e) = \mathcal{T}_i(e) + \mathcal{T}_e(e)$, and $\Gamma_0 = \{(A, B) \mid A \in \mathbb{I}, (A, B) \in \mathbb{T}\}$.

For example, the initial state of \mathcal{TDS}_{run} is $\mathcal{S}_0 = \langle \Delta_0, F_0, f_{t0}, \Gamma_0 \rangle$ where $\Delta_0 = \{\{en_{c11}^A\}, \{en_{c8}^B\}, \{en_{c6}^J\}\}$, $F_0(en_{c11}^A) = F_0(en_{c8}^B) = F_0(en_{c6}^J) = 1$, $f_{t0}(en_{c11}^A) = 4$, $f_{t0}(en_{c8}^B) = 1$, $f_{t0}(en_{c6}^J) = 3$ and $\Gamma_0 = \{(en_{c11}^A, en_{c7}^A), (en_{c8}^B, en_{c7}^B), (\{en_{c6}^J, en_{c6}^B\}, en_{c6}^J)\}$.

For convenience, the state $\langle \Delta, F, f_t \rangle$ is denoted as $\{\langle e, F(e), f_t(e) \rangle \mid e \in \Delta\}$. The availability function F is similar to the marking of Petri nets. Given an event e and $F(e) = n$, n is called the *availability value* of e .

Given a synchronism set C , the *latest available time delay* of the events in a synchronism set is denoted by $Max\{f_t(e) \mid e \in C\}$. Note that since the absolute time of the occurrence of the events in a synchronism set is computed from the initial state of a system, one cannot directly determine which events occur in what order before the system starts to run.

Definition III.3 Let $\mathcal{TDS} = \langle \mathcal{E}, \mathbb{I}, \mathbb{T}, \mathbb{S}, \mathbb{C}, \mathbb{W}, \mathbb{F}, \mathcal{T}_i, \mathcal{T}_e, \mathcal{T}_t \rangle$ be a time dependency structure and $\mathcal{S}_1 = \langle \Delta_1, F_1, f_{t1}, \Gamma_1 \rangle, \mathcal{S}_2 = \langle \Delta_2, F_2, f_{t2}, \Gamma_2 \rangle$ be two of its states.

\mathcal{S}_1 can evolve into \mathcal{S}_2 by executing a transformation dependency (A, B) , denoted by $\mathcal{S}_1 \xrightarrow{(A, B)} \mathcal{S}_2$, if the following conditions hold:

- (1) $(A, B) \in \Gamma_1$,
- (2) $\nexists (E, F) \in \Gamma_1 : Max\{f_{t1}(e) \mid e \in E\} + \mathcal{T}_t((E, F)) < Max\{f_{t1}(e) \mid e \in A\} + \mathcal{T}_t((A, B))$,
- (3) $\Delta_2 = \{e \in \Delta_1 \mid e \notin A \vee (F_1(e) - (1+x) > 0 \wedge e \in A)\} \cup B$,
- (4) $\forall e \in \Delta_2 : F_2(e) \leq \mathbb{W}(e) \wedge F_2(e) = \begin{cases} F_1(e) - (1+x) & : e \in A \setminus B \\ F_1(e) & : e \in (\Delta_1 \setminus (A \cup B)) \\ F_1(e) - (1+x) + y & : e \in A \cap B \\ F_1(e) + y & : e \in (\Delta_1 \setminus A) \cap B \\ y & : e \in B \setminus \Delta_1 \end{cases}$

where $y = |\{(X, Y) \in \mathbb{T} \mid X \cap B \neq \emptyset\}|$ and $x = |\{(A, X) \in \mathbb{T} \mid \exists e \in X, \exists e' \in B, \exists C \in \mathbb{C} : e \neq e' \wedge \{e, e'\} \in C\}|$,

(5) $\Gamma_2 = (\Gamma_1 \setminus (\{(A, B)\} \cup B^c)) \cup B^T \cup B^S$ where $B^T = \{(B, X) \mid (B, X) \in \mathbb{T}\}$, $B^S = \{(X, Y) \in \mathbb{T} \mid X \in \mathbb{S}, X \subseteq \Delta_1 \cup B, B \subseteq X, Y \subseteq \mathcal{E}\}$ and $B^c = \{(W, X) \in \mathbb{T} \mid W \subseteq \mathcal{E}, \exists e \in X, \exists e' \in B, \exists C \in \mathbb{C} : e \neq e' \wedge \{e, e'\} \in C\}$, and

(6) $\forall e \in \Delta_2 : f_{t2}(e) = \text{if } e \in B \text{ then } Max\{f_{t1}(e') \mid e' \in A\} + \mathcal{T}_t((A, B)) + \mathcal{T}_e(e) \text{ else } f_{t1}(e)$.

According to the condition (2) of the preceding definition, we have $\mathcal{S}_0 \xrightarrow{(en_{c8}^B, en_{c7}^B)} \mathcal{S}_1$ in the running example, and then we have $\Delta_1 = \{\{en_{c11}^A\}, \{en_{c7}^B\}, \{en_{c6}^J\}\}$ (by the condition (3)), $F_1(en_{c11}^A) = F_1(en_{c7}^B) = F_1(en_{c6}^J) = 1$ (by the condition (4)), and $\Gamma_1 = \{(en_{c11}^A, en_{c7}^A), (en_{c7}^B, en_{c6}^B), (\{en_{c6}^J, en_{c6}^B\}, en_{c6}^J)\}$ (by the condition (5)). Thus, $\mathcal{S}_1 = \langle \Delta_1, F_1, f_{t1}, \Gamma_1 \rangle$ where

$f_{t1}(en_{c11}^A) = 4$, $f_{t1}(en_{c7}^B) = 4$, and $f_{t1}(en_{c6}^J) = 3$ (by the condition (6)).

A time dependency structure can be used to reason about the behavior and properties of a real-time system. We define some properties of a time dependency structure here.

Definition III.4 Let $\mathcal{TDS} = \langle \mathcal{E}, \mathbb{I}, \mathbb{T}, \mathbb{S}, \mathbb{C}, \mathbb{W}, \mathbb{F}, \mathcal{T}_i, \mathcal{T}_e, \mathcal{T}_t \rangle$ be a time dependency structure and \mathcal{S}_0 be the initial state of \mathcal{TDS} . Let $\mathcal{S}, \mathcal{S}'$ be two states of \mathcal{TDS} . A state \mathcal{S} is said to be *reachable from* \mathcal{S}' , denoted as $\mathcal{S}' \xrightarrow{*} \mathcal{S}$, if there exist the states $\mathcal{S}'_1, \dots, \mathcal{S}'_{n-1}$ such that $\mathcal{S}' \xrightarrow{d'_1} \mathcal{S}'_1 \xrightarrow{d'_2} \dots \xrightarrow{d'_n} \mathcal{S}$ ($d'_i \in \mathbb{T}, i \in \{1, \dots, n\}$). $Sta(\mathcal{TDS})$ denotes the set of all reachable states in \mathcal{TDS} .

IV. SCHEDULING AND ISOLATION CONTROL

In the section, we will introduce the notion of a schedule and analyze the isolation relationship of mobile objects in a real-time mobile system in order to explore the isolation.

Definition IV.1 Let $\mathcal{TDS} = \langle \mathcal{E}, \mathbb{I}, \mathbb{T}, \mathbb{S}, \mathbb{C}, \mathbb{W}, \mathbb{F}, \mathcal{T}_i, \mathcal{T}_e, \mathcal{T}_t \rangle$ be a time dependency structure.

A sequence $f = \mathcal{S}_0 X_1 \mathcal{S}_1 \dots X_n \mathcal{S}_n$ is called a *full sequence* of \mathcal{TDS} iff $\mathcal{S}_0 = \langle \Delta, F, f_t, \Gamma \rangle, \mathcal{S}_1 = \langle \Delta_1, F_1, f_{t1}, \Gamma_1 \rangle, \dots, \mathcal{S}_n = \langle \Delta_n, F_n, f_{tn}, \Gamma_n \rangle$ are states in \mathcal{TDS} and $\forall i \in \{0, 1, \dots, n\}, X_i \subseteq \mathcal{E}$ such that $\mathcal{S}_0 \xrightarrow{*} \mathcal{S}_1 \xrightarrow{*} \dots \xrightarrow{*} \mathcal{S}_n$ and $\forall i \in \{1, \dots, n\}, \forall e_1, e_2 \in X_i : (X_i \cap \Delta_i = X_i) \wedge (f_{ti-1}(e_1) = f_{ti-1}(e_2))$. Here, the sequence $s = X_1 \dots X_n$ is called a *schedule* of \mathcal{TDS} or is said to be *schedulable* in \mathcal{TDS} . $Sches(\mathcal{TDS})$ denotes the set of all the schedules in \mathcal{TDS} .

As the Definition IV.1, $f_{run} = \mathcal{S}_0 \{en_{c8}^B\} \mathcal{S}_1 \{en_{c11}^A, en_{c7}^B\} \mathcal{S}_2 \{en_{c7}^A, en_{c6}^B, en_{c6}^J\} \mathcal{S}_3 \{en_{c6}^J\} \mathcal{S}_4$ is a full sequence of \mathcal{TDS}_{run} , and $s_{run} = \{en_{c8}^B\} \{en_{c11}^A, en_{c7}^B\} \{en_{c7}^A, en_{c6}^B, en_{c6}^J\} \{en_{c6}^J\}$ is a schedule of \mathcal{TDS}_{run} .

A schedule is an ordered event set sequence, where the events in the front event set occur prior to those in the back event set. The scheduler of a system in fact is a controller that restricts the behaviour of such a system so that given scheduling requirements are met [1].

Definition IV.2 Let \mathcal{TDS} be a time dependency structure and $s \in Sches(\mathcal{TDS})$. The *restriction of \mathcal{TDS} to the schedule s* is denoted by $\mathcal{TDS}|_s$.

In this definition, $\mathcal{TDS}|_s$ means the time dependency structure \mathcal{TDS} whose behavior is restricted to the schedule s or the time dependency structure \mathcal{TDS} runs in terms of the control of the schedule s .

Proposition IV.1 Let $\mathcal{TDS} = \langle \mathcal{E}, \mathbb{I}, \mathbb{T}, \mathbb{S}, \mathbb{C}, \mathbb{W}, \mathbb{F}, \mathcal{T}_i, \mathcal{T}_e, \mathcal{T}_t \rangle$ be a time dependency structure and let s be a schedule in \mathcal{TDS} , then $Sta(\mathcal{TDS}|_s) \subseteq Sta(\mathcal{TDS})$.

The proposition shows that the states of scheduled mobile system are part of those of the original system, respectively.

Definition IV.3 Let \mathcal{TDS} be a time dependency structure and $s = X_1 \dots X_n \in Sches(\mathcal{TDS})$. The *restriction of \mathbf{A} to the schedule s* is defined as $\mathbf{A}|_s = \{A \in \mathbf{A} \mid \exists \mathcal{M} \in \mathbf{M} : en_A^M \in X_1 \cup \dots \cup X_n\}$.

In fact we use $\mathbf{A}|_s$ to denote the set of all the ambients that are involved in the schedule s .

Definition IV.4 Let \mathcal{TDS} be a time dependency structure. Let $\mathbf{M}_s \subseteq \mathbf{M}$. Let $A \in \mathbf{A}, \mathcal{M}_1, \mathcal{M}_2 \in \mathbf{M}_s$ and $A, \mathcal{M}_1, \mathcal{M}_2 \sqsubset \mathcal{TDS}$.

TABLE I
STATES OF THE TIME DEPENDENCY STRUCTURE OF THE RUNNING EXAMPLE SYSTEM

Source state	$\langle \Delta, F, f_t \rangle$	Γ	ED	Target state
S_0	$\{ \langle en_{c11}^A, 1, 4 \rangle, \langle en_{c8}^B, 1, 1 \rangle, \langle en_{c6}^J, 1, 3 \rangle \}$	$\{ (\{en_{c11}^A\}, \{en_{c7}^A\}), (\{en_{c8}^B\}, \{en_{c7}^B\}) \}$	$(\{en_{c8}^B\}, \{en_{c7}^B\})$	S_1
S_1	$\{ \langle en_{c11}^A, 1, 4 \rangle, \langle en_{c7}^B, 1, 4 \rangle, \langle en_{c6}^J, 1, 3 \rangle \}$	$\{ (\{en_{c11}^A\}, \{en_{c7}^A\}), (\{en_{c7}^B\}, \{en_{c6}^B\}) \}$	$(\{en_{c11}^A\}, \{en_{c7}^A\}), (\{en_{c7}^B\}, \{en_{c6}^B\})$	S_2
S_2	$\{ \langle en_{c7}^A, 1, 7 \rangle, \langle en_{c6}^B, 1, 7 \rangle, \langle en_{c6}^J, 1, 3 \rangle \}$	$\{ (\{en_{c7}^A\}, \{en_{c3}^A\}), (\{en_{c6}^B, en_{c6}^J\}, \{en_{c7}^B\}) \}$	$(\{en_{c7}^A\}, \{en_{c3}^A\}), (\{en_{c6}^B, en_{c6}^J\}, \{en_{c7}^B\})$	S_3
S_3	$\{ \langle en_{c3}^A, 0, 10 \rangle, \langle en_{c5}^J, 1, 10 \rangle \}$	$\{ (\{en_{c5}^J\}, \{en_{c5}^B\}) \}$	$(\{en_{c5}^J\}, \{en_{c5}^B\})$	S_4
S_4	$\{ \langle en_{c3}^A, 0, 10 \rangle, \langle en_{c5}^B, 0, 13 \rangle \}$			

Note that "ED" means currently executed transformation dependencies.

\mathcal{M}_1 is said to be *isolated from* \mathcal{M}_2 for \mathcal{A} in \mathcal{TDS} , denoted by $\mathcal{M}_1 \circ_{\mathcal{A}} \mathcal{M}_2$ in \mathcal{TDS} , iff either $\forall s \in \text{Sches}(\mathcal{TDS}), \mathcal{A} \notin \mathbf{A} \uparrow_s$, or $\forall s = B_1 \cdots B_n \in \text{Sches}(\mathcal{TDS}), (\exists \mathcal{X} \in \mathbf{A}, \nexists en_{\mathcal{A}}^{\mathcal{M}_2} \in B_1 \cup \cdots \cup B_n : en_{\mathcal{A}}^{\mathcal{M}_1} \in B_1 \wedge en_{\mathcal{X}}^{\mathcal{M}_1} \in B_n) \vee (\exists \mathcal{Y} \in \mathbf{A}, \nexists en_{\mathcal{A}}^{\mathcal{M}_1} \in B_1 \cup \cdots \cup B_n : en_{\mathcal{A}}^{\mathcal{M}_2} \in B_1 \wedge en_{\mathcal{Y}}^{\mathcal{M}_2} \in B_n)$.

\mathbf{M}_s is the set of mobile objects which need to isolate in order to avoid collision. For example, in the running example, we let $\mathbf{M}_s = \{A, B\}$ because of vehicle A and B need to isolate while John as a passenger and the vehicle B are not isolated from each other in the ambient $c6$ so that John takes the vehicle B .

This definition shows that if \mathcal{M}_1 is isolated from \mathcal{M}_2 , this means one of the following three cases holds: (1) \mathcal{M}_1 and \mathcal{M}_2 do not enter \mathcal{A} , (2) one of \mathcal{M}_1 and \mathcal{M}_2 enters \mathcal{A} , and (3) when the two mobile objects \mathcal{M}_1 and \mathcal{M}_2 both need to enter \mathcal{A} , one does not enter the ambient \mathcal{A} until the other exits \mathcal{A} .

Theorem IV.1 Let $\mathcal{TDS} = \langle \mathcal{E}, \mathbf{I}, \mathbf{T}, \mathbf{S}, \mathbf{C}, \mathbf{W}, \mathbf{F}, \mathbf{T}_i, \mathbf{T}_e, \mathbf{T}_t \rangle$ be a time dependency structure. Let $\mathbf{M}_s \subseteq \mathbf{M}$. Let $\mathcal{A} \in \mathbf{A}$, $\mathcal{M}_1, \mathcal{M}_2 \in \mathbf{M}_s$, $en_{\mathcal{A}}^{\mathcal{M}_1}, en_{\mathcal{A}}^{\mathcal{M}_2} \in \mathcal{E}$, and $\mathcal{A}, \mathcal{M}_1, \mathcal{M}_2 \sqsubset \mathcal{TDS}$. Let $s = X_1 X_2 \dots X_n \in \text{Sches}(\mathcal{TDS})$.

If $\forall s_1 = X_i X_{i+1} \dots X_j \in \text{Sches}(\mathcal{TDS}]_s, \exists x \in \mathbf{A} : x \neq \mathcal{A} \wedge en_{\mathcal{A}}^{\mathcal{M}_1} \in X_i \wedge en_{\mathcal{A}}^{\mathcal{M}_2} \in X_j \wedge en_{\mathcal{A}}^{\mathcal{M}_1} \in X_{i+1} \cup \dots \cup X_j$, then $\mathcal{M}_1 \circ_{\mathcal{A}} \mathcal{M}_2$ in $\mathcal{TDS}]_s$.

In the running example, because of $s_{run} = \{en_{c8}^B\} \{en_{c11}^A, en_{c7}^B\} \{en_{c7}^A, en_{c6}^B, en_{c6}^J\} \{en_{c7}^B\} \in \text{Sches}(\mathcal{TDS})$, we have $s_{run1} = \{en_{c11}^A, en_{c7}^B\} \{en_{c7}^A, en_{c6}^B, en_{c6}^J\} \in \text{Sches}(\mathcal{TDS}]_{s_{run}}$. Since $en_{c7}^B \in \{en_{c11}^A, en_{c7}^B\}$, $en_{c7}^A \in \{en_{c7}^A, en_{c6}^B, en_{c6}^J\}$, and $en_{c6}^B \in \{en_{c11}^A, en_{c7}^B, en_{c7}^A, en_{c6}^B, en_{c6}^J\}$, we have $A \circ_{c7} B$.

The theorem states that we can decide whether two mobile objects are isolated from each other for a single ambient under a given schedule.

Theorem IV.2 Let \mathcal{TDS} be a time dependency structure. Let $\mathbf{M}_s \subseteq \mathbf{M}$.

If $\forall \mathcal{M}, \mathcal{N} \in \mathbf{M}_s, \forall \mathcal{X} \in \mathbf{A}, \forall s \in \text{Sches}(\mathcal{TDS})$, \mathcal{M} is isolated from \mathcal{N} for \mathcal{X} in $\mathcal{TDS}]_s$, then $\forall \mathcal{M}', \mathcal{N}' \in \mathbf{M}_s, \forall \mathcal{X}' \in \mathbf{A} : \mathcal{M}' \circ_{\mathcal{X}'} \mathcal{N}'$ in \mathcal{TDS} .

Theorem IV.2 in fact shows that given the set of mobile objects and the set of ambients, we can decide whether multiple mobile objects are isolated from each other for multiple ambients under a given schedule by checking the

available movement events of the states in a real-time mobile system.

V. CONCLUSION

A time dependency structure has been introduced and discussed. Based on the time dependency structure model, we have presented an approach for modeling a real-time mobile system. We have also defined a schedule for the isolation of mobile objects and have investigated the isolation schedulability analysis in a real-time mobile system. These results may be used for intelligent transportation systems and autonomous driving systems. In the future, we will further explore the isolation control and scheduling policies of the concurrent complex real-time mobile system. In practice, we will develop the scheduling policy generation method and wish it to be really used for autonomous driving.

Abstract—Trace links between software artifacts provide available traceability information and in-depth insights for different stakeholders. Unfortunately, establishing trace links is a fallible, tedious, and labor-intensive task. To alleviate these problems, many Information Retrieval (IR) methods, such as Vector Space Model (VSM), Latent Semantic Indexing (LSI) and their variants, have been proposed to establish trace links automatically. In recent years, short-text artifacts (or even lack of documentation) become a new trend as more and more software systems are developed abiding by agile methodologies. It makes the effects of traditional IR-based trace links generation methods even worse. In this paper, Biterm Topic Model (BTM), which is good at dealing with short text, is introduced to solve the problem. A hybrid method combining VSM and BTM is proposed to generate requirements trace links. The empirical experiments conducted on three real and frequently-used datasets indicate that the hybrid method can achieve better performance, and the results can reach the “acceptable level” directly.

Keywords—requirements traceability, information retrieval, vector space model, biterm topic model, short-text artifacts

I. INTRODUCTION

Requirements traceability (RT) is defined as “the ability to describe and follow the life of a requirement, in both a forward and backward direction [1]. In other words, it can provide visibility of the required aspects of the software and system development process, which contributes to a better understanding of the software system under development [2]. Thus, RT is one of the most important Requirements Engineering (RE) activities. Practically, traceability information has been proven vital to a wide variety software engineering activities, such as requirements consistency checking [3], change impact analysis [4], software reuse [5], and verification and validation (V&V) [6].

In early research and practice, RT is often accomplished by linking requirements to various software artifacts (e.g., design documents, source codes, and test cases) manually through a requirements traceability matrix [7]. However, as software systems evolve over time, RT activities are always time-consuming, tedious, and fallible [8]. As described in our previous work, determining how to improve the automatic degree and efficiency of a consistent and effective tracing process is an important challenge for both academia and industry [9].

To overcome this challenge, Information Retrieval (IR) techniques have been introduced and become the most popular techniques in the area of trace links generation [9]. A typical process of generating trace links by IR-based techniques for natural language artifacts, generally consists of the following steps: document preprocessing, candidate link generating, analyzing and refining [5]. After preprocessing, trace links can be automatically established using IR-based models, such as Vector Space Model (VSM)

[10, 11, 12], Latent Semantic Indexing (LSI) [13, 14, 15], and Probability Model (PM) [16, 17, 18].

In IR-based requirements tracing methods, requirements documents and target artifacts are usually regarded as queries and documents, respectively. And these methods aim to match a query of keywords with a set of objects in the software repository and rank the retrieved objects based on how relevant they are to the query using a predefined similarity measure [19, 20]. The tenet underlying IR-based tracing methods is that artifacts having a high textual similarity probably share several concepts, so they are likely good candidates to be traced from one another [20, 21, 22]. This tenet bases on the assumption that consistent terminologies have been used throughout the project’s lifecycle.

However, as projects evolve, new and inconsistent terminologies gradually emerge into the systems, which declines the performance of retrieval engines [20]. Besides, short-text, low quality text, and different expression preferences in different artifacts also negatively affect the performance of IR-based methods. To deal with all the problems, many strategies have been proposed to improve IR-based tracing methods [9, 23]. In an empirical study [24], the statistically analysis result shows several widely used IR-based tracing methods, which include VSM, LSI, Jensen-Shannon (JS), are almost equivalent. Meanwhile, another study [25] also draws an important conclusion that Latent Dirichlet Allocation (LDA) is able to capture some important information missed by other exploited IR methods, while its performance is lowest. These two conclusions indicate the opportunity to improve performance through combining different techniques, such as VSM and LDA, VSM and Relational Topic Model (RTM) [26]. However, two shortcomings still impede the combination techniques to get good performance on short-text artifacts tracing: firstly, they severely suffer from the severe data sparsity problem [27]; secondly, they cannot draw good results without enough learning corpus.

The empirical results introduced above motivates our work. A novel topic model which is good at dealing with short texts and lack of learning corpus problem.

In this paper, (1) Biterm Topic Model (BTM), good at dealing with short texts and lack of learning corpus, is introduced to generate trace links for the first time; and (2) a good-effect combination way—collection “union” operation (\cup)—is proposed to combine VSM and BTM to constitute candidate links set.

The remainder of this study is organized as follows. Section II provides background information, Section III reports the process of our approach, and Section IV presents the details of experiment. Experiment results are presented and discussed in Section V. Finally, in Section VI, the conclusions and future work are discussed.

*Corresponding author.

II. BACKGROUND

A. Starting Point for Discussion

How to evaluate the quality and usability of RT techniques is vital to propose new automatic RT techniques. The paper [30] proposed an acceptable and practical one according to their industrial practices, as shown in Table I. The standard also shows that candidate link lists with high recall and low precision are preferable to candidate link lists with high precision and low recall [30], as human analysts are much better in examining a given link list and determining whether it belongs to the answer set than they are in detecting whether the current set of links is sufficient.

TABLE I. STANDARDS FROM HAYES^[30]

Measure	Acceptable	Good	Excellent
Recall	60% — 69%	70% — 79%	80% — 100%
Precision	20% — 29%	30% — 49%	50% — 100%
Lag	3 — 4	2 — 3	0 — 2

The scalability of methods is another widely concerned issue. In other word, requirements tracing methods are expected to be able to achieve high quality for both “small” and “large” datasets. According to [30], a “small” dataset consists of 3000 combinatorial links or less. For example, a dataset consisting of 27 use cases and 87 test cases would have $27 \times 87 = 2349$ combinatorial links. Conversely, any dataset with more than 3000 combinatorial links is considered large.

In this work, we refer the quality evaluation standard of requirements tracing methods and the size boundary of dataset presented by [30], which is a starting point for discussion with researchers and practitioners.

B. Related works

In LDA, each document has a corresponding multinomial distribution over T topics and each topic has a corresponding multinomial distribution over the set of words in the vocabulary of the corpus. In [25], LDA has been introduced to generate trace links and capture some important information missed by other exploited IR methods, while its performance is low — the precision is less than 0.1. In [26], another topic model named RTM has been used to requirements traceability recovery. RTM is established with a foundation on LDA. Specifically, the process of modeling document-words distribution is identical to the LDA generative process. In their work, they propose a two-steps approach to combine similarity scores computed by two different IR methods for trace links generation. Firstly, the similarity scores of the two methods are mapped to a standard normal distribution. Secondly, the normalized scores are combined through a weighted sum. The value of confidence parameters for two IR methods need to be determined by users based on their experience. Since the homologous of their principle, two common shortcomings impede they generate trace links.

On the one hand, both LDA and RTM reveal the latent topics within the text corpus by implicitly capturing the document-level word co-occurrence patterns [28]. Since a lot of software artifacts are short texts, directly applying either LDA or RTM on this kind of artifacts will suffer from the severe data sparsity problem[29]. On the other hand, lacking

enough learning corpus may be another threat to impede the wide use of LDA and RTM. It is because insufficient learning corpus may not lead to good results in two different modeling processes.

Compared to these related works, our work introduce a new topic model named BTM to generate trace links for the first time. This model solve the severe data sparsity problem on short texts and the bad learning results problem on insufficient learning corpus. Besides, obtaining union (\cup) is proposed as a good-effect way to improve the candidate links set. The details of our approach will be presented in the next section.

III. OUR APPROACH

In this section, the overall process of our approach and the details of combining VSM and BTM to generate trace links will be presented.

A. Artifacts feature analysis

Generally, there are two kinds of text artifacts:

(1) Short text artifacts. This kind of artifacts only contain several words, such as “One sentence” text artifacts. For example, the requirement 103 in EBT only has one sentence: “A user shall register as a subscriber”.

(2) Long text artifacts. This kind of artifacts contains abundant contents to be traced on, such as structural text artifacts. For example, an artifact “use case” always includes use case name, summary, and description; and an artifact “test case” usually consists of test case name and pre/postconditions, as presented in TABLE II and III.

TABLE II. AN EXAMPLE OF USE CASE FROM EASYCLINIC

<i>UC01</i>	
Use case name:	input registry laboratory
Summary:	The Operator has been recognized by system and has all the data that characterize the the registry of the laboratory. The data in the S I O not be modified Success. The registry of the laboratory is properly inserted inside the S I O .
Description:	1.View the mask to enter information needed 2.Inserts data about the registry of laboratory 3.Confirm placement 4.Verify the data entered 5.Stores data 6.Notify operation it is finished with success

TABLE III. AN EXAMPLE OF TEST CASE FROM EBT

<i>TC141</i>	
Test case name:	Establish Trace (2.1.1)(2.2.1)
Preconditions& Postconditions:	Preconditions: Subscriber is registered Steps Subscriber establishes a trace between a UML artifact and a requirement. Postconditions: A trace is established between the UML artifact and the requirement.

As VSM is good at analyzing long text artifacts and BTM is good at analyzing short artifacts, different preprocessing processes are adopted according to their features.

B. BTM-based tracing method

As described in Section I, directly applying conventional topic models (e.g. LDA and RTM) on short texts do not work well as these models implicitly capture the document-level word co-occurrence patterns to reveal topics, and thus suffer from the severe data sparsity and lacking enough

learning corpus in short documents [28]. Thus, uncovering the topics within short-text artifacts and their relevance becomes a new challenge.

In [28], Yan propose a novel method for modeling topics in short texts, referred as biterm topic model (BTM). The key idea of BTM is to learn topics over short texts based on the aggregated biterms, namely word pairs, in the whole corpus to tackle the sparsity problem in single document. In other word, any two distinct words in an artifact are firstly extracted as a biterm. For example, in the short-text use case “The user can change password.”, if the stop words “The” and “can” are ignored after preprocessing, there are three biterms, i.e. “user change”, “user password”, and “change password”.

As presented in [28], suppose α and β are the Dirichlet priors. The specific generative process of the corpus in BTM can be described as follows:

1. For each topic z
 - (a) draw a topic-specific word distribution $\phi_z \sim \text{Dir}(\beta)$
2. Draw a topic distribution $\theta \sim \text{Dir}(\alpha)$ for the whole collection
3. For each biterm b in the biterm set B
 - (a) draw a topic assignment $z \sim \text{Multi}(\theta)$
 - (b) draw two words: $w_i, w_j \sim \text{Multi}(\phi_z)$

Figure 1 shows the biterm topic model, where θ is the topic probability distribution in the BTM corpus; ϕ is the topic-word pair probability distribution; z is the serial number of topic for corresponding word pair, T is the number of topics; w_i, w_j are two words in the biterm; B is the number of word pairs in the entire corpus; all the word pairs shares the same topic distribution in corpus, each topic corresponds to a polynomial distribution of several word pairs and this Multinomial distribution is recorded as Φ , each word pair corresponds to a topic; α and β are the hyperparameters of Dirichlet prior distribution.

Fig. 1. Biterm topic model

As shown in Fig.2, the BTM-based trace links generation process can be divided into the following phases:

(1) Preprocessing. The preprocessing process is divided into two kinds: for short text artifacts, the pre-processing process contains stop words removal, part of speech tagging and word stemming; for long text artifacts, the upper pre-processing process is only executed on the most representative part of the artifact. For example, only the use/test case name is retained for the whole use/test case described in Table II/III.

(2) Biterms Extracting. In this step, any two distinct words got from the preprocessed source and target artifacts (namely the document collection) are firstly extracted as a biterm. And these biterms are used as the preprocessed corpus to train BTM.

(3) Biterm topic modeling. To use the preprocessed corpus training BTM, three parameters, including T , α and β , need to be set according to the experience related to the dataset. The outputs of this phase are: 1) topic distribution; 2) topic-word pairs distribution; and 3) document-topic distribution.

(4) Text similarity calculating. In this step, document-topic vectors must be established firstly. Based on these vectors, JS distance is used to represented the relevance between source and target artifacts. Note, it is different from cosine similarity since two texts are more similar when JS distance is smaller. After that, links are ranked according to JS distance.

(5) Candidate links generation. The generated links with top N similarity scores are selected as the candidate links.

Due to space limitations, we will not repeat the content about the specific probability calculation formulas of step (3) and JS distance calculation formulas of step (4). The details can be found in [28], where the BTM is proposed for the first time.

C. VSM-based tracing method

As shown in Fig.2, the VSM-based tracing method used in our approach can be divided into the following phases:

(1) Preprocessing. Both short artifacts and long artifacts are directly performed typical pre-processing steps: stop words removal, part of speech tagging and word stemming.

(2) Documents' vectors generation. A document d in the document collection is represented as a vector of keyword weights $d = (w_1, w_2, \dots, w_N)$, and the vocabulary of the entire collection is represented as (v_1, v_2, \dots, v_N) . The weight w_1 is calculated as the product of term frequency-inverse document frequency model (TF-IDF). Similarly, the query Q is also converted into a vector, represented as $q = (q_1, q_2, \dots, q_N)$.

(3) Text similarity calculation. And then, the relevance between document D and query Q is computed as the cosine of the angle between the vectors d and q , as represented in formula (1).

$$\text{sim}(d, q) = \cos(d, q) = \frac{\sum_{i=1}^N w_i \cdot q_i}{\sqrt{\sum_{i=1}^N w_i^2 \cdot \sum_{i=1}^N q_i^2}} \quad (1)$$

(4) Candidate links generation. After computing the cosine similarity, the retrieved objects are ranked based on the similarity scores. The artifacts with high textual similarity are likely good candidates to be traced from one another. In our approach, taking top N is adopt to determine the candidate links. In other words, the top N trace links with the highest scores will be selected as candidate links.

D. The hybrid method

Since complementarity exists between the VSM and BTM, “union” operation (\cup) has a great chance to improve the effect on combinations of precision and recall. The basic idea behind the hybrid method is that two IR methods, VSM and BTM, can be viewed as two experts who provide their expertise to generate candidate trace links. Both experts express judgments based on the textual similarity between two artifacts. The specific method is as following:

Suppose 1) the space size of a dataset is N ; 2) the dataset consisting of L true links and the count of the final candidate

links is nL ($n < N/L$); 2) the select ratios of VSM and BTM are λ and $1-\lambda$, respectively. Then, top $\lambda \times nL$ candidate links generated by VSM and top $(1-\lambda) \times nL$ candidate links generated by BTM are selected to construct the final trace links set. Note, after duplicate links removal, the count of the final trace links may be less than nL as some of the candidate links generated by VSM and BTM are same.

Finally, the candidate links generated in our hybrid method will be provided to analysts to obtain the final trace links as shown in Figure 2.

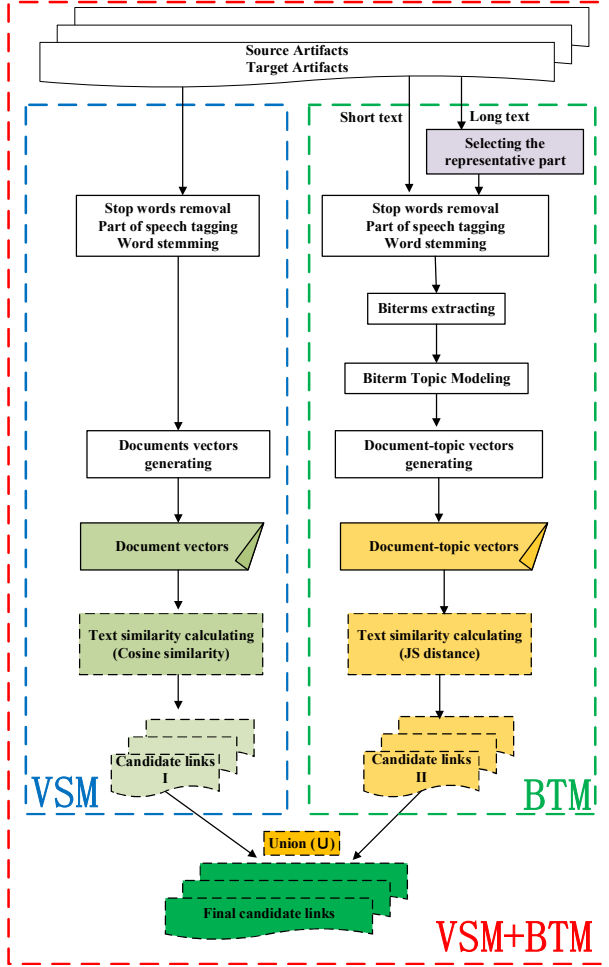

Fig. 2. The hybrid trace links generation method

IV. Experiment

This section describes the empirical experiments carried out on three real and frequently-used datasets to indicate that (1) it is reasonable to use different preprocess steps for VSM and BTM, (2) the hybrid method outperforms standard stand-alone IR methods, namely VSM and BTM.

It is note that the reason why LSI, JS and other similar methods are not regarded as comparison targets in our experiments is that VSM, LSI, JS and some similar methods are almost equivalent [24].

A. Research Question

To identify rationality and usefulness of the proposed hybrid method, the following two research questions need to be answered:

RQ1: Is it reasonable to use different preprocess steps for VSM and BTM?

RQ2: Does the hybrid method improve the quality of trace links generation and to what extent can this method achieve?

B. Datasets

Three datasets, WARC, EasyClinic, and EBT, are used to conduct the experiments. They are able to be downloaded at: <http://www.coest.org/>. The datasets are listed as following:

(1)WARC: This dataset includes 43 functional requirements (FRS), 21 non-functional requirements (NFR), 89 software requirements specification (SRS).

(2)EasyClinic: It is a small student-created dataset in English and Italian which contains diverse artifacts, including 30 Use Cases (UCs), 63 Test Cases (TCs), 20 Interaction Diagrams (IDs) and 47 Code Class descriptions (CCs). Note, only a subset of EasyClinic is chosen to conduct the experiment, as shown in Table III.

(3)EBT: It is an Event-Based Traceability (EBT) system, which contains 41 Requirements (Rqs), 25 Test Cases (TCs) and 52 Code Classes (CCs). Similarly, a subset of EBT is chosen to conduct the experiment, as shown in Table III.

Table IV shows the characteristics of each dataset used in the following experiments. Aiming to improve the availability of our method, the values of the parameters used in experiments are listed in Table V.

TABLE IV. DATASETS USED IN EXPERIMENTS

Dataset	Source	Target	Space (N)	True links (L)	Scale
WARC	43 FRS	89 SRS	3827	78	large
	21 NFR	89 SRS	1869	58	small
EasyClinic subset	30 UCs	63 TCs	1890	63	small
EBT subset	41 Rqs	25 TCs	1025	51	small

Note: "Space" represents the maximum counts of trace links.

TABLE V. PARAMETERS USED IN EXPERIMENTS

Dataset	T	α	β
WARC (FRS-SRS)	35	1.35	0.01
WARC (NFR-SRS)	35	1.35	0.01
EasyClinic (UC-TC)	20	1.25	0.01
EBT (Requirements-TC)	20	1.25	0.01

Note: $\lambda = 0.7$ is assigned to generate final trace links.

C. Quality Measures

Precision (P) and Recall (R) are the standard IR metrics to assess the quality of different requirements tracing techniques. Precision measures accuracy and recall measures coverage [17]. The combinations of precision and recall are used to evaluate the requirements tracing methods based on Hayes' standard described in Section II.

V. RESULTS AND DISCUSSION

In the following section, the findings of the experiments are clarified. After that, the potential threats are discussed.

A. Results

Before discussing and analyzing the results for **RQ1** and **RQ2**, some marks shown in Figure 3, 4, 5, 6 and 7 are illustrated.

As shown in Table I, the "Acceptable", "Good", and "Excellent" results must have a recall rate more than 60% and a precision rate no less than 20%. Therefore, in Figure 3

to 7, three areas, distinguished by green, blue, and pink dotted box, in the upper right corner of the coordinate axis are used to represent these three types of results, which are superimposed as “effective areas”.

For **RQ1**, experiments have been just performed in EasyClinic and EBT, as the WARC has no long-text artifacts. As Figure 3 shows, the quality of VSM on “long-text” (the preprocessing step is following the first step described in Section 3C) is obviously better than the quality of VSM on short-text ((the preprocessing step is following the first step described in Section 3B) in effective areas. However, BTM is better at dealing with short-text, as shown in [28]. Thus, it is reasonable to use different preprocess steps for VSM and BTM.

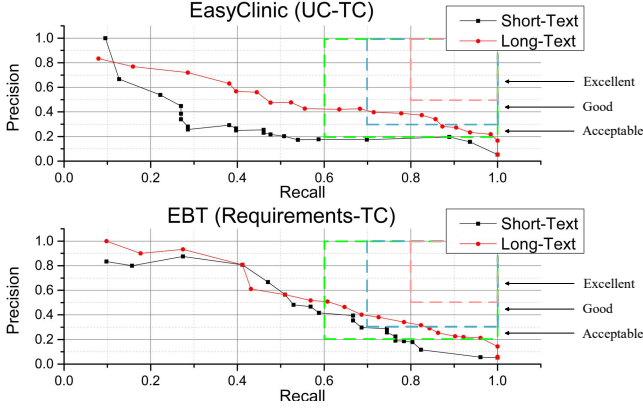

Fig. 3. The precision/recall distributions of VSM in short and long-text.

For **RQ2**, as shown in Figure 4, 5, and 6, all the red curves that fall in the effective area exceed the blue and black curves. In Figure 7, although both red and black curves can fall in the “Good” area, the quality of the red curve is better than the black one, which shows the combined method achieve the highest recall in the effective area.

Through the above analysis, the following conclusions can be summarized:

- (1) The hybrid method outperforms VSM and BTM in all three datasets. In other words, the hybrid method improves the quality of trace links generation;
- (2) The results of the hybrid method achieve “Good” level in EasyClinic, EBT and WARC (FRS-SRS) and “Acceptable” level in WARC (NFR-SRS).

Fig. 4. The precision/recall curves of hybrid method and the standard VSM, BTM method in WARC (FRS-SRS).

Fig. 5. The precision/recall curves of hybrid method and the standard VSM, BTM method in WARC (NFR-SRS).

Fig. 6. The precision/recall curves of hybrid method and the standard VSM, BTM method in EasyClinic subset (UC-TC).

Fig. 7. The precision/recall curves of hybrid method and the standard VSM, BTM method in EBT subset (Requirements-TC).

B. Validity threats

This section aims to discuss the potential threats that influence the findings of this work. The following two aspects are discussed in this part.

Construct validity: (1) Since complementarity exists between the VSM and BTM, “union” operation (\cup) has a great chance to improve the effect. Therefore, it is reasonable to use these two methods to construct a hybrid tracing method. (2) As the result of RQ1 shows, VSM is good at analyzing long text artifacts and BTM is good at analyzing short artifacts, different preprocessing processes are adopted

according to their features. It ensures better effect can be obtained by the hybrid method. (3) The metrics used in our evaluation are recall and precision, which have been widely adopted for assessing the traceability accuracy of IR methods. Thus, we believe that they can sufficiently quantify the accuracy of three compared methods.

Conclusion validity: (1) In this work, experiment has been conducted on three real and frequently-used datasets. And, sufficient results and findings are summarized to illustrate the improvement. It illustrates the validity of our conclusions. (2) As the experiment results show, the hybrid method is able to achieve “Good” effect on small datasets as well as large datasets. The proposed hybrid method has a great chance to be generalized and introduced to other software systems and projects with various requirements and subsequent artifacts. (3) The validity of our experiment can also be affected by the chosen value of the parameter T , α , and β in the employed biterm topic model. We choose the value of three parameters based on our empirical evidence. In the future, we will obtain the optimal values by using some advanced techniques, such as optimization and machine learning.

VI. CONCLUSIONS AND FUTURE WORK

In this paper, Biterm Topic Model (BTM), which is good at dealing with short texts and insufficient corpus, is introduced to generate trace links for the first time. After that, BTM is then combined with VSM to improve the effect of the standard IR methods. The experiments conducted on three real and frequently-used datasets in both large and small scale indicate that our method outperforms standard stand-alone IR methods, namely VSM and BTM.

In the future, we plan to perform detailed analysis about why BTM can complement some trace links for VSM-based tracing method. And then, some advanced parameter configuration techniques will be proposed to reduce the difficulty of using our method. Besides, all kinds of specific applicable scenarios for our method will be presented to improve the availability. Moreover, some refining strategies may be introduced to further improve the quality level.

ACKNOWLEDGMENT

Themis: a tool for validating ontologies through requirements

Abstract—The validation of ontologies, whose aim is to check whether an ontology matches the conceptualization it is meant to specify, is a key activity for guaranteeing the quality of ontologies. This work is focused on the validation through requirements, with the aim of assuring, both the domain experts and ontology developers, that the ontologies they are building or using are complete regarding their needs. Inspired by software engineering testing processes, this work proposes a web-based tool called Themis, independent of any ontology development environment, for validating ontologies by means of the application of test expressions which, following lexico-syntactic patterns, represent the desired behaviour that will present an ontology if a requirement is satisfied.

I. INTRODUCTION

In software engineering it is inconceivable to deliver a software product without its pertinent tests which guarantee that it fulfills all its requirements. Besides, there are several approaches integrated into the software development process whose aim is to test the software. Unit testing [1], which validates that each unit of the software performs as designed, and behaviour-driven development [2], which focuses on the behaviour the software product is implementing, are examples of these approaches. Moreover, there are specific syntaxes, such as Gherkin,¹ which generate unambiguous specifications of software to automate the testing process.

However, in ontology engineering there is a lack of clearly defined testing processes in order to be able to ascertain whether an ontology satisfies its functional requirements [3], which state the particular knowledge that should be represented. Such ontological requirements used to be written in form of competency questions [4] or natural language sentences. The main issue when performing testing processes in the ontology engineering field is the ambiguity of the ontological requirements, which sometimes are difficult to formalize into tests and to translate into axioms. Therefore, inspired by software engineering and its specific syntax for the definition of tests, we propose Themis,² a tool which provides a set of test expressions based on lexico-syntactic patterns (LSPs) related to ontological requirements. These LSPs allows to relate different types of requirements with the axioms needed to implement them in an ontology, and such implementations are used by Themis to identify whether a requirement is satisfied.

Themis can be used by both domain experts and ontology developers to validate ontologies regarding their functional requirements. Other type of requirements, such as non-functional ones (e.g., “the ontology URIs must be in English”) are not considered in this work as they cannot be formalized into axioms and, therefore, they cannot be automatically checked.³ Moreover, the proposed tool allows to execute tests on multiple ontologies simultaneously, in order to check ontological commitments between them.

The paper is organized as follows. Section 2 presents the state of the art on ontology testing tools. Section 3 presents Themis and Section 4 describes a use case in which Themis was integrated into a research project. Finally, Section 5 presents the conclusions we obtained and gives an overview of future work.

II. STATE OF THE ART

Currently, there are several methodologies and tools that support executing tests on an ontology, in order to validate that the ontology satisfies the pertinent requirements.

Regarding methodologies for testing ontologies, Vrandečić and Gangemi [5] introduced the idea of testing ontologies by borrowing ideas from software engineering, proposing techniques such as testing with axioms and negations or formalizing competency questions. Another work presented by Peroni is SAMOD [6], an ontology development methodology that uses tests for validation. These two approaches are focused on methodological aspects but do not mention how to implement the tests or how to maintain traceability.

Another approach to implement testing is the one presented by Ren et al. [7]; in this work the authors use natural language processing to analyse competency questions written in controlled natural language from where they create competency question patterns that could be automatically tested in the ontology. Additionally, Keet and Lawrynowicz proposed a test-driven development of ontologies [8] in which the competency questions are formalized into axioms and added to the ontology if they are not present.

Concerning testing tools, the OntologyTest tool [9] allows a user to define and execute a set of tests to check the functional requirements of an ontology; these tests are stored in an XML file for future reuse. It is worth mentioning that

DOI reference number: 10.18293/SEKE2019-117

¹<https://docs.cucumber.io/gherkin>

²<http://themis.linkedata.es>

³For the sake of clarity, from now on we are going to refer to functional requirements simply as requirements.

Another work related to ontology testing tools is Scone,⁴ a tool for scenario-based ontology evaluation, which is based on Cucumber⁵ and uses controlled natural language to define ontology scenarios which create mock individuals. Additionally, Blomqvist et al. [10] presented an agile approach and tool available as an Eclipse plugin. This tool supports three types of test, namely: (1) verification example, (2) inference verification and (3) error provocation. The first two are concerned with verifying the correct implementation of a requirement and the third is intended to expose faults. All the tests are stored in a different OWL ontology with information about the requirement, e.g., type of test or expected output. By saving these test suites in an ontology it allows the user to reuse them and to maintain traceability between the requirements and all the associated information. However, these tools neither explains how to implement these tests nor how to use them.

Even if all these works proposed solutions for testing through requirements, several of these works do not allow the reuse of the tests, limiting the testing process only to a single ontology. Moreover, there is a lack of information about how to translate a requirement into a test.

III. THEMIS IN THE TESTING PROCESS

A. Test design

⁴<https://bitbucket.org/malefort/scone>

⁵<https://docs.cucumber.io>

⁶<https://protege.stanford.edu>

⁷<https://www.w3.org/TR/owl2-manchester-syntax>

Themis supports a list of possible tests expressions which are extracted from LSPs and that can be executed on an ontology. LSPs are understood as “formalized linguistic schemas or constructions derived from regular expressions in natural language that consist of certain linguistic and paralinguistic elements, following a specific syntactic order, and that permit to extract some conclusions about the meaning they express” [13]. The LSPs used by Themis were extracted from the CORAL corpus⁸ which, based on the NeOn modelling components [14], analyses 834 ontology requirements in order to identify LSPs based on the goal that each requirement has regarding its implementation in an ontology, e.g., a relation between two concepts. Therefore, these LSPs indicate the implementation in the ontology associated with a particular requirement template, which can be used to generate the corresponding tests.

In the Themis web user interface the user enters the test expression or set of test expressions that represent the desired behaviour of a requirement. Such translation between requirements and test expressions should be done manually

⁸<http://coralcorpus.linkeddata.es>

⁹<http://themis.linkeddata.es/examples.html>

TABLE I
TEST EXPRESSION CATALOGUE

Test goal	Test expression syntax	Test expression example	Example of requirement associated
T1 Equivalence	A EquivalentTo B	SecuritySchema equivalentTo Security	Security schema is equivalent to security
T2 Subsumption	A subClassOf B	Sensor subClassOf Device	A sensor is a type of device
T3 Disjointness	A disjointWith B	Sensor disjointWith Actuator	A sensor cannot be an actuator
T4 Property between two concepts	A subClassOf P some B	Bird subClassOf build some Nest	Birds build nests
T5 Universal restriction	A subClassOf P only B	User subClassOf interactsWith only Application	A user can only interact with the systems by means of an application
T6 Multiple inheritance	A subClassOf B and C	Sensor subClassOf System and Device	A sensor must be a system and a device
T7 Symmetry	A Symmetric(P) B	Partnership subClassOf symmetricProperty(hasPartnershipWith) some Organization	There is a partnership between two organizations
T8 Maximum cardinality	A subClassOf P max [num] B	Person subClassOf hasAddress max 1 Address	A person has at most 1 address
T9 Minimum cardinality	A subClassOf P min [num] B	Device subClassOf hasManufacturer min 1 string	A device has at least 1 manufacturer
T10 Cardinality	A subClassOf P max [num]B	Device subClassOf hasManufacturer exactly 1 Brand	A device has exactly 1 brand
T11 The ontology contains the individual	I type A	StriatedPardalote type Bird	A Striated Pardalote is an example of bird
T12 Subsumption and relation between classes	A subClassOf [ClassB] that [PropertyP] some C	Price subClassOf UnitOfMeasure that isCharacterizedBy some Currency	The price, which is a type of unit of measure, is characterized by a value using currency
T13 Minimum cardinality and relation between classes	A subClassOf [PropertyP] min [num]B and B subClassOf [PropertyP] some C	Device subClassOf performs min 1 Function and Function subClassOf accomplish some Task	A device performs at least 1 function and each function accomplishes some task
T14 Minimum cardinality and universal restriction	A subClassOf [PropertyP] min [num]B and B subClassOf [PropertyP] only C	Person subClassOf hasTask min 1 Task and Task subClassOf hasGoal only Goal	A person performs at least one task and each task has a goal
T15 Definition of a disjoint set of classes	A subClassOf B and C subClassOf B that disjointWith A	Carnivora subClassOf MarineMammals and Sirenia subClassOf MarineMammals that disjointWith Carnivora	Marine mammals are divided into two different types: Carnivora and Sirenia

using the guidelines provided in Themis website.¹⁰ As an example, the user can enter the test expression *Event subClassOf InteractionPattern* in order to check a subsumption relation in the ontology expected from the requirement “An event is a type of Interaction pattern”.

Additionally, Themis allows the users to export a set of test expressions, i.e., a test suite, as an RDF file in order to be able to reuse it. Listing 1 shows an example of the test expressions *Action subClassOf InteractionPattern* and *Event subClassOf InteractionPattern* in RDF syntax. Such test expressions aims to check subsumption relations in the ontology. This RDF file uses the ontology Verification Test Case¹¹ ontology to describe each test case.

This RDF file can be improved by adding the requirements associated to the tests, in order to provide a link between the test case and the requirements from which it is extracted. Listing 1 shows the test expressions *Action subClassOf InteractionPattern* and *Event subClassOf InteractionPattern* with the URIs of requirements associated, together with the description of the requirements which specifies what is an action and what is an event.

Listing 1. Example of improved test suite in RDF file

```
@prefix dc: <http://purl.org/dc/terms/> .
@prefix vtc: <http://w3id.org/def/vtc#> .
@prefix xsd: <http://www.w3.org/2000/01/rdf-schema#> .
@prefix vicinity: <http://vicinity.iot.linkeddata.es/vicinity/requirements/report-wot.html#> .
@prefix : <#> .

: test-case-3 a vtc:TestCaseDesign;
  vtc:isRelatedToRequirement vicinity:wot16;
```

¹⁰<http://themis.linkeddata.es/tests-info.html>

¹¹<http://w3id.org/def/vtc>

```
dc:description "What is an action? The Action interaction pattern is an interaction pattern that targets changes or processes on a Thing that take a certain time to complete"
vtc:desiredBehaviour "Action subClassOf InteractionPattern"^^xsd:string .
```

```
: test-case-4 a vtc:TestCaseDesign;
  vtc:isRelatedToRequirement vicinity:wot17;
  dc:description "What is an event? The Event interaction pattern is an interaction pattern that enables a mechanism to be notified by a Thing on a certain condition.";
  vtc:desiredBehaviour "Event subClassOf InteractionPattern"^^xsd:string .
```

These RDF files can be also loaded in Themis, which will extract the test expressions that in the ontology are stored as *desiredBehaviour* data properties. The test suites can be modified and adapted to a particular ontology by the user. This functionality allows to reuse test suites already defined and published on the Web, e.g., test suites already defined for the ontology to be analysed, or test suites defined for other ontologies that could be used to check alignment.

B. Test implementation

During the test implementation activity each test expression is formalized into a precondition, a set of auxiliary term declarations and a set of assertions to check the behaviour. The precondition is a SPARQL query which checks whether the terms involved in the ontology requirement are defined in the ontology. The axioms to declare auxiliary terms are a set of temporary axioms added to the ontology to declare the auxiliary terms needed to carry out the assertions. Finally, the assertions to check the behaviour are a set of pairs of axioms and expected results that represent different ontology scenarios. For each pair, the axiom is temporary

added to the ontology to force a scenario, after which the reasoner is executed. The expected result determines if the ontology status (i.e., the ontology is inconsistent, there is an unsatisfiable class or the ontology is consistent) after the addition is the expected one in the case the requirement was satisfied. If all the status concurs with the expected status, then the requirement is satisfied. Figure 2 summarizes the flow of this test implementation.

Fig. 2. Test implementation flow

Themis creates the implementation of each test expression listed in Table I. Once the user enters the test expression to be checked, Themis identifies the type of test and generates the correct implementation. As an example, if the test expression added by the user is *Action subClassOf InteractionPattern*, Themis will identify that it is of type *T2 Subsumption* and that the implementation includes¹²:

- **Preconditions:** Class Action and class InteractionPattern exist
- **Axioms to declare auxiliary terms:** Declaration of \neg Action and \neg InteractionPattern
- **Assertion 1:**
 - **Axiom:** Action' $\sqsubseteq \neg$ Action \sqcap InteractionPattern
 - **Expected status after adding the axiom:** Consistent
- **Assertion 2:**
 - **Axiom:** Action' \sqsubseteq Action $\sqcap \neg$ InteractionPattern
 - **Expected status after adding the axiom:** Unsatisfiable class
- **Assertion 3:**
 - **Axiom:** Action' \sqsubseteq Action \sqcap InteractionPattern
 - **Expected status after adding the axiom:** Consistent ontology

¹²This implementation is described by means of Description Logics symbols.

C. Test execution

Finally, during the test execution activity, the implementation of the test is executed in the ontology to be tested. At this point, the ontology URI needs to be indicated, as well as the URIs of each term in the test expression in order to be able to execute it, e.g., the terms Action and InteractionPattern in the ontology with URI <http://iot.linkeddata.es/def/wot#> will be <http://iot.linkeddata.es/def/wot#Action> and <http://iot.linkeddata.es/def/wot#InteractionPattern>, respectively. These terms URIs needs to be extracted from the glossary of terms of the analysed ontology.

Themis proposes a glossary of terms where the terms are extracted from the fragments of the URIs of each concept. Table II shows an excerpt of a glossary of terms created by Themis for the ontology VICINITY Web Of Things.¹³ This preliminary glossary of terms can be modified by the users if needed. Even though in this case the terms coincide with the URIs' fragments, that is not required.

TABLE II
EXCERPT OF GLOSSARY OF TERMS

Term	URI
Event	http://iot.linkeddata.es/def/wot#Event
Action	http://iot.linkeddata.es/def/wot#Action
InteractionPattern	http://iot.linkeddata.es/def/wot#InteractionPattern
CommunicationProtocol	http://iot.linkeddata.es/def/wot#CommunicationProtocol
isProvidedOverProtocol	http://iot.linkeddata.es/def/wot#isProvidedOverProtocol

The test execution activity consists of three parts: the execution of the query which represents the preconditions, the addition of the axioms which declare the auxiliary terms, and the addition of the assertions. After the addition of each axiom, the reasoner is executed to report the status of the ontology. The addition of the auxiliary axioms needs to always lead to a consistent ontology. In the case of the assertions, the agreement between the reasoner status after the addition of all the axioms and the status indicated in the test implementation determines whether the ontology satisfies the desired behaviour. All the results of each step are stored in RDF files, in order to enable traceability between them and the requirements.

Themis uses OWL API¹⁴ to load the ontologies and to add axioms, and uses Pellet¹⁵ as the reasoner to check the ontologies consistency. Themis can execute a test expression on several ontologies simultaneously, allowing the users to identify common knowledge and commitments between a collection of ontologies regarding their requirements.

Four possible results can be returned for each test and each ontology:

- 1) *Undefined terms:* if the ontology does not pass the preconditions, i.e., the terms in the test expression are not defined in the ontology to be analysed.
- 2) *Passed:* if the ontology passes the preconditions and the results of the assertions are the expected ones.

¹³<http://iot.linkeddata.es/def/wot>

¹⁴<http://owlapi.sourceforge.net/documentation.html>

¹⁵<https://www.w3.org/2001/sw/wiki/Pellet>

- 3) *Absent relation*: if the ontology passes the preconditions and the results of the assertion are not the expected ones but there are no conflicts in the ontology.
- 4) *Conflict*: if the ontology passes the preconditions and the results of the assertion are not the expected ones, and the addition of the axioms related to the test expression leads to a conflict in the ontology.

As an example, Themis can determine that the test expression *Action subclassOf InteractionPattern* is passed in the VICINITY Web Of Things ontology¹⁶ but has undefined terms in the oneM2M ontology¹⁷, due to the fact that the latter ontology does not consider the modelling of such concepts related to actions or interaction patterns.

IV. APPLICATION OF THEMIS

Themis has been used during the ontology development process of the VICINITY European h2020 project,¹⁸ where five ontologies are currently under development.

The five ontologies to be analysed in the project, i.e., the VICINITY Core (Core), the Web of Things (WoT), the WoT mappings (Mappings), the VICINITY Adapters (Adapters), and the Datatypes (Datatypes) ontologies, belong to the VICINITY ontology network and aim to provide interoperability in the IoT domain. The Core ontology represents the information needed to exchange IoT descriptor data between peers through the VICINITY platform; this ontology is being created by following a cross-domain approach and implements requirements from different domain experts. The WoT ontology aims to model the Web of Things domain according to the W3C WoT Interest Group¹⁹ descriptions. The Mappings ontology represents the mechanism for accessing the values provided by web things in the VICINITY platform. The Adapters ontology aims to model all the different types of devices and properties that can be defined in the VICINITY platform. Finally, the Datatypes ontology aims to model the required and provided datatypes that are used in the interaction patterns of the platform.

Table III summarizes the number of requirements defined for each ontology, as well as the number of test cases extracted from them. These requirements represent the needs asked by the domain experts in order to model the VICINITY platform. More information about these ontologies is available in the VICINITY ontology network portal.²⁰

The test cases were extracted by using the test expression catalogue provided in Table I. Each requirement is translated to one or more test expressions, selecting the most appropriate one from the test catalogue. Several test cases can be related to the same requirement. The test suite associated to each ontology, where all the test expressions are stored, was exported to an RDF file and uploaded to the VICINITY ontology portal,²¹ with the aim of reusing them in

future releases of the ontology to assure that all the previous requirements are still satisfied.

TABLE III
DETAILS OF THE ONTOLOGIES

Ontology	Number of requirements	Number of tests
Core ontology	50	50
WoT ontology	24	24
Mappings ontology	15	15
Adapters ontology	127	154
Datatypes ontology	11	12

Once all the tests were defined, Themis was executed in order to identify if there are tests that are not passed by the ontology. Figure IV summarizes the obtained results of such execution. As the table shows, the majority of the requirements are passed by the ontology. However, there are several tests whose results are *absent relation*, which means that the ontology passes the preconditions, the results of the assertion are not the expected ones but there are no conflicts in the ontology. These results warn the ontology developers that there are some tests that, even though they do not cause any conflict in the ontology, they are not implemented, at least completely, in the ontology.

TABLE IV
TESTING RESULTS OF THE VICINITY ONTOLOGY NETWORK

Ontology	Number of tests	Undefined terms	Passed	Absent relation	Conflict
Core	50	0	34	16	0
WoT	24	0	22	2	0
Mappings	15	0	13	2	0
Adapters	154	0	154	0	0
Datatypes	12	0	12	0	0

Additionally, the VICINITY ontology network should be aligned with the requirements of several standards in the IoT field in order to reuse concepts and patterns of well-known resources, namely: (1) the ETSI SAREF ontology²² [16], the W3C SSN ontology²³, (3) OCF standards²⁴, (4) the oneM2M ontology [16] and (5) ISO/IEC 30141:2017 [17]. Therefore, the requirements related to these standards were collected, and the associated tests were defined by using the test expression catalogue. Table V summarizes the number of requirements and test cases associated.

TABLE V
DETAILS OF THE EXTERNAL ONTOLOGIES

Ontology	Number of requirements	Number of tests
ETSI SAREF	70	70
W3C SSN	24	24
OCF	27	27
oneM2M	33	33
ISO/IEC 30141:2017	36	36

Themis was also used to check if the VICINITY ontology network satisfies the test expressions defined for the requirements of these ontologies and standards. From the execution

¹⁶<http://iot.linkeddata.es/def/wot>

¹⁷<https://git.onem2m.org/MAS/BaseOntology/raw/master/base.ontology.owl>

¹⁸<https://vicinity2020.eu/vicinity/>

¹⁹<http://w3c.github.io/wot/>

²⁰<http://vicinity.iot.linkeddata.es/>

²¹<http://vicinity.iot.linkeddata.es/vicinity/testing.html>

²²<https://w3id.org/saref>

²³<http://www.w3.org/ns/ssn/>

²⁴<https://openconnectivity.org/>

of Themis, it could be deduced that the VICINITY ontology network satisfies several tests, but did not take into consideration some concepts related to these ontologies and standards, as the developers did not consider it necessary for the project domain definition. However, it could also be concluded that there were no conflicts between the VICINITY ontology network and these ontologies and standards. Therefore, it can be determined that the VICINITY ontologies, even though they do not satisfy all the requirements related to the analysed IoT standards, are not incompatible with them. Table IV summarizes the results obtained after Themis execution. More information related to the results is available in the VICINITY ontology portal.²⁵

TABLE VI
TESTING RESULTS OF THE EXECUTION OF THE STANDARDS'
REQUIREMENTS IN VICINITY ONTOLOGY NETWORK

Standard	Number of tests	Undefined terms	Passed	Absent relation	Conflict
ETSI SAREF	70	66	4	0	0
W3C SSN	24	9	13	0	0
OCF	27	21	6	0	0
oneM2M	33	31	2	0	0
ISO/IEC 30141:2017	36	22	14	0	0

V. CONCLUSIONS AND FUTURE WORK

In this work we present Themis, a web-based tool to validate ontologies regarding their functional ontology requirements. To validate an ontology, Themis supports a set of different types of tests expressions, which are extracted from a collection of lexico-syntactic patterns with the aim of easing the formalization of requirements into tests cases. These lexico-syntactic patterns link requirements templates with possible implementations in an ontology and the test expressions check that these implementations are satisfied by a given ontology. Moreover, lexico-syntactic patterns use ontology design patterns to identify possible implementations. Therefore, Themis can also check if an ontology is satisfying a particular test following the ontology design patterns associated to the lexico-syntactic pattern.

Additionally, Themis allows to execute tests on a collection of ontologies simultaneously, which can be used to analyse the overlap of ontological commitment between them. This could be relevant if a developer requires to analyse whether a particular ontology is compliant with a given ontology or standard. The execution of tests on a collection of ontologies can also be used to ease the reuse of ontologies based on their requirements, due to the fact that the user is able to check which ontology satisfies the set of requirements he or she needs to cover.

As part of the continuous process of improving Themis, new tests can be added to the tool if new types of requirements or lexico-syntactic patterns are found. Furthermore, it is also planned to provide more types of results to the users, in addition to the four types that are provided so far.

This addition of possible results aims to help the users to detect more accurately which is the problem when a test is not passed and, therefore, to ease the repairing task. Future work will be also directed to the development of a REST service to be integrated in other ontology engineering tools, such as OnToolology.²⁶

VI. ACKNOWLEDGMENTS.

This work is partially supported by the H2020 project VICINITY: Open virtual neighbourhood network to connect intelligent buildings and smart objects (H2020-688467) and by a Predoctoral grant from the I+D+i program of the Universidad Politécnica de Madrid.

Abstract—Participatory Design has a large number of techniques that can be used for requirements elicitation and interaction design. However, choosing a technique (or set of them) suitable for both processes can be challenging. In this sense, in this paper, we present a semio-participatory methodological process – SPIDe – for requirements elicitation integrated with interaction design, by means of a case study, with the objective of investigate if the results of SPIDe application satisfies the needs and desires of users, and how communication process occurs during SPIDe application. This paper contributes to the use of Semiotics and Participatory Design for requirements engineering and interaction design, to the integration of both areas, and to the SPIDe application.

Index Terms—User participation, human factors, Semiotic Engineering

I. INTRODUCTION

Several human factors influence software conception and development. Some of these factors are research topics in Software Engineering and Human-Computer Interaction (HCI), as for example gender, ethnicity, personality, culture, and social environment [2]. Communication is also one of these factors [2], and one of the current challenges of Requirements Engineering (RE).

Communication is a cultural process and is a study object of Semiotics, which is realized through signs [3]. De Souza [3] argues that the user interface (UI) is a channel of communication in human-computer interaction. But for the UI conception it is necessary to know users’¹ needs, desires, and constraints for a solution, in order words, it is necessary to know the requirements.

A requirement is therefore an attribute which is defined in order to solve a given problem according the users’ needs, desires, and constraints [1]. For requirements to be elicited, there must be communication between users and requirements

engineers². Communication is the key of RE and must be effective [4]. However, for this effectiveness to take place, it is not enough to simply put the engineer in contact with users, but also to use techniques that facilitate communication [4].

From this perspective, Rosa and Matos [13] consider that the users’ effective participation, in the role of design partners, can facilitate communication between designers, engineers, and users, during requirements elicitation and interaction design, which in turn can also facilitate interaction/communication between users and software.

In this paper, we present SPIDe [10]–[13] (a semio-participatory methodological process), and an investigation about *if the results of SPIDe application satisfies the needs and desires of users, and how communication process occurs during SPIDe application*. For this, a case study was carried out and the data was analyzed using open and axial codings of Grounded Theory. This paper contributes to the use of Semiotic and Participatory Design to integrate requirement elicitation and interaction design.

This paper is organized in 5 sections as follows: SPIDe is presented and detailed in the next section. In turn, the research methodology is described in Section 3; the research results and the conclusions are presented in Sections 4 and 5, respectively.

II. SPIDe

To facilitate the communication between the designer and users through the UI, Rosa and Matos [13] suggest that users become interaction co-authors using the semio-participatory process. Thus, Rosa and Matos [13] developed a process for interaction (re)design called SPIDe. SPIDe is (currently) composed of five PD techniques (contextual inquiry, storytelling, brainstorming, braindraw, and think-aloud) and is based on communication-centered design (CCD) [10], as shown in Figure 1. CCD is an interaction design practice based on Semiotic Engineering [13]. Starting from the interaction concept as a communication between the designer and the

DOI reference number: 10.18293/SEKE2019-200

¹We assume as “problem owners”, the customers, subject-interested, (potential) end users, or stakeholders. The term *user* will always indicate this group.

²In this paper, when considering the *engineer*, we take into account subjects that practice the Requirements Engineering and all other professionals who work in the software conception and development, such as system developers and analysts.

users through the UI (as defined by Semiotic Engineering) [3], the interaction design for the CCD is a process of messages construction/manipulation sent from designers to users [13].

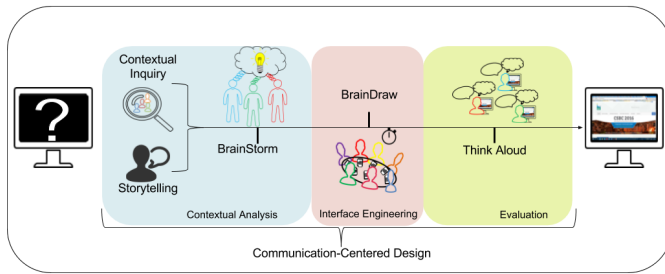

Fig. 1. SPIDe process [10], [13].

1st stage: Contextual Analysis

The first stage is the contextual analysis, which has three PD techniques: *contextual inquiry*, *storytelling*, and *brainstorm*. The contextual analysis stage aims to get to know the users, identify their contexts, characteristics, problems, desires, needs and understand how it is possible to resolve their problem. In addition, it is at this point that the engineer must understand the impact that the solution will produce on users and their environment. This is because the designer is in direct contact with users and their everyday contexts, either by observing the activities carried out by the users through contextual inquiry or listening to their stories through storytelling. At that moment the engineer also knows the socio-cultural context of the users, either through the words told (storytelling) or by immersion in the daily work (contextual inquiry), and together with users, think the problems and possible solutions (brainstorm).

2nd stage: Interface Engineering

The next stage is the interface engineering. This stage has the objective of producing prototypes for the solution envisioned in the previous step. For this, Rosa and Matos suggested the use of *braindraw* [13]. Braindraw is a technique where users draw the software UI in a collaborative way [9], [13]. The users must be divided into groups of at least 2 and at most 8 participants [9]. Color and graphite pencils, pens, erasers are available and each user receives a sheet of paper. Users should draw their ideas of the software UI and at a set time (e.g. 2 minutes) re-pass the paper to those on the left until each paper was drawn twice by each participant.

Through braindraw, users use their signification systems and previous knowledge to draw an UI considered appropriate for use and containing the problem's solution. Developing it in a collaborative way leads to a fusion of ideas, in which all participants are contributors i.e. the drawing contains characteristics of signification systems of their participants/users [9].

3rd stage: Evaluation

Finally, the evaluation stage aims to evaluate the produced prototype. At this time, users use their signification systems to interact with the solution that they have designed, with designer mediation. This stage is composed of the *think-aloud* technique.

For the application of this technique, the designer must design a protocol where the users must follow while interacting with the prototype. During the interaction, the user should speak aloud, as the technique name suggests, about their thoughts, wishes, difficulties, criticisms, suggestions, feelings, and emotions [13]. The interaction should be recorded for further analysis. With think-aloud results, it is possible to identify positive and negative experiences, as well as to identify communication noises that must be repaired before the final version is developed.

A. Researches around SPIDe

The researches presented by Rosa and Matos [13], and Pita et al. [10] specifically deal with interaction design, where communication between designer and user is restricted to the UI (i.e. to HCI). Investigating the communication message composition presented by de Souza [3], Rosa et al. [11], [12] identified that there is a relationship between the message conception and the requirements elicitation process. In this sense, the researchers initiated a project in order to identify if it is possible to elicit requirements through SPIDe.

Initially, a systematic literature review (SLR) was carried out to identify previous research reports that use SPIDe's techniques applied to requirements elicitation [12]. With the SLR, it was identified that only storytelling and brainstorm techniques have already been applied to requirement elicitation; leaving a research gap on the application of other SPIDe techniques, separately or together. In turn, an experimental study was conducted to identify if it is possible to elicit requirements through SPIDe. With the experimental study, the researchers had a positive conclusion [11]. However, this study limits the requirements elicitation, and the researchers did not address how semio-participatory can favor requirements elicitation integrated with interaction design and how the communication happens between designer, engineer, and users. To investigate this gap, in the next section, we present the research methodology.

III. METHODOLOGY

In order to investigate if the results of SPIDe application satisfies the needs and desires of users, and how communication process occurs during SPIDe application, we carried out an exploratory case study [7], [14]. Data was collected using a logbook [6], a semi-structured interview [7], [14], and Technology Acceptance Model Questionnaire (TAM) [5]. The data analysis was done through the open and axial codings of Grounded Theory [15]. The research was based on the construction of software for a music band in which seven subjects, four users and three specialists, participated. This section details the research planning and execution.

A. Research Planning

1) *Research Questions*: To guide the research, the research question is: *is SPIDe effective to make communication feasible for requirements elicitation and interaction design?*

2) *Case Study*: The case study of this research is the software conception for the music band of the Assembly of God church of Ondina, in Salvador/Brazil. The case study was chosen by convenience. The band leader asked the researchers to create a smartphone app to help the band's musicians to perform their activities. The researchers considered that the project was adequate to apply SPIDe and to execute the research, given that in order to construct the demanded solution it was necessary to elicit requirements and also to design the interaction. Complementary, the band members (three subjects) and church pastor³, agreed to participate.

3) *Participants and Roles*: Seven subjects participated in the study⁴, and these were divided into two teams: (a) users and (b) specialists.

All members (three) of the band, Anderson (vocalist and bandleader), Diego (guitarist), and Erick (drummer) and the church pastor (João). The specialists' team was formed by one master and two doctoral students with proven experience in their roles in the software industry. The specialists assumed three roles, namely: SPIDe applicator, requirements engineer, and interaction designer.

4) *Data Collection Procedures and Artifacts*: Three procedures and artifacts were used to collect data. These procedures are widely used in empirical studies of Software Engineering and HCI. The procedures and artifacts are detailed below.

(a) Logbook [6] – The logbook is an artifact where all participants (specialists and users) can take notes, sketches, calculations and describes feelings, ideas, criticisms, suggestions, observations and other information in support of the research.

(b) Semi-structured interview [7], [14] – The semi-structured interview was performed individually, only with the users, after all SPIDe steps were performed, at a moment agreed between users and researchers.

(c) Technology Acceptance Model Questionnaire (TAM) [5] – The TAM aims the identification of the perception about the usefulness and ease of use of SPIDe. The TAM was applied only to the specialists, who answered objective questions on a four-point scale, between totally agreeing and totally disagreeing. Subjective questions were added in order to evaluate negative and positive aspects of SPIDe; aspects of requirements elicitation and interaction design were not contemplated; and the benefit of SPIDe for requirements elicitation and for interaction design in an effective way.

5) *Analysis Procedures*: The data collected through the procedures and artifacts presented previously was analyzed by means of two phases (of the three) of the Grounded Theory [15]. Since the objective of this research is to construct knowledge about how communication occurs through SPIDe, we only used the open and axial codings. Open coding (1st phase) has the objective of creating codes through abstractions

related to the collected data. In turn, in axial coding (2nd phase) the codes created in the open coding are analyzed, and relations between them are established, in order to evidence and discover concepts about the research object [15].

B. Execution

We conducted SPIDe in 4 non-consecutive days of October 2018. In this application, the researchers, in agreement with SPIDe applicator, it was decided not to apply the contextual inquiry, because, in order to apply the technique, the specialists should participate in the band practicing and in church services, which could cause discomfort for both teams, specialists and users.

Initially, it was planned that each stage of the SPIDe would be applied in one day, thus accounting for three days, non-consecutive. However, on the first day of the research, in which the storytelling and brainstorm would be applied, only Anderson and Diego appeared, and in turn, on the second day, João and Erick attended. Faced with the difference of users who attended the first and second days SPIDe applicator decided to reapply storytelling and brainstorm. This impacted on adding one more day to the SPIDe application. In this days the logbook was also distributed. The third day was dedicated to braindraw and the fourth day to thinking-aloud.

Following the thinking-aloud application, the specialists' team answered the TAM and returned their logbook to the researchers. Subsequently, the researchers contacted the users to conduct the interviews. Nevertheless, the researchers were only able to interview users Anderson, Diego, and Erick, because João did not attend the scheduled meetings. The researchers collected the users' logbook, but due to the lack of contact, it was not possible to collect João's. In turn, Erick did not write in his logbook.

IV. RESULTS ANALYSIS

After data collection, this was analyzed using the open and axial codings of the Grounded Theory [15]. We analyze the data collected through logbook, TAM and semi-structured interviews together, to provide a unified view of the users' team and the specialists' team.

Initially, we showed that the communication between the users was effective since they actively participated in the software conception process because they had "[...] *time and freedom to speak*". According to Anderson, "*the fact that we had plenty of time was what helped us [the users' team] to express everything we had to say*". The analysis results indicate that users expressed themselves naturally and "[...] *funny way, helping both design and requirements*".

Users also pointed out that after applying storytelling they recognized their problem with the help of the SPIDe applicator. While they wrote their ideas in brainstorm's post-its, it was noted by the specialists' team, that users could not describe an exact solution. But when they discussed the ideas together with the specialists' team, the solution was clarified and created together, collaboratively. This expresses that through SPIDe it is possible to build mutual knowledge (between users and

³The pastor was invited to participate as he was considered an important stakeholder by the band members and the researchers.

⁴All subjects signed a consent form to participate in the research. The participants also authorized their names publication, except the pastor, who received a fictitious name.

specialists) on the problem and solution like is provided by the PD ideology [8].

In addition to speaking and writing (which corresponded to the data analysis associated with the context analysis), the users' team could also have signs that they consider appropriate to the UI and also use their previous knowledge. This is demonstrated in braindraw sketchings. Through the interview, Diego pointed out that he had put a button on the UI to have a preview of the song they would play. To do this, he was inspired by the music streaming application Spotify®. Another use of previous knowledge was to have the heart to signify that music is a favorite and stars to rank in notes. Both are signs that are already used in other software, are part of the users' signification systems and are built from their relationship with the culture and society they live.

According to the interaction designer, in interface engineering, the users' creativity "[...] has reached significant levels". According to Diego, "*the creation of the application was based on our ideas*". But it was not just the sheet and drawing. With sheet rotation for all participants, as indicated by braindraw [9], it was possible for everyone to draw a part of the UI. Users elected "*the best [UI] design*" democratically, in accordance with what is determined in the PD ideology [8].

After the interface engineering, the specialists turned the drawings into mid-fi prototypes and the users were invited to evaluate it. The specialists have reported that evaluation by think-aloud for some users is not satisfactory. The interaction designer and the SPIDe applicator associated the evaluation with Semiotic Engineering and described signification and communicability problems. In her notes, the SPIDe applicator mentioned that the way in which think-aloud is performed is similar to Communicability Evaluation Method and suggested a change in techniques.

Through the analysis of the collected data, it was still possible to identify that the users consider themselves co-authors of the software. This is because everything has been built collaboratively, between the users and the specialists' team. Thus, according to the research participants, SPIDe reflects what Rosa and Matos [13] thought about the interaction co-design, and goes to a collaborative requirement elicitation. According to the specialists through TAM, the co-authoring provided by SPIDe enables effective communication.

Therefore, SPIDe enables users, their activities, needs, desires, and environments to be (re)cognized (through the use of storytelling and brainstorming) collaboratively; from this, a solution is defined (by means of brainstorm), and also drawn (by braindraw) in a collaborative way. And from the knowledge built in the previous step and with their signification systems, users then interacted with the prototype and evaluated it (through think-aloud).

V. CONCLUSIONS

This paper presented a semio-participatory methodological process SPIDe; and a case study, with analysis via Grounded Theory, to investigate if the results of SPIDe application sat-

isfies the needs and desires of users, and how communication process occurs during SPIDe application.

We concluded that through SPIDe, it is possible for specialists to understand the users desires, needs, and socio-cultural context, given that software conception comes together and initializes from the ideas of its future users. In turn, the problems and solutions that come from the users are clarified as techniques are applied. The specialists' participation is not limited to the observation or techniques application, but these also act in the mediation of communication, to facilitate the mutual construction of knowledge. In this sense, we can conclude that there is evidence in this case study that it is possible to establish effective communication through SPIDe, and achieve satisfactory UI design results, in which users are co-authors. The refinement of SPIDe, as well as the comparison with other processes, are themes for future work.

ACKNOWLEDGMENT

We would like to thank each of the participants of our research, and LARSyS (UID/EEA/50009/2019). This work is supported by the CAPES-DS (Grant #1673896); and CAPES-PDSE (Grant #88881.189073/2018-01).

Abstract—Agile software development is a particularly intense knowledge activity in which the success depends greatly on the experience of the professionals involved in the process. Knowledge Management Strategies play an important role in assisting knowledge acquisition and sharing among Agile teams. In this scenario, this paper answer the following research question: What is the impact caused by the use of Agile practices in the process of organizational knowledge acquisition at software development companies? The objective is to analyze strategies for Knowledge Management among teams and evaluate the impact caused by the adoption of Agile practices on the Organizational Learning process. For this, we proposed a model which it was possible evaluate this impact. Thus, a survey was conducted with 455 respondents in order to validate the proposed model. The data collected in this research was processed and analyzed using Structural Equation Modeling. The results corroborates the impact of software development practices on Knowledge Management Strategies and Organizational Learning. Additionally, this study provides mechanisms for software engineering professionals to implement strategies that contribute to the knowledge acquisition and sharing in their teams.

Index Terms—Agile, organizational learning, SEM, agile tailoring

I. INTRODUCTION

Software development teams adopt different approaches for Knowledge Management with the objective of broadening the understanding of individuals, maximizing the productivity of teams and promoting improvements of quality indexes of the projects [1], [2]. In addition, it generates competitive advantage for the company from the application of the available knowledge [3].

Over the last two decades, Agile methods have gained focus in the software engineering research area [4], [5]. Different organizations have changed their processes of software development and adopted Agile practices. However, Agile methods depend on communication and interaction among individuals so that knowledge sharing takes place [6]–[8] and the strategy used is based on customization [9]. In the other words, in practice, Agile methodologies can be combined with traditional approaches, which organizations adopt and customizes the approaches according to their need, using a hybrid software

development approach [10]. In spite of providing a simpler and less bureaucratic process, the Agile methods face difficulties such as the sharing and management of the knowledge the teams had [1], which impact the process of Organizational Learning (OL) at software companies.

So, the present study was guided by the following research question: What is the impact caused by the use of Agile practices in the process of organizational knowledge acquisition at software development companies? The aims of this study are: (1) to investigate which Agile practices are more frequently used by software development teams; (2) to investigate which Knowledge Management Strategies are the most diffused among software development teams that adopt Agile practices; and (3) to propose an empirical model capable of measuring the impact caused by the adoption of Agile practices in the Organizational Learning.

To achieve these goals, this research conducted a survey with 455 professionals from software development companies that utilize Agile methods and practices. The data was collected by using a questionnaire and analyzing it applied to structural equations modeling (SEM). The results demonstrate the possibility of identifying that Agile practices have meaningful influence over the strategies used by the teams in order to share knowledge and affect significantly the Organizational Learning in IT companies. As contribution of this study, we emphasize the importance of Agile practice in the learning process of individuals and organizations. Furthermore, the proposed model represents a breakthrough in literature that lacks empirical studies for Agile methods adoption [11]. We also highlight that the research instrument as well as the parameters used in our research may be reproduced in order to enlarge the comprehension of how Knowledge Management and software engineering correlate, especially when using Agile methods.

The rest of the paper was organized as follows: Section II shows the proposed model. Section III discusses the research method adopted. Section IV presents the results of the study and the Section V presents the threats to validity. The conclusions and future work are presented in Section VI.

II. PROPOSED MODEL

The proposed model in this paper suggests that the adoption of Agile methods affects both Knowledge Management Strategies and the Organizational Learning process. This relationship is justified by the fact that Agile methods are based on learning processes [12]. The use of these methods requires a constant learning stream from teams [13] and Knowledge Management practices are embedded in Agile practices [1], [14]. In this respect, in literature we found the following constructs that compose the model: (a) Agile Adoption, (b) Knowledge Management Strategies and (c) Organizational Learning (OL).

After researching the literature, the construct related to Agile methods adoption was subdivided into two constructs that classify Agile practices into "Project Management Practices" (PMP) and "Software Development Practices" (SDP). We choose this subdivision because agile methods tailoring is a reality in companies that adopt agile methods [15] and the utilization of agile methods as constructs maybe not be suitable for our objectives. This subdivision is based on the justification that methods such as Scrum are more focused on management practices while XP provides more development practices [16], [17]. Moreover, this division provides a method to verify how each proposed Agile practice group impacts the Organizational Learning.

Concerning the "Knowledge Management Strategies" (KM Strategies) construct, the variables used are the strategies that show how organizations promote knowledge sharing [18], [19] and therefore influence the Organizational Learning process [20], [21].

The last construct of this model is the "Organizational Learning" and it has variables of the constructs considering the levels that learning occurs in the organizational environment. [22]. The Figure 1 shows the variables that compose the constructs proposed in this model.

A. Research hypotheses

From the proposed model to conduct this study, 5 hypotheses were drawn up in order to respond to the proposed research question. The proposed hypothetical model:

- **H1:** The adoption of Agile practices for project management has direct influence over the Knowledge Management Strategies used by the teams.
- **H2:** The adoption of Agile practices for project management has direct influence over the process of Organizational Learning.
- **H3:** The adoption of Agile practices for software development has direct influence over the Knowledge Management Strategies used by the teams.
- **H4:** The adoption of Agile practices for software development has direct influence over the process of Organizational Learning.
- **H5:** The adoption of Knowledge Management Strategies influence directly the Organizational Learning process.

The proposed hypothesis H1 and H3 claim that Agile practices adoption by software development teams significantly affect the KM strategies they use. Even though the organizations to where these teams perform have no set Knowledge Management processes, the Agile methods are based on learning processes [12] and the use of these practices contributes to the production and knowledge sharing among team members, since the practices of Knowledge Management are incorporated into Agile practices [1], [14]. In addition to that, software development activities require constant learning and sharing of information as well as cooperation among individuals is crucial for the success of software projects [2].

As for H2 and H4, the model proposed in this study presents a direct influence on Organizational Learning processes when using Agile practices. OL is considered a change that occurs in organizations due to acquired knowledge and experience [22]. This change is identified from the moment individuals in the organization gain new knowledge, new products and services are proposed and also work routines are improved, meaning an alteration in the behaviour of the company [3], [22]. The OL process starts by the production and sharing of knowledge which are activities related to the individual [23]. Once shared, this knowledge produces a common understanding that spreads among the work group [21] and this allows the production and modification of products, services and company routines [3], [22].

In this respect, the adoption of Agile practices encourages the knowledge sharing among individuals [24], [25], meaning experience and knowledge being acquired and shared. Moreover, the adoption of Agile practices and methods require a culture prone to cooperation and knowledge sharing from the organization [4], [24], [25], since a culture led by knowledge sharing is an essential prerequisite for OL to happen [1].

At last, the H5 hypothesis claims that Knowledge Management Strategies directly impact the Organizational Learning process. KM is a process in which the objective is to protect the knowledge resources of an organization [23] and enhance the productivity by means of strategies to knowledge acquisition and sharing [20]. In addition, effective strategies for Knowledge Management provide mechanisms for the production of new knowledge, so that the existing knowledge may be shared among individuals of the organization and the available knowledge turns into a competitive advantage [1], [3]. As a result, knowledge is created by means of Organizational Learning processes managed by Knowledge Management Strategies [21]–[23].

III. METHOD

In order to evaluate the proposed model, a survey questionnaire was performed. A survey questionnaire is suitable for a standardized data collection and allows the researcher to gather relevant information in order to get answers for the research hypotheses [26].

The proposed questionnaire was composed of 38 items subdivided in 4 parts: (1) respondent characterization, (2) use of Knowledge Management Strategies, (3)

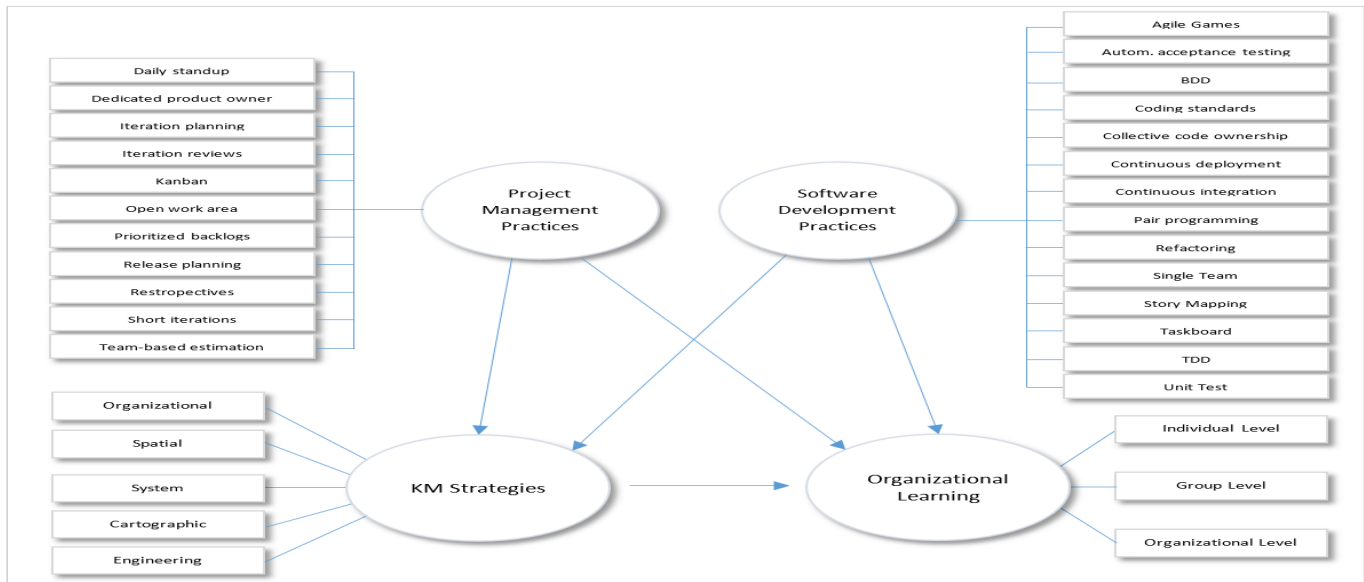

Fig. 1. Research model with constructs and variables.

Organizational Learning and (4) use of Agile practices. Hence, five queries were used to characterize the sample, which include the following item: the individual's job position at the company, schooling, experience with agile methods, level of agile methods knowledge and company stature. The questionnaire was composed by items related to Knowledge Management Strategies, Organizational Learning Agile Practices and it can be seen by link: <https://www.dropbox.com/s/htr6z8ibx1a5pux/sbsi-2019.pdf?dl=0>

IV. RESULTS

This section presents the analyzed results obtained from the data collected utilized for this research.

A. Descriptive analysis of the sample

The survey questionnaire was answered by 455 valid respondents. Among them 52.75% act on the development team as programmers, testers, designers. 30.99% are professionals in management and leadership position such as Scrum Masters and project managers. As for the education, 40.88% of respondents hold graduate degree and 44.62% postgraduate degree or an MBA. 5.05% of individuals mentioned are students in the process of graduating. 11.2% have knowledge on Agile methods, adopt practices on their daily routine but never effectively used these methods in projects. However, most participants are currently embracing Agile methods on projects for their companies, meaning that 20.2% have worked with Agile methods for less than a year and 30.33% have around 1 to 3 years of experience in Agile methods and practices. Emphasizing that 44.62% of respondents consider themselves professionals that have intermediate knowledge on the subject and 26.59% claim to have advanced knowledge on Agile methods. Another highlight is on the fact that 59.12% of individuals work for big companies.

B. Structural Model

To verify the quality of adjustments, the R^2 was used to represent in a scale from 0% to 100% how much the independent constructs explain the dependent ones. Therefore, the values below 25% represent a weak explanatory capacity, the ones between 25% and 50% indicate a moderate explanatory capacity and the values above 50% highlight a substantial explanatory capacity [27].

The Gof value [28] was also used to obtain a geometric average of AVE in all constructs and R^2 from the model. Such measure also ranges from 0% to 100%. It is worth emphasizing that when the PLS approach is used, Gof has no capacity to differentiate the valid models from the invalid ones and must not be applied on models with formative constructs [29]. In this case, Gof allows only a roundup of AVEs and R^2 of the model in one statistics, which could be useful for future adherence comparisons of different samples of the model.

Table I presents the endogenous, which are constructs influenced by other constructs and also introduces the exogenous which are constructs capable of influencing the endogenous ones. Table I shows the values found for the structural model, meaning β value, the standard error for β (S.E.(β)), the Confidence Interval (CI), p-value and R^2 . Highlighting that the proposed model has a Gof of 37.85%. In addition to that, the Confidence Interval was aligned with the results found by p-value, which points out the validity of these results.

TABLE I
STRUCTURAL MODEL EVALUATION

Endogenous	Exogenous	β	S.E.(β)	C.I. - 95%	p-value	R^2
Knowledge Management Strategies	Project Management Practices	0.11	0.06	[0.00 ; 0.24]	0.058	26.5%
	Software Development Practices	0.43	0.06	[0.32 ; 0.55]	0.000	
Organizational Learning	Project Management Practices	0.01	0.06	[-0.11 ; 0.13]	0.859	31.3%
	Software Development Practices	0.16	0.06	[0.04 ; 0.28]	0.007	
	Knowledge Management Strategies	0.45	0.05	[0.35 ; 0.55]	0.000	

Through the analysis of the construct "Knowledge Man-

agement Strategies”, the results indicated a soft (p -value = 0.058) and positive ($\beta=0.11$; [0.00; 0.24]) influence of the construct ”Project Management Practices” (PMP) over the construct ”Knowledge Management Strategies”. In this case, it means that the higher the usage of Agile practices for project management, the higher the usage of strategies for Knowledge Management will be. Moreover, there was a meaningful (p -value = 0.000) and positive ($\beta=0.43$; [0.32; 0.55]) influence of the construct ”Software Development Practices” (SDP) over the construct ”Knowledge Management Strategies”. This influence is directly proportional, which means the higher Agile practices to software engineering or software development ones are, the higher the Knowledge Management Strategies will be. Thus, the constructs ”Project Management Practices” and ”Software Development Practices” were capable of explaining 26.50% of the variability of the construct ”Knowledge Management Strategies”, which means that there is a moderate explanatory capacity. These data are presented on Figure 2 describing the structural model of this analysis.

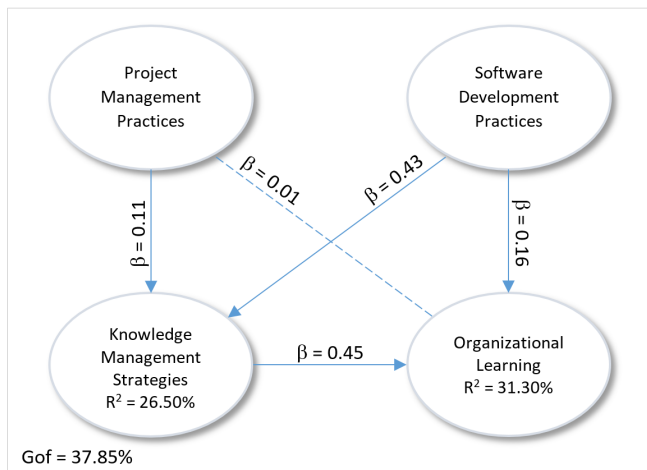

Fig. 2. Structural Model Presentation.

Regarding the construct ”Organizational Learning”, there was no meaningful influence of the ”Project Management Practices” ($\beta=0.01$; [-0.11; 0.13]). On the contrary, the results demonstrated meaningful and positive influence (p -value = 0.007) of the construct ”Software Development Practices” ($\beta=0.16$; [0.04; 0.28]) over the ”Organizational Learning”. Hence, having high SDP affects directly the Organizational Learning which tends to be high as well. A meaningful and positive influence (p -value = 0.000) of construct ”Knowledge Management Strategies” ($\beta=0.45$ [0.35; 0.55]) was also identified over the construct ”Organizational Learning”. Consequently, the growth of ”Knowledge Management Strategies” imply the growth of ”Organizational Learning”. The PMP, SDP and KM Strategies were able to explain 31.30% of the variability in ”Organizational Learning”, which indicates a moderate explanatory capacity. These data are presented in Figure 2.

C. Analysis of hypothesis

In this section, the proposed hypothesis is discussed and the results are confronted with the literature presented in the introduction of this work.

As presented on Section IV-B, the hypotheses H1 and H3 referring to the influence of the Agile practices adoption over Knowledge Management Strategies, were confirmed. The marginally significant and positive influence between constructs ”Project Management Practices” and ”KM Strategies” confirm the hypothesis 1. Furthermore, the meaningful and positive result found between constructs ”Software Development Practices” and ”KM Strategies” confirm hypothesis 3.

Thus, it is possible to state that Knowledge Management Strategies used by teams that adopt agile methods have direct influence due to the set of Agile practices employed by these teams. It is worth mentioning that the results of the study showed that Agile practices such as ”practices for software development” [16], [30] present a higher influence over Knowledge Management Strategies. The practices in this group also present further alignment with social aspects concerning KM and provide mechanisms aimed at individual learning [5], [16].

By assessing the results from the H1 and H3 hypotheses, it is possible to relate them with the results obtained in others researches [14], [31]. The hypotheses H2 and H4 refer to the influence of Agile practices in the Organizational Learning process. The results obtained through the questionnaire confirmed only the H4 hypothesis, which points to a meaningful influence of the construct ”SDP” over the construct ”Organizational Learning”. In this respect, the use of Agile practices for software development has direct influence over the process of Organizational Learning although such influence was not confirmed for Agile practices for project management (H2). The confirmation of the H4 hypothesis may be for the reason that the Software Development Practice (SDP) encourage the knowledge sharing among individuals [24], [25] and provide a set of practices aligned with the social aspects of learning [5]. Additionally, Agile practices and methods require a change in the culture of the organization, that is, it must be guided by learning and constant update [16].

The non-confirmation of the H2 hypothesis diverges from the results reported by authors that consider practices for project management, such as daily meetings and retrospectives, as efficient mechanisms for the process of Organizational Learning [32]. Schwaber and Beedle [31] state that knowledge sharing takes place by four Agile practices of project management (sprint planning, daily meeting, sprint reviews and retrospectives). However, Hoda, Babb and Nørbjerg [13] emphasize that in an environment under pressure for results and deliveries compromise learning due to the lack of ceremonies and Agile practices related to learning.

The confirmation of these hypotheses (H1, H3 and H4) converges with the discussion regarding the nature of Agile methods and practices, which means that agile methods are based on learning processes [12] and Knowledge Management

practices are incorporated into agile practices [1]. Furthermore, software development activities demand that teams constantly produce new knowledge [13] and share it so that success is achieved in software projects [2], contributing for product construction and improvement of the processes kept by organizations.

Finally, the last hypothesis proposed by the hypothetical model (H5) establishes that the use of strategies for Knowledge Management influence directly the process of Organizational Learning. The results from this study lead to a meaningful influence of construct “KM Strategies” over the construct “Organizational Learning”, which confirms the hypothesis 5. The application of appropriated Knowledge Management Strategies provide mechanisms for Organizational Learning to take place, meaning that new knowledge is produced and shared among individuals [1], [3]. This process produces a suitable environment for the development of new products and services, and besides that provides means for the improvement of the routines of the organization [21], [22].

D. Discussion

From the results, it was possible to identify the goals of this research. First, (1) to investigate which Agile practices are more frequently used by software development teams, it was verified the frequency in which professionals use practices described as “Agile practices for project management”. As for practices described as “agile practices for software development”, the results indicated that they are not often used. Only the practices “Unit Testing”, “Taskboard”, “Single Team”, “Continuous Integration”, “Collective Code Ownership” and “Coding Standards” were described as usual practices in the daily work of teams. Even though this result demonstrates that most Agile practices of software development are rarely used by the teams, the results from the present study converge with other researches done by companies from the IT area [30]. This outcome helps us reach the first goal of this paper, which consists of identifying the frequency on which Agile practices are used by teams.

Second, (2) to investigate which Knowledge Management Strategies are the most diffused among software development teams that adopt. The data collected in this research demonstrated the Knowledge Management Strategies described as System, Engineering, Organizational and Spatial are present in companies that adopt these methods. Only the use of strategies from Cartographic school [20] got impartial values for the respondents, which demonstrates that the companies do not map the competencies of employees. Even though the participants of this research identified and agreed to most KM strategies, we also identified strategies established by the Behavioral school (Spatial and Organizational) with bigger indexes of concordance than the ones from the Technocratic schools (System and Engineering). These results are justified by the characteristic of the sample obtained through the questionnaire, which was composed by professionals who work in teams that have adopted Agile practices and methods. These results are in conformity with the results of other authors who

showed the strategies predicted by Behavioral schools as the most used ones in Agile environments [18], [19], [33], while Technocratic strategies are more present in organizations that use the traditional methods [19].

The last objective, (3) to propose an empirical model capable of measuring the impact caused by the adoption of Agile practices in the Organizational Learning. The fulfillment of this objective allows to answer the proposed research question. From the analysis of the collected data, it was concluded that these practices for project management do not influence significantly the Organizational Learning process. However, the results show that Agile practices for software development have positive and meaningful influence on Organizational Learning. It was also possible to identify that the use of KM strategies have meaningful and positive influence on Organizational Learning. Therefore, agile practices and Knowledge Management Strategies enable to explain the 31.3% of variability in Organizational Learning in software companies. In addition, highlighting that Agile practices (for project management and software development) have meaningful influence on strategies used by Agile teams to Knowledge Management and sharing. The use of Agile practices makes it possible to explain 26.5% of the variability in Knowledge Management Strategies used by the teams.

V. THREATS TO VALIDITY

In this paper, some threats to validity have been identified and some measures have been adopted to mitigate them. The first, the data collection instrument used for this study. There was the possibility that the participants of the research could find difficulties to understand or fill in the questionnaire. In order to prevent this from happening, a previous test was made with the individuals in the same parameters from the original research. From this test, it was possible to measure the average time spent on answering the questions as well as identifying and discussing points for improvement. The items indicated by the individuals taking part in the test were adjusted in the data collection instrument.

The second, the possibility of professionals who were not aware about Agile methods and practices to answer the questionnaire and compromise the data collected. In order to mitigate this, five questions were included in the data collection instrument to characterize the sample. Thus, it was possible to remove from the research database the questionnaires in which participants affirmed having no knowledge concerning Agile methods and practices.

A hypothetical model was proposed seeking to validate it from an empirical research that allows for the generalization of the results obtained. For this reason, the regional character of the data collection was an issue to the research, since the obtained results could express the characteristics of one region of the country instead of the whole software production sector. To prevent this, other than the snowball technique, data collection has been made in three different events in two capitals. Even though data about the work place has not been asked from participants, the events chosen for data collection

have national expression and receive audience from all over the country, especially the Agile Trends event that took place in São Paulo at the occasion of the data collection.

VI. CONCLUSION

In this study, we proposed a hypothetical model composed by four constructs and conducted a survey with 455 respondents to enable the validation of the the proposed model. The data collected was analyzed from the technique of Structural Equations Modeling (SEM). Thus, with the results of this work it's possible verify that Agile practices have positive and meaningful influence on OL, KM strategies have meaningful and positive influence on Organizational Learning and the Agile practices have meaningful influence on strategies used by Agile teams to Knowledge Management and sharing.

As future work, we suggest the validation of the proposed model, collecting data in companies previously chosen and case studies in these organizations in order to engage in qualitative evaluation when interviewing experienced professionals in Agile methods and practices. Thus, the results obtained in this work may be confronted with the reports of the professionals interviewed. Nevertheless, we can not generate the findings of this study, because the present research was conducted in a specific country, Brazil. Therefore, replication of this survey in others countries is also recommended.

Abstract – Student evaluation criteria is a non-trivial variation point in a Student Information System software product line. It can vary significantly in different institutions, or even in different areas of a specific institution, and also over time. This paper presents a highly flexible model-driven development solution to incorporate and change one or many different evaluation criteria in each specific product of the line, where a domain expert should be able to model each set of student evaluation criteria, and automatically transform it into software code, without involvement of software engineers. For this purpose, we created a domain-specific modeling language DSCHOLAR and a model-to-code transformation *dscholar2Code* to model and automatically implement such a software component. They were both validated using a case study and proof of concept, respectively.

Keywords – Domain-Specific Modeling Language; MDD; Academic Application; Student Evaluation Criteria, Student Information System.

I. INTRODUCTION

Around the world, the evaluation criteria of higher-level education institutions students vary significantly among countries, institutions, different areas of the same institution, and over time.

External factors can impact an institution's evaluation criteria. In some places, the government applies country wide student evaluations to measure the quality of its institutions. The institutions may respond by performing internal simulations of the government evaluation, and the results of these simulations are sometimes factored, in some way, into the grade students get for each individual subject they are taking. Each institution will use some specific strategy to do this, in ways that stimulate students to improve their performance in government evaluations.

Internal factors can also impact the institution evaluation criteria. In one university, for instance, some courses (but not all of them) have an entrepreneurship project whose evaluation must be factored into the students' regular classes grades – in different ways depending on the semester the student is in.

Another factor is the dissemination of distance learning under graduate courses, where, typically, the flexibility of evaluation criteria is more pronounced.

Also, some institutions have the same rules for all its students, while others have rules for each specific course or even rules defined by each teacher individually.

The context for this work is the design and development of a Student Information System (SIS) for the management of academic and support functions of higher-level educational institutions. It is designed to be a software product family (SPL) [1] for deployment in many institutions, with many common functionalities, but also significant non trivial variability points, such as the evaluation criteria. Therefore, each product of the family can be adapted for the specific needs of the educational institution and can also easily evolve.

This paper focuses specifically on the solution created for one specific variability point of the product line: student evaluation criteria in higher-level educational institutions.

Many approaches deal with variability in product families. We used a model-driven development (MDD) approach [2] to model the evaluation criteria component of our SPL, according to the institution's needs, and to generate its code automatically. In order to support it, a small domain-specific modeling language (DSML) was developed specifically for the domain of evaluation criteria of educational institutions, and a model-to-code transformation was developed to automatically translate the models produced in this DSML into C# language software code.

The MDD / DSML software tool selected for this project was Microsoft DSL Tools [7], a set of plugins hosted by Microsoft Visual Studio that comprises a wizard and a graphical environment for DSML creation and editing; a DSML validation engine; and a transformation generator that creates transformations that translate DSML models into high-level programming language code.

The rest of the paper is organized as follows: section II briefly introduces SPL and MDD approach as well as the technology used in the project; section III discusses some related works; section IV describe the DSML and its validation respectively; section V details the transformation; section VI presents the solution validation; and section VII presents the conclusions and future works.

DOI reference number: 10.18293/SEKE2019-089

II. BACKGROUND

Among the approaches proposed to increase the productivity of development processes and the quality of software products, SPL and MDD stand out particularly in a context of an information system that needs non-trivial and extensive customization for each specific customer as it evolves.

A. *Software Product Lines and Model-Driven Development*

An SPL is a set of software products with similar features that share a common infrastructure and the parameterization of differences among the products [3]. The features of an SPL are usually classified as mandatory or optional and can be used to specify variabilities and commonalities among software products. The development of software using SPL is based on a set of core assets, defined according to the commonalities and variabilities of a specific domain, used to derive new products of the line.

MDD is a software development approach based on higher abstraction level models, and (semi) automatic transformation of these models into other lower abstraction level models, and frequently, in the end, into source code [4]. These models are typically expressed as UML diagrams or by using DSMLs. Therefore, the use of MDD requires the definition/adoption of a modeling language as well as transformations to convert models, instances of the modeling language, into other models and code.

Those who propose DSML-based variants of MDD typically argue that software representation through DSMLs is more expressive and more straightforward than using general-purpose modeling languages, such as UML, and can be used by a broader universe of professionals, particularly domain experts, not just experts in UML modeling.

B. *SIS product family*

A SIS “consists of several basic functional modules to support features such as system setup (e.g. managing users, roles, countries, buildings, rooms, faculties, and departments), academic setup (e.g. managing courses, course sections, and study plans), admissions, student record management (e.g. managing personal information, scholarships, schedules, grades, transcripts, major transfers, etc.), registration (i.e. adding and dropping courses), final exam scheduling, grade processing (i.e. entering grades, computing Grade Point Averages (GPA), and viewing transcripts), graduation, and reporting” [5].

A SIS can be best understood as a product family because different institutions will have many similar software needs but also many typically non-trivial specificities.

III. RELATED WORKS

MDD has been used to develop the variable parts of a product in an SPL for more than ten years, usually in telecommunications, banking, embedded systems and automotive domains [8].

Many authors propose development approaches based on SPL integrated with MDD through which models are generated

using DSMLs. Among them, [9] propose the use of DSMLs to configure instances of product families. [10] argue that building a language and framework for a narrow domain makes more economic sense in the context of a software product family. Multiple DSMLs are required to describe a business application. [11] propose the use of DSMLs to deal with both product family variability and that of a single product over time. [1] claim that DSMLs are useful to define the specific configuration of a particular member of a family of systems. They also consider that, in general, it is necessary to define several different DSMLs for a complete application. [12] argues that libraries or frameworks are alternatives to building a DSML and that a DSML should only be developed when there is sufficient domain knowledge and conventional programming techniques fail to provide adequate abstraction mechanisms.

Regarding specific case studies that integrate SPL and MDD, [13] propose FArM (Feature-Architecture Mapping) method, which is based on a series of transformations that generate architectural components that encapsulate the business logic of each transformed feature, and the interfaces directly reflect the interactions of the feature. [14] presents a case study in the automotive domain, comprising guidelines for the development of architectural transformations on a model that represents different points of view of a system. [15] performed a case study in the health domain to illustrate the transformation process for product generation of an SPL. They used DSMLs to model the architecture and the application. Then they modeled points of variability according to the needs of some users who used the application and automatically transformed those models into products with the requirements requested by the users.

In the same way as the works mentioned above, we integrate SPL and MDD. However, we apply this strategy to support the development of systems in the education domain, where, to the best of our knowledge, it has not been used before.

IV. DSCHOLAR DSML

This section presents the DSML defined to support the development components for evaluation criteria using MDD.

DSCHOLAR is a domain-specific modeling language defined as part of our MDD solution to represent the domain of student evaluation criteria used in the SIS product line. To create the DSCHOLAR metamodel, we used the process proposed by [16]. It is bottom-up, iterative and incremental, where we start with examples, define one version of the metamodel based on those examples, and iterate through other examples, and so on.

DSCHOLAR’s abstract syntax is presented in figure 1, where a model that represents a specific evaluation criterion comprises one *Entity* and many *Evaluations*

An *Entity* represents the area to which the same evaluation criteria applies, such as a university or department of a university – or even a single class of an academic subject. An *Evaluation* represents the specification of an evaluation that is applied by the *Entity*, in each academic period. Each *Evaluation* has four attributes: *name*, *weight* (the relative weight of one evaluation relative to the others), *description* and *sequence* (the sequence in time of each evaluation). The relationship between an *Entity* and

their corresponding *Evaluation* is defined through the association *EntityReferencesEvaluation*.

In DSCHOLAR, *Evaluation* is a general concept, specialized by five other concepts: *Mandatory Evaluation*, which must be applied; *Optional Evaluation*, which is part of the evaluation criteria but that may be applied at the teacher's discretion; *Various Evaluations*, that applies when teachers are free to define a number of evaluations not predefined by the evaluation criteria; *Extra Evaluation*, which is a special evaluation whose grade is to be added to that of another evaluation grade; and *FinalEvaluation*, which is applied only when the student does not reach the Entity average.

There is a composition relationship between an *Evaluation* and itself. This means that the grade of a student in a particular evaluation may be a composition of grades of sub-evaluations, each with its own specific weight.

Some OCL constraints (not showed here due to a lack of space) were specified in order to guarantee model integrity, e.g. to ensure that the sum of the weights of sub evaluations corresponds to the weight of the super evaluation.

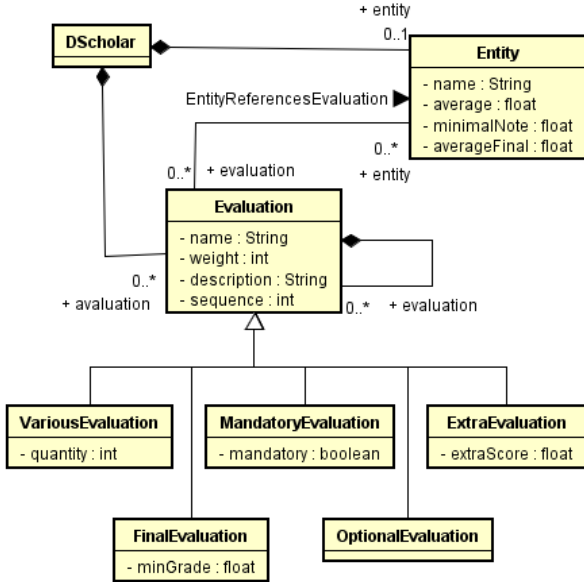

Figure 1 - Abstract Syntax of DSCHOLAR

Figure 2 shows an example of a model defined for a specific university. As can be seen, there is one *Entity*, named *Private Institution* and three *Evaluations*, named *Evaluation1*, *Evaluation2* and *Evaluation3*, with their respective relative weights (30, 40, 30). In this example, all the courses at the *Private Institution* adopt the same evaluation criteria. The round-cornered rectangle of the first two evaluations as well as the Boolean values (true) at the bottom of them is the concrete syntax used to specify that all of them are mandatory evaluations. The third evaluation is an optional one, which is depicted by a rectangle in a different color.

Regarding the number of *Optional Evaluations* in a model, there are two different modeling options. If the quantity of optional evaluations is already defined for an *Entity*, each one of these evaluations is represented by an instance of an *Optional*

Evaluation modeling element in the respective model. Or, each teacher can define their quantity so that the model will have only one instance of *VariousEvaluations* and an attribute *quantity* is used to define the upper boundary of this quantity.

In Figure 2 the grade of *Evaluation 2* is a composition of *Test Evaluation*, *Arhte Evaluation* and *AIC Evaluation*, each with their respective weight. The *Arhte Evaluation* is an extra one (with a different color and small icon), which means that its grade will be added to the grade calculated by the weighted mean of the other sub-evaluations of *Evaluation 2*. For example: if the weighted mean of *Test Evaluation* and *AIC Evaluation* is 8 for a student, and the grade of *Arhte Evaluation* is 1 for the same student, the student's final grade in *Evaluation 2* will be 9.

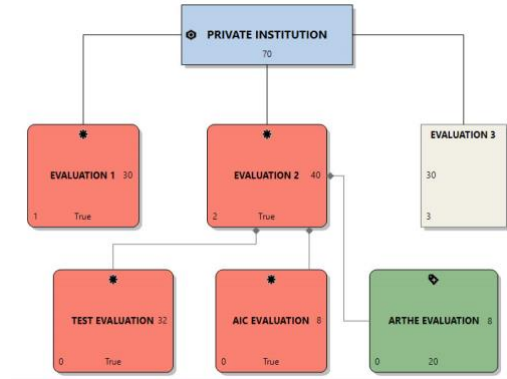

Figure 2 - Evaluation criteria model for a private University

V. CODE GENERATOR

This section presents the transformation, named *dscholar2Code*, developed to support code generation of the component Evaluation Criteria of the SIS. The transformation receives as input a DSCHOLAR model specifying the evaluation criteria of a specific institution or one of its units and generates as output the correspondent code in C# language.

A five stages process was defined to specify the transformation *dscholar2Code*. The first stage, named *Product Design*, concerns the architecture and design definition. The MVC (Model-View-Controller) architectural pattern [18] was used because it is well suited for a web information system. For the component *Evaluation Criteria*, the Model layer was specified using the DSCHOLAR metamodel as input.

The second stage, *Implementation Strategy Definition*, deals with the identification, in the class structure modeled by the previous step, of the elements of each class which are variable or static. The variable elements must be dynamically generated, and the static ones are generated manually. Based on this, for each class, the code snippets which should be generated automatically, and which snippets should be static are determined.

For the component Evaluation Criteria, the templates defined for the View layer are also dynamically customized using the DSCHOLAR model as input. The Control layer is manually generated as it does not vary according to the evaluation criteria. The Model layer comprises dynamically and statically generated code. The code to be statically generated was the structural part of the class *Entity* and the declaration of its attributes, such as

entityName, *meanGrade*, *lowestGrade* and *finalMeanGrade*. The part to be dynamically generated was the methods *loadEntity()* and *generateEvaluationsList()* because they contain information that varies according to the student evaluation criteria of the input model.

At stage 3, *Transformation Rules Definition*, transformation rules must be specified. They map the elements of DSCHOLAR and the bits of code that are dynamically processed by the transformation *dscholar2Code*. The transformation code reads a model and manipulates its elements through tags in order to dynamically generate code that is inserted in the respective template source code. Therefore, in order to specify transformation rules, we map each relevant element of DSCHOLAR metamodel into a tag in the transformation code.

Stage four is called *Transformation Implementation*. The language used to implement the transformation code is based on templates, where a predefined template contains the code parts which are static as well as the specific points where the dynamic code must be inserted when generated.

A loop-like programming structure was used, which reads a model (like the one shown in Figure 3) in search of instances of the *Entity* and *Evaluations* elements as well as their attributes in the input model. Figure 4 shows the implementation of the method *generateEvaluationsList()*.

```
Public void loadEntity(){
    <# foreach(Entity ent in this.Dscholar.Entity){ #>
        this.entityName = "<# ent.name #>";
        this.meanGrade = <# ent.meanGrade #>;
        this.lowestGrade = <# ent.lowestGrade #>;
        this.finalMeanGrade = <# ent.finalMeanGrade #>;
    <# } #>
}
```

Figure 3 - Part of the code of the method *loadEntity()*

The method *loadEntity()* assigns a value to each attribute of each object of the *Entity* class existing in the input model. The code in Figure 3 illustrates the search for an instance of type *Entity* in a DSCHOLAR model, and the storing of its attributes *entityName*, *meanGrade*, *lowestGrade* and *finalMeanGrade* in the instance of the C# *Entity* class being generated.

```
public void generateEvaluationList(){
    <# foreach (Evaluation av in this.Dscholar.evaluations){ #>
        <# if (av.Targets.Count == 0){#>
            <# if (av.GetType().GetProperty("mandatory") !=
            null){#>
                this.evaluations.Add(new Evaluation("<# av.name
            #>",<# av.weight #>",<# av.description #>",<# av.sequence
            #>, 1 ));
            <# } } }#>
        }
}
```

Figure 4 - Code of the method *generateEvaluationList()*

The code of the method *generateEvaluationList()* (Figure 4) is dynamically generated based on the list of *evaluations* that are part of each entity in the input model. As a result, it will fulfill a list in the C# code (named *evaluations*) which contains all the corresponding evaluations of the input model. When this generated code is executed it scrolls the list instantiating each one of the evaluations.

Once the transformation is implemented, it is tested

(*Validation Transformation*, stage 5 in our method). This is described in the next session.

VI. PROPOSAL EVALUATION

In order to evaluate our proposal we performed a case study, to evaluate the expressiveness of DSCHOLAR in specifying evaluation criteria in different scenarios, and a proof of concept, to evaluate the correctness of the code generated by the transformation *dscholar2Code*.

The case study consisted of the specification of different evaluation criteria at four universities. To assist the validation, we followed the metamodel design method proposed by [16] and the guidelines for software engineering experimentation presented in [17]. The questions underlying the validation are: Q1. Do the language constructors sufficiently specify all the needs of a university evaluation criteria? Q2. Is it necessary to add new constructors in the DSML to enable the specification of different evaluation criteria scenarios?

Data collection was done using a direct method, through the application of a questionnaire during the execution of the study; and an independent method, through the analysis of the documentation produced by the participants, i.e. a model, written in our DSML. The metric used to evaluate the study was *DSML coverage*, which was measured two indicators: *#UC* (used constructors) and *#MC* (missing concepts). *#UC* measures the number of DSML constructors used in a model, collected from the model produced by the teaching staff; *#MC* measures the number of concepts present in the university academic evaluation criteria that could not be modeled by our DSML, collected in the questionnaire answered by participants. *#UC* is used to identify how many constructors as well as which of them has been validated through the study. *#MC* is used to improve the DSML. The goal is that after some validations, the *#MC* becomes zero, indicating that the metamodel covers the definition of many kinds of evaluation criteria.

As we iteratively validated and modified the DSML during this study, at the end of the fourth validation, we observed that all the concepts defined in our DSML were used in the models produced, i.e. *#UC=100%*. Therefore, we can say that it covers the necessary constructors to instantiate the models (related to Q1). Moreover, the missing concepts identified during the process were included and are now part of the language (related to Q2). We know that the study results are limited and do not provide statistical evidence to support general conclusions. However, we believe that it can be considered an initial step in planning future case studies. The validation reached its goal, i.e. the DSML has enough expressiveness to specify evaluation criteria at different universities.

The transformation *dscholar2Code* was validated using a proof of concept, to evaluate the coherence of the generated code in relation to the model input model specified using DSCHOLAR. To guide the transformation evaluation, the following research questions (RQ) were defined: RQ1: are all the evaluations specified in the model present in the component code? RQ2: are the evaluation criteria defined in the input model included in the component code? RQ3: are the mean grades correctly calculated? In RQ1 we want to know if all the evaluations were considered when generating the code and in

RQ2 we want to evaluate if the evaluation details (e.g. weight) were all mapped to code.

The validation was performed using models of three different universities. These models were specified in the case study carried out to validate the DSCHOLAR modeling language. At the end of the tests we observed that: (i) the code generator produced the code corresponding to the models in all the cases tested (related to RQ1); (ii) the grades calculated in our system were equal to the ones calculated in the university systems (related to RQ2 and RQ3). Based on these results, we conclude that, for the examples used, the transformation has covered all the evaluation criteria of the three universities, and is therefore satisfactory for the established purpose.

VII. CONCLUSIONS

In this project, we improved the development of Student Information Systems providing them with flexibility and productivity in modifying and evolving student evaluation criteria. The integration of SPL and MDD approaches was decisive in this improvement. In order to support it, we defined a small DSML, typical for each sufficiently complex variation point; the source code is partially manually generated using software frameworks, and partially automatically generated through transformations that generate code that integrates with the frameworks.

Our strategy is to evolve our SIS line iteratively, i.e. analyze variability points and, when adequate, provide them an MDD solution to improve development, as we did with the evaluation criteria component.

The solution allows a domain expert to model the evaluation criteria, using the small, easy to use DSML DSCHOLAR. Some training may be necessary for teachers or other non-IT professionals to use it, but the language has very few modeling elements and relationships types, which should facilitate its use.

Automatic code generation was achieved with the *dscholar2Code* transformation, but only to the point where C# source code is automatically generated. To achieve full automation, a mechanism that compiles and deploys the code in the production environment must be created and integrated with a configuration management mechanism that appropriately stores and selects the right binary code in each situation.

DSCHOLAR provides a way to identify each set of specific evaluation criteria, by identifying the *Entity* that uses these evaluation criteria. As a result, each professional authorized to define and to apply the evaluation criteria must be associated to a specific *Entity*. The Entity can be as encompassing as an entire University or as granular as a single teacher or class.

DSCHOLAR and *dscholar2Code* have been tested in case studies and a proof of concept and, although it has been demonstrated to be satisfactory, it has limitations. We are, however, working on a case study with professionals from several other universities to more accurately assess the solution and reach more generalized conclusions.

This project will evolve to cover other variation points of the SIS product family and to implement the build/deploy/configure mechanisms outlined in this section.

chris.porter@um.edu.mt

Abstract—Information Anxiety is defined as “stress caused by the inability to access, understand, or make use of information necessary for employees to do their job”. Even though it is in itself an intangible phenomenon, it is widely acknowledged and has been linked to impaired decision-making ability, information withdrawal, information avoidance, burnout and other health issues. The ICT industry is acknowledged to be a fully fledged knowledge industry. That is to say that its workers are mainly tasked with creating, understanding, applying and distributing knowledge as part of their day-to-day job. The industry is also characterised by disruptive innovations, continuously changing technologies and customers who constantly change their mind about what they want systems to do.

In this paper, we present the results of a study which tracked 18 participants for a period of one month in order to investigate the presence of information anxiety in the Maltese ICT industry. Our results indicate that information anxiety is present in non-trivial levels amongst our cohort of participants, with information overload being the predominant cause. Also, participants working in a quality assurance (QA) function are more exposed to the phenomenon as well as being exposed to a wider variety of sources of anxiety than developers. Experience is also shown to be a factor with participants being less prone to symptoms of information overload as they gain more experience in the field.

Index Terms—Information Anxiety, Software Engineering, Empirical Study

I. INTRODUCTION

In 1956, white-collar workers outnumbered blue-collar workers for the first time in US History [1]. Since then, a substantial portion of the commercial world (especially in western economies) has transitioned to the so-called “knowledge economy”. Even though balance sheets list bank balances and material assets, it is widely acknowledged that knowledge is now the primary commodity and knowledge flows are regarded as the most important factors in the economy [2]. Knowledge workers are employees who deliver value to an organisation through the creation, storage, retrieval, dissemination and most importantly, application of knowledge. Yet, where as manual labourers tend to have very well defined and routine jobs with known inputs and specific outputs, knowledge workers have a more dynamic and less tangible context to deal with.

The ICT industry is a prime example of a knowledge industry, composed exclusively of knowledge workers. A

typical software engineer is expected to possess up-to-date in-depth technical knowledge as well as intimate knowledge of whatever domain she happens to be working in, so as to be able to deliver technical solutions in that domain. These technical solutions tend to be highly complex in nature and constantly evolve so as to (1) help customers remain competitive in dynamic markets; and (2) remain current with latest developments and best practices in technology. In the course of a working day, a software engineer will participate in several knowledge-centred activities. These include attending meetings in which status updates are communicated, discussing solutions to technical problems with peers, implementing technical solutions, responding to customer and management queries, fixing issues, mentoring peers, and so on. This can become overwhelming. Misra and Stokols [3] lament the rapid growth and transmission of information in the digital age and argue that this poses new challenges for individuals dealing with the onslaught of communications from multiple sources. Unless properly managed, these challenges can lead to anxiety and burnout, which in turn leads to employees losing interest, exhibiting lower activity and feeling powerless [4]. This is where the phenomenon of *information anxiety* becomes more tangible.

Wurman [5] defined *Information Anxiety* as being the “stress caused by the inability to access, understand, or make use of information necessary for employees to do their job”. Considering the contribution that the ICT industry makes to national economies [6], as well as its key role in helping other industries to grow and flourish [7], we argue that the industry needs to be aware of information anxiety, be able to detect it, and subsequently manage it.

A. Research Questions

Whilst talk of employees burning out and leaving companies can be heard around many water coolers and in the halls of conference coffee breaks, to date and to the best of our knowledge, there has been no empirical study that demonstrates the presence of information anxiety in the ICT industry. In this paper, we begin to bridge this gap by following 18 ICT professionals in Malta for a period of one month in order to investigate the following research questions:

DOI reference number: 10.18293/SEKE2019-095

- RQ1: To what extent is information anxiety exhibited by employees in the Maltese ICT Industry?
- RQ2: What insights can be gained regarding the sources of information anxiety in the Maltese ICT industry?

II. INFORMATION ANXIETY

The term *information anxiety* was first coined by Wurman three decades ago, and was defined as “stress caused by the inability to access, understand, or make use of information necessary for employees to do their job” [5]. Since then, information anxiety has been studied in a number of contexts and from a variety of points of view. A substantial portion of the literature equates information anxiety with information overload. Hartog [8] sets out a whole set of lingo that has evolved around the concept including terms such as *info-glut*, *techno-stress*, and *information addiction*. Burkhardt et al. [9] define information anxiety as “a feeling of being overwhelmed that comes when confronting a large information task”. Using more visual language, McCarthy [10] defines it as “a kind of stupor, a feeling that we simply can’t keep up, can’t read fast enough, don’t know how to locate the information we need, don’t have time to sort through or think about all the data surrounding us”.

A. Sources of Information Anxiety

Whilst the tendency in the literature is to equate information anxiety with information overload, we argue that knowledge needs in the ICT are so complex that it is worth considering Wurman’s [5] wider definition and his explanation about the causes of the phenomenon. Wurman states that information anxiety can be caused by one or more of five possible causes: (1) an individual’s *inability to understand* the information required to carry out a task; (2) *feeling overwhelmed by the amount of information* that needs to be understood in order to complete a task (information overload); (3) someone not knowing whether the information required to complete a task *exists or not*; (4) knowing that information exists but not knowing *where to find it*; and finally (5) knowing where the information is but *not having access to it*.

B. Effects of Information Anxiety

Several studies have been carried out with the intent of uncovering the effect of information anxiety on employees. The three most common themes to emerge are (1) an impact on job performance; (2) psychological impact; and (3) a detrimental effect on the health of individuals.

1) *Impact on Job Performance*: After studying managers in a cross-national survey, Waddington [11] reports that 43% of managers claimed that information anxiety impaired their decision-making ability. A decade later, Williams [12] reported similar findings on impaired judgement in a similar study. Bawden and Robinson [13] claim that damage-limitation strategies resorted to by employees who were exposed to information anxiety tend to reduce their effectiveness and result in a negative impact on their employing organisation. Misra and Stokols [3] studied 484 undergraduate students

and found that those exposed to high levels of information anxiety devoted less time to contemplative activities. In the context of a knowledge organisation, this would result in employees not investing the time in innovation that is essential for maintaining a competitive edge.

2) *Psychological Impact*: Katopol reports that individuals exposed to information anxiety can have any combination of sensations including feeling overwhelmed, intimidated, fearful, lost, threatened, stressed, uncomfortable and/or timid [14]. Fox reports that the phenomenon leaves employees feeling a sense of loss of control [15] whilst Waddington [11] found a link to tension and reduced job satisfaction.

C. Detrimental effect on Health

In more severe and prolonged cases, information anxiety has been observed to affect individual’s physical health. Misra and Stokols [3] positively correlated higher levels of perceived information anxiety with incidences of physical health problems. Waddington [11] also reports that 42% of managers in his study believe that information overload affects their physical health. Similar conclusions were reached by Ifijeh [16], as well as Bawden and Robinson [13].

D. Measuring Information Anxiety

The main stumbling block with addressing information anxiety is the fact that it is difficult to detect before it reaches harmful levels. A review of the literature revealed two alternatives for measuring the levels of information anxiety in individuals.

Based on the argument in health research communities that the impact of objectively stressful events depends largely on one’s perception of their stressfulness [17], Cohen et al. [18] propose their Perceived Stress Scale (PSS). The method involves asking participants to answer 14 questions with one of *never*, *almost never*, *sometimes*, *fairly often* or *very often*. The answers are assigned numerical values of 0 through 4 for questions with a negative bias¹ and 4 through 0 for questions with a positive bias². The PSS score is calculated by summing the scores of all 14 questions and through three case studies, Cohen et al. showed the measure to be a reliable and sound predictor of various psychological indicators such as depressive symptomatology and social anxiety.

In order to assess information anxiety in the Canadian Air Force, Girard and Allison [19] used Wurman’s [5] five causes of information anxiety as a starting point. Participants in their three studies rated their agreement with statements on a scale of 1 (strongly disagree) to 5 (strongly agree). The statements were as follows:

- 1) I would not understand the data required to complete this task.
- 2) I would feel overwhelmed by the amount of data to be understood to complete this task.

¹Example: In the last month, how often have you felt nervous or stressed?

²Example: In the last month, how often have you felt the you were on top of things?

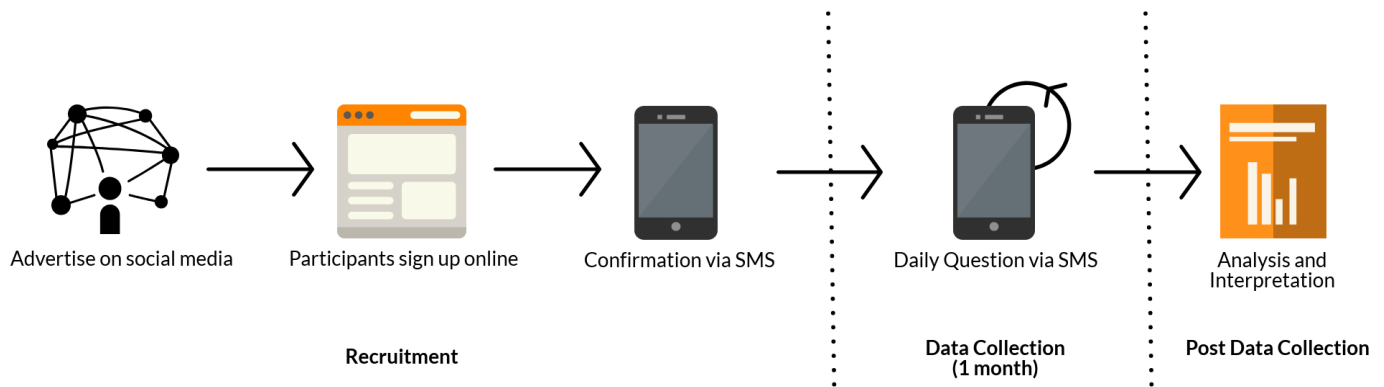

Fig. 1. An overview of the research protocol adopted for this study.

- 3) I would not know if certain data necessary for this task exists.
- 4) I would not know where to find data necessary for this task.
- 5) I would know exactly where to find the data, but I would not have the key to access it.

By summing up the ratings of individual components, Girard and Allison were able to measure the overall level of information anxiety experienced by an individual at a particular point in time. Although simple in nature, the measure is expressive both in terms of overall information anxiety, as well as in terms of the contribution of individual sources of anxiety.

III. METHODOLOGY

The research protocol was designed with the goal of regularly collecting empirical data from participants over a period of one month whilst minimising disruption to participants' daily routines. When considering the two alternatives for measuring information anxiety discussed in Section II-D, Cohen et al.'s approach [18] was ruled out because requiring participants to answer 14 questions on a regular basis would be disruptive. Instead, a modified version of Girard and Allison's [19] survey instrument was adopted. The method was aligned to the requirements of this study such that only one of the questions was asked to each participant every day. This reduced the disruption caused to participants whilst also collecting multiple data points as we followed individuals over a period of one month.

A survey mechanism utilising SMS technology was designed and implemented. As depicted in Figure 1, the study was partitioned into three phases. In the first phase, participants were recruited by means of adverts in social media groups that directed interested people to a sign-up form that collected some basic demographic information. They were later asked to confirm their participation via SMS so as to ensure that we were able to communicate with them over that medium.

The second phase consisted of data collection. Every working day for a month, participants received one question via

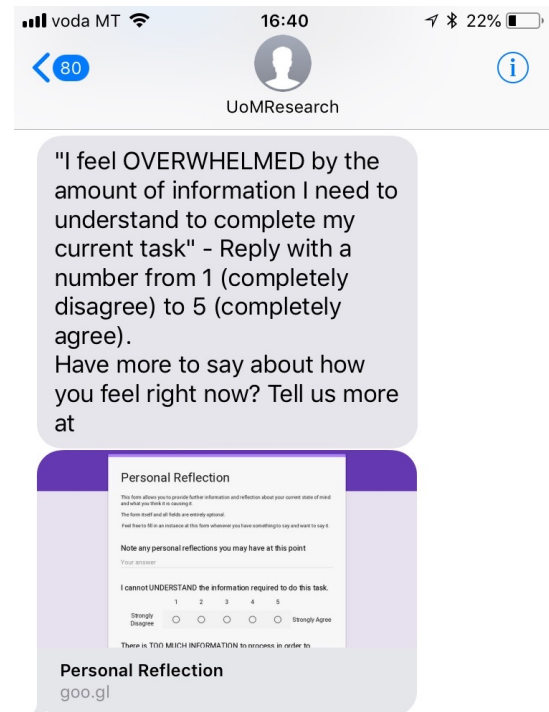

Fig. 2. A typical question sent to participants via SMS, including a link to the personal reflection form.

text message similar to the one shown in Figure 2 every day at 11am. The choice of question was randomised but once a question was asked, it would not be asked again before all other questions had been asked to the same participant. The time that questions were sent to participants was chosen deliberately so as to maximise the chance that participants have arrived at work, gone through their morning rituals and have started working. In order to minimise disruption, candidates were required to reply to each question by a text message containing a number between 1 (strongly disagree) and 5 (strongly agree). Participants were also provided with a link to a personal reflection form whereby they could optionally

provide further insight.

Finally, after the data collection period was over, the data was collated, analysed and interpreted.

IV. RESULTS

In this section, we present a digest of the key observations we gained from analysing the data collected during the study.

A. Participant Demographics

Eighteen participants signed up and participated in the study. Four demographic attributes were collected as information about participants: role, industry, experience and level of education. There was a relatively uniform distribution in all attributes except for education in which 11% of participants were educated to post-secondary level, 78% to undergraduate level and 11% to postgraduate levels. Participants were highly responsive during the study when it came to SMS responses, with a mean response rate of 79%. However, no participants availed themselves of the online reflection form to provide more unstructured information.

B. Initial Analysis

An initial analysis of the data revealed that when one analyses the cohort as a whole, only 17% of responses indicated levels of information anxiety. This was interesting to us as it went contrary to our initial hypothesis that information anxiety is significant problem in the industry. However, as we dissected the data further to consider participant demographics and individual sources of information anxiety, a more comprehensive picture emerged.

When one considers individual sources of information anxiety, it turns out that eight participants (44%) had a mean rating higher than three for at least one source. All eight of these participants indicated that information overload was the main cause of anxiety, with five participants indicating at least one more cause.

C. The influence of job role

Figure 3 plots a box chart showing the distribution of ratings provided by participants for each source of information anxiety, as well as the combined ratings of all sources, split by job role. One can immediately notice that job role seems to have a determining influence on the overall levels of anxiety registered by individuals. When considering all five sources of anxiety collectively, QA analysts registered comparatively high levels of anxiety with a median value of 2.5 and an upper quartile rating of 4. This contrasts with an upper quartile rating of 2 and 3 for software engineers and project leaders respectively.

Software engineers exhibited arguably negligible ratings across all sources of information anxiety except for information overload. The median of 2.5 and upper quartile value of 4 here indicates that there is a significant perception amongst software engineers in our cohort that they have too much information to process and feel overwhelmed by it. Furthermore, both QA analysts and project leaders exhibit

higher levels of anxiety as a result of information overload with over 50% of ratings from QA analysts being at or above 3.

Consistent with the other two roles, the QA Analyst cohort exhibited was mostly affected by information overload. However, the same cohort also has significant complaints of participants struggling with understanding, being unable to locate information and not having access to information. Project leaders have exposure to a wider range of anxiety sources than developers but the levels of complaints for the upper quartile only ever go beyond 3 for information overload.

D. The influence of experience

The most inexperienced participants reported the least problems related to being unable to understand information related to do their job. The highest problem in this area surfaced amongst participants with 6-10 years of experience in the industry. Conversely, participants with 3-5 years of experience reported the highest levels of information anxiety with 39% of information overload ratings for this cohort being 4 or 5. The data indicates that as participants gain experienced, they suffer less from information overload.

E. The influence of industry

We also analysed data from the point of view of industries in which participants worked. However, except for a marginally higher level of anxiety being reported by participants in the Gaming industry, the data indicates that the domain in which participants work does not have an obvious influence on the levels of information anxiety experienced.

F. Threats to Validity

The study suffers from two main threats to validity. Firstly, the sample size of 18 is not necessarily representative of the industry as a whole. Secondly, the duration of the study (1 month) when compared to the lifetime of a typical project. Having said that, the study is, to the best of our knowledge, the first of its kind to shed light on the levels of information anxiety in the ICT industry and lessons learned here will be taken forward to larger and more longitudinal studies that are being planned by the authors.

V. DISCUSSION

In this section we discuss the results of the exercise in the context of the research questions specified in Section I-A.

A. Presence of Information Anxiety in the ICT Industry

Although the data does not indicate an outright epidemic when it comes to information anxiety amongst our participants, it does indicate that there is cause for concern. This can be better appreciated when one considers that results obtained using Gurrard and Allison's [19] formula for calculating information anxiety can be misleading if one does not consider that it is an aggregating formula. This is because, our data shows that an individual is most likely to be exposed to one source of information anxiety. There were cases where individuals were exposed to two or at most three sources at any point

Fig. 3. Distribution of ratings for sources of information anxiety for Software Engineers (black), QA Analysts (dark grey) and Project Leaders (light grey).

in time but these were very rare. It is therefore likely that Girrard and Allison's formula will even out to a mean, as evidenced by their own studies where the mean value for anxiety readings hovered around 2.5. However, this does not mean that no information anxiety is present. Rather, we argue that a prolonged high rating for even one source of anxiety on one participant should be cause for concern and trigger an investigation to understand the circumstances leading to this.

Whilst it was out of scope for this particular study, individual employees ratings should also be examined over time to look for patterns that might be detrimental to employees psychological health. For example, regular short bursts of high anxiety would produce low average scores but employees could still have significantly negative experiences as a result.

Notwithstanding the small sample of participants, in answer to RQ1, the data collected for this study suggests that information anxiety is sufficiently present in the Maltese ICT industry to cause employers to devise ways of detecting it and measuring it.

B. Insights regarding the sources of Information Anxiety

The results from this study lead us to make three conclusions when it comes to the sources of information anxiety.

1) *The predominance of Information Overload:* Information overload was consistently shown to be the predominant cause of anxiety amongst our participants when compare to the other four sources regardless of job role, experience level or industry. This indicates that the literature's focus on information overload is well founded but not complete. For example, QA analysts demonstrated elevated levels of anxiety across multiple sources of anxiety. In such cases, whilst employees are still being suffering from anxiety the required solutions would be different to those required when the root cause is information overload.

2) *QA Analysts have an anxiety-inducing job:* The indication that QA Analysts suffer from higher levels of anxiety than other job roles is further explained when one examines the individual sub-components of information anxiety as experienced by people in this role. QA analysts tend to act as bridge communicators between the technical side of an organisation

(software engineers) and the so called product side of the business. The need to straddle two different worlds in which people often speak different languages and dialects. That is to say that whilst a software engineer might speak in terms of concepts such as algorithms, efficiency, load balancing and so on, a product-side employee would speak in terms of features, customers and other domain-specific concepts. QA analysts are responsible for ensuring that the technical side of the business delivers the right artefacts to the product side of the business and it is this straddling of two worlds that likely leads to elevated levels of anxiety.

3) *Experience is a factor:* One of the finding of the study is that symptoms of information overload decrease amongst participants with more experience. This is probably due to experienced individuals being able to develop soft skills for setting up barriers against information overload. For example, the simple act of saying No, I cannot deliver this extra feature in the next 2 weeks. has the effect of shielding an individual against any anxiety that might have resulted from committing to the extra task and setting himself up for failure. Individuals who have been around for longer are more capable of gauging the effect that a task might have of them and are more comfortable refuting that work.

VI. RELATED WORK

As discussed in Section I, to date and to the best of our knowledge, there has been no empirical study that demonstrates the presence of information anxiety in the ICT industry. The work the came closest to this is that of work that Mäntylä et al. [4], who did not explicitly discuss information anxiety but did discuss the ICT sector and highlight a number of related concepts and symptoms.

Mäntylä et al. claim that employees in the ICT sector are susceptible to "psychological diseases such as burnout, which lead developers to lose interest, exhibit lower activity and/or feel powerless" [4]. They propose a set of metrics called the VAD metrics, named after the first letter of three attributes which they measure: (V)alence, the level of enjoyment exhibited by individuals carrying out a task; (A)rousal, the level of alertness and readiness to act; and (D)ominance, the level to

which individuals are in control of their task. Using a database of 13,915 manually rated English words as created by Warriner [20], Mäntylä et al. calculated VAD scores on 700,000 Jira³ tickets containing over 2,000,000 comments. This resulted in a number of interesting conclusions regarding how valence, arousal and dominance in individuals varies based on how long a ticket remains open, how its priority changes and when it is eventually resolved. For example, their results indicate that burnout (low valence, low dominance and high arousal) is more likely when working on high priority issues that take a long time to resolve. Whilst Mäntylä et al. do not make the link with information anxiety, as discussed in Section I, software engineering is a knowledge-intensive activity and a prolonged unsolved issue is likely to be caused by a lack of understanding, information overload or issues with finding and/or accessing relevant information.

VII. CONCLUSION AND FUTURE WORK

In this paper we discussed the methodology and results of a study that was designed and executed to shed light on the presence of information anxiety in the ICT industry. By tracking anxiety levels amongst 18 participants on a daily basis for one month, we discovered that information anxiety is indeed present at non-trivial levels with information overload being the predominant cause. We also discovered that QA Analysts are more likely to suffer from the phenomenon, as are less experienced individuals. Finally, we discovered that the domain in which employees work does not have a significant bearing on anxiety levels.

A. Recommendations

This study contributes a non-intrusive data collection protocol that can help companies shed light on levels of information anxiety amongst their employees. Implementing a similar mechanism which collects data at possibly less regular intervals using company's intranet or time-sheet system would provide managers with valuable empirical data. This data can subsequently be analysed and tracked such that any emerging problems with information anxiety can be investigated and addressed before they cause substantial harm. Furthermore, the knowledge that employees in certain job roles are more susceptible to the phenomenon should lead to a review how these roles could be restructured in order to lessen the likelihood of information anxiety emerging.

B. Future Work

Having taken the first step towards investigating information anxiety in the ICT industry, we plan continuing this work across two prongs of research. number of related projects in the near future. Firstly, we would like to *set up a longitudinal study* which spans a longer period, ideally a year or more. This would allow us to gain insights into how and why anxiety levels change over time. We anticipate that the main

problem with such a study would be maintaining participant engagement, and to this end we are currently investigating the possibility of utilising gamification to achieve this.

Secondly, we would like to investigate the sources of anxiety in more detail. In particular, we are interested in understanding if there are any relationships between specific components and whether these are amplified in particular contexts. Insights gained in this area could lead future studies with a more refined focus on specific contexts or sources of anxiety.

³Jira is a commonly used tool in the ICT industry which enables stakeholders to report issues with software (or request new features) and track work and discussions by developers whilst development progresses.

A Case Study of a Software Development Process Model for SIS-ASTROS

Camila Hübner Brondani, Otávio da Cruz Mello, Lisandra Manzoni Fontoura
Departamento de Computação Aplicada – DCOM
Universidade Federal de Santa Maria – UFSM
Santa Maria, Brazil
{chbrondani, odmello, lisandra}@inf.ufsm.br

Abstract — **Context:** technological innovation projects, developed in universities in partnership with companies and/or the government need processes that can handle the characteristics of the institutions involved. The academic environment is often used to dynamic methods, but contracts require plan-driven processes. **Goal:** the goal of this research is to understand the needs of the parties involved (university and government/enterprise) and provide an adapted software process to satisfy those necessities. **Method:** a case study considering a project between the Federal University of Santa Maria (UFSM) and the Brazilian Army (BA) for the development of an Integrated Simulation System was conducted. Initially, problems in the development were detected and a process was defined. It was then evaluated and improved over the iterations, through team meetings. **Results:** the experience acquired in the project was consolidated as lessons that could be used to assist the process definition of projects with similar characteristics. **Conclusion:** innovation projects involving the collaboration of universities, government and/or companies are successful if an adequate process is established to treat specificities of the academy, not only in relation to characteristics of the work but also the team.

Keywords—*process, triple helix, ASTROS, case study.*

I. INTRODUCTION

The university today, besides the academic activities and the pure research, promotes the development of applied research aiming to generate innovation solutions from issues presented by governmental institutions and enterprises. The triple helix thesis states that universities are distancing themselves from having a secondary social role, although important, of providing higher education and research, and is taking a primary role equivalent to the industry and the government, generating new industries and companies [1].

In this context, the Federal University of Santa Maria (UFSM) started a project to develop an Integrated Simulation System for the Brazilian Army (BA) in 2015. One of the initial challenges of the project was defining an adequate process model. Since there was an agreement between the BA and the UFSM with predetermined goals and deadlines, a plan-driven process model would be more satisfactory. On the other hand, the research needed for the system development could not be predictable, requiring investigation, prototype development and evaluation. The set of requirements was vague; the team was formed of high-skilled workers with autonomy. Based on these aspects, agile methodologies could be considered more proper.

Understanding the peculiarities of a project involving the university and government is crucial to choose an adequate process model that can satisfy the needs of both parties.

In this article, we will describe the lessons learned during four years of a research project between the UFSM and the BA and the process model that was used in this development, adapted over the iterations. Our goal is that the lessons learned and the process model can assist the definition and/or adaptation of models that are used in projects involving universities and governmental institutions or private companies.

The project in question proposes the development of a Tactical Virtual Simulator aiming the military training in tactical operations related to the use of an ASTROS battery (Artillery Saturation Rocket System).

Some important characteristics of the project are: need of meeting semi-annual goals pre-defined at the start of the project, difficulty of defining requirements due to the system's complexity, the unfamiliarity of the development team with the area of application, high-skilled workers, and constant need of innovative solutions research.

Those attributes led the definition of the software process. An evolutionary and iterative life cycle was defined, where intermediary versions of the software are generated and evaluated constantly by the client, easing the definition of new requirements for the next iteration. Besides that, milestones were defined with the purpose to satisfy contractual obligations. The process was evaluated and improved over the course of the project and the experience acquired was consolidated as learned lessons to be used in the development of other similar software projects.

This article is organized as follows: in Section II, important concepts to the comprehension of this work are introduced. In Section III, related works are discussed. In Section IV the context of the case study is described. In Section V, we define the proposed process. In Section VI, discussion and analysis are presented. At last, in Section VII we discuss our final considerations and comment on future works.

II. BACKGROUND

Modeling of software process has been a very challenging problem and constantly debated in the software development community in the past 30+ years, largely due to the complex nature of the software development process that involves not only the technical knowledge and skills but also

many other factors, such as human, management, quality assessment, and cost [2]. The modeling of business processes aids in the comprehension and optimization of existing business processes, and also in the conception of new business processes to make organizations more competitive and efficient [3].

Software development strategies have gradually shifted from the traditional waterfall model to more dynamic and responsive iterative, multi-cycle strategies. The reason usually cited is the need to minimize risk in the process [4].

Traditional iterative software development efforts such as spiral development or iterative enhancement can be considered adaptations of the waterfall software life cycle [5]. This is because these methods generally assume that the entire documentation required by the waterfall method will still be produced, but will be rewritten and updated during each cycle rather than once for the entire software process [5].

Agile processes are different from traditional software processes in that the time per cycle is very short and many fewer formal methods are employed. They focused on repeated lightweight practices for rapid and continuous delivery of software in small chunks with close collaboration from the customer as well as among members of the development teams.

No rigid plan or requirement is determined in advance, as these can change during the development process. Being flexible and adaptive to changes are in the DNA of agile methods while still achieve the ultimate goal of producing customer satisfied software within the time and cost framework [5]. Extreme Programming and Scrum are two software development processes that fit this description [5].

Many software development methodologies fall in between plan-driven development and agile development, and exhibit several of the characteristics of agile development. Examples include incremental development, prototyping, and DSDM (Dynamic Systems Development Method) [6].

To mitigate the impacts of abrupt paradigm changes and support organizations that don't want to stop following all traditional practices some proposals were developed for hybrid processes that incorporate principles of agile and traditional paradigms [7].

III. RELATED WORK

The study from Cotugno and Messina [8] presents an overview of the development process, focusing on the Scrum methodology adopted by the Italian Army for the development of software systems using open code technologies.

Benedicenti et al. [9] relate the experience of an agile application in the defense sector. They describe the experience of creating a control and command system for the Italian Army. The delivery of the project happened after 13 sprints of five weeks, meeting all the needs of the users and satisfying the regulatory requirements of the army. Acquiring this positive result demanded collective effort to change the development culture, since there was natural resistance to change, and the need of highest possible support level to

guarantee the continuity of the selected process. The article presents the positive results quantified.

As well as this article, the work from Cotugno and Messina [8] and Benedicenti et al. [9] describe methodologies and techniques used in the software development in an military environment. The main difference is that both are only focused on agile methods.

The work from Jenkis [10] describes the implementation experience of PRO-SOFTWARE, a software quality project involving the government, industry and academy (the triple helix). The goal was strengthening the software industry in Costa Rica, assisting organizations in improving their software processes. Therefore, Jenkis [10] proposes a methodology based on the quality improvement using the Capability Maturity Model (CMM) as base.

IV. CASE STUDY DESIGN

In order to address the research objective, we designed an exploratory case study, which involved a real-world software project. We define a software process based on identified process and analyze this process over several iterations. This section describes the design of the case study.

A. Project Context

The SIS-ASTROS project started in 2015, and is predicted to end in 2020. The main goal of the project is the development of an integrated simulation system to support the teaching of doctrines related to the use of a rocket artillery battery. The development team is formed of 7 doctor professors, 3 researchers, 4 developers, 7 master's degree students and 13 undergraduate students.

In addition, the requirement of the projects were described in high level of abstraction, the UFSM's team did not have the knowledge of the domain and the project required some innovative solutions, mainly related to the simulator's integrity, 3D scenarios generation and autonomous navigation. It is predicted to transfer the technology to the BA at the end of the project.

On the other side, the professors and researchers have long experience in the research field, developing researches to provide innovative solutions in different areas of computer science.

B. Methodology

At the beginning of the development, there was not a process model clearly defined in the project, so the artifacts were not standardized and the flow of activities did not follow a pre-defined roadmap. This scenario brought difficulties in the project management and fomented the definition and elaboration of a software process for the project. Therefore, from this necessity, this research project was initiated. The methodology used by the team to conduct the case study was composed of the four phases described below.

Diagnosis: identification of the problems happening on the project and possible solutions. In this stage, many problems related to the inexistence of a defined software process were found. The discovery of the problems occurred through meetings with the parties involved in the project.

Planning: from the problems identified in the last stage, a process model to be used in the project was proposed, aiming to solve these problems and satisfy the characteristics and necessities of the project and the team at the same time.

Implementation and Evaluation: during the three following years, the process was implemented and improvements were incorporated to it, intending to adapt the project to current needs.

Analysis: the results obtained over the course of the project are presented and the acquired experience is described as lessons learned.

C. Problems Diagnosis

The issues found during the Diagnosis phase can be summarized as follows.

Unfamiliarity with the application domain

The UFSM team did not have knowledge about military doctrines neither terminologies of the field. The manuals were rich in details and very extensive, making it difficult for the team to understand and learn.

Difficulties related to requirements definition

Being an innovative software, the set of requirements was not defined. There were a lot of concerns and doubts about how the simulation system would work and which features would be necessary.

Complexity of solutions

Complex and innovative computational solutions were required to solve the technical issues found during the development.

Rework

The team project was composed of workers with different skill levels, the professors and the researches were high skilled, master's degree students possessed an average level of skill and undergraduate students were low skilled. Since there was a large number of trainees, many problems in the source code were found, like defects, lines that were hard to comprehend and maintain, and issues related to class structuring.

Communication difficulties

Due to the hierarchic communication structure with the client, the information goes through several levels until the

decision taking. This communication flow causes problems like developmental delay, when for example, the team needs to wait for an answer to a doubt.

High team turnover

The students remain in the project while they are taking their graduation or master's degree course, on average two years. Therefore, we have high turnover.

Requirements instability/Changing Requirements

Constant changes in requirements, mainly during the test phases. Many changes occur because of divergent opinions, often due to lack of vision of the whole.

V. PROPOSED PROCESS OVERVIEW

In the planning phase, a software process was developed with intent of proposing solutions to the issues identified during the diagnosis phase while meeting the needs and peculiarities of the government and the academy. On one side, we have a stakeholder that gives priority to software documentation, rigid definition of iterations and deadlines, while on the other side, we have a self-managing team that is focused on development and coding.

The process initially defined was constantly evaluated through the phases and iterations (Implementation and Evaluation phase). The evaluations were performed during meetings, when the parties involved would discuss which practices gave positive results and which should be reviewed, and with this feedback, the process was improved.

The current process is described in Figure 1 (life cycle vision), Figure 2 (iteration activities) and Figure 3 (change management sub-process activities).

Some considerations about the process are described in the following section.

A. Process Life Cycle

Aiming to include the formal deliveries, foreseen in the contract, the life cycle was organized in phases and iterations, as depicted in Figure 1. Two phases are planned: initiation and construction, finished with a major milestone.

The initiation phase only happens once and is responsible for defining an overview (abstract) of the system in development and giving a clear comprehension of the business domain that is related to this system.

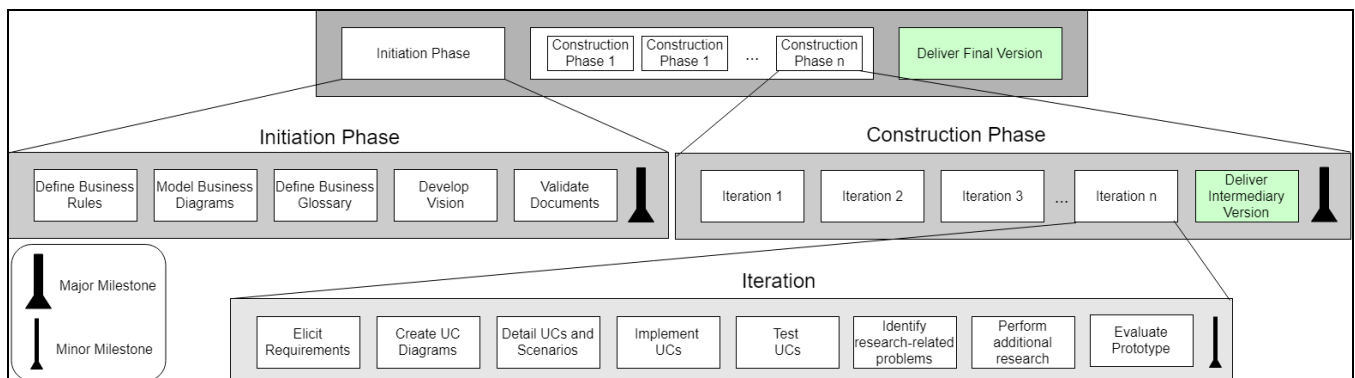

Fig. 1. Life Cycle Vision

The construction phase, on the other hand, is responsible for the execution of the technical activities that will generate a new version of the software. A project can have as many construction phases as needed, and each one can have multiple iterations. Both phases must respect contractual obligations, for this reason, they are finished with a major milestone that indicates a formal delivery to the client.

Since the phases usually refer to bigger time spans (semesters, years), it was chosen to break them in many iterations with the purpose of speeding up the process. Each iteration has its complete development cycle, from requirements definition to version evaluation (Figure 2). The software versions developed in the iteration are always delivered when the phase ends (major milestone). The number of phases and the amount of iterations in each of these phases depend on the project and can be adjusted.

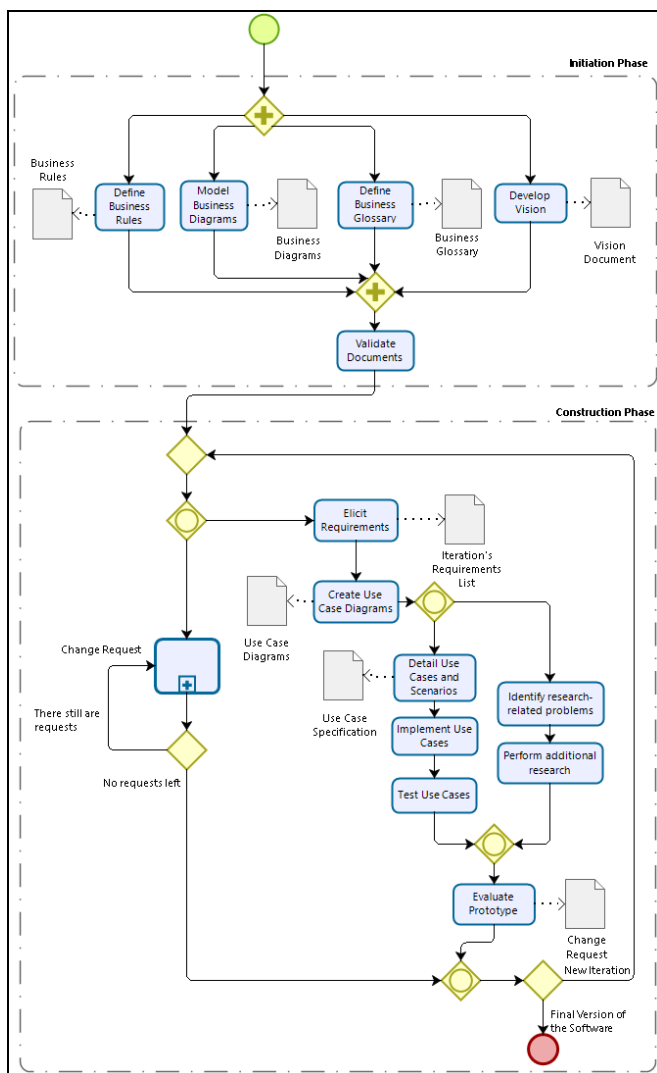

Fig. 2. Iteration Activities

At the end of the iteration, meetings with the client are held to present the intermediary version of the software, in which possible improvements, changes and evolutions are discussed. These meetings are important to track the current progress of the development team.

B. Activities and Artifacts

The initiation phase is composed of four main tasks that happen at the same time: define business rules, model

business diagrams, define business glossary and develop vision. These tasks generate the artifacts business rules, business diagrams, business glossary and vision document, which are formally evaluated by the client. Before the construction phase starts, it is extremely important that the artifacts generated during the initiation phase have been approved by all the stakeholders (task validate documents). When the respective documents are finished and approved, successive iterations start in each phase. Each one has a set of tasks that generate an intermediary version of the software. In the first task, the stakeholders meet to define the requirements that must be implemented in the cycle.

After the requirements of that iteration are defined and prioritized, the specification and detailing tasks start. Diagrams and requirements specification documents are created to assist the team members during the development and the technology transfer process. All the artifacts created in this phase are managed in a requirements management tool.

The tasks identify research-related problems and perform additional research are executed simultaneously, due to constant innovative solutions research. These are incorporated in the simulator in the next iteration.

Once the modeling ends, the team can finally start implementing and testing. If there are issues with a feature that cannot be fixed during the defined cycle, or the programmers are late in the development, an artifact is generated reporting the features that could not be finished, so they can be implemented in the next cycle. As soon as the iteration finishes, the client validates the intermediary version of the software, defining additions or changes that should take place. These are documented and serve as input for the next iteration's requirements definition.

Change requests can be submitted at any time, either to include or modify a requirement that was previously defined. In the main process, the procedure of submitting a change request is seen as a sub-process (Figure 3).

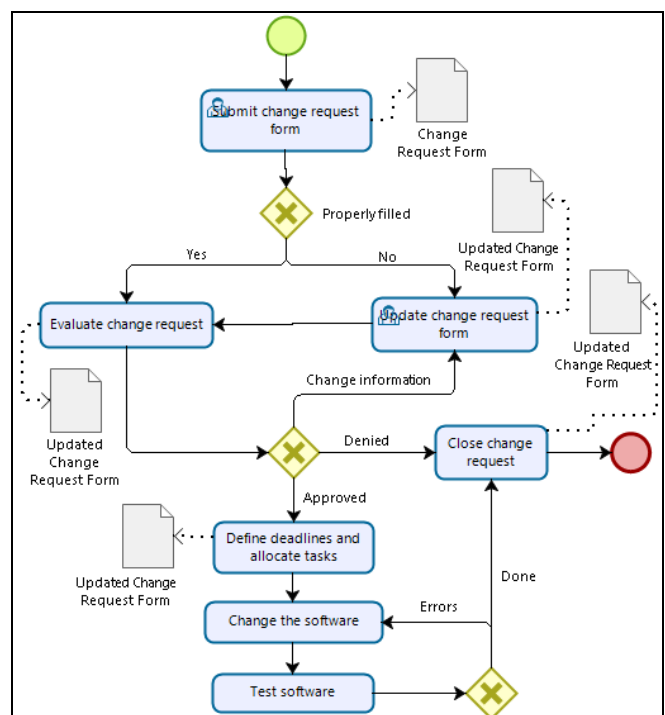

Fig. 3. Change Management Sub-process Activities

This sub-process is basically a flow of activities to manage the changes in the project. First, a stakeholder submits a change request, which is reviewed by a committee and, if the request is relevant, the change is incorporated in the version of the software. However, there are times when no requests are submitted in an iteration, so the change management process will not necessarily occur in the flow, therefore, being optional.

C. Roles

The project team was organized in levels: researcher professors (part time), professionals and researchers (full time), master's degree students and trainees (part time). The researcher professors guide the students in solving research problems and developing their academic works.

Professors are also responsible for the project management. Professionals and researchers are in charge of planning the tasks to be assigned to each member of the team, communicating obstacles to the management and organizing the daily routine of the team. Master's degree students are responsible for guiding the undergraduate students in their activities, helping solving issues regarding tasks assigned to them. The product owner is responsible for the communication between the development team and the client; all the requests from the team are centered on this person, which will track them until they are complete.

The team is collaborative, all the workers are assigned to close workrooms and there is constant exchange of knowledge between the team members.

VI. DISCUSSION AND ANALYSIS

The plan-driven approach served as foundation to the process definition. Using the basic principles: analysis, design, construction and verification, we have the basis for the flow of activities, supporting development of specific documents related to each phase of the project. The contractual aspect of the project, that demands deliveries on a timeframe, is contemplated with milestones at the end of each phase. The documents submitted are important for the requirement of technologic transference at the end of the project.

Allied to traditional models, we've decided to apply some characteristics of agile methodologies to the process as well, in order to emphasize the collaborative and communicative principles of the team and the final user, allowing incremental deliveries and also supporting the constant change requests without affecting or causing time and/or financial damage to the project [11].

Therefore, the method used in the creation of the process was defined as a hybrid between plan-driven and agile models, using the most advantageous characteristics, aligned with the goals of the project. In addition, for each issue found, actions were taken in the software process, aiming to solve or minimize them. They are described below.

Unfamiliarity with the application domain

The solution found was including some tasks at the start of the process with the purpose of comprehending the application domain. Diagrams that represented the domain were elaborated in collaboration with the stakeholders. Besides that, glossaries were also created, that are being

maintained through the course of the project. The BA team has been formally validating these documents.

Difficulties related to requirements definition

It was decided to work on intermediary versions of the software that were evaluated periodically by the BA team. When all the parties approved the prototype, a new set of requirements for the next iteration would be defined.

Complexity of solutions

It required applied research and development of master's essays and final papers exploring necessary solutions for the development of the simulator guided by a researcher in the field.

Rework

The solution was the constant refactoring of the source code, especially at the beginning of the project. Before the formal deliveries, there were periods intended for the code refactoring, with the purpose of improving legibility and documentation, as well as removing unnecessary code lines. We now focus on continuous source-code reviewing. Additionally, there is an internal hierarchy where experienced members assist new ones, helping them developing high-quality artifacts.

Communication difficulties

A formal communication flow was defined so that the parties involved track the information requests.

High team turnover

Some experienced professionals (researchers and programmers) were hired full time. Teamwork is encouraged and constant experience exchange between trainees and experienced members happen, thus, the team shares the knowledge of the system.

Requirements instability/Changing Requirements

Usage of incremental and iterative development, focused on periodic presentations of the intermediary version of the software. A formal change request process was also created.

Based on the results obtained by the execution of the process and the continuous monitoring of the team and the client since the beginning of the project up until now, it was possible to define some of the best practices and adopted decisions that reflected positively on the quality and progress of the project. It is believed that these practices can be applied in software development projects that involve academy and government and/or industry.

Client's periodic homologation

Iterative development allows the team to deliver a functional product to the client at the end of each iteration or cycle. The client can use this prototype over a period of time and provide feedback for the developers in terms of definition of new requirements, change requests and issue reporting. Usually, changes are incorporated into the requirements baseline to be implemented in the next iteration.

Use of diagrams to represent the business domain

Business diagrams helped the team to comprehend the business domain, making future communications more fluid. These diagrams were also used by the client to communicate

with other parties involved in the project. It was possible to represent the BA doctrines fully and clearly, preventing the team from reading manuals that are complex and difficult to understand.

Cooperative work

Team members can learn from each other. The more experienced guide the less experienced. Additionally, each team member knows what the others are developing, and can exchange information. The development of a particular activity becomes priority of the group as a whole, and not property of a certain team member only. The master's degree students mentor undergraduate students in research, that way, team members develop a common sense of responsibility that brings them closer.

Effective communication

The agile processes support the idea of face-to-face communication as the most effective and efficient method of transmitting information in the development team. The UFSM team is allocated in a sole environment. However, since the client team is located in another state, face-to-face communication is not possible. Therefore, to build an efficient communication method, it was necessary to center the communication on the Product Owner. This person is responsible for bringing the military vision to the project and evaluating, along with the team, the enhancements or changes that should take place to ensure that the software fulfill the needs of the BA. Bimestrial face-to-face meetings are scheduled.

Definition of a change management process

The change management process helped to monitor change requests and limited the number of unnecessary requests without the global comprehension of the system.

In the SIS-ASTROS project, we have defined one initiation phase and five construction phases, with duration of six months each. In each construction phase, three bimestrial iterations were established, since there are many part-time workers in the project that need to conciliate their work in the project with their academic obligations, teaching, in the case of professors, and classes and university assignments, in the case of students.

During this time, we managed to meet the goals defined in the project within the time and budget. The BA is satisfied with the results obtained and future projects are being discussed. The formal change request process reduced rework, and the amount of defects in the software has been dropping over time at the same pace performance (response time) has been increasing.

VII. CONCLUDING REMARKS

Projects involving the collaboration between universities and government and/or industry are successful if suitable procedures to handle the needs and peculiarities of the parties involved are established. In the described case study, hybrid process types proved to be satisfactory because they explore plan-driven characteristics – based in contracts, at the same time agile methods are suitable for innovative projects, which involve high-skilled professionals.

It was possible to experience practices from both investigated process in this project, reflecting positively in the developmental quality and progress, solving issues previously detected and establishing a set of learned lessons that can be used in other similar software development projects.

As future work, the main idea is to review the process periodically along with the team, continuously verifying the relevance of the activities and artifacts. As the process is thoroughly used, it may be possible to optimize some activities, thereby making the process less bureaucratic.

The fact that this approach was only applied in one project, even if in successive iterations during three years, was a limitation associated with this article.

ACKNOWLEDGMENT

We thank the Brazilian Army for the financial support through the SIS-ASTROS Project (813782/2014), developed in the context of the PEE-ASTROS 2020.

Abstract—Global ontologies must provide a balance of reusability-usability to minimize the ontology reuse effort in different applications. To achieve this balance, ontology design methods focus on designing layered ontologies that classify into abstraction layers the common domain knowledge (reused by most applications) and the variant domain knowledge (reused by specific application types). This classification is performed from scratch by domain experts and ontology engineers. Hence, the design of reusable and usable ontologies that represent complex domains takes a lot of effort. Considering how common and variant software features are classified when designing Software Product Lines (SPLs), we argue that SPL engineering techniques can facilitate the domain knowledge classification taking as reference existing ontologies. In this paper, we show the experiences of applying SPL and ontology design techniques in combination to design a reusable and usable global ontology for the energy domain. Domain experts and ontology engineers evaluated the proposed method. The results show that SPL engineering techniques enable a systematic and accurate domain knowledge classification, thus saving ontology design effort.

Keywords—ontology design; ontology reusability; ontology usability; Software Product Line; energy domain.

I. INTRODUCTION

Ontologies are formal vocabularies that represent a data domain as a set of concepts and relations. The main ontology elements are classes (to represent entities, i.e., *device*, *appliance*), instances (individuals that belong to a certain class, i.e., *MU_fridge*, *MU_building_11*) and properties (relations that relate classes and individuals, i.e., *isA*, *isIn*) (Fig. 1). With these elements, ontologies enable to create a generic knowledge that can be shared across different software applications [1].

Among the different ontology types, *global ontologies* include common vocabularies to provide a common domain knowledge representation (i.e., Soupa [2]). The knowledge of global ontologies is a reference to develop ontologies for specific applications (*application ontologies*) [3]. This common knowledge representation overcomes the vocabulary differences and the heterogeneity of ontologies in the domain concerned to enable interoperability between ontology-based applications [3].

A global ontology must represent abstract knowledge to support different applications: it must be *reusable* [4]. However, if the ontology is too abstract, the effort of adapting it to satisfy

Figure 1: Ontology example

specific knowledge requirements would be high. Therefore, a global ontology must be as specific as possible to minimize the ontology reuse effort when it is reused to develop application ontologies: it must be *usable* [4]. Both reusability and usability are objectives in “*in natural conflict*” [4]. Hence, a global ontology must achieve a balance of reusability-usability so that it is reused in different applications with moderate effort.

To date, *layered ontologies* have been applied to achieve a balance of reusability-usability (i.e., OntoCape ontology [4]). They separate and classify into abstraction layers the *common domain knowledge* (reused by most applications) and the *variant domain knowledge* (reused by specific application types). We consider an *application type* a family of applications that perform similar tasks. In addition, the knowledge of each layer is divided into ontology modules, which represent the knowledge of a particular topic of the represented domain (each module imports the modules whose knowledge it requires or extends) [5]. Layered ontologies enable ontology developers to reuse only the necessary knowledge at the proper level of abstraction to develop application ontologies, thus reducing the ontology reuse effort in different applications [6].

Current methods applied to design reusable and usable ontologies [4], [7], [8] provide guidelines to define the ontology layers and the knowledge they include. However, they do not provide systematic guidelines to decide whether the domain knowledge is common or variant and in which layer it is placed. Domain experts and ontology engineers define and classify from scratch the common and variant domain knowledge. Ontologies are usually developed in complex domains (i.e., energy) [7]. Hence, a significant effort is required to classify the ontology knowledge from scratch by applying existing methodologies when designing reusable and usable ontologies.

Layered ontologies are quite similar in concept to Software

Product Lines (SPLs), software families that contain common reusable parts and variable parts that depend on specific customer needs [9]. To design SPLs, software features for a set of applications are analyzed and classified into *common features* (common to most applications) and *variant features* (implemented by specific applications) [9]. This process is known as *commonality and variability analysis* (CVA) [8]. This analysis is usually performed systematically taking as reference the software feature similarities and differences of legacy applications to complement domain experts' and software engineers' expertise [8]. This approach avoids classifying the software features from scratch, thus reducing the SPL design effort [10]. In addition, the software features reused by few applications are identified and the accuracy of the software feature classification is maximized [10].

After several decades of ontology development, many ontologies are available and developed to support certain application types. Hence, the CVA applied to design SPLs can be replicated in the ontology engineering field to design reusable and usable ontologies. The similarities and differences of the knowledge represented by existing ontologies can be analyzed. This analysis would complement domain experts and ontology engineers' expertise and prevent them from classifying the domain knowledge from scratch. In addition, the variant domain knowledge reused by specific applications could be identified, thus leading to an accurate domain knowledge classification.

In this paper, we show the experiences of applying SPL engineering techniques and ontology design principles in combination to design a reusable and usable global ontology for the energy domain. We discuss how applicable are SPL engineering techniques to design reusable and usable ontologies and the benefits they bring to the ontology design process.

The paper is structured as follows. Section 2 motivates the application of SPL engineering techniques to design a reusable and usable global energy ontology. Section 3 positions the proposed method with current ontology and SPL design methodologies. Section 4 describes the process we followed to design a global energy ontology by applying SPL engineering and ontology design techniques in combination. In Section 5, domain experts and ontology engineers evaluate the proposed method and Section 6 summarizes the learnt lessons. Section 7 summarizes the conclusions of the study and the future work.

II. MOTIVATIONAL SCENARIO

From the beginning of the current decade, ontologies that represent the knowledge from different energy domains have been developed. These ontologies support energy management applications focused on improving the current grid sustainability to make the Smart Grid vision a reality [11]. These applications can be classified into different types according to the Smart Grid scenario/infrastructure where they are deployed, i.e., Smart Home or building energy management applications. We define these application types as *Smart Grid scenarios*. Each Smart Grid scenario encompasses more specific application types. For instance, within Smart Home energy management applications, there are applications focused on home energy assessment or appliance Demand Response (DR) management. To see in more detail this classification we refer the reader to [12].

Energy ontologies are heterogeneous, since they represent the same energy domains (i.e., energy equipment data) with different vocabularies [12]. The energy management in real scenarios will require the knowledge exchange among applications that operate in different scenarios. This knowledge exchange is hampered by the heterogeneity of energy ontologies. Hence, there is the need to create a global ontology that provides a common energy domain representation [12]. It should support different energy management applications and provide balance of reusability-usability to minimize the ontology reuse effort in each application. Since the energy domains are complex, the application of existing reusable and usable ontology design methodologies would require a great effort. Since there are many developed energy ontologies, their knowledge similarities/differences can be analyzed to save ontology design effort.

III. RELATED WORK

The first knowledge classification proposals correspond to frameworks that classify ontologies according to their generality/specificity level. Guarino [13] presented the first ontology classification framework, which was refined by Gomez-Perez [14]. Layered ontologies (introduced in Section 1) are based on the aforementioned frameworks and they are the main approach to design ontologies that provide a balance of reusability-usability. In the last decade, several reusable and usable ontology design methodologies (based on the layered ontology approach) have been proposed. Spyns et al. [8] presented the DOGMA methodology, which specifies how to represent and separate the common and variant domain knowledge to design ontologies that provide a balance of reusability-usability. Thakker et al. [7] set out a methodology to develop reusable and usable ontologies for complex domains. Morbach et al. [4] developed the OntoCape ontology, a reusable and usable ontology for the chemical process engineering domain. In these methodologies, the classification of the domain knowledge is performed from scratch based on domain experts' and ontology engineers' expertise. They analyze the knowledge requirements of the application types that will be supported by the ontology (in collaboration with stakeholders). In contrast, in the method presented in this paper the common and variant domain knowledge is identified and classified through a CVA of existing ontologies conducted by applying SPL engineering techniques. Apart from this differential aspect, the proposed method applies the ontology design principles applied by current methodologies.

Regarding SPL design approaches, Pohl et al. [9] provide guidelines and enumerate the techniques to conduct a CVA. The proposed method follows these guidelines. In addition, several works have combined techniques from ontology and SPL engineering. Most of these works consist on the use of ontologies to improve the representation of common and variant software features of SPLs [15], [16]. In other works, ontologies and SPLs have been applied in combination, i.e., to manage cloud service configurations [17]. The proposed method also combines ontology and SPL techniques. In this case, SPL engineering techniques are applied to improve the ontology design process.

Figure 2: DABGEO design steps

IV. PROPOSED METHOD

This section explains the process we followed to design a global energy ontology: the DABGEO ontology. DABGEO provides a common energy domain representation and classifies the domain knowledge into abstraction layers to provide a balance of reusability-usability. DABGEO and its documentation are published online¹, so that ontology developers can understand its structure and reuse it. The DABGEO design and development team included energy domain experts and ontology engineers. DABGEO was designed by applying SPL engineering and ontology design techniques in combination. The design process followed four steps (Fig. 2), described in the following subsections.

A. Step 1: Ontology Structure Definition

In this step, the DABGEO structure was defined by the domain experts based on the layers proposed by the methods reviewed in Section 3. DABGEO includes three layers (Fig. 3). The *common-domain layer* represents the knowledge common to the Smart Grid scenarios. Variant domain knowledge still common to more than one Smart Grid scenario is included in the *variant-domain layer*. The *domain-task layer* includes the knowledge reused in specific Smart Grid scenarios and is divided into the *Smart Grid scenario* and the *application type* sublayers. The former represents the knowledge reused by a certain Smart Grid scenario and the latter represents the knowledge reused by a certain application type of a Smart Grid scenario. The lower the layer, the more specific the knowledge it represents. Hence, the modules from low-level layers will import the modules from upper layers. For more information about the ontology structure, we refer the reader to the ontology publication page¹.

B. Step 2: Domain Knowledge Hierarchy Definition

In this step, domain experts and ontology engineers defined and structured DABGEO knowledge. The knowledge was defined as a knowledge hierarchy where the represented domains were divided into specific knowledge pieces. This knowledge hierarchy enabled (1) to separate the abstract knowledge that is likely to be reused in most of applications from the specific knowledge and (2) to classify of the defined knowledge pieces into the layers of the ontology structure (performed in Step 3). Fig. 4 shows part of DABGEO knowledge hierarchy, which includes three elements:

- *Domains*: the domains represented by the ontology are located in the first level of the hierarchy. For instance,

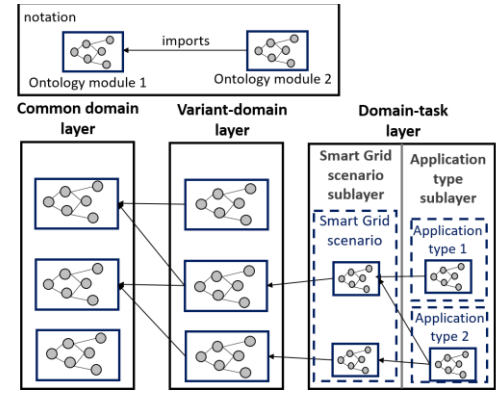

Figure 3: DABGEO ontology structure

the *energy equipment domain* encompasses the knowledge about energy devices and their operation.

- *Subdomains*: they cover the knowledge of an important part of the domain and are located in the second level of the hierarchy. For instance, the *energy equipment domain* encompasses the *energy consumption systems* and *device operation* subdomains, which represent the knowledge about energy consumption devices and device functional features respectively.
- *Knowledge Areas (KAs)*: in the third level of the hierarchy, consider a KA as a potential module of the designed ontology that encompasses the knowledge of a specific topic of a subdomain. For instance, within the *energy consumption systems subdomain* the *appliances KA* represents the knowledge about appliance types. KA can be divided into “child” sub-KAs that represent more specific knowledge. For example, the *appliances KA* includes the *white goods* and *brown goods* KAs, which represent the knowledge about white and brown goods types respectively. Hence, a sub-KA extends the knowledge of a “parent” KA. Finally, some KAs may require the knowledge from other KAs to represent the knowledge they encompass. For instance, the *energy consumption systems operation KA* describes the states and functionalities of energy consumption systems. It requires the knowledge of *device state* and *device functionality* KAs, which represent the knowledge about device states and functionalities respectively.

The proposed method classifies the ontology domain knowledge based on a CVA of existing energy ontologies. Thus, the knowledge hierarchy includes the knowledge represented by existing ontologies. The domain experts and ontology engineers collaborated to perform a manual analysis of the elements of existing ontologies in the Protégé ontology editor² to identify the domains they represent and to divide them into KAs. The identified domains were divided into subdomains, which were divided into KAs taking as reference the Competency Questions (CQs) answered by existing ontologies. CQs are the queries that ontologies should answer to ontology-based applications, and they are used to define the ontology functional

¹ <http://www.purl.org/dabgeo>

² <https://protege.stanford.edu/>

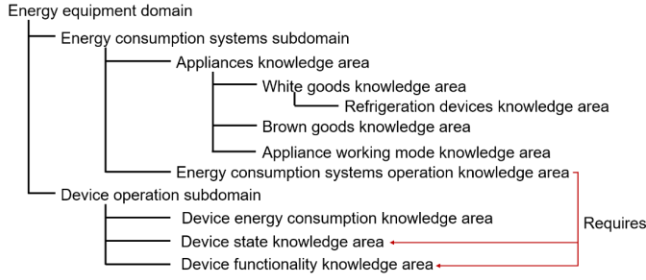

Figure 4: Part of the knowledge hierarchy of DABGEO

requirements [18]. To answer each CQ the ontology must include a specific part of the represented knowledge [18]. Thus, CQs are a natural guide for splitting the ontology knowledge into KAs [19]. CQs offer an abstract method to divide the knowledge represented by existing ontologies regardless of their heterogeneity. However, the CQs defined to develop ontologies are not always available [19].

Therefore, ontology engineers manually analyzed the elements of existing energy ontologies (classes and properties) to identify and extract the CQs they answer. This strategy is also followed when designing SPL taking as reference existing applications [20]. For instance, the existing energy ontologies include the *consumesEnergy*, *actuallyConsumesEnergy* and *maxConsumesEnergy* properties to answer the *What is the energy consumption of a device?*, *How much energy is a device consuming?* and *What is the maximum energy consumption of a device?* CQs respectively. To avoid an unmanageable number of KAs, the CQs covering similar topics were grouped by domain experts to define a KA that encompasses all the knowledge required to answer grouped CQs. For instance, the aforementioned CQs describe knowledge about device energy consumption. They were grouped into the *device energy consumption KA* (it also includes CQs answered by other energy ontologies), which encompasses the knowledge that answers these CQs. The defined KAs were classified into domains and subdomains according to the knowledge they represent and into a hierarchy level according to the knowledge they require or extend.

Finally, the domain experts provided a complete description of each KA and the knowledge it encompasses.

C. Step 3: Knowledge Classification

In this step, the ontology engineers classified each defined KA into one layer by applying SPL engineering techniques. First, the existing energy ontologies were analysed manually with Protégé to determine whether they represent each defined KA. If the ontology contained classes or properties related with the knowledge encompassed by the KA, the KA was considered as represented. The domain experts collaborated with ontology engineers to give additional explanations about the knowledge encompassed by KAs. It is worth mentioning that if a “child” KA was represented by the ontology, the “parent” KA that represents more abstract knowledge was also considered as represented.

Second, a CVA of existing ontologies was conducted to determine whether the KAs were common to Smart Grid scenarios. In particular, the *application-requirements matrix* technique proposed by Pohl et al. [9] was applied (taking as reference application-requirements matrix applied by Moon et al. [21]) to determine whether the KAs are common to Smart Grid scenarios depending on how many ontologies represent them. One application-requirements matrix was created to classify the KAs of each subdomain. As an example, Table 1 shows the application-requirements matrix of a set of KAs of the *energy consumption systems* and *device operation subdomains* (34 KAs were defined in total for these subdomains). The left column contains the KAs of the subdomain. The top rows list the Smart Grid scenarios and the energy ontologies classified by the Smart Grid scenarios they support (this classification can be consulted at [12]). To simplify the matrix, we have omitted a couple of ontologies. The matrix indicates if an ontology represents a KA (‘X’) or not (‘-’). With this information, we could deduce which Smart Grid scenarios reuse each KA. We considered that a Smart Grid scenario reuses a KA if the KA is represented by at least one ontology developed to support the Smart Grid scenario. KAs were classified into common and variant according to their *commonality ratio* (CV ratio) (right column in Table 1): the ratio of the number of Smart Grid scenarios that reuse the KA to the total number of Smart Grid scenarios. In particular, 75% was used as the threshold value of the CV ratio to classify the KAs. The KAs equal or above the threshold were considered as

TABLE 1: APPLICATION-REQUIREMENTS MATRIX

Ontologies Knowledge areas	Smart Grid scenarios								Commonality ratio
	Smart Home energy management			Building/district/city energy management		Organization energy management		Smart Grid Demand Response management	
	ThinkHome ontology	EnergyUse ontology	SAREF4EE ontology	SEMANCO ontology	BOOnSAI ontology	DEFRAM project ontology	DERI Linked dataspace	ProSGV3 ontology	
Appliances	X	X	X	X	-	X	-	X	100%
Brown goods	X	X	-	-	X	-	X	X	100%
White goods	X	X	X	X	-	-	-	X	75%
Refrigeration devices	X	X	-	-	-	-	-	X	50%
Device energy consumption	X	X	X	-	X	-	X	X	100%
Energy consumption systems operation	X	X	-	-	-	-	-	-	25%
Appliance working mode	-	-	X	-	-	-	-	-	25%

TABLE 2: CVA AT APPLICATION TYPE LEVEL

	Smart Home energy management		
	Home energy assessment	Home energy saving advice	Home appliances Demand Response management
Ontologies	ThinkHome ontology	EnergyUse ontology	SAREF4EE ontology
Knowledge areas			
Energy consumptions systems operation	X	X	-
Appliance working mode	-	-	X

common, while the rest were considered as variant.

Third, each KA was classified into one layer according to the CVA results. The common KAs were placed in the *common-domain layer*. Variant KAs reused in more than one Smart Grid scenario were assigned to the *variant-domain layer*. The KAs reused only in one Smart Grid scenario were assigned to one of the sublayers of the *domain-task layer* according to a CVA at the application type level. The KAs reused by more than one application type of a Smart Grid scenario are likely to be reused in more application types of that scenario and were placed in the *Smart Grid scenario sublayer*. The KAs reused only by one application type were assigned to the *application type sublayer*. Following the sample CVA of Table 1, the *energy consumption systems operation* and the *appliance working mode* KAs were reused only by Smart Home energy management applications. Thus, they were included in the CVA at application type level (Table 2). The *energy consumption systems operation* KA was reused by more than one Smart Home energy management application type. Hence, it was placed in the *Smart Grid scenario sublayer*. The *appliance working mode* KA was reused only by one Smart Home energy management applications and placed in the *application type sublayer*.

D. Step 4: Definition of the Ontology Modular Structure

In this step, the ontology engineers structured the knowledge of each layer into ontology modules to complete the ontology design. This step was performed taking as reference the ontology modularization principles applied by the main reusable and usable ontology design methods: loosely coupling and self-containment [5]. One module was defined for each KA and placed in one ontology layer/sublayer according to the CVA results. The modules were related according to the knowledge dependencies defined in Step 2. The modules of the *Smart Grid scenario* and *application type* sublayers were classified into the Smart Grid scenario/application types where the KAs they represent are reused.

V. EVALUATION

The ontology design method presented in Section 4 was evaluated by domain experts and ontology engineers. A group of domain experts and ontology engineers conducted Steps 1 and 2 and different ontology engineers (eight in total) conducted Steps 3 and 4 to design parts of DABGEO. Each ontology engineer performed Steps 3 and 4 individually in a blind

process. A survey was performed to capture the knowledge classification obtained by each ontology engineer. The survey also included a questionnaire to identify the main advantages and improvement aspects of the proposed method. This questionnaire can be found online in the appendix: https://innoweb.mondragon.edu/innoweb/questionnaire_SPL_ontology_method.pdf.

Fig. 5 shows the number of modules defined by each engineer for each ontology layer. It also shows the number of modules of the *domain-task layer* that were classified into each energy management application type. It is worth mentioning that the designed ontology parts were limited to support three application types (shown in Fig. 5). In general terms, the number of modules defined by each ontology engineer was similar in all layers. This similarity is due to the high *degree of consensus* with which the ontology engineers classified the defined KAs into layers. We understand by degree of consensus of a KA the percentage of ontology engineers that classified the KA into the same layer. The average degree of consensus of the KAs was 76%. Therefore, there was a high consensus when classifying the common and variant domain knowledge. In addition, 81% of the KAs that were classified into one application type within the *domain-task layer* by most of ontology engineers, were not classified into other application types by other ontology engineers. Hence, the knowledge reused only by specific application types was identified.

Regarding the questionnaire, we received eight responses from participants of the proposed method evaluation. 100% respondents considered that the application of SPL engineering techniques was useful and 80% would recommend the proposed method to design reusable and usable ontologies in other domains apart from the Energy. According to the respondents, the main benefits of the proposed method are the following: (1) it provides clear and mechanical steps to classify the ontology domain knowledge taking as reference existing ontologies and (2) the CVA of existing ontologies provides a detailed classification of the knowledge reused by specific application types, while keeping separate the knowledge reused by most applications. On the other hand, the main improvement aspect deals with the required manual effort. Although the proposed method prevented from classifying the domain knowledge from scratch, it required a significant manual analysis effort to check whether each KA is represented by existing ontologies.

VI. LESSONS LEARNT

Considering the similar knowledge classifications obtained in Section 5, domain experts and ontology engineers could apply the steps of the proposed method to (1) perform a CVA of existing ontologies and (2) classify the domain knowledge into different layers. The evaluation participants did not need to perform an analysis of the requirements of each application type to classify the common and variant domain knowledge of DABGEO from scratch. In addition, they considered the proposed method useful and easy to follow. Hence, we can state that the CVA of existing ontologies complements domain experts and ontology engineers' expertise when designing

Figure 5: Ontology modules of each layer

reusable and usable ontologies in complex domains, thus saving ontology design effort. In addition, the ontology engineers identified the variant domain knowledge reused in specific applications. Thus, we can state that the CVA of existing ontologies enables an accurate domain knowledge classification. Bearing in mind these benefits, ontology developers should consider applying SPL engineering techniques when designing ontologies that (1) will be reused in different applications and (2) represent complex domains. In particular, existing ontologies should be identified and their knowledge should be divided and classified into different abstraction levels. Then, the ontologies should be analyzed to classify the domain knowledge based on their knowledge similarities and differences through a CVA.

Despite of these promising results, the CVA should be conducted with tool support to automate the process of checking whether certain KAs are represented by existing ontologies. In particular, tools that check (semi)automatically if a set of CQs are answered by ontologies should be developed. These tools can take as input the CQs encompassed each KA to check whether existing ontologies represent the KAs [18].

VII. CONCLUSIONS AND FUTURE WORK

In this paper, we have shown the experiences of applying SPL engineering and ontology design techniques in combination to design DABGEO, a reusable and usable global energy ontology. The proposed method analyses the knowledge similarities and differences of existing ontologies to classify the common and variant domain knowledge into different layers. The method was applied by domain experts and ontology engineers to design part of DABGEO. The results show that that the application of SPL engineering techniques enables a systematic and accurate domain knowledge classification that complements domain experts and ontology engineers' expertise. Hence, ontology design effort of reusable and usable ontologies is saved. Bearing in mind these benefits, the proposed approach should be applied to design ontologies that will be reused in different applications and represent complex domains.

Our current work is focused on defining a methodology based on the proposed method, so that it can be applied and replicated in other complex domains apart from the Energy. We are working on describing in detail and generalizing each step. The medium-term work will focus on incorporating tool support to reduce the manual ontology analysis effort.

Nanjing, China

{220163720, wanglulu, bx.li}@seu.edu.cn

Abstract—MVC architectural pattern is widely used in software architecture design. It helps decouple the processing and the visualization of system data. Identified MVC architectural pattern helps understand how the software is actually implemented based on MVC architectural pattern, and further improve the consistency between design and source code. This paper proposes an ontology-based MVC architectural pattern identification method. Firstly, we use the combination of design patterns to describe the structure of MVC architectural pattern, so as to construct the MVC ontology of concept layer. Then we construct a program dependency graph by extracting the dependencies between entities in the target system, and build the ontology of instance layer. Finally, the MVC architectural pattern ontology of the specific target system is inferred by ontology reasoner in order to obtain MVC architectural pattern and the pattern elements included in each component. We use open source projects as the benchmark, and the experimental results show that our method effectively identifies the MVC architectural pattern and the pattern elements in software system.

Keywords—MVC; Architectural Pattern; Pattern identification; Observer Pattern; Strategy pattern; Ontology

I. INTRODUCTION

Architectural style is often used to describe the architecture [1], the architectural style is also known as the software architectural pattern. MVC is a software architectural pattern that widely used in desktop applications and Web information systems [3], which greatly improved the speed and stability of the system, also makes the software easy to maintain and easy expansion. But with the evolution of software, software design changes and the loss of software documentation make it difficult for developers to understand the architectural pattern of software. Such software is often difficult to maintain. Understanding the architectural pattern of the system is very helpful for the maintenance work. Bass et al. mention that some 80% of all costs in software development are related to maintenance activities [2]. Therefore, it is very meaningful to research the MVC software architectural pattern identification.

This paper studies the identification of MVC architectural pattern. At present, there is no set of theory and technology at home and abroad to support MVC architectural pattern identification. But there are some studies on the identification of architectural pattern. J. Paakki et al. regarded the problem that mining pattern from UML diagrams as a constraint satisfaction problem in 2000 [4]. J. Peters proposed an architectural pattern matching method based on Semantically Rich Modular Architecture [5], using genetic algorithm to match

pattern instance. M. Lungu proposes an architectural pattern identification method that uses a source code structure as a pattern and builds on a lower-level pattern extracted from source code, iteratively and interactively produces a more advanced view [6]. H. Yan introduced the tool DiscoTect, which identifies the architecture pattern of the runtime object-oriented system [7]. Mavridou Anastasia pointed out that architecture can be represented by logic, and architectural style can be described by configurations [8]. Thomas Haitzer proposed a semi-automated architectural pattern identification method based on architecture primitives [9]. The Service-oriented Architecture pattern identification method based on model checking was proposed by Penta and Sandonep in 2007 [10].

From the above related works, it can be concluded that the identification of architectural pattern requires two aspects of work: describing the architectural pattern and matching the description of the architectural pattern with the source code. However, the related work still has the following shortcomings.

- Lack of automation, the above methods are not highly automated, which makes it difficult to implement.
- Existing research does not identify specific pattern elements in the software system and does not provide a more detailed reference for developers and maintenance personnel. Pattern element is the pattern-related class in software system.

This paper proposes an ontology-based MVC architectural pattern identification method, which can automatically identify the MVC pattern instances in a specific target system, the pattern instances include the MVC architectural pattern and the pattern elements. The contributions of this paper mainly include the following three points. Firstly, the observer design pattern and the strategy design pattern are used to represent the MVC architectural pattern composition principle, and the ontology formally describes the MVC architectural pattern, the observer pattern and the strategy pattern. Secondly, the ontology inference engine is used to match the formal description of the MVC architectural pattern with the specific target system. The ontology inference engine can automate this process. Finally, read the source code and documentation of target system manually is used to verify the correctness of the identification result and effectiveness of the method. The recall rate, the precision and the F1-measure of the MVC architectural pattern and pattern elements are calculated to measure the effectiveness of the method.

This paper is structured as follows: In the section 2, the MVC architectural pattern and ontology are introduced. In the

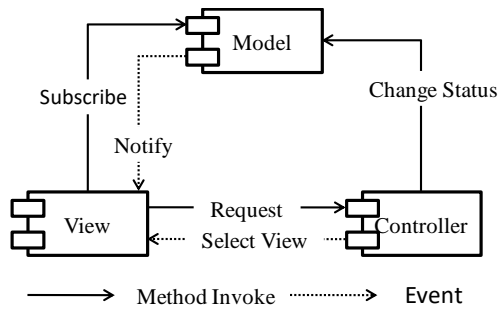

Fig. 1. MVC architectural pattern ^[17]

section 3, the research method of this paper is introduced. In the section 4, the experiment and evolution is introduced. Section 5 contains conclusion and future work.

II. BACKGROUND

A. MVC architectural pattern

The Model-View-Controller(MVC) architectural pattern divides an interactive application into three components ^[11]. First created by Trygve R and implemented in the Smalltalk-80 environment. The model contains core functions and data; the view displays information to user; the controller processes user's input. Both the view and controller form the user interface, and the change propagation mechanism ensures consistency between the user interface and the model.

MVC decouples views and models by establishing a subscribe/notify protocol between them ^[12]. A view must ensure that its appearance reflects the state of the model. Whenever the model's data changes, the model notifies views that depend on it. In response, each view gets an opportunity to update itself. So, the model-view relationship is an example of the Observer design pattern. The View-Controller relationship is an example of the Strategy design pattern. Encapsulate the response mechanism in the Controller object. To implement different response strategies, simply replace them with different kinds of Controller instances. Fig.1 shows MVC architectural pattern.

B. Ontology

In computer science, ontology refers to "a formal, clear and detailed description of a shared conceptual system" ^[13]. Ontology is used to express related concepts, entities and formal relationships between specific domains. The ontology can effectively describe the abstract relationships between specific domain concepts, and ontology can also reason in order to excavate the implicit relationship between abstract concepts. Ontologies generally use ontology language for related expression work. Currently, description logic (DL) and framework logic (FL) ^[15] are generally used to define ontology. In this paper, since the description logic is used to define the ontology, the DL is introduced below.

DL is a formal language used for the description of ontology, the relationship between the concepts of ontology and the relationship between individuals of concepts. Description logic has excellent expressive ability and logic-based inference ability, and the description logic has clear

inference algorithms ^[14]. The W3C international standard OWL and RDF language is based on the DL. The description logic system contains three parts: concept, role and individual. The assertion between concepts is called TBOX, and the assertion between individuals is called ABOX.

1) TBOX

TBOX is a set of axioms in description logic, which contains the connotation knowledge of the application domain, and uses the terminological axioms to describe the assertions between concepts. The general term axiom has two forms: inclusion and equality.

2) ABOX

ABOX is a set of description logic used to describe the relationship between individuals. It is an extension of the concept in the application domain to instantiate assertions axiom of individual and facts between individuals. Generally, there are two forms of instantiation axioms: concept assertion and role assertion.

The ontology of concept layer in this paper is to express through the OWL language, and the ontology of instance layer is to express through the RDF language, in order to build the ontology of MVC architectural pattern for a specific target system.

III. METHODOLOGY

The ontology-based MVC architectural pattern identification method proposed in this paper aims to identify the MVC architectural pattern and pattern elements in open source software. The method is mainly for the project that developed by JAVA. The method is mainly divided into three steps. Fig. 2 shows the overall process of the method.

- The first step is to represent the MVC architectural pattern as the observer pattern and the strategy pattern, and then describe the MVC architectural pattern formally by using the DL in order to form the MVC architectural pattern ontology of conceptual layer, the ontology of conceptual layer is also the Tbox in DL that mentioned in the second chapter.
- The second step is to use the code parsing tool to extract the dependencies between the entities in the source code, and use the RDF language to represent the dependencies of the entities in the source code into triples to form ontology of instance layer, the ontology of instance layer is also the Abox in DL that mentioned in the second chapter. Then, combining the MVC architectural pattern ontology of concept layer with the ontology of instance layer to form the MVC architectural pattern ontology of specific target system;
- The third step is to derive the expected result from the MVC architectural pattern ontology of the specific target system using the ontology inference engine, including whether the MVC architectural pattern is applied and the MVC architectural pattern elements in the target system.

Fig. 2. The process of our method

A. Ontology of concept layer

The MVC pattern consists of three components: model, view, and controller. The pattern separates the model and view through the Observer pattern. The view is the observer in the Observer pattern. The model is the subject in the Observer pattern. Once the model data changes, the model will inform the relevant view. MVC controller is a component that accepts user input and responds to user input. The Strategy pattern is implemented, the view is the Context in the Strategy pattern, and the controller is the strategy in the Strategy pattern. On the other hand, most Java GUI applications use the Swing toolkit or the AWT toolkit, so the classes in View must inherit the base classes in JavaSwing and AWT. According to this feature, you can identify the specific class of the view in MVC.

The identification of the MVC pattern is transformed into the identification of the design pattern. The ontology of constructing the MVC architectural pattern is to construct a combination of two design pattern ontology and transform the abstract architectural pattern into a specific design pattern, thereby mapping the relationship between the pattern components to specific source code. Table I shows the DL of the main part of the ontology of concept layer.

B. Ontology of specific target system

Building the MVC architectural pattern ontology of a specific target system is mainly divided into two steps. Step one is to extract information for the target system. The purpose of information extraction is to extract the dependencies between entities in the target system in order to construct Program Dependence Graph (PDG). The entity includes methods and classes; in step two, the PDG is converted into an RDF triples, and the individual in the DL is added to the MVC architectural pattern ontology of concept layer to form an MVC architectural pattern ontology of the specific target system.

1) extract information

This paper is mainly for the Java open source project, using JAVA Development Tool(JDT) to complete the information extraction work. The main flow of JDT extraction is to first generate the Abstract Syntax Tree (AST) of the source code, and then construct the PDG according to the information on the AST.

The construction of program dependency graphs is to obtain the dependencies between classes and methods by traversing the AST. Constructing a PDG for the method of this paper requires extracting the following information, as shown in Table II.

TABLE I. DL OF THE ONTOLOGY

DL of MVC pattern: $MVCPattern \equiv \exists \text{containsElement.Model}$ $\cap \exists \text{containsElement.View}$ $\cap \exists \text{containsElement.Controller}$
DL of Observer pattern: $ObserverPattern \equiv \exists \text{containsElement.AbstractSubject}$ $\cap \exists \text{containsElement.ConcreteSubject}$ $\cap \exists \text{containsElement.AbstractObserver}$ $\cap \exists \text{containsElement.ConcreteObserver}$ $AbstractSubject \equiv Interface$ $\cap \exists \text{containsElement.AbstractNotify}$ $ConcreteSubject \equiv NomalClass$ $\cap \exists \text{containsElement.ConcreteNotify}$ $AbstractObserver \equiv Interface$ $\cap \exists \text{containsElement.AbstractUpdate}$ $ConcreteObserver \equiv NomalClass$ $\cap \exists \text{containsElement.ConcreteUpdate}$
DL of Strategy pattern: $StrategyPattern \equiv \exists \text{containsElement.AbstractStrategy}$ $\cap \text{containsElement.ConcreteStrategy}$ $\cap \text{containsElement.Context}$ $AbstractStrategy \equiv Interface$ $\cap \exists \text{containsElement.AbstractAlgorithm}$ $ConcreteStrategy \equiv NomalClass$ $\cap \exists \text{containsElement.ConcreteAlgorithm}$

TABLE II. TYPE OF DEPENDENCY

Dependency Edge	Master	Slave
extend	Class	Class
implement	Class	Class
composite	Class	Class
invoke	Method	Method
instantiation	Method	Class
aggregation	Class	Class

2) Building ontology

Firstly, convert PDG to RDF triples, RDF (Resource Description Framework) uses the triples to represent the relationship between entities, which is divided into three parts: subject, predicate and object. It effectively describes the relationship between classes, methods and other entities in the source code, the RDF triples can be regarded as ABOX in the DL. The subject indicates that the vertex of master in the graph, the predicate indicates the dependency in the PDG, and the object indicates the vertex of slave in the PDG; then, add the RDF triples to the ontology of the MVC architectural pattern concept layer, where the subject and object of the RDF triples are regarded as the individual in the DL, the predicate of the RDF triple corresponds to the role in DL. After adding RDF triples, the MVC architectural pattern ontology of the specific target system is formed.

C. Inference the MVC architectural pattern

Inference is essentially the process of drawing conclusions from existing facts according to certain rules^[16]. The inference process is mainly applied to the ontology inference machine. The inference engine mainly has two functions: ontology conflict detection and acquisition of implicit knowledge. Ontology conflict detection is to ensure the logical consistency between classes and individuals in the ontology. Obtaining implicit knowledge is that inference unknown knowledge according the established rule. The current inference engines are mainly divided into two categories, one is the inference engine based on the traditional description logic. The representatives of such inference engines are RACER, FaCT++, Pellet, et al. Others the inference engine are based on inference rules. Representatives are Jena, Jess. The inference engine mainly used in this paper is the Jena inference engine.

Inferring the MVC architectural pattern ontology of specific target system is to infer the existence of the pattern instances in the ontology through the inference rule. The key step of inference is to write the reason rules. The inference rules are written according to the MVC architectural pattern composition principle. The main process is to derive the unknown facts defined in the MVC concept layer ontology based on known facts such as individual and object attributes. Individuals are classified into classes defined by the concept layer of MVC architectural pattern.

According to the MVC architectural pattern concept layer ontology, we can divide the inference rules into five parts. The first part of the inference rules is written by JavaSwing inheritance rules, the purpose is to identify the classes related to GUI. The second part of the inference rules use the composition principle of observer pattern in order to identify View and Model. The third part of the inference rule is written by the principle of strategy pattern, which is to identify View and Controller. The fourth part of the inference rule is based on the inference results of the previous three steps to infer the MVC architectural pattern and the pattern elements. The fifth part of the inference rule is common rules. As shown in Table III, it is the inference rule of the observer pattern.

TABLE III. RULES OF OBSERVER PATTERN

Rules of Observer pattern: [observer_rule:(?observer rdf:type JAVA:NormalClass), (?observer JAVA:isA ?Aobserver), (?Aobserver JAVA:contain ?Aupdate), (?observer JAVA:contain ?update), (?update JAVA:override ?Aupdate), (?subject JAVA:isA ?Asubject), (?subject rdf:type JAVA:NormalClass), (?subject JAVA:aggregation ?Aobserver), (?Asubject JAVA:contain ?Anotify), (?subject JAVA:contain ?notify), (?notify JAVA:override ?Anotify), (?notify JAVA:invoke ?Aupdate) -> (?observer rdf:type OB:ConcreteObserver), (?Aobserver rdf:type OB:AbstractObserver), (?subject rdf:type OB:ConcreteSubject), (?Asubject rdf:type OB:AbstractSubject)]
--

IV. EXPERIMENT AND EVALUATION

A. Purpose and metrics

The purpose of experiment is to verify the effectiveness of our pattern identification method, we evaluate the effectiveness of our research method through three metrics: Precision, Recall, and F1-measure. Finally, analyzing the advantages and disadvantages of the method through experimental data. The calculation formula for the three metrics is as follows:

- Precision=(TP)/(TP + FP)
- Recall= TP / (TP+ FN)
- F1-measure=2*Precision*Recall / (Precision + Recall)

B. Experimental setup

The method of this paper is implemented in Java language. The operating system is macOS 10.12.6, the JDK version is 1.8.0_121, and the development platform is Eclipse neon.2. The MVC architectural pattern ontology is constructed by Protégé, the information extraction tool is JDT, the specific target system MVC architectural pattern ontology is constructed by Jena, and the ontology inference is completed by Jena inference engine.

C. Result of Overall

In this section, we identify 20 popular open source projects, and then verify the correctness of the identification results and the effectiveness of the pattern identification method by analyzing the official documents and source code of 20 projects. Determine whether the project adopts the MVC architectural pattern by reading source code and official documentation. Finally, experimental data is obtained by comparing the recognition results with the verification results.

The results of the identification of 20 excellent open source projects are shown in the table IV. The first column of the table indicates the project name, the second column indicates the identification result, √ indicates that the identification result is MVC, × indicates that the identification result is not MVC, and the third column indicates that actual pattern of the project, √ indicates that the project adopts the MVC architectural pattern, and × indicates that the project does not adopt the MVC architectural pattern.

Through the results in the table V, the statistical data is shown in table V.

According to the calculation formula of Precision, Recall, and F1-measure, the following results can be calculated:

- Precision=(TP)/(TP + FP) = 0.75
- Recall= TP / (TP+ FN) =1.00
- F1-measure=2*Precision*Recall / (Precision + Recall) =0.86

According to the above results, the Precision is 0.75 and the Recall is 1.00, which indicates that the method in this paper can effectively identify whether the MVC architectural

pattern is used in the software system, but there are still false positives.

D. Result of Part

In this section, we present three open source projects that use the MVC architectural pattern to verify the correctness of the pattern elements and the effectiveness of the method. The three open source projects are Clone, Mario, and Terrier. Firstly, it introduces the overall situation of three project. Then it gives the identification result of the three project. The identification result is the class related to the MVC pattern in the project, which is the pattern element. Then the paper understands the three projects by manually reading the source code, and classifies the classes related to MVC pattern in three projects. Finally, experimental data is obtained by comparing the identification results with the verification results.

Clone is a strategic game based on the MVC architectural pattern, which developed by Java. Mario is a popular adventure game developed in Java, similar to the Super Mario developed by Nintendo. Terrier is a highly flexible, efficient, and effective open source search engine, readily deployable on large-scale collections of documents. The basic information of the source code of three projects is shown in Table VI.

For the above three projects, due to the limitations of the paper length, we only give the identification results of Clone. The identification results of Clone are shown in Table VII.

In Table VII, classes in bold indicate false positives. The statistics of the identification results of the three projects are shown in Table VIII.

E. Analysis and Conclusions

By counting the identification results of 20 projects, we calculated that Precision is 0.75, Recall is 1.00, F1-measure is 0.86. The F1-measure is relatively high. Therefore, we can draw the conclusion that the method in this paper can effectively identify whether the MVC architectural pattern is

Project Name	TP	FP	FN	Precision	Recall	F1-measure
Clone	39	7	0	0.85	1.00	0.92
Mario	128	54	21	0.70	0.86	0.77
Terrier	412	123	82	0.77	0.83	0.8

used in the software system. But there are still false positives, the reasons for false positives are as follows:

- There is a false positive because the method uses a rigid rule to infer whether there is an MVC architectural pattern in the software system. It does not rule out that some software systems have dependencies that satisfy the inference rules, but not the MVC architectural pattern.

By counting the identification results of three projects, we can see that the F-measure of each project is higher than 0.7, and the value of recall is higher than precision. Therefore, we can draw the conclusion that the method of this paper can effectively identify the class related to the pattern in the software, which we call the pattern element. The main reason for the false positives is that some classes that satisfy the inference rules but are not related to the pattern are also identified. The main reason for the false negative is that some classes have the characteristics of the pattern elements, but these features are not implemented according to the standard of MVC architectural pattern.

F. Threats to validity

There are potential threats to validity of our results. The first threat to validity is the method has only been validated for projects developed in the Java language, and has not been validated for projects developed using other object-oriented languages.

The second threat to validity is the method only validates 20 popular open source projects, and the code size of these 20 projects is less than 500k. Sample data is not very comprehensive.

V. CONCLUSION AND FUTURE WORK

This paper proposes an ontology-based MVC architectural pattern identification method, which can automatically identify the architectural patterns and pattern elements of MVC in software. By combining the MVC architectural pattern ontology of concept layer and the ontology of instance layer, the MVC architectural pattern ontology of the specific target system is formed, and then the ontology is inferred to obtain the MVC architectural pattern and the pattern elements. Through the statistics and analysis of experimental data, we analyzed the causes of false negatives and false positives, and summarized the advantages and disadvantages of the methods. The novelty of this method is as follows:

- Applying the design pattern to the identification of the architectural pattern makes the description of the MVC architectural pattern closer to the source code and easier to understand.
- The method also identifies the pattern elements in the software and provides developers and maintenance personnel with a more detailed reference.
- The automatic identification of the MVC architectural pattern is realized, because the method can reuse the same set of MVC architectural pattern ontology of concept layer for different systems, needn't to generate a different set of descriptions for each specific target system, and the ontology inference engine can automatically complete the architectural pattern matching process.

In the future work, firstly, we must improve the identification precision and recall of the MVC architectural pattern and pattern elements. The components and pattern elements of the MVC architectural pattern are closely related to the functionality of the software. We should consider the functional information of the class in the process of identification, so that the process is no longer limited to rigid rules; in addition, the identification of variants of the MVC architectural pattern is also worth doing, such as MVP(Model-View-Presenter) architectural pattern, which are widely used in Android, MVVM(Model-View-ViewModel) pattern using WPF technology.

Abstract—Identifying dependency between various artifacts in a large scale software system is a non-trivial task. As the software evolves, multiple artifacts like files, docs, classes, database scripts, etc., are likely to undergo change concurrently. Such artifacts tend to have a dependency between them, otherwise referred to as logical coupling. Researchers have used *Support and Confidence* as an association rule based measurement to predict the levels of logical coupling among the software artifacts. However, employing a single change on a software artifact can span across various closely related changes when many code contributors are working on the same change. Thus it is important to pre-process and group these semantically related change-sets before identifying logical coupling. In this paper, we propose a method to identify logical coupling and group semantically related change sets. We evaluate our method on real-world git repositories and document our observations.

Index Terms—Cosine similarity, dependency, logical coupling, repository mining, software evaluation, software maintenance, reverse engineering

I. INTRODUCTION

Large Software systems invariably comprise of artifacts written in different programming languages integrated by diverse technologies using a variety of implementation methods. Identifying the dependency between artifacts written in two different programming languages is a non-trivial task. For example, a JavaScript method may depend on a web service written in C#. Tracking such dependencies gets increasingly difficult over a period of time and as they tend to become the origins of defects in an overall software project.

Heuristically, identifying dependencies from code-revision history is considered to be lightweight than conducting a structural analysis of the entire artifact. In the case of code-revision history, a small amount of information is required to be analyzed in order to understand the dependency. Such information is typically stored via the log files of version control system like GIT, SubVersion, TFS etc. Almost in all cases, such dependencies are primarily documented in the form of a free-text comment. Thus, dependency analysis can be performed between two or more artifacts written in different languages without having trouble in parsing and analyzing the content of the artifacts. Logical coupling is one such implicit dependency observed between two or more software artifacts. It has been found that artifacts that are considered to be logically coupled artifacts when they change together

frequently during the evolution of a system [9]. It can reveal dependencies that are *not structural* and therefore are not present in the code or in the documentation.

The reliability of all the existing studies on logical dependencies is inherently connected to the accuracy of the approach used to identify such dependencies [14]. Version Control Systems (VCS), that are atomic-featured in their nature have a *change-set* - which is comprised of mutually checked-in files that result in a single commit. In general, software practitioners often rely on the existence of the atomic commit feature and consider the change-set as the actual set of files that were changed together by a code-developer while working on a given code-based task. In the case of multiple developers implementing the same change, such code-change can span across a series of consecutively connected and closely related individual change-sets. Therefore, by simply inspecting the change-sets in isolation may lead to incomplete or incorrect results with respect to the association of logical coupling.

In the past, researchers have proposed approaches to understand logical coupling. Grouping commits with the same authors using sliding time window concept was widely used [14]. However, semantic relationships between the artifacts - like the same work item or issue number, cosine similarity of two revision comments, etc. have not been explored by researchers. *Cosine similarity* is a popular measure in Information retrieval and Data Mining areas. It can be used to measure the similarity between two documents with respect to their textual content [11]. In this paper, we present our preliminary work by utilizing such techniques to identify the logical dependency between artifacts leading to an increase in change-set identification and accuracy. In this paper, we:

- suggest an approach to improve logical coupling detection using semantic relations drawn from the revision comments and cosine similarity.
- perform a preliminary evaluation of the proposed approach for grouping semantically related change-sets.

The rest of the paper is organized as follows. In Section 2, we introduce the cosine similarity and grouping semantically related change-sets. In Section 3, we present the results of our preliminary evaluation. In Section 4, we present some related work. Finally, in Section 5, we state our conclusions and future work.

TABLE I
TERM FREQUENCIES WEIGHT(S)

Term	SaS	PaP	WH
1. Term Frequencies Count			
affection	115	58	20
jealous	10	7	11
gossip	2	0	6
wuthering	0	0	38
2. Log Frequency Weight			
affection	3.06	2.76	2.30
jealous	2.00	1.85	2.04
gossip	1.30	0	1.78
wuthering	0	0	2.58
3. Weight After Length Normalization			
affection	0.789	0.832	0.524
jealous	0.515	0.555	0.465
gossip	0.335	0	0.405
wuthering	0	0	0.588

II. GROUPING CHANGE-SETS

Software Practitioners tend to work on code usually spread across multiple change-sets, with multiple developers working on it at the same time. To group these change-sets, the semantic relations of the change-sets' comments can be utilized. For large scale software projects, the following can be observed as grouping criteria for change-sets (i) if and only if two comments have higher semantic similarity (or) (ii) if and only if two comments have same referencing work item or an issue number mentioned in it.

A. Cosine similarity

Cosine similarity is considered as a common measure for similarity computation [6]. Cosine similarity is used to fetch the similarity of words with respect to input query in regards to the text documents queried. To perform this computation, both the input query and the documents are converted into their respective unit vector of words (\vec{x}_i, \vec{y}_i) . We use the below equation 1 to compute the cosine similarity here, where x_i, y_i are the term frequency (tf) weight of a unit vector (term) in the revision comment x, y. Term frequency is the number of times a term occurs in a revision comment.

$$sim(x, y) = \cos(\vec{x}, \vec{y}) = \vec{x} \cdot \vec{y} = \sum_{i=1}^{|V|} x_i y_i \quad (1)$$

Let's look at the case where we wish to calculate cosine similarity of the books: *Sense and Sensibility* (SaS), *Pride and Prejudice* (PaP) and *Wuthering Heights* (WH). Table I lists the Term Frequencies in each of the documents, Log Frequency Weight (calculated by formula " $w = 1 + \log_{10}(tf)$ ") and Length Normalized Weight. A vector can be length-normalized by dividing each of its components by its length. We use Level-2 normalization (commonly referred as Euclidean norm) as defined in equation 2:

$$\|\vec{x}\| = \sqrt{\sum_i x_i^2} \quad (2)$$

Finally we compute cosine similarity of documents as listed below:

- $\cos(SaS, PaP) \approx 0.789 \times 0.832 + 0.515 \times 0.555 + 0.335 \times 0.0 + 0.0 \times 0.0 \approx 0.94$
- $\cos(SaS, WH) \approx 0.79$

The resultant values can be used to assess the extent of similarity based on a predefined threshold values. In equation 3, we used '0.8' as a threshold to measure semantic similarity. We have conducted a preliminary data analysis using the available datasets and have considered 80% as a reasonable threshold for desirable similarity values. This value can be provided by the developers assessing the similarity. However, reducing the threshold can result in poor precision, where as increasing the threshold may result in poor recall. So, it is required for developers to follow the standard threshold which is widely accepted to avoid poor precision and poor recall.

$$x \overset{GC}{\rightsquigarrow} y \stackrel{def}{=} \begin{cases} 1 & \text{if } sim(x, y) \geq 0.8 \text{ \& } datediff(x, y) < \alpha \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

However, in some cases relying on the cosine similarity index can result in false positives. For example, in some project like SignalR project [4] developers tend to put generic comments like "*addressed code review comments, fixed formatting, made changes as per code review feedback*" for ongoing activities. As part of our study, we exclude these kind of change-sets from grouping. Also, we compare the time difference of change-sets before grouping them i.e. if the time difference is more than a few months then we consider such changes as not related.

B. Hash tags

Another technique for grouping change-sets is based on the hashtags associated with the commits of co-changed artifacts. For instance, if we consider the instances of commits from Table II of two large scale open source projects like SignalR [4] and NopCommerce [2] hosted on GitHub and Codeplex, we see that in the example-1, commits '203cafc' and '5ad051a' have similar comments. In case of example-2, the developers tend to associate work item or issue number in the comment for future references, like in Git repository, the hash tags #2376 are associated with the comments.

We group change-sets having same hash tag values based on the mathematical formulae given in equation 4.

$$x \overset{GC}{\rightsquigarrow} y \stackrel{def}{=} \begin{cases} 1 & \text{if } HashTags(x) \cap HashTags(y) \neq \emptyset \\ 0 & \text{otherwise} \end{cases} \quad (4)$$

C. Our Approach

The proposed approach is described in Algorithm 1. As shown in the algorithm, the initial steps required to build a postings list [6] for each revision so as to help in identifying the change-sets having same tokens. Once the posting list is built using Algorithm 2, the entire revision history is looped through (shown in line numbers 6-12) to get semantically related change-sets and group them in a

TABLE II
MOTIVATING EXAMPLES

Example 1
Commit: 203cafc DumpingDisconnect.Net Comment: Removing handling Disconnect message in the .NET Client as the server no longer sends Disconnect messages.
Commit: 5ad051a DumpingDisconnect.JS Comment: Removing handling Disconnect message in the .JS client as the server no longer sends Disconnect messages.
Example 2
Commit: 9c762c4 #2376 Reject failed invocation with a single JS object representing HubExce...
Commit: f9bfbe3 #2376 Tests verifying HubException details are sent to clients
Commit: 35cfccb #2376 Flow HubExceptions which to clients even with detailed errors disabled

list. The ‘getRelatedChangeSets’ subroutine returns semantically related change sets for the current iteration of the revision based equation (3, 4). The change-sets are then added to a dictionary of the list of semantically grouped change-sets.

Algorithm 1: Change set grouping algorithm

Result: Grouped Change Sets List

```

1 procedure group_changeset
2 revisionLists ← git.GetRevisionListIterator();
3 while rev in revisionLists do
4   | addToPostingList(rev.Id, rev.Comment);
5 end
6 Map(groupId, revisionList) changeSetGroups;
7 int groupId ← 1;
8 while revision rev in revisionLists do
9   | revList ← getRelatedChangeSets(rev.comment);
10  | changeSetGroup.Add(groupId, revList);
11  | groupId++;
12 end
13 end procedure

```

Algorithm 2 describes the subroutine used to create Postings List Index. The revision id and the associated comment are passed as input parameters to this routine. The parameters are further processed to remove all characters except ‘[0-9a-b]w’ using regular expression match thereby tokenizing the string with words and their occurrences in the comments. Each token with its revision id to the Postings List Index is added to the postings list. The sample posting list is listed in Table III.

TABLE III
SAMPLE POSTING LIST

Token	Postings List
commerce	doc1, 4; doc2, 5;
tokenize	doc1, 50; doc3, 23;

Algorithm 2: Postings list builder subroutine

Result: Generate Postings List

Input: RevId and Comment

```

1 procedure addToPostingsList
2 // get hashmap of terms with frequency count
3 tokensList ← getTokens(comment);
4 while token in tokensList do
5   | if postingsList.get(token.key) then
6     | | postingsList.Get(token.key).Add(token);
7   else
8     | | postingsList.Add(token.Key, token);
9   end
10 end
11 end procedure

```

Algorithm 3 describes the subroutine responsible for returning semantically related change-sets. It accepts revision ‘comment’ as a parameter. It converts the comments to tokens and queries the postings list dictionary for these tokens to fetch the posting list. Each posting list returned is reviewed against the criteria mentioned in the equation to return the related change-set list.

Algorithm 3: Fetch semantically related change-set

Result: Generate Postings List

Input: Comment

```

1 procedure getRelatedChangeSets
2 tokens ← getTokensList(comment);
3 postingsList ← getPostingsList(tokens);
4 List < revID, Comment > revisionList = null;
5 while post in postingsList do
6   | bool isRelevant ← false
7   | if hasSameHashTag(comment, post) then
8     | | isRelevant ← true;
9   end
10  | if cosine(comment, post.comment) > 0.8 then
11    | | isRelevant ← true;
12  end
13  | if isRelevant then
14    | | revisionList.Add(post.revID, post.Comment);
15  end
16 end
17 end procedure

```

III. PRELIMINARY EVALUATION

In this section, we provide details of our preliminary evaluation using our proposed approach to group change-sets in few C# programs. we used NGit [1] to traverse the Git repository change-sets. We used two open source projects (SignalR and NopCommerce) that had substantial revision history to evaluate our approach. SignalR is an ASP.Net library that provides real-time communication support to a web application and NopCommerce is an ASP.Net based e-commerce web system.

TABLE IV
MANUAL EVALUATION OF IDENTIFIED GROUPING

NopCommerce			SignalR	
#	Appropriate?	Commits & Notes	Appropriate?	Commits & Notes
1	Yes	8bacf936baf4, efc731eeecb6, fd4ab9f67cce Enhancement for store owner to search unpublished and published products	Yes	ae9d5f7d57db, 8a2245b17d41 Modification for Forever Frame JS client
2	Yes	e6ec8e0b83ee, 782d3b87a6e3, c87537559940, d2792ada31c8 : Changes for product search and user friendly product name	Yes	0611ce61abe9, 261bb48fbca8 Changed the logic of addQs question mark query string detection
3	Yes	d40a89b56610, d0c04fc618d4 Modification related to custom validation	No	7996107ffbea, 877bcd59c454 Different instances of 'Removed unused code'
4	Yes	c5fe44ff76b8, 74e4a8e6c154, 28fb664d5c5f Modifications related to Shipping Address	Yes	240f6c58a5c3, de40de96a6b0, ff0bc98c2d34 Fix to ensure connection with LongPolling client
5	Yes	5e559b08a9ea, 050ddf2133e2 Enhancement related to filter shipments and Orders by warehouse	Yes	0b71d56, a60d923, 9c762c4, f9bfbe3e, 35cfccb Modifications related to HubExceptions
6	Maybe	305d4c1268b9, 3bf134f2c758, 9cdd0b2699b3 First two commits are related to store mapping to setting and third is related to store mapping to categories	Yes	8dc620093097, dd39b641bc27, 94ff30dd5821 Updates to crank for automation, and more Stress metrics
7	Yes	7a62bbdc9b24, c55d3897bf68 Localization changes for hard coded string	Yes	4148ea70f62d, 43aac84329b7 Handling of security errors in websockets
8	Yes	f020e98231f5, 95263d99979f Enhancement for friendly name of Affiliates	MayBe	a596aeb43c55, 5b47f9ba24a8 Updated self host sample.
9	No	188f4243ba1d, 8330d952235e First is the Fluent library update and second is the Entity Framework library update	Yes	143aa036367b, 7be649699e1d Changed Web Socket implementation to not send an empty frame at the end
10	Yes	57b7c7fdc445, 410eae6cd1f8 Modification for manufacturer store mapping	Yes	f81f6c2, 1118b15, cdaaa33, 3 5b65d0 Ensure JS SSE & WS transports will attempt reconnecting multiple times
11	Yes	d2f341323abc, fbd49df6f2dd, f02244dc5fae Enhancement for shipping rate computation for 'FedEx', 'UPS' and 'by weight'	Yes	4cf7d2b, 730aa53, c6ffb08, 41317c9, 56e4002, 8dc3ac4 :Exception handling unresolved endpoints in ServiceBus scale-out
12	No	bcecd04eb644, 5cfc2977138, b559ca0aa2e4 Author forgot a file to checkin in previous commit, but comments were same in all the commits	Yes	5ad051a9822b, 203cafdc1cbe Handling of disconnect message in JS and .Net
13	Yes	c3782eef4eba, b80d4cdecfa1 Added "Order paid" message template sent to a customer	Yes	1162f9163ba8, 47c7084ec3a4, ccdade4488ef added checks for null and empty values in the send and group methods in hub and persistent connection
14	-	-	Yes	bddcb70, 7dfa876, 13f2ffe, 9ff238e, 61c0c5c, 212fb4e Modification as per the static code analysis tool 'FxCop', Usually these are not related changes as FxCop is used to check naming conventions

We calculated the basic descriptive statistics for the number of commits grouped together. As listed in Table V, in case of NopCommerce project, 357 change-set groups were created with 1017 commits which are 19.44% of the actual commits with a maximum of 11 revisions and an average of 2.85 commits per change-set. In SignalR project, 301 change-set groups were created with 969 commits which are 21.49% of the actual commits with a maximum of 22 revisions and an average of 3.21. The figure 1 displays a Scatter Plot view of length versus number of change-set groups created for NopCommerce and SignalR projects respectively. Overall, there is a little dispersion in the values as evident by the standard deviation.

To corroborate the results of our algorithm, we have made attempts to conduct an inspection of a few random samples [3]

TABLE V
CHANGESSET GROUP STATISTICS

Project	NopCommerce	SignalR
Total commits	5229	4509
Active Since	2009	2011
# of groups	357	301
# of commits grouped	1017	969
% of commits grouped	19.44	21.49
Max	11	22
Avg	2.85	3.21
StDev	1.48	2.7

from the 658 change-set groups identified by our algorithm. We inspected 13 samples from each NopCommerce and SignalR to verify whether the revisions were grouped to a single

Fig. 1. Scatter plot of length versus change set groups

purpose or not. By verifying the revision files, comments, and diff code - we were able to judge whether the grouping made sense. We have used a statistical random sample size calculator [3], which enabled us to generalize our results with a margin of an error of 20% and confidence level of 80%. The results of our inspection are listed in Table IV.

In ‘NopCommerce’, out of 13 samples 11 were semantically related. In two samples which were not semantically related, ‘Sample 6’ had two revisions ‘305d4c1268b9, 3bf134f2c758’ related to ‘store mapping changes for settings’ but its third revision ‘9cdd0b2699b3’ was related to ‘store mapping for categories’. Additionally, their comments appeared to be semantically related but as per the code paths, it seemed that they were not actually related to each other. In the other ‘Sample 12’, the first revision ‘188f4243bald’ was related to the latest update of ‘fluent’ library and the second revision ‘8330d952235e’ was related to the latest update of ‘EntityFramework’ library and hence they were not semantically related.

In ‘SignalR’, out of 14 samples, 11 were semantically related. In three samples that were not semantically related, ‘Sample 8’ had two revisions related to self-host changes as per the comments but post analyzing the changed code a semantic relation could not be established in both the revision changes, hence we marked it as ‘MayBe’. In ‘Sample 3’, the revisions were done to remove unused code in multiple places but the author provided the same comments for both of them which resulted in high cosine similarity responsible for their grouping. In ‘Sample 14’, it had the fixes of the naming conventions identified by the static analysis tool named ‘FxCop’.

We have observed that our approach is able to semantically group change-sets which has the potential to enhance the identification of logical dependency with a margin of 20% error in detection. As per our sample analysis, we did not notice any instance of grouping by HashTag that is not semantically related, however the groups which were created

by semantic (cosine) similarity had few instances that were not related.

IV. RELATED WORK

Gall et al. are the first to introduce the concept of logical coupling [9] by analyzing the dependencies in 20 different product releases of a telecommunications switching system. D’Ambros et al. have made attempts to visualize logical coupling using an interactive visualization approach called Evolution Radar [7]. This approach was not composite and extensive enough for large software systems. Graves et al. [10] have shown that the future occurrence of faults can be easily predicted by the past revision histories of the software system. However, this reliability of this prediction can be questioned as it was never evaluated against a real-world evolving software product. Logical coupling has also been employed to predict changes in the software product [15] and was used to infer code decay [8]. There are many such use-cases which are introduced and practiced by software researchers. Mockus et al. [12] have found that the rate of widespread of a change over sub-systems and its related artifacts is a strong indicator for a presence of defects in a respective change. However, it requires a strong empirical validation on a real-world data set.

Ambros et al. [5] have reverse engineered a software system using an interactive visualization technique called the Evolution Radar, which can effectively break down the amount and complexity of the logical coupling information. Manishankar et al. [13] proposed new measurement for improving detection accuracy of evolutionary coupling by blending the concept location in a code-base to determine whether the changes to the co-changed entities are corresponding in nature and are thus related. Gustavo Ansaldi Oliva et al. [14] have proposed an approach to group timely-close and semantically-related change-sets containing the same author and commit message by using a sliding time window concept. In spite of such significant research being brought out by a variety of software practitioners, the semantic relationship between the artifacts was never made by linking the approach to detect logical coupling. The existing approaches are built under the assumptions that the developer will check-in all the related files in a single commit, whereas this is not a practical scenario. In contrast to existing state-of-art approaches, our approach is considerably different as it considers grouping of change-sets semantically in order to enhance the detection of logical coupling.

V. CONCLUSION AND FUTURE WORK

In this paper, we proposed a simple approach to group semantically related change-sets in atomic-commit featured Version Control Systems before performing logical coupling identification. We used Cosine Similarity and work item hash-tag match to group various change-sets. We were able to group almost 20% of the revisions. As part of our validation, we implemented the proposed algorithms in our approach to group various change-sets and presented preliminary evaluation results for the same. Our evaluation revealed promising results with a margin of error 20% in ‘Cosine Similarity’

grouping of change-sets. Whereas in ‘HashTag’ evaluation, we found that almost all the samples were semantically related. Intuitively, the results could easily be interpreted to conclude that ‘HashTag’ grouping provided a high degree of accuracy in grouping the change-sets, whereas ‘Cosine Similarity’ had few instances of false positives.

As part of our future work, we plan to detect hashtags by using pattern recognition techniques using a new algorithm that can reduce the possible HashTag patterns from the revision comments. We also plan to develop a technique to filter semantically unrelated files and exclude false positives. We observed that most of the false positive are related to ongoing design tasks “like refactoring, merge of branches”. Therefore we will plan to develop a filtering rule to exclude such change-sets as part of our future data sets. In regards to our present analysis, we have only targeted the main/trunk branch for detecting change-set groups. In the future, we would explore the possibilities to work with multiple branches. In regards to existing approaches, we ought to conduct an empirical study to understand the efficiency of our approach against the rest. We will be working further to enhance the effectiveness of our approach by evaluating it against large code-base.

Abstract— Since Correlation Filter appeared in the field of video object tracking, it is great popular due to its excellent performance. The Correlation Filter based tracking algorithms are very competitive in terms of accuracy and speed as well as robustness. However, there are still some fields for improvement in the Correlation Filter based tracking algorithms. First, during the training of the classifier, the background information that can be utilized is very limited. Moreover, the introduction of the cosine window further reduces the background information. These reasons reduce the discriminating power of the classifier. This paper introduces more global background information on the basis of the DCF tracker to improve the discriminating ability of the classifier. Then, in some complex scenes, tracking loss is easy to occur. At this point, the tracker will be treated the background information as the object. To solve this problem, this paper proposes a novel re-detection component. Finally, the current Correlation Filter based tracking algorithms use the linear interpolation model update method, which cannot adapt to the object changes in time. This paper proposes an adaptive model update strategy to improve the robustness of the tracker.

Keywords—visual tracking; Correlation Filter; background modeling; re-detection and re-search; model update

I. INTRODUCTION

Video object tracking is a very important and popular study in the field of computer vision. It has applications in many areas, such as precision guidance in the military field, intelligent transportation and autonomous driving, and human-computer interaction. At present, more and more research results have been achieved in this field. Both tracking accuracy and speed have been greatly improved. However, it still faces many challenges, especially complex scenes such as lighting changes, motion blur, and occlusion [1]-[2].

We focus on single object tracking in this paper. At present, there are two types of methods in the field of object tracking. One is the generative approach, the other is the discriminative approach. It's not unfamiliar to generative models, such as classic mean-shift, particle filtering, kalman filtering and so on. Unlike the generative model, the discriminative model trains a classifier which can effectively distinguish between the object and the background. As far as the current research progress is concerned, the discriminative model is superior to the generation model.

The latest research progress of discriminative approach is Correlation Filter based algorithms. Correlation Filter is simply referred to as CF. Correlation is a concept in the field of signal processing. In real life, many problems can be solved with Correlation functions. It measures the degree of similarity of two signals at a time. Therefore, the more similar the two signals are, the larger the correlation value is. Been inspired by this idea, the MOSSE (Minimum Output Sum of Squared Error) tracker skillfully applies Correlation Filter to video object tracking [3]. Specifically, during the tracking process, we need to train a Correlation Filter template based on the object image block and desired output. When this template is applied to the candidate image blocks, the image block with the largest response value is regarded as the object. Why are Correlation Filter based algorithms capable of achieving so high speeds? This is mainly due to cyclic shift and Fourier transform, which can greatly reduce the computational complexity.

Nevertheless, there are still some problems to be solved in Correlation Filter based algorithms. (1) The problem of insufficient background information. It is well known that negative samples are very important in the training of classifier. However, in order to reduce the boundary effect caused by cyclic shift, the algorithm uses the operation of adding cosine window. This operation not only reduces the proportion of real samples, but also further reduces the background information. (2) The problem of tracking loss and model drift. In complex scenarios, tracking loss often occurs in the process of tracking. Traditional algorithms do not take measures to deal with this situation. (3) The problem of model updating cannot adapt to object changes. Classical algorithms often use fixed update rate to update the model linearly. This updating method has a great defect, it cannot reflect the change of the target in time. It can seriously affect tracking accuracy.

To solve these problems, this paper makes the following contributions. The proposed algorithm is based on DCF tracker. In order to improve the discriminant performance of the classifier, we combine the framework in CACF [4] with the DCF framework. Then, we add the operation of re-detection and re-search on the basis of the original algorithm flow. Here, re-detection depends on tracking confidence index. Finally, we introduce an adaptive model updating strategy, which can adapt to the appearance changes of the object in time. Experiments show that these measures are effective.

II. Related Work

Blome et al. first applied Correlation Filter to video object tracking. The MOSSE tracker uses an objective function with a minimum mean square error. Due to the full utilization of the

{Corresponding author: Weibin Liu, wblu@bjtu.edu.cn}
DOI reference number: 10.18293/SEKE2019-149

Fourier transform, the tracking speed of the algorithm is very fast. Its accuracy rate is 43.1% while maintaining 615fps. The disadvantage of the MOSSE tracker is that the feature representation is relatively simple, which greatly affects the tracking accuracy. The CSK (Circulant Structure with Kernels) tracker proposed by Henriques et al. solves the tracking problem from the perspective of machine learning [5]. It uses a cyclic shift sampling strategy to solve the problem of insufficient training samples that always exist in object tracking field. However, the shortcoming of the feature representation is still unresolved. Later, the KCF/DCF tracker was proposed [6]. It extends the feature representation of the image from the single channel gray features to multichannel HOG (Histogram of Oriented Gradients) feature. Compared with the CSK tracker, the tracking accuracy has increased from 54.4% to 73.2%. Among them, the difference between KCF (Kernelized Correlation Filter) and DCF (Discriminative Correlation Filter) is use of nuclear techniques. Similarly, the CN (Color Name) tracker extends the feature representation from gray features to color attributes [7]. The CN feature subdivides the RGB color into 11 common color in life [8]-[9]. To avoid high computational complexity, the algorithm uses the PCA method to process features. Later, Danelljan M et al. proposed the DSST (Discriminative Scale Space Tracker), which solves the multi-scale problem in object tracking [10]. During the tracking process, the algorithm designs two independent Correlation Filters to estimate the scale and the position of object. Another tracker that can solve multi-scale problem is SAMF (Scale Adaptive Filter with Feature Integration), which was proposed by Yang L. This algorithm combines the FHOG feature with the CN feature for the first time. It adopts a multi-scale detection algorithm in the field of object detection. Unlike the DSST tracker, the SAMF tracker [11] can simultaneously estimate the location and scale of the object.

At present, there are already some tracking algorithms that have done work on re-detection. The MOSSE tracker proposes a PSR indicator to measure tracking confidence. Then, LCT (Long-term Correlation Filter Tracker) introduces an additional Correlation Filter in the base of the DSST that can be used to detect object confidence [12]. If the tracking confidence factor does not meet the requirements, the algorithm initiates a research component. The algorithm uses the SVM classification algorithm to relocate. In terms of model updating, the LCMCF (Large margin tracking method with circulant feature maps) tracker proposes a robust model updating strategy [13]. The model is updated only when the tracking confidence coefficient reaches the historical mean. Otherwise, the model is not updated. In addition, the ECO tracker uses another more efficient way to perform model updates. The tracking model is updated every few frames [14].

III. OUR METHOD

In this section, we detail our proposed object tracking algorithm. Because the algorithm is based on the DCF tracker, we first introduced the basic tracker. Then, we introduced the core of this paper: global background modeling, re-detection component and adaptive model update strategy.

A. The Base Method: DCF tracker

The introduction of a large number of negative samples can improve the discriminative performance of the classifier during the tracking process. Many tracking algorithms determine the negative samples based on the distance of the object in the two frames. The overlap rate of these negative samples is actually very high. Therefore, the DCF tracker constructs training samples by cyclic shifting of the tracking object. As shown in Equation 1, the DCF tracker uses the regularized least squares classification algorithm to train the classifier.

$$\min_w \sum_i (f(x_i) - y_i)^2 + \lambda \|w\|^2 \quad (1)$$

Where f denotes a classification function, x_i and y_i represent training samples and expected outputs, respectively, W represents the weight of the classifier, and λ is a regularization parameter to prevent overfitting. Then we write it in the form of a matrix.

$$\min_w \sum_i (XW - y)^2 + \lambda \|w\|^2 \quad (2)$$

In formula 2, X and y represent the matrix form of x_i and y_i , respectively. To minimize the objective function, we take advantage of the nature of the cyclic matrix. The solution can be obtained by setting the derivative to 0.

$$\hat{w} = \frac{\hat{x}^* \odot \hat{y}}{\hat{x}^* \odot \hat{x} + \lambda} \quad (3)$$

Then, we introduce a kernel function to solve the problem of insufficient discriminant performance of the linear classifier. The kernel function maps the input data to a nonlinear feature space. Through the mapping, we can get the following expression:

$$w = \min_w \|\phi(X)w - y\|^2 + \lambda \|w\|^2 \quad (4)$$

Here, w satisfies $w = \sum_i \alpha_i \phi(x_i)$. Therefore, the above formula can be expressed as:

$$\alpha = \min_{\alpha} \|\phi(X)\phi(X)^T \alpha - y\|^2 + \lambda \|\alpha\|^2 \quad (5)$$

Through a series of derivations, the solution can be expressed as:

$$\alpha = F^{-1} \left(\frac{\hat{y}}{\hat{k}^{xx} + \lambda} \right) \quad (6)$$

Where k^{xx} is the first row of the kernel matrix k . The matrix k satisfies $k = \phi(X)\phi(X)^T$. In order to locate the tracking object in each subsequent frame, the DCF tracker also uses the cyclic shift to build the samples.

$$f(z_j) = w^T \phi(z_j) \quad (7)$$

z_j in Equation 7 represents a sample obtained by cyclically shifting the image block z , which satisfies $z_j = p^j z$. We can estimate the position of the object by calculating the detection values of all samples by the following formula.

$$\hat{f}(z) = (k^z)^T \alpha \quad (8)$$

Through the diagonalization operation, the above formula can be converted into:

$$\hat{f}(z) = \hat{k}^{xz} \odot \hat{\alpha} \quad (9)$$

Where k^{xz} is the nuclear correlation of x and z . Repeat this process and the tracking process is complete.

B. Global background modeling

In the tracking process of the KCF/DCF tracker, the search range is usually 1.5 times the size of the object. However, the operation of the cyclic shift is used in the construction of the sample, which brings the boundary effect. To alleviate the boundary effect, the DCF tracker adds a cosine window. However, the cosine window reduces not only the search range, but also the available background information available during the tracking process. In this paper, we combine the DCF framework with the framework in CACF to increase global context information.

During the training of the Correlation Filter, we sampled around the object. We train the ridge regression classifier using the object and the background image block. To get the closed solution, we regress the expected value of the global background image block to zeros. The objective function is:

$$\min_w \|A_0 w - y\|_2^2 + \lambda_1 \|w\|_2^2 + \lambda_2 \sum_{i=1}^k \|A_i w\|_2^2 \quad (10)$$

Where A_0 represents the cyclic matrix formed by the object image block, A_i represents the cyclic matrix constructed by the global background image block, and λ_1 and λ_2 are regularization parameters. In the objective function, the expected output value of the object image block is y . We recombine the object image block and the background image block to form a new matrix. This formula can be rewritten as:

$$f_p(w, B) = \|Bw - \bar{y}\|_2^2 + \lambda_1 \|w\|_2^2 \quad (11)$$

Here, B denotes a new matrix formed by combining the global background image block and the object, and \bar{y} denotes a label vector obtained by expanding the label y with 0. B and \bar{y} , satisfy,

$$B = \begin{bmatrix} A_0 \\ \sqrt{\lambda_2} A_1 \\ \vdots \\ \sqrt{\lambda_2} A_k \end{bmatrix} \quad \text{and} \quad \bar{y} = \begin{bmatrix} y \\ 0 \\ \vdots \\ 0 \end{bmatrix} \quad (12)$$

Since $f_p(w, B)$ is a convex function, by deriving the objective function and setting the derivative to 0, a closed solution for w can be obtained:

$$w = (B^T B + \lambda_1 I)^{-1} B^T \bar{y} \quad (13)$$

Using the property of the cyclic matrix, the above formula can eventually be converted to:

$$w = [F \text{diag}(\hat{\alpha}_0^* \odot \hat{\alpha}_0 + \lambda_1 + \lambda_2 \sum_{i=1}^k \hat{\alpha}_i^* \odot \hat{\alpha}_i) F^H]^{-1} F \text{diag}(\hat{\alpha}_0^* \odot \hat{y}) \quad (14)$$

By performing a Fourier transform on w , we can get:

$$\hat{w} = \frac{\hat{\alpha}_0^* \odot \hat{y}}{\hat{\alpha}_0^* \odot \hat{\alpha}_0 + \lambda_1 + \lambda_2 \sum_{i=1}^k \hat{\alpha}_i^* \odot \hat{\alpha}_i} \quad (15)$$

The next step is object detection. The response map can be obtained by convoluting the learned filter with the image block z (search window) in the next frame. Much like the DCF tracker, the detection formula for solving the response map can be expressed as:

$$\hat{r}_d = \hat{z} \odot \hat{\alpha}_0^* \odot \hat{\alpha}_0 + \sqrt{\lambda_2} \sum_{i=1}^k \hat{z} \odot \hat{\alpha}_i^* \odot \hat{\alpha}_i \quad (16)$$

C. Re-detection and re-search components

In the traditional Correlation Filter tracking algorithms, the principle of tracking is to apply the Correlation Filter template to the detect image blocks, and regard the position of the peak in the response map as the position of the object. However, there is a drawback in such a detection method which the position with the largest response value does not always track the actual position of the object, especially in some complicated scenarios. Therefore, it is likely to bring about model pollution with using this method for position estimation directly, which affects the accuracy of the tracking algorithm. In this paper, we introduce a re-detection and re-search operation to improve this problem. We used the APCE indicator to determine the tracking performance of the current frame [13]. The APCE calculation method is as follows:

$$APCE = \frac{|\max(\phi(t)) - \min(\phi(t))|^2}{\text{mean}(\sum_{m,n} (g_{m,n} - \min(\phi(t)))^2)} \quad (17)$$

Where $\phi(t)$ represents the response map of the t -th frame. When the APCE indicator does not reach the historical average, the re-detection component is turned on. We re-search for the object at the position corresponding to the other peaks of the response map. Then, the response maps obtained by the correlation filter template at all candidate image blocks are respectively calculated. Finally, we determine the image block with the largest response value as the object.

D. Adaptive model update strategy

During the tracking process, the object often undergoes various changes. Therefore, the tracking algorithm needs to update the model in time to adapt to this change to improve the robustness of the tracking algorithm. This is very challenging. In the classic Correlation Filter based tracking algorithms, both KCF and DSST tracker use the following linear interpolation update method.

$$\hat{x}^n = (1 - \gamma) \hat{x}^{n-1} + \gamma \hat{x} \quad (18)$$

$$\hat{\alpha}^n = (1 - \gamma) \hat{\alpha}^{n-1} + \gamma \hat{\alpha} \quad (19)$$

Where n is the sequence number of the current frame, \hat{x} is the target representation model represented by the predicted position image block, and $\hat{\alpha}$ is the classifier parameter, γ represents the model update rate. Currently, the model update rate is determined by empirical values and is constant. The larger the value of γ , the faster the model update rate. Conversely, the smaller the value of γ , the slower the model update rate. When a large change occurs in the object, such as posture change and in-plane rotation, etc., γ should be selected as a larger value. When the tracking environment changes greatly and the tracking object does not change much, γ should be selected as a smaller value. However, when γ is too large, the update rate is too fast and it is easy to cause model drift. In summary, setting the model update rate to a fixed value is not appropriate because it does not accurately reflect changes in the object. Moreover, this update method easily leads to over-fitting of the model to several frames

of images. For example, the updated model is particularly sensitive to occlusion and deformation. In this paper, we propose an adaptive model update strategy. Here, we introduce a penalty coefficient ξ to control the model update rate. ξ is determined by the following formula.

$$\xi = \frac{\max(\phi(t))}{\max(\{\phi(1), \phi(2), \phi(3), \dots, \phi(t-1)\})} \quad (20)$$

IV. EXPERIMENT RESULTS

A. Dataset and evaluation index

In order to test the performance of the algorithm, this paper uses the OTB-2013 and OTB-2015 datasets, which are very popular in the field of video object tracking. Prior to the advent of OTB-2013, there was no recognized database here, so the tracking performance of the algorithm could not be accurately tested and compared. The significance of OTB-2013 is profound, which greatly promotes the development of tracking algorithms. OTB-2013 includes a total of 50 video sequences, while OTB-2015 extends it from 50 video sequences to 100 video sequences. The datasets contain 11 tracking difficulties: illumination changes, scale changes, occlusion, deformation, motion blur, fast motion, in-plane rotation, out-of-plane rotation, out-of-field, background clutter, low resolution. There are 26 gray sequences and 74 color sequences in 100 video sequences. The tracking targets that appear in OTB-2015 dataset include 36 entities, 26 faces/headers, and a total of 58897 frames. The length of the video sequence includes short-term and long-term, and the longest video sequence has more than 3,000 frames.

The OTB-2013 and OTB-2015 datasets provide two evaluation indicators: precision and success rate. Precision is an indicator used to measure the center pixel position deviation. As shown in Figure 1, the estimated tracking frame of the algorithm is S' , and its central pixel position is (x', y') . The actual tracking frame is S , and its center pixel position is (x, y) . Use the Euclidean distance when calculating the center pixel deviation. Typically, the center pixel deviation threshold is set to 20 pixels. The success rate is calculated as follows:

$$\phi = \frac{S \cap S'}{S \cup S'} \quad (21)$$

Figure 2. Ground truth and actual tracking results comparison chart

B. Parameter setting and algorithm flow chart

In practice, we implemented the proposed algorithm using the MATLAB language. In this paper, the kernel function type is set to a linear kernel, the image block padding is set to 2, λ_1 is set to $1e-4$, λ_2 is set to 26, and the linear interpolation factor for adaptation is set to 0.012. When calculating the HOG feature, the cellSize is set to 4 and the orientation is set to 9.

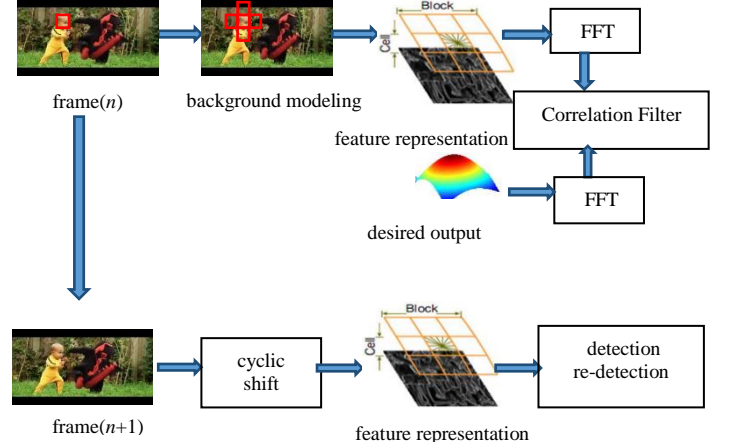

Figure 2. Algorithm flow chart

Figure 2 shows in detail the flow chart of the tracking algorithm proposed in this paper. Compared with the traditional Correlation Filter based algorithms, our proposed DCF_BM tracker has improved the training process of the Correlation Filter. On the negative samples of the training, not only the image blocks after the object cyclic shift are used, but also the image blocks around the object are also taken into consideration. In addition, an adaptive model update strategy is proposed in this paper to better adapt to object changes. Additionally, the re-detection and relocation components are also used in the DCF_BM tracker.

C. Performance testing and analysis

In this section, we compare the proposed algorithm with some of the Correlation Filter based trackers that have appeared in recent years. Because the KCF tracker has been significantly better than traditional trackers including Struck [15], TLD [16] and MEEM [17], we only compared algorithms include CSK, KCF, SAMF, DSST and Staple tracker [18].

Figure 3. Experimental results on OTB-2013 and OTB-2015

The experimental results of these algorithms on the OTB-2013 dataset are shown in (a) and (b) of the Figure 3. It can be seen that the DCF_BM tracker proposed in this paper has obtained the optimal tracking result on the OTB_2013 dataset. The precision is 83.0% and the success rate is 61.3%. Compared to the baseline tracker, it achieves significant improvements in accuracy and success rate (both 9%). The experimental results on the OTB-2015 dataset are shown in Figures (c) and (d) of the Fig. 3. We can find that the DCF_BM tracker proposed in this chapter still achieves the best performance. It has an accuracy of 80.7% and a success rate of 59.3%. Compared with the classic KCF tracker, it has increased by 11.0% and 16.0% respectively in terms of accuracy and success rate. From these comparisons, one can conclude that the work done in this paper is effective and can improve tracking performance.

In addition, by comparing the experimental results, the Staple tracker ranks second in each result graph. This is mainly because the tracker combines HOG features and statistical color histograms. The response map is linearly weighted to obtain the final response map. The boundary effect is inherently a defect in the Correlation Filter based tracking framework, while the pixel-level color probability features are not affected by this factor. So, from this perspective, the DAT [19] in the Staple tracker

mitigates the boundary effect. However, the Staple tracker roughly uses the linear weighting method in the specific implementation. The Correlation Filter response occupies a weight of 0.7, which plays a major role, while the color probability response occupies a weight of 0.3, which plays a supporting role. However, this simple weighting method has an obvious disadvantage in that it cannot adaptively determine the weights of the correlation filter response and the color probability response.

In order to further verify the performance of the DCF_BM tracker proposed in this paper under different challenges, the attribute analysis on the OTB-2015 dataset was also carried out. The tracking performance of our proposed tracker and several other advanced trackers is shown in Tab. 1 and Tab. 2. It can be seen that the DCF_BM tracker proposed in this paper achieves the best performance in almost all attributes, in terms of precision or success rate, except LR (low resolution). In addition, the performance of the DCF_BM tracker is improved under various attributes compared to the standard KCF tracker, which is due to the use of background modeling.

Especially in occlusion (precision 73.8% vs. 65.1%) and fast motion (precision 74.7% vs. 62.1%) scenes, there are significant improvements in tracker's performance. It is mainly due to the application of re-detection and re-search components. When there is an abnormality in the response map, such as in fast motion and occlusion scenarios, we can try to expand the search area and re-detect the tracking object.

V. CONCLUSION

In this paper, a tracking framework based on DCF tracker is proposed. The introduction of global background information solves the problem that the background information in the traditional Correlation Filter framework is very limited, thereby improving the discriminating ability of the classifier. The DCF tracker adopts the model updating method of linear interpolation, which is difficult to adapt to the change of the object. The DCF_BM tracker proposed in this paper introduces a penalty coefficient that controls the update rate of the model, which significantly improves this shortcoming.

Abstract—In traditional exemplar-based image inpainting algorithm, the confidence value will rapidly decrease to zero as the inpainting process progresses. As a consequence, it will lead to unreliable result of the priority calculation and wrong direction of the process. In addition, traditional methods usually use the sum of squared differences (SSD) criterion to search the optimal matching block. Since the matching criterion is single and the precision is limited, the process is easy to produce mismatch. In order to solve the above problems, an improved algorithm has been proposed in this paper. First, we proposed a new confidence update algorithm through replacing the previous linear function form by using a logarithmic function form, which can suppress the phenomenon that the confidence attenuation is too fast and improve the accuracy of guiding and inpainting direction. Then, we combine the physical distance between blocks and traditional SSD matching criterion to improve matching accuracy. The experimental results show that the algorithm overcomes the shortcomings of the traditional algorithm and provides higher quality image restoration effects and better visual effects.

Keywords—Exemplar; image inpainting; matching accuracy; Confidence term update

I. INTRODUCTION

Digital image inpainting technology has broad application prospects and is a prerequisite for image compression, image enhancement, image recognition and other technologies [1]. First, it need to research and solve how to better detect the damaged part of the image. Then, image inpainting algorithm can automatically inpaint the image according to the known information around the damaged area. Therefore, the research and exploration of image inpainting technology is a subject including both theoretical and practical value [2]. In the time, the requirements for images and video quality around us become higher and higher [3]. Therefore, it is particularly important to research on digital image inpainting.

Recently, many researchers have proposed effective image inpainting models. According to the inpainting theories, they can be divided into two categories: geometry based approaches and exemplar-based approaches [5]. Image inpainting techniques based on non-texture structures are often used to inpaint images with small damaged areas, such as scratch repair and text contamination repair [6]. In 2000, Bertalmio et al proposed BSCB model based on partial differential equation image inpainting [7]. The main idea of this model is to extending the isophote line of the damaged region's boundary and propagating

it into the damaged area. Although the BSCB model has a good inpainting result, it is based on the diffusion and transmission of the inpainting process. Objectively, it is very difficult to carry out mathematical analysis. Chan and Shen proposed the total variational model (TV model) [8] and the curvature-driven diffusion model (CDD model) [9] based on the BSCS model. Then, Telea proposed a fast matching algorithm (FMM) [10].

In 2004, Criminisi proposed the exemplar-based inpainting algorithm, which is on patch level [11]-[12]. Then, many exemplar-based image inpainting methods have emerged [13] and they have been widely used. In [14], Barnes proposed a new image editing algorithm PatchMatch to find approximate nearest-neighbor patches from image patches. This interactive technique has been used by Adobe photoshop because of the flexibility, convenience and simplicity. In [15], Liu used multiscale graph cuts in the process. In [16], Komodakis used MRF-based global optimization method to solve the inpainting problem, which is known as priority belief propagation (p-BP). There are some other researchers do some work based on priority belief propagation [17]-[18]. Then, Ruzic introduced context-aware patch-based image inpainting, where candidate patches are searched over the entire source region based on contextual similarity [19]. The author found a new priority calculation in [20] and make up for the shortcomings in Criminisi method. In [21], they used Pixel Inhomogeneity Factor (PIF) to replace the data term. In [22], Huang use the planar structure guidance to solve the inpainting problems. In [23], Deng separated the confidence term and data term, then he proposed an automatic algorithm to estimate steps of the new priority definition.

This paper proposed a novel algorithm for exemplar-based inpainting method. The main improvement is to change the matching criteria and confidence update function. First, we propose an improved confidence update function to maximize the accuracy of the guided inpainting direction. Then, we combine the physical distance between blocks and traditional SSD matching criterion to search the best matching patch. Novel method overcomes the drawback of Criminisi algorithm in visual inconsistency. We compare the method with two methods in some structure and texture pictures.

II. RELATED WORK

In this section, we mainly introduce the exemplar based inpainting method [12]. First, the image is divided into two parts: the target region is defined as the area which is to be inpainted,

{Corresponding author: Weibin Liu, wblu@bjtu.edu.cn}

DOI reference number: 10.18293/SEKE2019-152

using Ω to represent. The left area is called source region Φ . Additionally, $\delta\Omega$ represents the boundary of the target region. The inpainting task is to fill in the target region Ω using the image information from the source region Φ . The inpainting process is shown in Fig.1.

Fig.1 Inpainting process by Criminisi Method [12]

A. Deciding the filling order

This step is mainly aimed to determine the filling order of the patch in the target region. For each pixel p along the target region's boundary, we set a square patch φ_p which is centered on the pixel. In our paper, we set the patch size with 9×9 pixels throughout the process. After computing the priorities of all pixels along the boundary, we choose the pixel p with the highest priority as the center pixel, then the patch φ_p will be the target patch to be inpainted.

In Criminisi method [12], the filling priority is defined as follows:

$$P_{(p)} = C_{(p)} D_{(p)} \quad (1)$$

Where $C_{(p)}$ represents the confidence term and $D_{(p)}$ represents the data term and they are calculated by the following equations:

$$C_{(p)} = \frac{\sum_{q \in \varphi_p \cap \bar{\Omega}} C_{(q)}}{|\varphi_p|}, \quad 0 \leq C_{(p)} \leq 1 \quad (2)$$

$$D_{(p)} = \frac{|\nabla I_p^\perp \cdot n_p|}{\alpha}, \quad 0 \leq D_{(p)} \leq 1 \quad (3)$$

In equation (2), $\bar{\Omega}$ denotes the complementary set of target region Ω , $|\varphi_p|$ represents the area of the patch φ_p . During initialization, the function $C_{(p)}$ is set to

$$C_{(p)} = 0, \quad \forall p \in \Omega \quad (4)$$

$$C_{(p)} = 1, \quad \forall p \in \bar{\Omega} \quad (5)$$

For each pixel p on the boundary of target region, the confidence term $C_{(p)}$ equals to the ratio between the sum of pixels confidence in $\varphi_p \cap \bar{\Omega}$ and the total number of nonzero elements in φ_p . The higher of $C_{(p)}$, the more reliable information surrounding p . The intention is that we can inpaint the patch with more reliable information firstly.

Fig. 2 The iron of n_p and ∇I_p^\perp

Similarly, n_p is the unit vector orthogonal to the front $\delta\Omega$ in the pixel p and ∇I_p^\perp is the isophote vector (where \perp denotes the orthogonal operator). $D_{(p)}$ represents the strength of isophotes hitting the front $\delta\Omega$ at each iteration. Wherever, α is the

normalization factor. Data term guarantees that the picture is inpainted following by the isophotes, which will make sure the linear structure is first filling. Fig. 2 show the details of $D_{(p)}$.

B. Select the best matching patch

This step mainly does searching work whose aim is to find the best matching patch $\varphi_{\hat{q}}$ in the source region for the target patch φ_p whose priority is the highest. Equation (6) is the measurement of the similarity between each patch φ_q in the source region and the target patch φ_p :

$$\varphi_{\hat{q}} = \arg \min_{\varphi_q \in \Phi} d(\varphi_{\hat{p}}, \varphi_q) \quad (6)$$

$$d_{SSD}(\varphi_p, \varphi_q) = \sum \left[\begin{aligned} & (R_{\varphi_p} - R_{\varphi_q})^2 + \\ & (G_{\varphi_p} - G_{\varphi_q})^2 + (B_{\varphi_p} - B_{\varphi_q})^2 \end{aligned} \right] \quad (7)$$

The distance $d(\varphi_{\hat{p}}, \varphi_q)$ is defined as the sum of squared differences (SSD) of the known pixels in the two patches. The details is shown in equation (7) where R , G and B represents the value of intensity of each color channel.

C. Inpaint the unknown area and update the confidence term

In this step, the algorithm fills the unknown area by putting the best matching patch $\varphi_{\hat{q}}$ to the target patch φ_p in the corresponding region. After that, we need to renew the boundary of the target region $\delta\Omega$ and update the confidence term using the following equation:

$$C(q) = C(p), \quad \forall q \in \varphi_p \cap \Omega \quad (8)$$

Then, just continue to run the above steps until the unknown region is fully inpainted.

III. PROPOSED METHOD

In this section, the new update function for confident term and a new searching method are proposed.

A. Confidence term updating

Updating confidence term is an important step in Criminisi algorithm. Once the patch φ_p is filled, the unknown pixel becomes a known point which will result the confidence value changing. Criminisi algorithm simply uses the best matching patch to inpainting φ_p , and replace confidence term of the center pixel p with the corresponding pixel's confidence. It is equivalent to using the function $f(x) = x, x \in [0, 1]$ to update the confidence value. Along with the iterative process progresses, the confidence value will rapidly decrease and tend to zero, which may result in an incorrect inpainting direction.

In order to suppress the decay of confidence term in traditional methods, this paper proposes a new confidence update function. We suppose the function $h(x)$ as the following:

$$h(x) = \log_2(x + 1) \quad (9)$$

Using the improved confidence function, the update equation used in the confidence update phase will be the following:

$$C(q) = h(C(p)) = \log_2(C(p) + 1) \quad (10)$$

Where $\forall q \in \varphi_p \cap \Omega$.

B. The new matching method

The Criminisi algorithm uses SSD criteria in the matching processing to determine the similarity between sample blocks. Just calculate the sum of the squares difference of all known pixels in the block, and then select a target with the smallest error from the current repaired sample block as the best match in the source region. The matching formula is

$$\varphi_{\hat{q}} = \arg \min_{\varphi_{q \cap \Phi}} d(\varphi_{\hat{p}}, \varphi_q) \quad (11)$$

Since the matching principle is too singular, and only the color feature is considered. When adopt the global search method, multiple optimal sample blocks may appear at a distance from the area to be repaired. Then the algorithm randomly selects one as the matching patch. Because the algorithm is a serial repair, the error copy of a patch will affect the subsequent match, which is easy to cause error accumulation and the quality of repair is degraded.

In an image, it can be divided into several regions according to different structural features. For a general candidate to be matched, the matching block should appear in the same or similar region as its own structure. And the probability that the matching block appears in other regions is small. Sometimes even if such a situation occurs, it may be a mismatch. This is because the information of the adjacent space is highly correlated, and the pixels that are far apart are less correlated, so the probability that the matching patch appears in the neighborhood is the largest. In order to minimize the probability of mismatching, we proposes an improved patch matching principle that incorporates the distance between the candidate patch center point and the target patch center point into the original similarity measure function.

When searching for matching patches, we still choose global search. Because global search can overcome the shortcomings of local search's greedy character. So it can select the better matching patch to the greatest extent, and the target block inpaint can achieve global optimization. In the global search, we combine the SSD and physical distance for the calculation. The new matching formula is as follows:

$$d_{new}(\varphi_p, \varphi_q) = d_{SSD}(\varphi_p, \varphi_q) * e^{dis(p,q)} \quad (12)$$

In our new calculation method, we combine SSD and physical distance to find the optimal matching block. In order to avoid that the physical distance is zero, we use the exponential form of the physical distance to calculate. The experimental results show that the new matching criterion significantly reduces the false matching rate, and the repair results are more in line with the visual connectivity of the human eye.

IV. EXPERIMENT AND ANALYSIS

In the section, we test the proposed method on a few images with various background. Compared with the classical and state-of-art methods mentioned above, there are some improvements that can be seen from our results. Furth ermore, we set the same size for the square patch φ_p in the experiments for Criminisi's method, Deng's method and the proposed method for the fairness.

Fig. 3 Sky with a curve (a) original image (b) region need to inpainting (c)result made by[12] (d)result made by [23] (e) result made by proposed method

Fig. 6 Remove the Paragliding (a) original image (b) region need to inpainting (c)result made by[12] (d)result made by [23] (e) result made by proposed method

Fig. 7 Inpaint the red area in the sea(a) original image (b) region need to inpainting (c)result made by[12] (d)result made by [23] (e) result made by proposed method

Fig. 3 is the repair of a sky image. Obviously, a short line is emerged on the upper side of the curve in the result of Criminisi's method. Both Deng's algorithm and our algorithm avoid such mis-inpainting, and the results are more in line with real-life performance and human vision. The details of the inpainting results are shown in Fig. 4, which is more vivid to observation. In detail of the results, our method is much smoother than Deng's in terms of visual effects.

Fig. 5 is the image used in the Criminisi's paper. As can be seen from the results, the algorithm proposed by us has been greatly improved. Both competitive in terms of structure and texture. At the same time, we can see the effectiveness of the new algorithm in the subsequent of PSNR value. Fig. 6 is a target object removal for an image. The results are not clearly distinguishable. For this, we can use PSNR to judge. In the PSNR comparison in Table 1, we can observe that their values have not much difference, but there are still some. It can be seen that our algorithm is relatively better.

Fig. 7 is a representation of a seaside picture of a selected area. As can be seen from the results, the method we proposed on the repair of the coast is the best, and the results of the other two methods have spit out. Our results look smoother and more in line with real-life coastal conditions. Our method did not show particularly good results in the inpaint of the reef in the middle of the sea. In addition, in the three inpaint results, we are very clear to see the occurrence of fault phenomenon. This shows that we still have a lot of research space to solve the problem.

PSNR (peak signal-to-noise ratio) is an objective standard widely used for evaluating the quality of image processing. In order to evaluate the effect of the inpainted image, the PSNR value is usually used to measure the inpainting performance of the algorithm. The larger the PSNR value is, the smaller the degree of image distortion. Thus, the better the algorithm inpainting performance. PSNR is calculated as:

$$\text{PSNR} = 10 \log \left\{ \frac{255^2}{\frac{1}{M \times N} \sum_{i=1}^M \sum_{j=1}^N [f(i,j) - \hat{f}(i,j)]^2} \right\} \quad (12)$$

This paper also uses the PSNR to evaluate the effect of inpainting performance. Some PSNR values are shown in Table 1. It can be seen from Table 1 that the image inpainting methods proposed in this paper can obtain better results for images of different damaged regions. Since the structure and texture of the area to be repaired in Fig. 7 are relatively simple, the PSNR values of their results are similar regardless of the method. For images with more complex textures, as shown in Fig 6 and 8, the difference in PSNR values will be larger. Criminisi algorithm has difficulty in determining the confidence in the priority calculation and it is difficult to search for the best matching block, so that the PSNR value of the algorithm result is the lowest. Although Deng's algorithm improves the priority calculation, there is still problems in selection of the best matching block, which makes the PSNR value of the algorithm's result middle. Our method not only improves the confidence update, the selection of the best matching patch is strengthened. So, the PSNR value of our method gets the highest.

TABLE I.	Comparison of PSNR Value for different methods		
	Criminisi	Deng	ours
Sky	44.6362	46.9447	47.6480
Girl	13.8362	13.9845	14.0606
Paragliding	17.1514	17.1829	17.1924
Sea	25.7422	24.2435	26.9701

V. CONCLUSION

This paper proposes a new confidence update function and the new matching method. The new confidence update function can effectively reduce the phenomenon that the confidence attenuation is too fast, and improve the accuracy of the image guidance repair direction. At the same time, combining the physical distance between blocks and traditional SSD matching criterion as the new matching method effectively improves the matching accuracy. The proposed method obtains competitive results when handle pictures with strong structure or texture compared with other state-of-the-art inpainting methods. Nevertheless, our method performed not so well when the picture including both strong structure and texture.

Abstract—Trajectory similarity computation is one of the most fundamental functionality, which is applied in many fields, such as trip trajectory mining to find the most popular routes and similar ones, and identify the routes of animal migration and even the stock trends. There are two different kinds of search thoughts, the advanced deep learning method and traditional points matching methods. However, the exiting methods are not totally perfect to solve the trajectory similarity computation problem. The deep- learning method has original problem that it needs a large size of dataset resulting in the requirement of the training time much more than we expected. While the traditional points matching method often suffer from noise and non-uniform sampling rates, because points matching often treats it as two different sequences when the unequal points turn up. In other word, it is often sensitive to the noise which lowers the correct rate of the similarity computation. Based of the statement upon, we propose a new method — applying the interpolation and deformed integration to similarity computation. Experiments shows that our method is robust to the noise and non-uniform sampling rate.

Keywords—*interpolation; deformed integration; robust; similarity computing; self-similarity;*

I. INTRODUCTION

With the development of the GPS-enabled devices, trajectory data is being collected over time. In other word, the way we get trajectory data is more and more accessible. Generally, a trajectory is often represented by a sequence of discrete points or locations. And we can map it to a spatial domain, e.g., 2D Euclidean space, which leads to much many of the trajectory similarity computation methods. Computing similarity between two trajectories is fundamental functionality for many applications, such as the migration patterns of animals, identifying hot routes in cities to avoid traffic jam, recommending popular trip routes for travelers and trajectory clustering. As a classic computation problem, a large amount of

traditional methods have been proposed, such as longest common sub-sequence (LCSS) [2], edit distance on real sequences (EDR) [4], and dynamic time warping (DTW) [1]. Besides, recently, as the deep learning develops, a method related--t2vec [6], inspired by word2vec, had been proposed.

In most situation, the traditional methods are trying to make points pair match to minimize their distance. But such operation would suffer from some problems, such as the non-uniform sampling rates and noise. For example, due to the devices' inherent limitation, it may fail to grasp the exact location information. What's more, when bypassing the rough area, it is hard for the devices to locate the accurate position. They all cause the generation of the noise. And the devices may lower the frequency of recording out of energy consideration, which leads to the non-uniform and low sampling rates. To cope with the situation, deep-learning-based method had been proposed and achieved remarkable improvement. However, deep learning itself has inherent defect. It needs a large size of dataset. And the training time and the running time is often required much more than our expectation. To deal with the problems of non-uniform sampling rates, noise and low efficiency, we propose a new method — applying interpolation and deformed integration to trajectory similarity computation. Other than the points matching method, we choose the curve fitting to further research the similarity of different trajectories. The experiment shows us that our method is full of vitality, and it makes noteworthy improvement in both accuracy and efficiency. Overall, the paper makes following contributions:

1) We proposed a trajectory similarity computation model based on the curve fitting. And our method is robust to the non-uniform sampling rates and noise, and computes the similarity in linear time (we will discuss it in the later part).

2) We conduct extensive experiments to verify our method outperforming the traditional points matching method in both accuracy and efficiency.

3) We also compare our method with the traditional ones under different proportions of test set and label set.

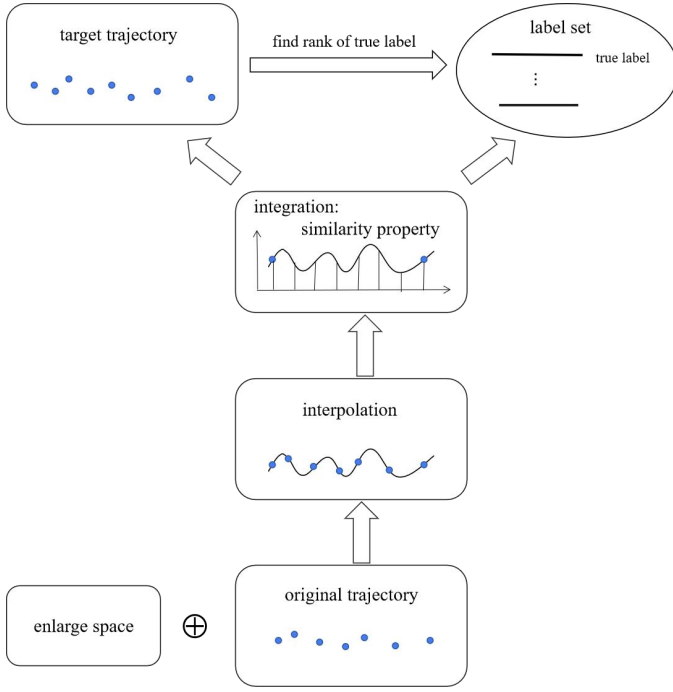

Fig. 1: Framework of proposed method

II. RELATED WORK

We briefly review the related work on the trajectory similarity computation. Computing the similarity, or say, the distance between two different trajectories is fundamental functionality in many computing tasks. And it is obvious that the accuracy and the efficiency is what we spot on. DTW [1] was first attempt at tackling the local time shift issue for computing trajectory similarity. T2vec [6] exploits deep representation learning to learn a vector inputted to the encoder-decoder framework to get a trained deep learning model. It highly increased the accuracy of the trajectory similarity computation, but being weak in the efficiency, which is left to be solved. In fact, not only t2vec method, almost every deep learning methods such as vRNN[8] share the same inherent defect. They need a large amount of data to train a model, which inevitably results in the long running time. And in some time, the loss of efficiency is unaffordable. APM[7] is another deep learning method. Despite the training time, it is worth mentioning that it solves the issue by learning transition patterns of anchor points from historical trajectories. EDR [4] was proposed to further deal with the problems of the spatial semantics in trajectories. Z. Chen et al. [15] proposed a kind of improved Frechet Distance to deal with the problem of the spatial sequences similarity computation to identify the most popular routes. To improve the robust to the variation in the sampling rates, EDwP[10] was proposed. What's more, EDwP uses the linear interpolation to compute the least loss of the insertion operation, which makes this method identical and inspires our computing measure. And ERP[3] and the model-driven approach MA[18] were proposed to better capture the spatial features in trajectories. They present different models

to speed the proceeding of capturing compared to other methods separately. Wang et al. [13] researched the effect of these similarity computation methods according to their robustness to noise and varying sampling rates.

Moreover, most of the aforementioned existing traditional measures for trajectory similarity computation has time complexity $O(n^2)$, while our method has the linear time complexity $O(n+v)$, where v represents the average length of trajectories, to measure the similarity, which reflects on the experiment -- our method is much more faster than others.

III. PROPOSED METHOD

In this part, we discuss the fundamentals of the proposed method. And then, we will prepare the preliminaries for the experiments. The method's framework is seen in Fig. 1.

A. Interpolation

Interpolation is a kind of curve fitting method to find a polynomial curve to best fit the discrete points. The definition of the interpolation: in an interval $[a, b]$, given n discrete points (x_k, y_k) , $k = 1, 2, \dots, n$, for every x , we need to find the corresponding y . $f(x)$ is defined in $[a, b]$, and

$$f(x_k) = y_k \quad k = 1, 2, \dots, n \quad (1)$$

And now, what we need to do is to find $g(x)$, for the n discrete points,

$$g(x_k) = f(x_k) \quad k = 1, 2, \dots, n$$

We call $g(x)$ an interpolation of $f(x)$ in $[a, b]$. In most cases, polynomial curve is applied when the fitting operation happens. Because for the given discrete points, the polynomial curve is much more convenient to conduct. And the sine-like polynomial curve is more stable because it usually approaches the reality than other fitting methods.

There are some reasons we adopt the interpolation instead of other fitting methods. According to the definition, we can get that the interpolation would absorb all the given discrete points without abandoning any of them. In our experiments, the most of trajectories in the dataset are collections of only dozens of latitude/longitude coordinates. For a complete route, each of them is needed. What's more, one of later operations is to distort some of the points of a trajectory (we will talk about it in detail lately) to simulate the noise in reality. That means it may destroy the simulated environment, or make the excessive operation to desert some points for the fitting.

So in this paper, we adopt *Lagrange Interpolation*, i.e., a sort of polynomial interpolation. In mathematics, Lagrange interpolation finds a polynomial that happens to take the observed values at each observed point. That means, it can provide a polynomial function that happens to cross all the given points in a two-dimensional plane.

Theorem *Polynomials that satisfy the interpolation condition (1) and whose degree does not exceed n exist and unique.*

The theorem can be proved in the establishment procedure of the Lagrange polynomial. Let set D_n be the collection of angular coordinates of the points (x_k, y_k) ,

$k=1,2,\dots,n$, $D_n=\{1,2,\dots,n\}$, there are n polynomials $p_j(x)$, $j \in D_n$, $\forall k \in D_n$,

$$p_k(x) = \prod_{i \in B_k} \frac{x - x_i}{x_k - x_i}$$

Where $B_k = \{i \mid i \neq k, i \in D_n\}$. And it is obvious the degree of $p_k(x)$ is $n-1$. Finally, we'll get the Lagrange interpolation:

$$L_n(x) = \sum_{j=1}^n y_j p_j(x) \quad (2)$$

As the operation above, the Lagrange Interpolation has been conducted and the theorem has been proved. In the later experiments, this interpolation is our important tool to do the fitting operation.

B. Similarity computation

After the above operation, we have got the fitting polynomial curve on the given several discrete points. Imagine that there are two trajectories, the target T and the compared one, S , represented by several latitude/longitude points individually. Using Lagrange Interpolation, we transform the trajectories into two fitting polynomial curves. And now, the problem transforms to how to measure the similarity of this two curves. In this paper, we are trying to apply a deformed integration to compute the similarity.

Conventionally, it is natural to integrate the difference between the two curves. Suppose that this two curves are $T(x)$ and $S(x)$. And the compared trajectory S is recorded from point a to point b ,

$$\int_{a \rightarrow b} |T(x) - S(x)| dx \quad (3)$$

Equation (3) roughly measures the similarity of the two trajectories. Intuitively, the more similar T and S are, the smaller (3) is. It is based on the start and end point of the compared trajectory. Logically, we want to find a trajectory similar to the target. As our experiments set, the compared trajectory is often shorter than the target one.

However, the experiments show that the results of the method above is not very acceptable and fails our original expectation at least. So we go about improving the integration.

There are some abuse in (3). It imports many meaningless features. As we operated before, we applied Lagrange Interpolation to transform the discrete points into the fitting curve. But when we get this step, we actually input countless points irrelevant to the trajectory into the 2-D Euclidean space. And once we adopt (3) as the similarity computation, we just add some meaningless number to the final result, which is proved to influence the result much. Not only in the accuracy, this integration also does not distinct the traditional trajectory similarity computation methods in the efficiency. We need to find the most similar trajectory for the target trajectory in a

label set. This integration requires to compute the similarity between the target and the undetermined trajectory dynamically as most the traditional method would do, which leads to time complexity $O(n^2)$. We need a more efficient method.

Our improvement is as follow. We just consider every single trajectory. And we reserve the Lagrange Interpolation to transform a trajectory T to a fitting curve $T(x)$. To avoid importing other meaningless features, get the span of this trajectory from the start point to the end point and divide it into m parts (1000 as our experiments set), calculate the value corresponding to the interval point on $T(x)$ and sum them all finally. Abstractly, we can regard the sum as the inherent "similarity property" of its corresponding trajectories. And the similarity measure of two trajectories is the absolute value of difference of the respective so-called similarity property, which leads to time complexity $O(n+v)$, where v represents the average length of the trajectories.

Suppose that there are a number of discrete points representing trajectory T in the interval $[p, q]$, and its similarity property is:

$$\sum_{i=0}^{m-1} T(p + \frac{q-p}{m}i) \quad (4)$$

For each trajectory, we can get (4) as the property is inherent. And measuring the similarity depends on the absolute value of the difference of (4). The algorithm is shown in Algorithm 1.

Algorithm 1:

Input: The original trajectory points sequence T ,
corresponding fitting curve $T(x)$,
interval m
similarity property P 's set D of the label set

Output: The rank of T 's true label

```

1 for  $u$  in  $m$  do
2    $P \leftarrow P + T(u)$  according to equation (4)
3 end for
4 sort  $D$ 
5 rank  $\leftarrow 0$ 
6 for  $i$  in  $D$  do
7   rank  $\leftarrow$  rank + 1
8   if  $P < D(i)$  do
9     break
10  end if
11 end for
12 return rank
```

C. Map trajectory to larger space

We get the complete measure of the trajectory similarity computation. But for the latitude/longitude space, the prepare is not enough for our experiments.

In order to pursue the accuracy and efficiency, we lose the stability of the results to some extent. Though such sacrifice is worthy and acceptable, we still want to debauch the loss and enhance the stability as much as possible.

And in this part, we propose an improved method which is to enlarge the space. For the latitude/longitude space, the points representing the trajectories are so intensive as 1 longitude difference is more than 100 km, that when we adopt the Lagrange Interpolation, the fitting curve would flog as the interpolation needs to cross all the discrete points. Flogging makes distortion. To make the fitting curve more smooth, we choose to enlarge the space.

The core rule is to reserve the relative distance between points but to enlarge the absolute distance. For simplicity, select a constant α and α times the distance between the points by fixing the start point of the trajectory. After such operation, we have enlarged the space.

And the experiments show that after enlarging the space, the result is more steady.

D. Noise and varying sampling rates

In fact, noise is common in the collected trajectory data. To simulate the actual situation, we need to add the noise to the collected trajectories. Firstly, we confirm a distorting rate r_l and randomly select a fraction of the points (indicated by r_l) and then, distort them by adding a Gaussian noise with a radius 30 (meters). Suppose that a point (x, y) is distorted,

$$\begin{aligned} x &= x + 30 \cdot dx, & dx &\sim \text{Gaussian}(0,1) \\ y &= y + 30 \cdot dy, & dy &\sim \text{Gaussian}(0,1) \end{aligned} \quad (5)$$

We now have the environment with noise. And another problem -- non-uniform sampling rate is left to cope with.

Due to the reality, such as the devices' inherent flaw and energy concern, we can not always obtain the regular lattice of trajectory points sequence. Likewise, we set the sampling rates.

Before we talk about the sampling rates, suppose that we have a points sequence \mathbf{T} , $\{T^{(i)}\}_{i=1}^n$, where n is the length of the points sequence \mathbf{T} , and we regard it the real route. Then, we create a sample from \mathbf{T} by randomly dropping some points with the sampling rates r_2 . For reality concern, we reserve the start point and the end point to avoid changing the underlying route of the sampled trajectory. In our experiments, the sampling rates varies from 0.2 to 0.6, and we compared with other traditional methods on the basis.

IV. EXPERIMENTS

We aim to verify the accuracy and efficiency of our proposed method on a taxi dataset. Compared to other three trajectory similarity computation methods which had been proved validly, we want to find our method outperforming in both accuracy and efficiency.

A. Experiment setup

Dataset: Our experiments are conducted on a real-world taxi dataset (<http://www.geolink.pt/ecmlpkdd2015-challenge>). It's collected in the city of Porto, Portugal. It contains over 1.7 million

trajectories. Each taxi reports its location at 15 second intervals. So each record consists of a series latitude/longitude points representing the trajectory. To reduce the contingency, we remove the trajectories which are less than 30 points. And there are about 1.2 million trajectories left.

Fig. 2: Mean rank versus distorting rate

Benchmarking Methods: We compare our method with three other traditional methods in accuracy and efficiency, namely DTW[1], LCSS[2], EDR[4]. The above three methods are applied in trajectory similarity computation in most cases. To analyze the performance of our method and other methods in the round, we set many contrast experiments. We fix the sampling rate in 0.6, and vary the distorting rate in [0.20, 0.25, 0.30, 0.35, 0.40, 0.45, 0.50, 0.55, 0.60]. Then, we fix the distorting rate in 0.4 and vary the sampling rate in [0.20, 0.25, 0.30, 0.35, 0.40, 0.45, 0.50, 0.55, 0.60]. In every same parameter setting, we try to make our method outstanding.

LCSS and EDR are two of the most widely adopted trajectory measures in spatiotemporal data analyses. LCSS adopts the length of the longest common sub-sequence as the measure of the trajectory similarity computation, while EDR adopts the edit distance. To a certain extent, this two methods are based on the point-to-point match. They seek the as much as more matched points pairs. And obviously, they both abandon the regularity of the points sequence in the x axis, leading to the inaccuracy. And DTW measures the similarity by warping the sequence to best achieve “feature to feature” aligned. But in the trajectory similarity computation, the warping operation may distort the original features of the points sequence, which would also result in the inaccuracy.

Our method proposes a different thinking relative to above three traditional methods. A mixture of the interpolation and “deformed integration” helps to keep the original features and avoid bringing in too many redundant ones.

Evaluation Platform: Our method is implemented in Python running in Windows 10 with an Intel Core i7-7700 CPU.

B. Performance evaluation

The trajectory dataset we adopt in our experiments is consist of points sequences representing trajectories, which means that the dataset lacks the ground-truth that makes it hard to evaluate the performance of our method and other compared methods in accuracy and efficiency.

(c)

We adopt a method called self-similarity[6] to perform the evaluation for our experiments. We randomly choose 10,000 trajectories from the dataset and for every sequence in the chosen trajectories, we down-sample and distort them to generate the sub-sequence due to the current sampling rate and distorting rate. And we get the label set of 10,000 trajectories.

And for every trajectory T from another 10,000 trajectories of the dataset, we can also get its sub-sequence S according to the current sampling rate and distorting rate. We call S the label of T . Now we get the point pair (T, S) and we regard T as the true route in reality, and S as the sampled data collected by the devices. Then we can say that S is the best match for T .

Fig. 3: Mean rank versus sampling rate

A good performance evaluation should keep stable regardless of the sampling or distorting strategy. And the self-similarity satisfies the requirement. So the next operation is to hide S in the label set. We try to find the k-nearest neighbors and figure out where the best match S ranks in the whole label

set. And we compare the mean-rank of our method to the other three ones.

C. Experiment in accuracy

As shown in Fig. 2, when the distorting rate is increasing, every method's mean rank augments generally, which corresponds to reality. The more distort, the more unmatched it gets. Likewise, in Fig. 3, as the sampling rate increases, the mean rank lowers by and large, which means the matching result is getting worse.

The above experiments show that the performance evaluation we adopt -- self-similarity is of stability and it is well adapted in our experiments proceeding. Self-similarity depicts the trend well as the distorting/sampling rate varies and the difference of all the compared methods under the same condition, which all render certain to the self-similarity for experiments.

And our experiments totally satisfy our previous thought. In every distorting rate and sampling rate, our method's mean rank is lower than other three ones, which means our method stands out. To achieve high accuracy, we pay the price of stability to some extent as the Fig shows. And we "enlarge the space" to minimize the cost as we originally wish to. It does work well in our experiments. The curve of our method increases/decreases steadily due to the "enlarge" operation, where we overcome the inherent defect to a large extent. The cost of the stability to enhance the accuracy is worthy.

The above experiments is conducted on basis of 5:5 proportion of the test set and label set. To explore further, we conduct experiments of 6:4, 7:3 and 8:2 proportions, seen in TABLE I, sampling rate denoted as S. rate and distorting rate denoted as D. rate. Due to interpolation, our method performs ordinarily while sampling rate gets low and the fitting curve distorts much, but stands out in most other situations.

D. Experiment in efficiency

Our method aims to stand out in efficiency, too. In the previous method analysis, our method involves “similarity property” in every trajectory, which reduces the time complexity. And we have recorded the running time of the compared methods, seen in Fig. 4.

Fig. 4: Comparison of running time

We recorded the running time of our method compared to the traditional methods. And we can get that our method is outperforming in efficiency.

E. Time complexity

In this part, we discuss the time complexity of our method compared to other traditional trajectory similarity computation methods.

Our method does not dynamically compute the similarity of trajectories. Instead, we introduce a concept of similarity property. And for every single trajectory, we just compute its similarity property. Then, all the trajectories has their own similarity property. So we just need to compare the similarity property to each other and we get the final results. As we analyse before, it is evident that our method’s time complexity is $O(n+v)$, where v represents the average length of trajectories.

Our method decreases the time complexity by almost one order of magnitude. But as sacrifice, we lose a little stability to some extent which we view worthwhile.

V. CONCLUSION AND FUTURE WORK

In this paper, we propose a trajectory similarity computation method -- a mixture of Lagrange Interpolation and a kind of deformed integration and we compare our method to the traditional similarity computation methods in accuracy and efficiency.

And we set the contrast experiments, which then shows our method stands out in both accuracy and efficiency compared to other methods at the price of stability to some extent. Then, we minimize the sacrifice in stability by the operation of “enlarge” the longitude/latitude space, which also achieves great result.

To evaluate the performance of our method compared to others, we exploit self-similarity, which meets the need of evaluation in performance analysis, such as stability and intuition.

There are some problems remained. On the basis of keeping the satisfactory time complexity, we can explore other measures to compute the similarity property. And we can also change the mean-rank evaluation and the distribution of top-k trajectories.

Abstract—The granularity of large patent classification systems hampers the reclassification process in which patent categories are broken down into smaller ones, suggesting new categories. As these groups belong to a constricted domain of knowledge, keywords and subject descriptors tend to be similar and therefore insufficient to differentiate documents. In this context, the identification of common cited references can be useful to define semantic relationship among patents. This work compares citation analysis based results obtained by three clustering algorithms, SOM networks, K-Means and Multi-SOM. An empirical experiment was conducted using a patent database from the United States Patent and Trademark Office with all patents of four subgroups classified by the Cooperative Patent Classification system. Practical results evaluated by statistical inference techniques showed that SOM performs better than the other algorithms to cluster that database. This study can contribute with the reclassification process for a subgroup level of current patent classification systems, demonstrating how citation analysis can be an alternative attribute to the automatic clustering process.

Index Terms—Clustering algorithms, Computational intelligence, Knowledge representation, Patent database, Statistical inference

I. INTRODUCTION

A patent is a public concession, whereby the government, in exchange for full disclosure of an invention, grants the inventor the right to exclude others for a limited time from making, using or selling this invention [1]. Patents are organized into classification systems according to their technical application and structural characteristics to aid the patenting and retrieval processes.

With the growth of digital patent collections, the number of patents at all levels of classification systems has been increasing and some groups need to be dismantled in order to generate new groups and facilitate access to information. Considering the patents subgroups, which are subsets in an equal knowledge area and have a lot of similar words in their

abstracts, it is a challenge to identify common characteristics using words as attributes of the clustering process.

The main objective of this work is to evaluate the performance of some algorithms of patents clustering using citations as attributes. For this, three clustering algorithms will be used on a United States Patent and Trademark Office (USPTO) patent database. This work was divided into five sections. Section II presents a description of the implemented algorithms and some related works. Section III presents the database and proposed methodology, while Sections IV and V show the results and final considerations.

II. THEORETICAL BACKGROUND

SOM networks are maps of artificial neurons developed by Teuvo Kohonen in the 1980s. These structures, based on topological maps present in the cerebral cortex, are responsible for the execution of the grouping process. Each input neuron is connected to an output neuron by its respective association weight. This network uses unsupervised learning. From the instant the network identifies the regularity between the input data, it generates internal representations to encode the input characteristics and automatically create new groups. These networks have the capacity for self-organization and are more similar to neurobiological structures than supervised networks. Many of the experiments reported in the literature describe the use of SOM in grouping documents so to organize them as an alternative format for information retrieval [2].

The Multi-SOM algorithm is an extension of the SOM algorithm. This algorithm uses simultaneously several maps of SOM to cluster input patterns. The amount of simultaneous maps is defined by the user. For the initial map, data training is performed using the SOM algorithm. For the generation of the next maps, the algorithm realizes the superposition and the communication between the previous and the current maps. To carry out the transition from one map to another, it is necessary to define the new nodes. These nodes are defined by using the

mean square composition of the four neighbors, directly from the lower level [3], [4].

Performing this procedure preserves the original neighborhood at the higher levels and also the topographical properties of the maps [3], [4]. The Multi-SOM algorithm used in this work was implemented using an R library called “multisom” [5] available for R language. This algorithm not only performs grouping of data but also estimates the optimum number of clusters. At the end, it returns the best result obtained for the input data.

K-Means is an unsupervised data clustering algorithm. The main idea of this algorithm is to define k centroids, one for each cluster. After defining the centroids, the algorithm associates the centroid with the closest data. Then the centroids are recalculated and the previous steps are repeated for the new centroids until the centroids no longer move or the stop criterion is met [6].

Meireles, Cendón and Almeida [7] presented a comparison of document clustering process using keywords and citations. The experiments were performed using a test database with 200 articles from a restricted knowledge domain. The first experiment used the keywords of the articles in the test database as attributes for the clustering process. The second experiment was carried out using the citations of the articles as attributes. Both tests were performed using a SOM network. The experimental results showed that, in a domain of restricted knowledge with a great similarity between documents, the use of keywords was not very efficient. On the other hand, the use of citations can be considered an important alternative.

Lai and Wu [8] proposed an approach to create a new patent classification system, to assist patent managers in evaluating the basic patents for a specific industry. Li, Chen, Zhang and Li [9] considered the structure of patent citation networks for patent classification. They adopted a Kernel-based approach to capture content information and citation-related information in patents, and their proposal outperformed Kernel’s which did not use citation network structures. Liu and Shih [10] combined content-based, citation-based and metadata-based classification methods to develop a hybrid-classification approach using a modified K-Nearest Neighbor (KNN) algorithm.

III. PROPOSED APPROACH

The database used in the experiment was extracted from USPTO. The Cooperative Patent Classification (CPC) system, which is used by USPTO, classifies patents into sections, classes, subclasses, groups, and subgroups. Figure 1 illustrates the organization of this patent database and it was highlighted the low level hierarchies subgroups used in this work.

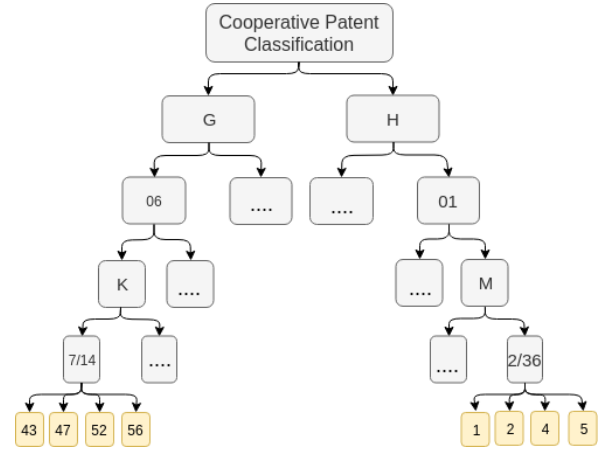

Fig. 1. Organization of the Database

In order to validate the proposed clustering process, two databases were created. Each database is composed by four subgroups randomly chosen in two distinct sections of the CPC system. In the hierarchy defined by CPC, the subgroups represent patent groups contextualized in the same area of knowledge. The first base is composed of subgroups G06K 7/1443, G06K 7/1447, G06K 7/1452 and G06K 7/1456 of the G06K subclass, named “recognition of data, presentation of data, record carriers, handling record carriers”, shown in Figure 1 only with their suffix 43, 47, 52 and 56. The second base is composed of subgroups H01M 2/361, H01M 2/362, H01M 2/364 and H01M 2/365 of the subclass H01M, named “processes or means, e.g. batteries, for the direct conversion of chemical energy, into electrical energy” represented in Figure 1 only with their suffix 1, 2, 4 and 5. Some patents of the subgroups are classified into more than one subgroup. In this work, only the first classification is considered and, therefore, the number of patents available is different from the number of patents selected for the database. Table I shows the name of the subgroups in the CPC system and the number of patents selected.

TABLE I
DATABASE

Sections	Codes CPC	Number of patents available	Number of patents selected
G	G06K 7/1443	505	452
	G06K 7/1447	302	263
	G06K 7/1452	93	78
	G06K 7/1456	227	117
H	H01M 2/361	213	185
	H01M 2/362	126	101
	H01M 2/364	33	28
	H01M 2/365	139	59

The methodology used to cluster the documents was divided into three execution steps and one analysis phase. In the first step, the citations of the patents contained in the selected subgroups were extracted. These citations were taken from the section of documents referenced by the patent. From this process, two binary citation matrices per document were

generated, one for each database, which inform the occurrence of a certain citation in each document. In these matrices, the digit 0 represents the absence of a citation in the document and the digit 1 represents the existence of a citation in the document. According to Borgman and Furner [11], the analysis of citations allows for the identification of relationships documents, regardless of the presence of equal terms. In this work, the occurrence of common quotes among patent documents is used as a mechanism to define the semantic relations between them.

In the second step, those matrices were used as inputs for each one of the three algorithms discussed in Section II. For each algorithm, the experiments were repeated for 30 times, to account for statistical validation. For the SOM network and K-Means, the number of clusters k was defined as 4, which was the number of subgroups of the database used for validation. The Multi-SOM does not need to receive as input the number of clusters. However, it is necessary to define the dimensions of the first map. Thus, the first map dimension was defined as 6×6 .

In the third step, an algorithm was implemented to evaluate the correspondence between the groups generated by SOM, Multi-SOM and K-Means algorithms and the original CPC subgroups presented in Table I. Finally, in the analysis phase, an objective comparison was performed using statistical inference, by hypothesis tests. In this test, the hypothesis tested (H_0) was the equality of average between the number of patents identified in step 3 and the number of patents selected in each subgroup. In this test, a categorization algorithm will be considered more efficient when the average is closer to zero. At the end, it was possible to infer if some of the algorithms were better or worse than the others, to solve that clustering problem. The alternative hypothesis (H_1) used for the Kruskal-Wallis H test and boxplot was the average difference in the number of patents clustered (ADPC) by each algorithm in the clusters, i.e. the difference between the number of patents identified, for example in group G1, and the number of patents selected in the corresponding original CPC subgroup. A low ADPC informs that the associated clustering algorithm groups together a number of patents similar to those of the original CPC subgroups.

IV. EXPERIMENTS

The experiments were divided into two phases. In the first phase, the tests were carried out with the database composed by the patents of section G. A total of 10,148 citations were extracted from the 910 patent documents. The matrices generated in this process were used for the clustering process. Fig. 2 shows the distribution of patents in the four groups generated by SOM algorithm, referred here as G_G1_S , G_G2_S , G_G3_S and G_G4_S . Kruskal-Wallis H test was performed to compare those samples from each of the groups generated, the test suggested that there were statistical differences between the three samples (with $p_0 = 5.31 \times 10^{-18}$ for the group G_G1 and with $p_0 = 3.08 \times 10^{-18}$ for the group G_G2). To find the difference of samples, a comparison was

performed by means of boxplot representations. This resulted in the plots of Fig. 3 and Fig. 4. It is possible to infer, with 95% of confidence, that SOM algorithm performs better than K-Means and Multi-SOM to cluster patents of this database by means of citations, as SOM averaged differences between number of patents identified on step 3 and patents selected in each subgroup (H_1) could not be rejected. Therefore, it is clear from this analysis that SOM performed much better than K-Means and Multi-SOM, as their ADPC is smaller than those by its counterparts.

To the groups identified by K-Means algorithm, it was added the termination KM (G_G1_KM , G_G2_KM) and to those identified by Multi-SOM, it was added the termination MS (G_G1_MS , G_G2_MS).

Fig. 2. Typical result of the clustering process using a SOM network

Fig. 3. Boxplot representation of results for G_G1

Fig. 4. Boxplot representation of results for G_G2

From the four groups created in the experiments, it was possible to identify two of them, which had a majority of patents, one from G06K 7/1443 and the other from the G06K 7/1447 subgroup. The other two groups had patents from the four used subgroups. Analyzing the first one created by SOM, named G_G1_S , with 696 averaged patents, 62.75% belonged to G06K 7/1443 subgroup of the documents database. K-Means and Multi-SOM created a big group with averages of 844.6 and 886 patents, respectively. From these, 58.60% and 54.85% in average were from the G06K 7/1443 subgroup. This indicates that K-Means and Multi-SOM algorithms failed to identify differences between documents from their citations, keeping the vast majority of patents in a single group.

The second group analyzed, created by SOM, named G_G2_S , had 133 patents in average. A total of 100% belonged to the G06K 7/1447 subgroup of the documents database. K-Means and Multi-SOM algorithms kept, in average, 100% and 28.57% of the patents from the G06K 7/1447 subgroup in G_G2_KM and G_G2_MS . But, while SOM was able to keep an average of 133 patents on G_G2_S , K-Means and Multi-SOM clustered only 35 patents in G_G2_KM and 14 patents in G_G2_MS respectively, in average. Table II presents the results obtained.

TABLE II
RESULT OF THE FIRST PHASE OF THE CLUSTERING PROCESS

Groups	Average cluster size	Average hit percentage
G_G1_S	696	62.75%
G_G2_S	133	100%
G_G1_KM	845	58.6%
G_G2_KM	35	100%
G_G1_MS	886	54.85%
G_G2_MS	14	28.57%

In the second phase, the tests were performed with the database composed of patents of section H. A total of 2,755 citations were extracted from the 373 patent documents. Fig. 5 shows the distribution of patents in the four groups generated by SOM algorithm, referred here as H_G1_S , H_G2_S , H_G3_S and H_G4_S . The Kruskal-Wallis H test suggested that there were statistical differences between the three samples of the three groups generated (with $p_0 = 1.26 \times 10^{-18}$ for the group H_G1 , $p_0 = 8.99 \times 10^{-19}$ for the group

H_G2 and $p_0 = 6.05 \times 10^{-17}$ for the group H_G3). To find the difference of samples, a comparison was performed by means of boxplot representations. The Fig. 6, 7 and 8 present a boxplot representation of the results in terms of ADPC. It is possible to infer, with 95% of confidence, that SOM algorithm performs better than K-Means and Multi-SOM to cluster patents of this database by means of citations, as SOM averaged differences between number of patents identified on step 3 and patents selected in each subgroup (H_1) could not be rejected. Again, it is clear that SOM's ADPC is significantly smaller than ADPC obtained by K-Means and Multi-SOM.

Fig. 5. Typical result of the clustering process using a SOM network

Fig. 6. Boxplot representation of results for H_G1

Fig. 7. Boxplot representation of results for H_G2

Fig. 8. Boxplot representation of results for H_G3

From the four groups created by the algorithms, it was possible to identify three with more similarity to the subgroups created by the specialists. These are equivalents to subgroups H01M 2/361, H01M 2/362 and H01M 2/365. These groups were named as H_G1 , H_G2 and H_G3 , respectively. The H_G1_S group created by SOM contains 247 patents in average, of which 57.82% were correctly grouped. K-Means and Multi-SOM have created the group H_G1_KM with 367 and H_G1_MS with 357 patents in average. From these, 57.17% and 56.58% were correctly grouped.

Analyzing the groups H_G2_S and H_G3_S it was identified that only SOM managed to create groups of a relevant size. The H_G2_S group created by SOM contains 48 patents in average, of which 78.30% were correctly grouped. The H_G3_S group created by SOM contains 45 patents in average, of which 57.41% were correctly grouped. Therefore, it is possible to state that the SOM has a more satisfactory result than K-Means and Multi-SOM, since it can better identify the differences between patent documents. K-Means and Multi-SOM clustered the vast majority of patents into a single group. These algorithms were not able, in these experiments, to identify differences between the documents that allowed them to be clustered in different groups. We believe that SOM could perform better than Multi-SOM to solve a given problem, even being nothing but a special case of Multi-SOM, because SOM can be more specific and specialized than Multi-SOM, thus being more precise. On the other hand, Multi-SOM is more general, and perhaps capable of dealing better with different instances of the problem. The percentage of patents correctly grouped by algorithms is very close, in some cases, this is due to the fact that the number of patents in the generated groups is very small. Table III shows the groups created, the average size of each cluster and the average percentage of patents correctly classified.

TABLE III
RESULT OF THE SECOND PHASE OF THE CLUSTERING PROCESS

Groups	Average cluster size	Average hit percentage
H_G1_S	247	57.82%
H_G2_S	48	78.30%
H_G3_S	45	57.41%
H_G1_KM	367	57.17%
H_G2_KM	3	58.70%
H_G3_KM	1	36.06%
H_G1_MS	357	56.58%
H_G2_MS	3	68.67%
H_G3_MS	2	50%

V. CONCLUSION

With the increasing number of patents and the development of new technologies, the classification systems employed by patent offices should be constantly reviewed to avoid accumulation of documents on certain subgroups. In a restricted domain of knowledge such as the subgroups of CPC system, it is difficult to use words as units of knowledge representation in an automatic clustering process because the subject descriptors and the words tend to be similar.

The main contribution of this work is to evaluate the performance of three clustering algorithms on a restricted knowledge domain, based on CPC sub-groups. The experiments brought the theory of citation analysis to a practical application of interest to the academic and industry communities. For the given scenarios, SOM networks showed superior performances compared with K-Means algorithm and Multi-SOM networks. Most of patent offices professionals and researchers in the domain of information retrieval and applied machine learning deal with the upper levels of classification hierarchies (class and subclass levels) and only some have tracked the problem on a more fine-grained classification (group and subgroup levels), as done in this work. For future work, it is expected to perform the comparison of the clustering process in a larger scale, using the upper hierarchy of the CPC system.

Abstract—ProcessPAIR is a novel method and tool for automating the performance analysis in software development. Based on performance models structured by process experts and calibrated from the performance data of many developers, it automatically identifies and ranks potential performance problems and root causes of individual developers. However, the current calibration method is not fully automatic, because, in the case of performance indicators that affect other indicators in a conflicting way, the process expert has to manually calibrate the optimal value in a way that balances those impacts. In this paper we propose a novel method to automate this step, taking advantage of training data sets. We demonstrate the feasibility of the method with an example related with the Code Review Rate indicator, with conflicting impacts on Productivity and Quality.

Index Terms—automatic performance analysis, personal software process, Performance analysis tool

I. INTRODUCTION

Process and product data produced in software development projects can be periodically analyzed to identify performance problems, determine their root causes and devise improvement actions. However, conducting the analysis manually is challenging because of the potentially large amount of data to analyze, the effort and expertise required, and the lack of benchmarks for comparison.

ProcessPAIR is a novel method and tool for automated performance analysis and improvement recommendation in software development [8]. Based on performance models defined by process experts and calibrated from the performance data of many projects, it automatically identifies and ranks potential performance problems and root causes of individual entities (developers, teams or organizations), so that subsequent manual analysis for the identification of deeper causes and improvement actions can be properly focused. ProcessPAIR was successfully applied in education and training environments [9]. ProcessPAIR is also of interest to high-maturity organizations (CMMI maturity levels 4 and 5), because it facilitates the implementation of practices of the Organizational Process Performance (ML4) and Organizational Performance Management (ML5) process areas [3].

However, the current calibration method used by ProcessPAIR is not fully automatic, because the optimal value of each

performance indicator must be provided by the process expert. In many cases, the optimal value follows directly from the definition and is located in one extreme of the scale (minimum or maximum). But in the case of performance indicators that affect other indicators in a conflicting way, an intermediate optimal value that balances those impacts need to be manually calibrated by the process expert. An example is the Code Review Rate (size unit reviewed per time unit). If code reviews are performed too fast, quality of reviews (Code Review Yield) is negatively affected, but if they are performed too slow, Productivity is negatively affected, and it is not easy to choose a review rate that balances these two conflicting impacts.

In this paper we propose a novel method to automate this step, and hence fully automate the model calibration process, taking advantage of training data sets. We show the feasibility of the method with a data set that includes Code Review Rate, Productivity and Code Review Yield data.

The article is organized as follows. Section II presents background information about ProcessPAIR. Related work is presented briefly in Section III. Section IV presents the proposed method and feasibility study. Section V concludes the article and points directions for future work.

II. BACKGROUND

A. The ProcessPAIR Approach

The ProcessPAIR approach involves three main steps (see Figure 1):

- 1) *Define*: Process experts define the structure of a performance model (PM) suited for the development process under consideration. In our approach, a PM comprises a set of top-level and child performance indicators (PIs), organized hierarchically by cause-effect relationships [7].
- 2) *Calibrate (or Learn)*: The PM is automatically calibrated by ProcessPAIR based on the performance data of many process users. The statistical distribution of each PI and statistical relations between PIs are computed from the training dataset, taking advantage of statistical and machine learning techniques [7].
- 3) *Analyze*: Once a PM is defined and calibrated, the performance data of individual entities can be automatically

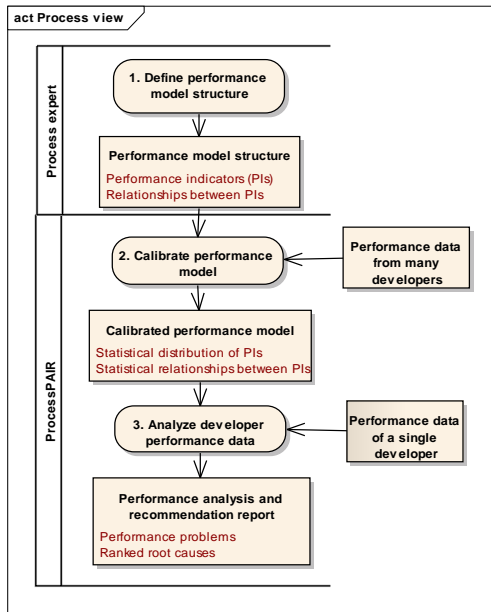

Fig. 1. UML activity diagram depicting the main activities and artifacts in the ProcessPAIR method.

analyzed by ProcessPAIR, to identify performance problems (in top-level PIs), identify potential root causes (related with child PIs), and rank those potential root causes.

The ProcessPAIR approach is supported by the ProcessPAIR tool, freely downloadable from <https://blogs.fe.up.pt/processpair/>. The tool is implemented as a standalone Java application, in order to protect the users data. It has a core framework and extensions for the processes of interest. An extension for the Personal Software Process (PSP), containing the definition of performance models for the PSP and data loaders from the most relevant project management tools used by PSP developers, was developed for education and training environments, but other extensions can be easily developed for other processes and contexts.

Further details about each step are given next.

B. Model Definition

The first step in our approach is the definition of the following elements of the PM:

- list of relevant PIs, including formulas for their computation from base measures, and the definition of the optimal value of each PI;
- subset of top-level PIs;
- cause-effect relationships between PIs, determined by a formula or statistical evidence;
- sensitivity coefficients [10] between PIs related by a formula (needed for ranking the identified root causes in the performance analysis step).

C. Model Calibration

The PM is automatically calibrated by ProcessPAIR from training data sets, generating the following data:

- approximate statistical distribution (cumulative distribution function) of each PI in the training data set;
- recommended performance ranges for each PI, needed for classifying values of each PI of a subject under analysis into three semaphores: green - no performance problem; yellow - a possible performance problem; red - a clear performance problem. Such ranges are calibrated automatically from the training data, so that there is an approximately even distribution of data points by the semaphores. In particular, the green range corresponds to the 1/3 data points closest to the optimal value, and the red range corresponds to the 1/3 data points farthest to the optimal value;
- regression models and sensitivity coefficients between PIs not related by a formula. Sensitivity coefficients between PIs not related by a formula are computed by first determining a regression model from the calibration dataset (a piecewise linear model organized as a regression tree [1]), and subsequently computing the corresponding sensitivity coefficient.

Some results of model calibration can be consulted in Figure 2. The example refers to the Code Review Rate, here named as Code Review Productivity. The approximate statistical distribution (cumulative distribution function) of this performance indicator, calibrated automatically by ProcessPAIR based on a training data set, is shown on the bottom left side. The 'green' and 'yellow' performance ranges are shown on the right; these ranges are calibrated automatically by ProcessPAIR, based on the commutative distribution function and the optimal value (calibrated manually by the process expert). The data points in the chart on the right show the values of this performance indicator for a series of projects under analysis. Different performance indicators defined in the performance model can be consulted in the tree view on the top left side. The Code Review Productivity has a green semaphore because its values lie mostly inside the green range.

D. Performance Analysis

Having defined and calibrated the PM, the performance data of individual entities (developers, teams or organizations) can be automatically analyzed by ProcessPAIR, to identify and rank performance problems and potential causes [7].

To rank the identified causes (child PIs) of performance problems in top-level PIs, it is used a ranking coefficient, that combines a sensitivity coefficient (measuring the impact of improving child PIs on top-level PIs) and a so-called percentile coefficient (measuring the difficulty of improving the child PIs).

The percentile coefficient is computed based on the distance of the observed values to the optimal value of each PI.

Hence the choice of optimal value has impact on both problem identification and root cause identification and prioritisation.

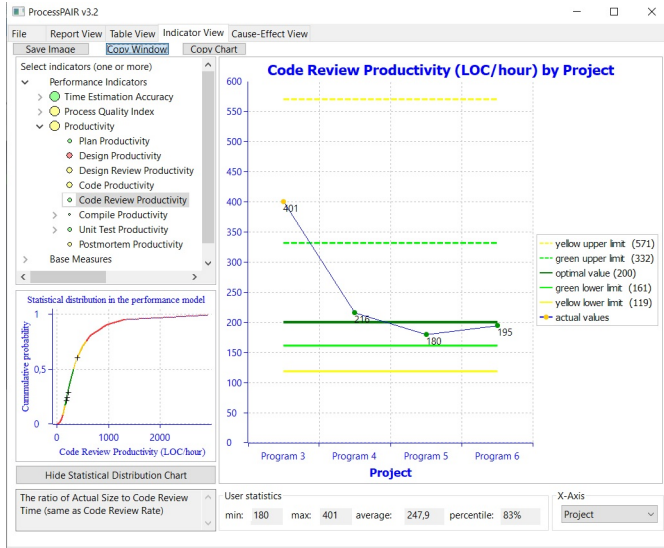

Fig. 2. ProcessPAIR user interface.

III. RELATED WORK

A. Optimal Code Review Rate

According to [4] [12], the time spent in reviewing a work product in relation to its size (review rate) is a leading indicator of the review yield (percentage of defects found).

In a published study [5], the recommended review rate of 200 lines of code (LOC) per hour or less was found to be an effective rate, identifying nearly two-thirds of the defects in design reviews and more than half in code reviews.

A team using the Team Software Process (TSP) obtained a process performance model (PPM) for establishing a target code review rate (number of lines of code reviewed per hour), based on the predicted impact on the code review yield (percentage of defects found in reviews), characterized as [12]:

- Regression equation: $CodeReviewYield = 146 - 0.364 \times CodeReviewRate$
- $R^2 = 94.1\%$, $p - value = 0.000$

According to this regression equation, the smaller the code review rate, the higher is the predicted code review yield (that, anyway, by definition, cannot exceed 100).

However, the quantitative impact on overall productivity was not analysed in those studies.

B. Productivity Measurement

Software development productivity is usually measured in function points per time unit or lines of code (LOC) per time unit [13] [6] [11]. However, both productivity measurement techniques have some limitations. On one hand, the measurement of function points remains subjective even after the completion of the software development project. On the other hand, productivity measures based on LOC have limitations due to the lack of counting standards and the dependence on the programming language [2].

In the data set we will explore for automatic calibration of the optimal value, there is no information about function

points, only size and time. The training data set contains data from more than 3000 individuals that developed the 10 projects of the standard PSP training (the same projects for all individuals, but with varying programming languages). Hence, we will take the average effort per project as a proxy for the functional complexity of each project, and calculate the individual productivity as the ratio between the functional complexity of the projects and the actual time (hours) spent by that individual.

IV. PROPOSED METHOD AND RESULTS

A. Method

Let us assume that a child PI X (such as the Code Review Rate) has conflicting impacts on two or more parent PIs Y_1, Y_2, \dots, Y_n (such as the Code Review Yield and Productivity).

The first step is to analyse the impact of the child PI X on a parent PI Y_i at a time, represented as a function f_i from X to Y_i . In order to arrive at a smooth function, we derive that function as follows: for each candidate optimal value x of X , we compute the mean value of Y in the data points that have the value of X within the green range corresponding to x .

Formally, denoting by S the training data set, p a data point in S , $Y_i(p)$ the value of Y_i in p , $X(p)$ the value of X in p , F the cumulative distribution function of X in S , and F^{-1} the inverse of F ,

$$f_i(x) \triangleq \text{mean}\{Y_i(p) | p \in S \cdot X(p) \in \text{Green}(x)\}$$

with

$$\text{Green}(x) = [F^{-1}(\frac{2}{3}F(x)), F^{-1}(\frac{2}{3}F(x) + \frac{1}{3})]$$

In the second step, we compute a combined impact function f_c , as a normalized average of the previous functions:

$$f_c(x) \triangleq \text{mean}\{\frac{f_i(x)}{\max(f_i)} | i = 1, \dots, n\}$$

The values of this function are adimensional values in the 0-1 scale.

Finally, we choose the value x of X that maximizes $f_c(x)$.

All the filtering procedures and calculations can be fully automated.

We implemented the calculations in a prototype tool taking advantage of evolutionary algorithms (genetic algorithms) to solve the optimization problem in a way that can scale to large data sets.

B. Results

In this study, for automatic calibration, we used a PSP data set available from the Software Engineering referring to 31,140 projects concluded by 3,114 engineers during 295 classes of the classic PSP for Engineers I/II training courses running between 1994 and 2005. In this training course, targeting professional developers, each engineer develops 10 small projects, following increasingly sophisticated process

Fig. 3. Impact of CRR on CRY

Fig. 4. Impact of CRR on Productivity

variants (PSP0, PSP1, etc.). Since code reviews are introduced only in the third project, we excluded the data points with zero time spent in Code Reviews. Since the Code Review Yield is undefined in case of 0 defects entering the Code Review phase, we also excluded data points with undefined Code Review Yield. In the end, we selected 9,650 data points (each corresponding to a project developed by a developer). Based on the selected data points, we computed the impact functions for the case of Code Review Rate, impacting Productivity and Code Review Yield. The resulting curves are presented in Figures 3, 4 and 5.

Figure 3 shows that, as expected, higher values of Code Review Rate are associated with lower values of Code Re-

Fig. 5. Combined impact of CRR on CRY and Productivity

view Yield, which declines more significantly in the 200-500 LOC/hour range.

Figure 4 shows that, as expected, higher values of Code Review Rate are associated with higher values of Productivity, with a more significant increase in the 100-600 LOC/hour range.

Figure 5 shows the combined impact of Code Review Rate on Code Review Yield and Productivity. The combined curve has some oscillations due to the close symmetry of the two component curves, with a peak value at 270 LOC/hour.

Hence, the computed optimal value is 270 LOC/hour. This value is a bit higher than the literature recommendation of 200 LOC/hour, but perhaps closer to common practice when productivity impact is also important.

V. CONCLUSIONS

The method proposed in this paper worked successfully for the case study presented, allowing the automatic calibration of the optimal value and range of a PI (Code Review Rate) with conflicting impacts on other PIs (Code Review Yield and Productivity). The derived optimal value (270 LOC/hour) is a bit higher than the literature recommendation (200 LOC/hour), which is justified by the fact that we are quantitatively analyzing not only the impact on review effectiveness (yield), but also on productivity.

As future work, we intend to implement the calibration method in the ProcessPAIR tool in order to automatically calibrate all the PIs with conflicting impacts on high-level PIs.

Abstract—This paper collects research papers on knowledge engineering 2009-2018 from the internationally-authoritative citation database Web of Science and uses the co-word analysis method to analyze these contents of literature. By statistical analysis of keyword frequency, the paper compiles the co-word table of the high-frequency words, uses statistical analysis software to make hierarchical clustering, and summarizes hot research topics in the knowledge engineering area.

Keywords—knowledge engineering; co-word analysis; topic research; data process

I. INTRODUCTION

In 1977, Professor B.A. Feigenbaum, a computer scientist at Stanford University in the United States, presented a new concept of knowledge engineering at the 5th International Conference on Artificial Intelligence. He believes that "knowledge engineering is the principle and method of artificial intelligence, providing a means to solve problems that require expert knowledge to solve. The proper use of the knowledge acquisition, expression and reasoning process composition and interpretation is based on knowledge. An important technical issue of the system." This type of knowledge-based system is an expert system built through intelligent software.

The method of co-word analysis was first described in detail in the mid to late 1970s by French biometrician. Co-word analysis is a content analysis technique that uses patterns of co-occurrence of pair of items (i.e., words or noun phrases) in a corpus of texts to identify the relationships between ideas within the subject areas presented in these texts [1].

Based on the co-occurrence frequency of pairs of words or phrases, co-word analysis has proved to be a powerful tool for knowledge discovery in databases. Word clustering has also been profitably used in the automatic classification of documents, see [2]. The underlying assumption is that words that typically appear together should be associated with similar concepts.

II. DATA SOURCE

This paper uses the international authoritative citation database Web of Science published by the American Institute of Scientific Information (ISI) as the source of literature information. The paper intends to analyze the knowledge engineering research topics, so that the search criteria are "topic or search keyword is knowledge engineering", the search scope is 2009-2018, and the search time was February 12 2019 in the web of science database. The database has the added categories for each topic for more e. In the "knowledge engineering" subject, the "computer science interdisciplinary applications" or "computer science artificial intelligence" categories have been chosen for the limitation of the papers' content. A total of 1550 related articles were retrieved. Each article record contains multiple fields, such as title, author keywords, citations, publication date, etc.

III. RESEARCH METHOD

This paper uses the methods of bibliometrics and content analysis to quantitatively and qualitatively analyze the data. The Bibliometric Method is a quantitative analysis method that uses mathematical statistics to study the external features of the literature. Content Analysis Method is an in-depth analysis of the content of the research object [3].

There are two types of keywords in the research papers. One is author keyword (DE field), the other is a supplementary keyword (ID field) ISI keyword which is extracted by ISI according to the title of the paper. In order to fully reflect the topic of research in the field of knowledge engineering in the past ten years, using the author keywords.

After the DE field is split with punctuation ":", the list of keywords is formed. In the former similar papers directly used the form co-occurrence to establish a co-word matrix, this article will further summarize the word forms differently. Lemmatization rules apply to the keywords list. Lemmatization is a process of assigning a to each word form in a corpus using an automatic tool called a lemmatizer [4]. Lemmatization reduces inflected forms of a word to their lexical root. With lemmatization turned on, a keyword is reduced to its "lemma". As a result, lemmatization can reduce or eliminate the variant spellings of a word express the same

concept. For example: citing、cites、cited and citation are the inflected forms of the cite. Lemmatization makes the mapping between cite and its each inflected form. In this paper, stemming rules also apply to the keywords processing. With stemming, words are reduced to their word stems. A word stem need not be the same root as a dictionary-based morphological root, it just is an equal to or smaller form of the word [5]. Stemming removes suffixes such as -ing and -es from keyword in order to cluster relevant keywords. For example, with stemming rules the keywords “vinyl recording” will be same as vinyl record. Stemming and lemmatization are closely related. The difference is that stemming merely drops suffixes such as -ing and -es, while lemmatization makes use of dictionaries that define pairs and clusters (e.g., defense, defenses) of words with the same meaning or with a shared morphological structure. Both lemmatization and stemming apply only to English language search terms. After the prototyping process, calculate the keyword frequency. Get the lemma keywords list with frequency.

From the literature of 1550 articles, the author keywords were merged through prototyping and stemming, and more than 4,000 concepts were obtained. On the basis of high-frequency word statistics, a co-occurrence matrix as TABLE I is established according to the frequency selection high-frequency keywords which frequency is greater than or equal to 10.

In the construction of the author's key common word matrix, this paper uses the Python program to prototype and stem the author keywords to establish a 203*203 matrix. The matrix is a symmetric matrix in which the data on the main diagonal is defined as the conceptual frequency, and the data on the non-main diagonal represents the number of times the two concepts appear together in the same paper. The concept here can be composed of multiple forms.

IV. BIBLIOMETRIC ANALYSIS

A. Published Time Distribution

The change in the number of academic papers is an important indicator for measuring the development trend of a field for a period of time. It is of great significance for evaluating the stage of the field and the development trend and forecasting future trends. The author makes diachronic systematic statistics on the distribution of 1550 documents, and

makes a distribution curve scatter plot, as shown in Fig. 1.

Figure 1. knowledge engineering published literature quantitative

It can be seen from the figure that the number of publications in knowledge engineering research has been growing steadily in the past decade, especially in 2012 and 2018, respectively, with two small peaks, 179 and 195. It shows that the industry has always attached great importance to the research of knowledge engineering, and knowledge engineering is still the current research hotspot.

B. Publications

Through statistical analysis, it is concluded that the top 24 journals published the most published papers accounted for 50% of the total papers in the entire knowledge engineering field. The journals of papers amount distribution as Fig.2. Providing high-quality academic papers for researchers in the

Figure 2. journal distribution

TABLE I. PART OF KEYWORD CORRELATION MATRIX

	Ontology	Knowledge engineering	Knowledge management	Ontology engineering	Knowledge representation	Knowledge-based engineering
Ontology	124	16	10	6	12	1
Knowledge engineering	16	88	3	1	10	1

Knowledge representation	12	10	2	5	43	1
Knowledge-based engineering	1	1	3	1	1	30

field of knowledge engineering, researchers would publish their fresh and novel related papers or find fresh topic content.

C. Analysis of highly cited papers

In descending order of the order in which the documents are cited, select top10 as shown in the following TABLE II. According to the content of the article, the authors try to analysis the distribution of research topics in the field.

As can be seen from TABLE II, the most cited is Natural Language Processing (Almost) from Scratch [6] written by Professor Collobert, R *et al*, cited as 1010 times. This paper is one of the most classic papers of neural network language model and word embedding. Its core goal is to train good word embedding to complete tasks such as part-of-speech tagging, phrase recognition, named entity recognition and semantic role tagging. This paper provides a good idea for the future use of neural networks for specific natural language processing tasks. NLP technology can be used for text mining, analysis of natural language texts, discovery of conceptual relationships between knowledge points and knowledge points, and assisting in knowledge acquisition for large-scale knowledge engineering. Use NLP technology as a tool to practice knowledge engineering.

In August 1977, Edward Feigenbaum proposed the concept of knowledge engineering for the first time. Since then, knowledge engineering has been a foundation of expert systems (also known as knowledge-based system) [7]. Since the beginning of the 21th century, the knowledge engineering's evolution has been focused on big data. A vast amount of data is generated and processed every day, and accessible content on the Internet is far beyond the exploration capabilities of data consumers, who usually can't locate the relevant information within an acceptable time frame. To cope with the challenges brought by the big data phrase of knowledge engineering's evolution, BigKE (Knowledge engineering with Big Data) [8] uses its frame work to offer several advantages over conventional knowledge engineering.

V. ANALYSIS OF MAINSTREAM RESEARCH TOPIC

Knowledge engineering is an applied science with its rich research fields. Topic analysis is a method of content analysis that understands the internal state of development of a discipline. The author intends to use high-frequency keywords to co-occurrence matrix and analyze several mainstream subject areas of knowledge engineering research, and to study knowledge engineering from a vertical direction.

Since the frequency of occurrence of each keyword itself is different, in order to eliminate the influence of the difference on the analysis below, the co-occurrence matrix is converted into the correlation matrix by Ochia coefficients, as show in TABLE III (part).The formula for calculating the Ochia coefficient is as follows: the Ochia coefficient of keywords K1 and K2 equals the number of co-occurrence of K1 and K2 is divided by A, and A is equal to the square of the product of the frequency of K1 and K2. According to the formula, the transformation of the co-occurrence matrix and the correlation matrix conduct.

The data in the correlation matrix is similar data, and its numerical value indicates the distance and similarity between the two keywords, that is, the larger the value, the closer the distance between the two keywords, the better the similarity [10]. In order to reduce the larger error caused by too many 0 values in the correlation matrix, the matrix is further transformed into a similar matrix, the larger the value, the closer the two keywords.

On the basis of the correlation matrix, get the hierarchical clustering. Euclidean Square Distance have been selected the measured range the in the process cluster analysis. The Average Linkage have been used for the distance of the clusters through the agglomerative hierarchical clustering technique. The result as Fig. 3 as below. According the research, the list of keywords frequency and the semantic relations between the keywords, the cluster tree divided into four sections: Smart learning and education, Knowledge acquisition, Knowledge basic algorithms and Knowledge engineering technology application.

A. Smart Learning and Education

Knowledge grid realizes the orderly organization and knowledge discovery of domain knowledge, which is the ideal environment for learning. The knowledge grid adopts ontology modeling based on description logic, which can realize reasoning and has great application prospects for satisfying individualized learning and guiding learning process [11]. The current far-reaching application of information technology in the field of education is about the study of educational

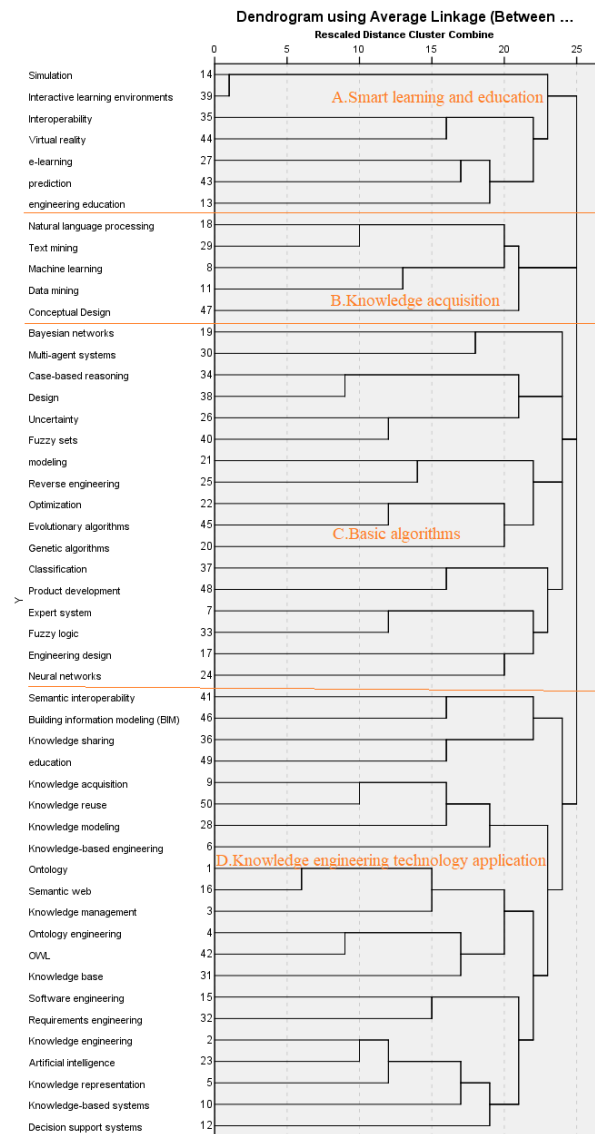

Figure 3. Keywords Hierarchical cluster tree

metadata, such as the Dublin Education Metadata Standard DC-Education and the IEEE-LOM Learning Object Model.

B. The Key Techniques of Knowledge Acquisition

"Technology" is the foundation for the application and innovation of knowledge engineering to realize its knowledge. This means. In the modern era of rapid development of modern information technology, key techniques of knowledge engineering are constantly innovating and advancing. "Knowledge Acquisition (KA)" is the process of extracting various expertise for problem solving from knowledge sources and transforming it into executable code on a computer [12]. Emerging knowledge acquisition techniques have Data mining, Web mining, text mining, etc., these techniques will help knowledge extraction in knowledge engineering and promote knowledge engineering to a deeper level.

C. Basic knowledge algorithms

Any calculation that follows the laws of nature can be called Computational Intelligence, sometimes called Soft Computing. It mainly includes three contents: fuzzy computing, which is introduced by human processing, fuzzy computing, which is based on the working rules of biological neural networks, and genetic algorithms and evolutionary calculations that mimic the "survival of the fittest" rule in the biological world (Evolution computing).

Machine learning processes can be effectively integrated into knowledge engineering pipelines using commonly available software frameworks that incorporate the mathematics and algorithms needed to perform deeper analysis than was possible before. Machine learning approaches fall into two broad classes: supervised learning and unsupervised learning. The supervised algorithms are given labelled training data, whereas unsupervised learning algorithms find structure within the input data. The construction of a knowledge engineering pipeline will typically need to leverage algorithms from both classes.

D. Knowledge Engineering Technology Application

Data science and technology have received widespread attention. Data-centric research methods and techniques in information, energy, medicine, sociology, etc. Various subject areas have been widely applied and recognized. Driven by the wave of urban informatization and the rise of data science, smart cities have become the new ideas and new practices of the next generation of urbanization on a global scale. "Smart City is built on the basic framework of digital cities. It is connected to the real city through the ubiquitous sensor network. The massive data storage, calculation, analysis and decision-making are handled by the cloud computing platform, and the results of the analysis decision are Automated control of various facilities" [13]. The information system as a smart city must have powerful computing power, sensing ability and data application capability, which will become the research field of knowledge engineering.

VI. CONCLUSION

With the help of the co-word analysis method, this paper analyzes the research topic in the field of knowledge engineering more intuitively and scientifically, and has made in-depth discussion, which has certain practical significance. Through the analysis of the authors, the following conclusions were obtained.

Starting from the analysis of the research topic based on co-word method. The word distribution of each document is used to establish a co-word matrix with lemmatization. After transforming it into a correlation matrix, it is hierarchically clustered by SPSS, and finally four subject groups are selected. In-depth content analysis, sorted out their main research content and hotspots.

ACKNOWLEDGMENT

This article has been helped, reviewed, and guided by Dr. Zheng Liu. I would like to express my heartfelt gratitude and sincere respect to her. The perseverance of the spirit of Dr. Liu, the profound knowledge, the work attitude of the facts, the generosity and the spirit of selfless dedication have always inspired me to constantly learn knowledge and pursue the realm of life. Thanks Dr. Haibo Li for his suggestion to modify the content of the article. There are too many people who have helped me, sincerely thank all those who care and help me, thank them for giving me the power to overcome myself, transcend myself, and constantly pursue, thank you all.

Finding Erroneous Components from Change Coupled Relations at Fix-inducing Changes

Ali Zafar Sadiq, Ahmedul Kabir and Kazi Sakib

Institute of Information Technology, University of Dhaka

Email: zafarsadiq120@gmail.com, kabir@iit.du.ac.bd, sakib@iit.du.ac.bd

Abstract—During the gradual process of software evolution, errors appear in different components of a software system. These errors are later on fixed by developers as part of corrective maintenance activities. However, if errors appear continuously from a particular component, that may indicate design flaws or code smells. Maintenance cost will greatly reduce if design flaws are treated as early as possible. To find out such flaws it may require time-consuming manual inspections. This paper tries to find out such components using the information of change coupled cluster of files or Java classes at fix-inducing changes. In this proposed approach, information (like class, method, parameter of method and variable names) from change coupled relation of a class at Fix-Inducing Changes (FICs) are used to provide information about erroneous components. Then the error history, of software components, is found by using cosine similarity of information from change coupled cluster of classes found in FICs to see with the architectural information found from authenticated sources. Finally, the error history of components is shown as the percentage of change coupled cluster of a class found in FICs of each 100 commits in the version control system.

Index Terms—Fix-Inducing Change, Software Quality Assurance, Software Change, Software Maintenance, Change Coupling

I. INTRODUCTION

Change is an inevitable part of the evolution of software. Frequently co-changing software artifacts form change coupled relation. Any change in an artifact will influence change in other artifacts which are change coupled with the former. This relation can also be considered to form a cluster of artifacts with respect to a file or class, which may be affected depending on the change of that class. So any class and its co-changing artifacts can be considered to be a part of a module or component which shows close interactions among themselves.

Changes are done to introduce new features into the system or to fix existing errors and any changes can introduce errors, flaws or failures in the system. Various works identified these erroneous changes [1] and analyze their impact [2]. The reasons behind these changes may be improper coding or careless implementation of algorithms. For analyzing these changes, various properties of change like files affected, time, experience of developer and many others taken into consideration [3] [4] [5] [6]. However, none of those explored the architectural components of a software system is affected by those erroneous changes during the process of software development and maintenance.

Continuous appearance of errors from a particular component indicates that either that part has design flaws or it needs

redesigning. To find out such components, manual inspection of files from source repository and bugs from bug repository is required. Moreover, the bug repositories will only provide information about reported bugs whereas many unreported bugs fixed by developers will remain hidden. So considering bug repository may give less information than the actual situation.

Various works tried analyze the quality of software systems and condition of architectural components [7] [8] [9]. Evolution radar used change coupling relation to show the condition of software components [7]. This work did not consider the erroneous changes and only focuses on design flaws based on change couple relation. Using the comments from the version control system, sticky notes are seen to provide useful information [8] but the concept of error is not seen there. Furthermore, the relationship between the evolution of software artifacts and the way they are affected by problems is visualized by D'Ambros et al but it did not consider component based analysis using commit history [9]. To the best of author's knowledge, none of the existing works explored by combining the information of change coupling relation and Fix-Inducing Changes of source repositories to find software components error history.

To find the erroneous components, firstly the fix-inducing changes are found by tracking the modified and deleted of error fixing changes. Then the entire history is traversed using a commit window of 100 commits. In every 100 commits, the classes (only Java classes are considered in this work) found in the FICs are noted. Then for each of those classes, that class itself and the cluster of other classes forming change coupled relation with that class are considered. Then for each of these cluster classes, information about class, method, method's parameter, and variable names are collected. Using the cosine similarity of the information obtained from each cluster with the architectural information from the authenticated source, the most probable component for each cluster is found. Then of the total clusters, what percentage of clusters belongs to which component is graphically represented. So, the main contribution of this paper is to propose a methodology to generate the error history of software components for the entire lifetime of any source repository.

II. METHODOLOGY

This work tried to utilize the change coupling information of classes found in fix-inducing change. Unlike [7] [8] [9],

this work focuses on components error history. Analyzing this history might play an important role in the fields of software architecture, evolution, decay, and similar others.

The entire process of the proposed methodology consists of three steps. Firstly, fix-inducing changes are extracted by using historical information. Then clusters of change coupled classes are identified by observing their changing relation. Lastly, the error history is analyzed by using cosine similarity between obtained change coupled cluster of classes and architectural information.

A. Finding Fix-Inducing Changes (FIC):

Bugs are errors of the system that causes the system to behave in unintended ways. The origin of the bugs are FICs which introduce errors in the software system. These are also known as bug introducing change, Figure 1 explains the entire process of finding fix-inducing changes. This process starts with finding fixing commits which are mainly committed in the version control system by developers with a comment containing keywords like “Fix”, “Bug”, “Patch” or their past and gerund form. Any number with hashtags indicating bug number along with those keywords were also considered to represent fixing commits. These commits contain the change to correct errors. This change is done by modifying or deleting some lines of code that is present in the immediate commit parent to a fixing commit. To obtain those lines that were modified or deleted, Diffj tool’s [10] source code is used after modifying it according to our need. Since Diffj ignores white space and other format changes, so it ignores the possibility of finding false FICs as mentioned by [11].

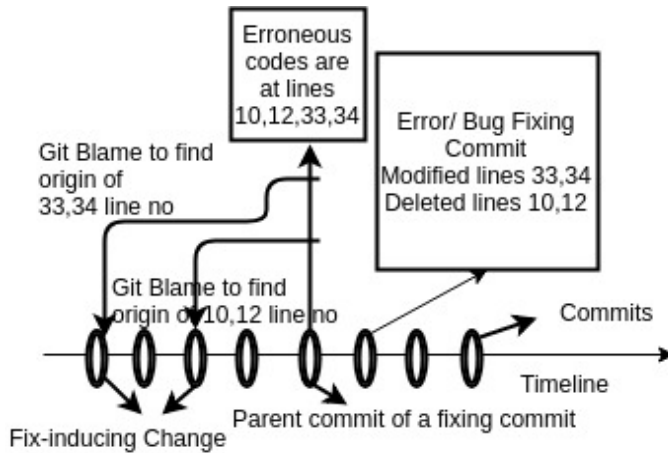

Figure 1: Finding Fix-Inducing Changes.

To track the origin of those lines in the parent commit of fixing change, Git blame command¹ is used [12]. The commits which were found are the FICs or changes introducing errors in the system. All FICs of the repository are found in this way.

¹git -c core.abbrev=40 blame -L(line number),+1 (FCParentHash) ^ - (filename)

B. Finding Cluster of Change Coupled (CC) classes:

CC classes are found by constructing a co-change matrix [13]. In this symmetric matrix, any cell, [A, B] and A≠B, represents of total changes of artifacts A or B, how many those changed together. Besides, in the cell [A, A] keeps track of how many times artifact A changed. Using appropriate support and confidence, the change coupled relation can be found among Java classes. Support represents how many times a class changed and confidence represents the likelihood, which means if there are 2 coupled artifacts, if one artifact changes, the probability that another artifact is going to change or not. In co-change matrix [A, A] represents support and confidence are represented by following Equation 1.

In Figure 2, there are 2 classes I and J. Among 5 changes of A and 3 changes of B, both of the co-changed 3 times. So the probability that if class A changes then class B will change or that confidence is obtained from equation 1 as $\frac{3}{5}$ or 60%. But if B changes then the confidence that A will change is $\frac{3}{3}$ or 100%.

CC classes were found by using different support and confidence in different works. Zimmermann et al used the support greater than 1 and confidence level 0.5 in their work [14]. However, Bavota et al considered elements that co-changing in at least 2% of the commits along with a confidence level of 0.8 [15]. Since, 0.8 confidence is high, in this paper 0.7 confidence level is used along with support 2 or more is considered. So in the considered 70% confidence and according to Figure 2, class J will have change coupled relation with I but not the opposite. This relationship is considered for classes found in FICs and the time period is taken from the 1st commit to the FIC. The source of finding this relationship, the co-change matrix is constructed by considering a n x n array, where n is the number of files or classes and co-changes of Java classes within the considered period is stored in that array. Then for each Java class, the change coupled relation with others are found based on considered support and confidence. Those other Java classes that have change coupled relation with a Java class is considered to form a cluster.

$$\begin{aligned} \text{Confidence}(A \rightarrow B) &= \frac{\text{support}(A \rightarrow B)}{\text{support}(A)} \\ &= \frac{\text{support}(A \cup B)}{\text{support}(A)} \end{aligned} \quad (1)$$

C. Commit History Analysis:

In this work, fixing changes are found by searching commits which later on leads to fix-inducing changes. Then using a commit window of 100 commits the entire commit history of source repository is traversed. However, the initial 20 commits were omitted for repository setup issues. After that commit window is used to traverse commits, i.e. 20-120, 120-220 and so on. For 100 commits in each window, FICs are analyzed for their contents. Figure 3 shows the entire process. After getting all FICs, these are sorted. Then traversing with commit

Figure 2: Example of Co-Change Matrix and Commit Timeline

frame of 100 commits, all FICs that falls within the frame can be found out.

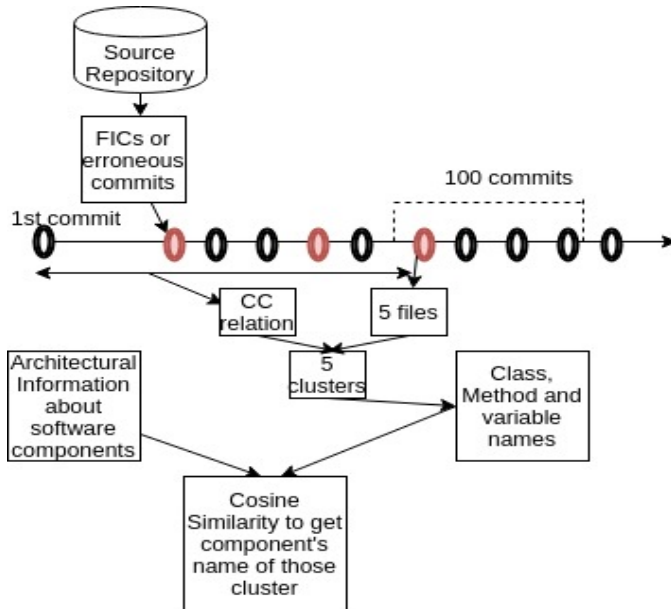

Figure 3: Commit History Analysis process to show the erroneous components.

In the contents of those FICs, firstly files with .java extension were searched. Then those files or classes were taken. For each of those class, cluster of classes found from the change coupled relation (with at least 2 support and 70% confidence) formed from 1st commit to that FIC are taken. Then that class in FIC along with its classes in change couple cluster are explored for their class, variable and method names. Then architectural information are taken from authenticated source and those information were first cleared of their stop words and then by applying the porter stemming algorithm their root words are taken. After that cosine similarity between those architectural information of different components and change coupled cluster information is taken to find out the most probable component for the cluster. After getting names for

each of these clusters, what percentage of total cluster belongs to which cluster can be easily known. Frequent appearance of the same component in commit history found by traversing with a commit window of 100 commits means that component is vulnerable to errors and responsible for costly corrective maintenance of the software system.

III. EXPERIMENTATION

This experiment is carried out in a virtual machine where operating system is Ubuntu 18.04 with 64 GB memory and 16 core CPU. For this experiment, among the popular Java repositories, 2 java repositories are selected for the study. These are as follows:

Repository Name	Source	Total Commits	Commits Analyzed	Number of Java classes	Lines of Code
Google Guava [16]	Github	4798	4020	3170	768858
jEdit [17]	Github	8000	8000	600	196194

TABLE I: General description of repositories.

Of the used 2 repositories, Google Guava is a source repository of library classes maintained by Google developers. This provides more functionalities than existing java collection framework and contains other features like hashing, graph, range etc. The commits of this repository started from June 2009 to the last commit updated in August 2018. In the case of jEdit, it is a text editor written in Java. In its source repository, commits started in 2001 and the last one is a patch commit in August 2019. By looking at commit history it can be said that the gradual development and maintenance is very slow in recent times.

Using the above mentioned repositories, the experiment is methodologically conducted. Firstly, Fixing changes were found by analyzing commit comments. After that, diffj [10] is used to find the lines that were modified or deleted from FCs parent commit. Since diffj ignores cosmetic and format changes, possibilities of finding false FICs are thus reduced. Then those identified lines are tracked by using Git Blame command to find the FIC commits where the last modifications are made. The total number of FCs and FICs that are found in both repositories are showed in Table II.

Repository Name	Fixing Commits	Fix-Inducing Commits
Google Guava	597	486
jEdit	2752	2270

TABLE II: Total Fix-Inducing Commits and Fixing Commits of each repository

The FICs are then sorted to find according to commit timeline. Then using a commit window of 100 commits, the entire history is traversed. For each FICs within the commit window, the .java files or classes are being collected. For each

class in FIC, a cluster of CC formed through the gradual development of the Change Couple relation throughout the lifespan of a project was analyzed. From the CC cluster of class in FIC and that class, information about classes, methods, and variables were collected. These are used to find cosine similarity with the description of components available from authenticated sources. Then of total clusters what percent belongs to a particular component for a particular 100 commit is found out.

Architectural information for google guava is collected from authenticated sources like in GitHub or their main website. In the case of jEdit, their main website is used to collect information about components. The obtained result mainly depends on this architectural information as cosine similarity is performed on this information.

IV. RESULT ANALYSIS

The results are obtained by conducting an experiment on the first 4000 commits of Google guava and 8000 commits of commits of jEdit. From the experiment, the name of components of google guava repository is obtained from [16] and that of jEdit is obtained from [17]. Table III and IV contains the name of the components considered.

Components	Description
Basic utilities	Deals with nulls, preconditions, common object methods, ordering, and throwables
Collections	It is an extension of JDK's collection system. It deals with immutable collections, new collection types, powerful collection utilities, and throwables.
Graphs	It mainly represents a graph, network and has structured data.
Caches	Local caching and support a wide variety of behaviors
Functional idioms	It is used to simplify the code greatly.
Concurrency	It contains powerful abstractions to write correct code.
Strings	It has useful string operations like joining, splitting and padding.
Primitives	It contains operations on primitives like int or char which is not provided by JDK
Ranges	It is an API to deal with both continuous and discrete ranges on comparable types.
I/O	It contains simplified I/O operations which specifically deals with I/O streams or files.
Hashing	It deals with hashing problems.
EventBus	It deals with publish-subscribe-style communication between components.
Math	It contains more optimized and tested math utilities, not provided by the JDK.
Reflection	It contains guava utilities for Java's reflective capabilities.

TABLE III: Information about components of Google Guava repository from github [16].

Components	Description
General	General features of the jEdit text editor providing writing and correcting facilities.
Source Code Editing	Dealing with source codes of different programming language.
Search and Replace	Different functionalities dealing with search.
File Management	It consists of everything related to files, like opening, editing, renaming and other such actions.
Customization	It consists of configurations to deal with users preference like customizable keyboard shortcuts etc.
Extensibility	Various plugins can extend the current abilities of jEdit to provide more functionalities.

TABLE IV: Information about components of jEdit repository from github [17].

The name of the components are the features or modules found from the architectural information of corresponding sources. In Figure 4a the x-axis represents the commit number and y-axis represents the percentage of clusters obtained from FICs within the commit window of 100 commits. In Figure 4a, it is clearly visible that the file management part contributed a dominant portion to introduce errors into the software system. After it is found that file management, SourceEdit, and extensibility related classes are responsible for introducing errors into the system. jEdit being a text editor, surely works on file management will be more and it is expected to produce more errors. Next comes doing programming using jEdit, classes which manage it was producing more errors in the earlier phase of development which later on is replaced by extensibility. This might be because works on extensibility feature increased in later phase.

From Figure 4b, it is seen that seen that different components of the software system are affected at different times. However dominant top three are related to Math, Ranges, and Primitives. This may be associated with the nature of the project which is a library project. So mainly fixing occurs in classes when there are problems with continuous or discrete ranges, primitives with float or int values and calculations related to math.

Through Figure 4a and 4b, any developer can understand classes of which components are producing more errors and thus can try to identify design flaws or code smells so that these can be addressed to improve the quality of software.

V. THREATS TO VALIDITY

The main factors for which construct validity might be threatened are described here. Firstly, only commit comments are searched to identify fixing changes without linking those to bug repositories. To create a link between fixing changes with bug report of the bug repository becomes a problem when the bug ids are not available. So for those cases linking with fixing changes might lead to unfair situation [18]. Besides, the main goal of this study is to find erroneous components. Secondly,

(a) Error History of components in jEdit Repository

(b) Error History of components in Google Guava Repository

Figure 4: Error History of components

there can be varying behavior in the contents of commits. Unrelated classes in bug fix can lead to wrong fix-inducing changes. But it is found that related works are committed together and 15% of all bug fixes to consist of multiple tangled changes [19]. Thirdly, all fixes may not be actually corrective maintenance [20]. However, using 10 random searches in FCs, only bug fixes are found. The main purpose of those FCs was corrective maintenance,

This work only considers java classes as Diffj, which is used for differencing modified and deleted source code lines between files of two commit version, can work only in java repositories. In the future extension, different types of project in different languages will be analyzed. Again, rather than error history, fixing history can also be obtained by considering the fixing changes. All of this information will be used to conduct further research in the fields of software architecture, decay and quality assurance.

VI. RELATED WORK

Evolution of software cannot be explained solely by structural dependency [21]. It is found that rather than structural dependency, change coupling plays a more effective role in fault proneness and are more relevant [22]. Historical information about CC classes can be used to predict further changes based on CC relation [23]. Similarly, based on CC relation, Zhou et al used Bayesian Network to predict changes [24]. Furthermore, Fluri et al used tree edit operations in AST to classify changes depending on how the change is made [25]. Rather than considering static measures, Arisholm et al proposed dynamic coupling measures by taking into account inheritance, polymorphism, and dynamic binding [26]. Moreover, whether or not frequent code changes represent code smell or design issues was investigated by Ratzinger et al and it is found that those changing software parts may be candidates for refactoring [27].

Frequent changes indicate unstable situations as changes do not satisfy the requirements and correctness expected from the

software system. Due to these frequent changes errors may be introduced in the system which is shown by D'Ambros et al [28] as change coupling measures have a strong relationship with software defects. These erroneous changes which introduced a bug or error in the system are called Fix-Inducing Change by Sliwerski et al [29]. Moreover, information of FICs and Fixing changes can be used for bug prediction [30] [31], localization [32] as well as to find out affected parts [33].

Very few works considered combining information from both change coupling and Bug/Errors. It is found that the change coupling relationship in recent commits is more correlated with recent FICs compared to commits from origin [34]. Furthermore, works of D'Ambros [7] [9] focused on analyzing software evolution and quality, and did not use the combined information to understand the error or maintenance history of software components.

VII. CONCLUSION

The main achievement of this work is to propose a methodology to analyze the erroneous components by using the change coupled relation at fix-inducing changes. Having knowledge of this information will help the software developers to find out which part of the system is continuously responsible for change and producing bugs. To do this, if separate information about architectural components is available then cosine similarity can be used. Otherwise, Latent Dirichlet Allocation can be used to find topics or probable components. However, in that case, manual labeling is required. From the obtained information, error-prone components can be easily identified. Then quality can be further enhanced by refactoring and re-engineering these error-prone components.

Abstract— The production of quality software is a basic and essential Software Engineering goal. A software product quality assessment should be started at the early stages of a development process, to detect and correct problems before they propagate, making their correction more expensive. For that to be possible, it is necessary to assess the quality of each artifact generated during the development process, to allow the production of defect-free artifacts improving the final product quality. In this work, we propose an approach for the generation of quality plans during the tailoring of software process. When the user selects the quality practices to be used in a project, a set of activities satisfying those practices are inserted in the project's software process, along with their associated artifacts. Our goal is to define the quality assessment plans for these artifacts. The approach was validated through case studies of real projects in different companies, involving experts with large software development experience. The interviewees analyzed the approach and considered the proposal of this work as positive because it facilitates the definition of assessment plans, the plans are adequate to the selected criteria and that quality control during the process decreases rework.

Keywords— *Software Quality; Software Artifacts; Process Tailoring; Quality Practices.*

I. INTRODUCTION

It is consensual that software quality is highly influenced by the adoption of a software development process, this is mainly due to the management practices and the continuous pursuit for higher quality brought in by the processes, leading to software with fewer defects. The quality assurance activities aim to evaluate artifacts quality at each development stage, avoiding error propagation. Al-Kilidar et al. [1] state that, instead of trying to measure the quality of a software system as a whole, one should try to evaluate each intermediate software development product which, when combined, may provide for a broad idea about the whole system quality. However, even though quality is a recurrent issue in Software Engineering, most organization lack experts capable of defining their product's desired quality features. Furthermore, quality features definition and classification alone are not sufficient without a discussion about the means to reach those features and the relevant roles involved [2].

In this paper, it proposes a systematic approach for defining a quality assessment framework for artifacts generated or transformed by the activities that make up an tailored software process. The framework is composed by a metamodel, a knowledge base based upon the CMMI quality model [3], an assessment process and a supporting tool.

Briefly, the process engineer selects a set of quality practices that should be satisfied by the project. Practices are associated with activities that are recovered from the knowledge base and inserted in the project-specific process. For each activity, a set of artifacts is described, which are then evaluated regarding their quality elements using the ISO/IEC 9126 [4]. These, in turn, are described in a metamodel that links the assessment process to artifacts characteristics such as their purposes, their stakeholders, their corresponding methods and metrics. The final result is the definition of quality assessment plans for the artifacts described in the tailored software process.

These plans are based on the idea that a software product quality assessment may be started at the first stages of a software process [5]. Besides, they help the process engineers who need to customize the process for specific projects, allowing an organization to implement a set of quality practices from a stored knowledges base.

This paper is divided as follows: Section 2 presents the proposed framework, which includes: a) a metamodel, b) a knowledge base, c) an artifacts quality plan implementation process and d) a support tool. Section 3 shows the case studies. Finally, Section 4 presents our thoughts, conclusions and future work perspective.

II. THE DEFINITION OF AN ARTIFACT QUALITY ASSESSMENT PLAN

In this work, quality plans to assist evaluators, engineers and other stakeholders in the validation of software artifacts, are generated as a result of a process tailoring. For this, a set of tasks was proposed, as shown in Figure 1.

Initially, it is necessary to inform the characteristics of the process (task 1) and the process architecture that will be used in the adaptation (task 2). The next step is to select quality practices (task 3). Based on this information, a set of activities that meet the reported criteria will be retrieved from the knowledge base (task 4). The process engineer should select the activities that he wishes to include in the tailored process (task 5). When selecting the activities, the tailored process is created (task 6). In the next task, quality assessment plans for the artifacts are generated (task 7).

The tailoring is based on a process framework that integrates the necessary elements to instantiate tailored processes and to define quality plans. This framework is composed by a metamodel that presents the set of elements considered relevant for software artifacts quality assessment (described in section A), a knowledge base (described in section B), an assessment process (described in section C) and a supporting tool (described in section D).

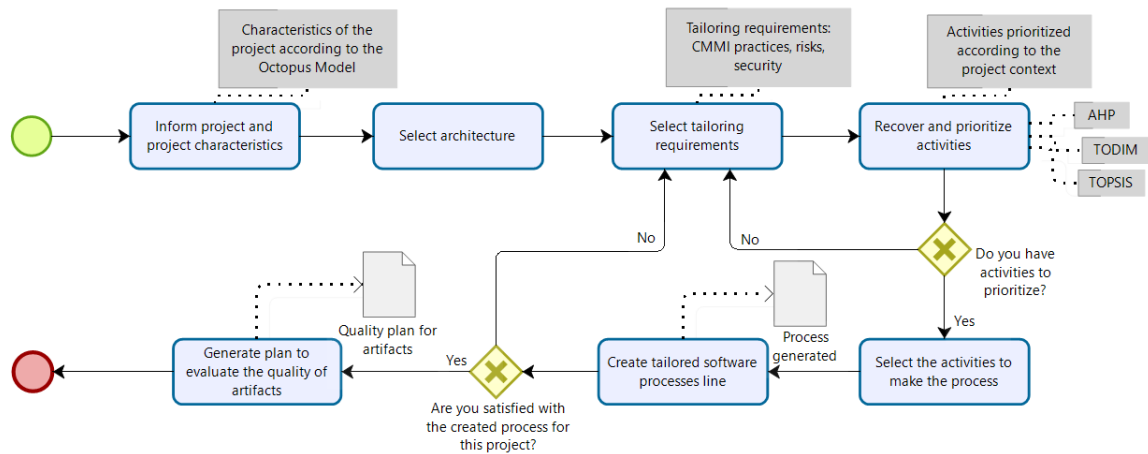

Fig. 1. Modeling Software Process Tailoring Approach to Quality Assessment of Artifacts

A. The Metamodel

The Quality Assessment of Artifacts in Process metamodel (QAPro-M) aims to provide and structure both the processes elements and the quality elements to be used in the assessments, helping the stakeholders to achieve a common vision of the quality requirements of a given project. It also allows for a structured decomposition of the elements, concepts and relationships necessary for this vision. The metamodel definition was based upon three basic requirements proposed by Trendowicz et al. [6]: flexibility, reusability and transparency.

The flexibility is associated to the software quality dependence on the context. The assessment model must be flexible enough to adapt to the different approaches resulting from each software project's organizational environment. For the present work, flexibility also refers to the differences among the very artifacts produced during a software development project phases. The documents, UML models, source code and other artifacts, each have their own particular characteristics. The assessment framework must then allow the evaluators to identify those characteristics and define which assessment proposals are best for each of them.

At the same time, reusability is associated to the preservation of knowledge from past experiences and its use on future projects, with a direct impact on development time and cost and, consequently, on the projects profitability. Naturally, reusability in an assessment project depends on projects similarity. Nevertheless, reuse may also refer to the measured data and to quality features and their relationships. Reuse also allows for model refinement, making it more precise and efficient.

Finally, an assessment model must provide a rational and transparent analysis about the relationships between quality features and sub-features, and about how they affect each other. For instance, the development team must be able to see how a class diagram modularization – that will later be used to define the database tables – allows for a better understanding of the software structure. However, it is a known fact that over-normalization may impair database performance, affecting the whole system. One solution to circumvent the transparency issues is to allow the interested parties themselves to define, consensually, the most relevant assessment metrics and methods, the ones that better represent each artifact, using the metamodel to reduce or eliminate any ambiguities and redundancies.

The QAPro-M, depicted in Figure 2, is composed by 23 classes. The metamodel central class is the **activity**. A set of activities from the same area is a **discipline**. Disciplines are distributed along interactive **phases** that sum up to form the development process **lifecycle**. An activity is composed by tasks, each **task** containing one or more roles. A **role** is a function or job carried out by a person in a project. The **project** class represents the projects defined for an **organization**. An organization may then have many projects, and each project may have many processes. This way, if a **process** does not fulfill the organization expectations, it may be evolved, the process new version being created based on the current one. When creating a new project or activity, it is possible to define a **situational context** for them. For project contextualization we used the Octopus Model that describes the following contextual factors: size, stable architecture, business model, team distribution, rate of change, system age, criticality and governance [7].

The process tailoring takes the activities and the tailoring criteria into account. Each activity has one or more **tailoring criteria**, whose function is to define which requirements may be satisfied by that activity instantiation, retrieving from the database the activities satisfying those criteria.

As a quality model, we chose to use CMMI, each organization can use the most appropriate model for their needs. Then, each **maturity level** is composed by a set of **process areas**. These, in turn, are composed by **specific goals**. Each specific goal is composed by a set of **specific practices**.

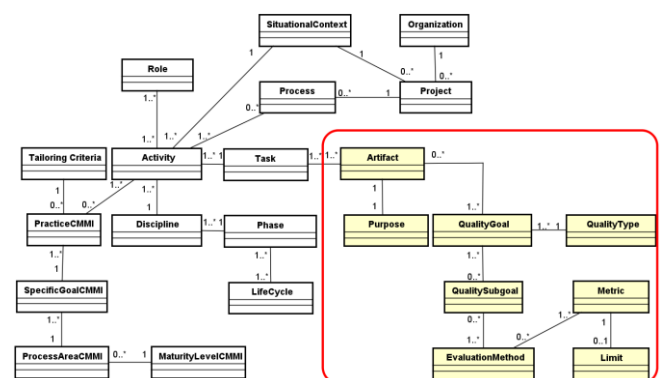

Fig. 2. Quality Assessment of Artifacts in Process - Metamodel (QAPro-M)

The **artifact** class represents the tasks outcomes. Artifacts are linked to a **purpose**, which identifies the artifact's intention and purpose inside the lifecycle, as well as the reasons why that artifact should be assessed.

The quality plan, on its turn, comprises the set of elements responsible for the artifact's assessment. The plans are related to the **quality goal** class. A quality goal represents an artifact's quality features or attributes of interest from a specific stakeholder. The metamodel allows for the quality goals to be identified by a **quality type**. ISO/IEC 9126 is an instance of a quality type, having 6 features, each feature subdivided into **quality subgoals**. The **evaluation method** identifies how a certain quality subgoal should be evaluated. These methods are generalized to allow for a specific methods and **metric**. Also, each metric defines a **limit** value as its acceptable value.

B. Knowledge Base

The first step towards defining the quality plan was to populate the knowledge base. Data was gathered from scientific literature, and included specific models and researches. The knowledge base is expandable, and may be grown based on the expert's experience from past projects.

In order to include quality-focused tailoring requirements, the CMMI quality model practices were incorporated to our approach. This way, the processes engineer may choose the desired organizational maturity level to be attained, the process area, the specific goal and, finally, the CMMI practices related to the goal to be reached by the process. Then the activities needed to satisfy the chosen practices are retrieved from the knowledge base in order to build the tailored process.

We started by analyzing the Requirements Management and Configuration Management process areas. We chose Requirements Management, since a project without well-defined and managed requirements has a far less probability of reaching its goals. Therefore, ensure the management of requirements is paramount to a project success. Likewise, Configuration Management is essential in order to produce quality software, since changes during development are inevitable. The practices described by CMMI were connected to activities and artifacts capable of satisfying each practice.

In order to organize the activities stored in the knowledge base in software processes, we used process architectures. Architectures are composed by the elements used to define a software process. They define the "skeleton" that a process must have, establishing the main elements and how they relate to each other [8]. In Figure 3, the architecture defined for the Requirements and Configuration and Change Management discipline can be viewed.

For each component, one or more activities are retrieved. The activities are prioritized using multi-criteria techniques such as AHP (Analytic Hierarchy Process), TODIM (an acronym in Portuguese for the Brazilian developed Iterative and Multi-criteria Decision Making Method) and TOPSIS (Technique for Order of Preference by Similarity to Ideal Solution), taking into account the activity and the project's situational context.

Afterwards, a specific process for the project is composed by retrieving elements previously included in the

process architectures. So, using architecture allows for the retrieval of a set of activities prioritized accordingly to the project context and tailoring requirements. From the process architecture previously defined and the activities retrieved, prioritized and selected using the mathematical methods, it is possible to create the tailored process.

In previous work [9] we describe the process tailoring approach in detail. In this work, we extend this approach to incorporate process tailoring using quality criteria and to generate quality plans for assessing software artifacts.

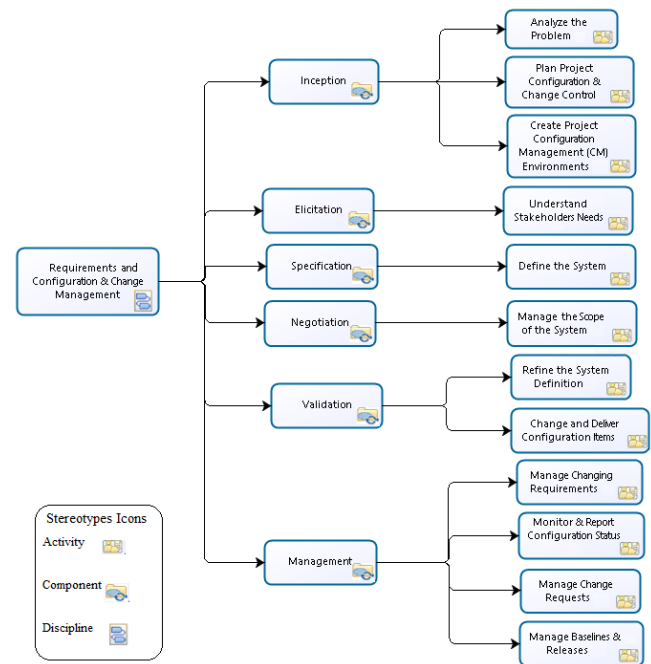

Fig. 3. Architecture for the Requirements and Configuration & Change Management discipline

C. Quality Plans Elaboration Process

The artifacts quality assessment process was build based on the ISO/IEC 14598 [10]. This standard was chosen both for its compatibility with the concepts laid out by the quality models and because it describes an assessment process for the quality features described by the ISO/IEC 9126 [4]. Some ISO/IEC 14598 sub-processes were adapted to reflect specific aspects of the software artifacts assessment.

The assessment process proceeds through the following steps: a) define the assessment requirements (defining what should be assessed); b) specify the assessment (selecting the goals or quality features related to the assessed object detailing assessment methods, metrics, limits and practices for each artifact); c) design the assessment (producing the assessment plan including the documentation of the procedures previously defined that will be used later to define the selected artifacts quality).

ISO/IEC 14598 last phase is the assessment execution, consisting of the products and its components inspection, measuring and testing, according to the assessment plan. As this is an execution-dependent task, not related to the process definition, it falls beyond the scope of this paper.

At the end of phase 3, the data describing the quality plans defined during the specific project assessment process

may be stored for use as a reference for future projects assessments.

As an example of the quality plan creation and the proposed approach workings, let us consider the user selected the CMMI practice “Obtain Commitment for the Requirements”. This practice belongs to the “Manage Requirements” Specific Goal, which in turn is part of the “Requirements Management” Process Area described in CMMI maturity level 2. The Typical Working Product for this practice is the “Documented commitments to requirements and requirements changes”.

Once this CMMI practice is selected, the knowledge base is searched for the activities that satisfy the practice. For instance, the “Manage Change Requests” and the “Manage Requirements Changes” activities from the RUP [11] disciplines “Configuration and Change Management” and “Requirements” will be retrieved and prioritized. After the activity’s prioritization, if this activity is selected to compose a tailored process, the goal would then be the generation of execution plans for the artifacts and process activities quality assessment.

Each activity has one or more input and output artifacts linked to a quality plan, describing how to assess them considering specially its features, objectives, stakeholders, assessment methods and metrics, in order to improve the final product’s quality. Figure 4 shows the metamodel instantiation for the “Change Request” artifact from the “Manage Change Requests” RUP activity assessment. This artifact’s objective is to document and follow the product’s change requests. The main quality goal is maintainability, based on the ISO/IEC 9126-proposed internal quality. From there the analyzability and changeability sub-goals may be explored. These goals and sub-goals may be assessed by specific methods and quantified by related metrics.

The quality plans main task is to organize the data structured by the metamodel, so the evaluators have a solid, clear and understandable reference when assessing the project’s artifacts, based on the quality goals they think are the most relevant for the final product.

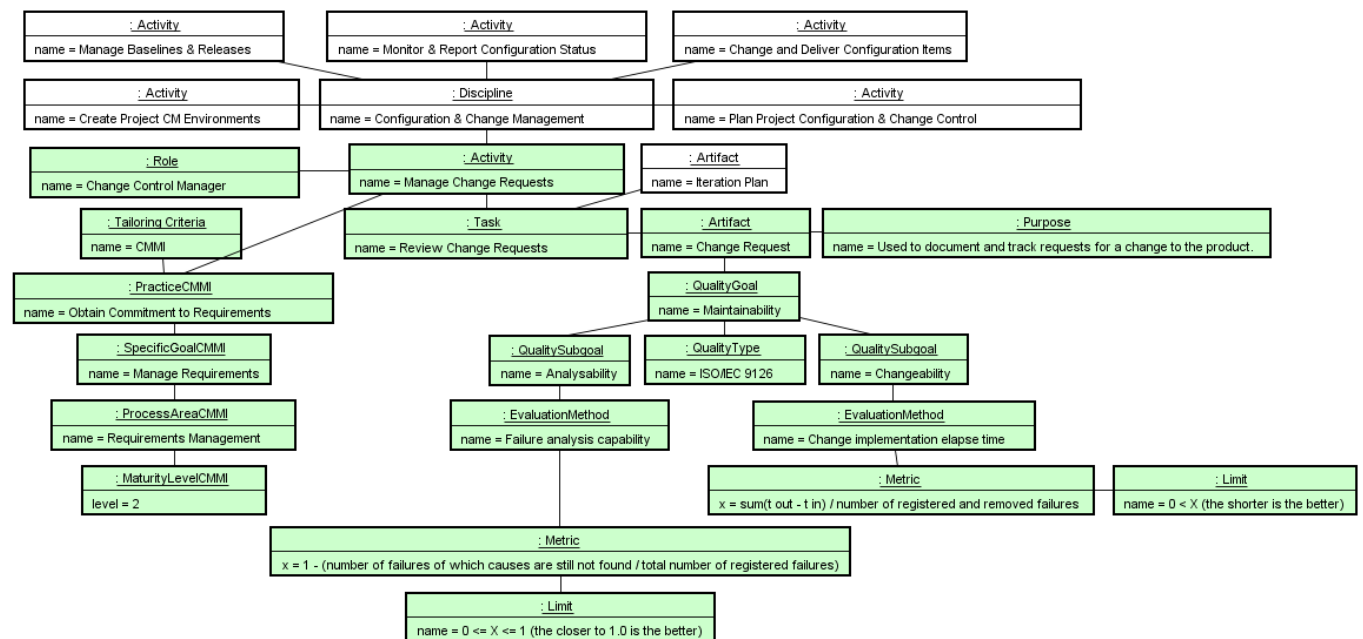

Fig. 4. Instance of the QAPro-M

D. QAPro System Support Tool

The Quality Assessment of Artifacts in Process (QAPro System) tool was developed from as extension of the MfTPt tool [9]. For the quality plans to be generated, instances of quality elements (described in QAPro-M) must have been defined and stored in the knowledge base.

The first activity of the systematic is the contextualization, for this we used the Octopus Model, allowing for the definition of values for each of its eight factors in the project (Figure 5-A). After that, it is necessary to define the desired architecture for the process tailoring.

The selection of requirements to be considered in the tailoring process are the Specific Practices of the Requirements Management e Configuration Management CMMI process area, shown in Figure 5-B.

Figure 5-C shows the architecture activities retrieval and prioritization according to the project context and the tailoring requirements, using the AHP, TODIM and TOPSIS methods. The process engineer selects the activities.

Finally, the last task consists in the generation of the plan to assess the created process artifacts. This step proceeds as follows: for each activity in the created process, a task is selected and then the artifact for which the quality assessment plan is to be obtained. The assessment specification for each selected artifact is then shown, with its objective, its quality goals and sub-goals, the quality type, the assessment method as well as the metric and the eventual limit value used for this artifact assessment (Figure 5-D).

This documentation will be used later by the quality analyst to define the selected artifacts quality. The idea behind the plan is to present quality elements in a clear and understandable way, to allow it to serve as a guide for evaluators during the process artifacts quality assessment.

However, the evaluators are free to modify any quality element according to the artifacts quality assessment needs. Thus, the flexibility and transparency requirements are kept during the assessment process.

III. CASE STUDY

In order to validate this proposal, we carried out five case studies involving different real software projects from different companies. The case studies were carried out by three project managers, a compliance analyst and a systems analyst, so we could obtain a point of view from professionals in the field.

A. Case Study Configuration

The case studies were carried out in projects with different business domain. Each case study was divided in three phases:

Data collection: the participant (project member) filled a form identifying your profile, the project context and the tailoring requirements to be satisfied by the process.

Tailored process creation and quality plans generation: with the data informed and using the QAPro System support tool, the process was defined to meet the project's requirements and quality plans were generated for each artifact selected for the process. The results were sent to the participant for evaluation.

Interview and analysis: the participant experts were interviewed to evaluate the generated process and plans. The interview had 15 questions divided in 3 topics: software process, software quality and artifacts quality plans. Each interview lasted approximately 40 minutes, depending on the expert. After that, the results of the case studies were analyzed aiming to evaluate the applicability of the work.

B. Case Study – ASTROS Integrated Simulation System

To illustrate the validation process, this case study is described in detail. This project aims at the research and development of a virtual tactical simulator for military training. The interviewee was the project manager.

The project was characterized by the following attributes: a) Size (Medium); b) Team Distribution (Collocated); c) Criticality (Comfort Loss); d) Stable Architecture (New); e) Rate of Change (Less than 10); f) Governance (Simple rules); g) Business Model (In house) e h) Age of System (New development). The specific CMMI practices chosen were: Understand Requirements, Obtain Commitment to Requirements, Manage Requirements Changes, Identify Configuration Items, Establish a Configuration Management System, Create or Release Baselines, Establish Configuration Management Records, Perform Configuration Audits.

After the prioritization methods results analysis, the following activities were selected to compose the process: Plan project configuration & change control, Understand stakeholder needs, Define the system, Change and deliver configuration items, Monitor & report configuration status, Manage change requests, Manage baselines & releases.

Quality plans were suggested for the following artifacts: Configuration Management Plan, Stakeholder Request, Software Requirements Specification, Supplementary Specification, Workspace, Configuration Audit Findings, Change Request, Test Results, Test Log and Work Order.

These quality plans along with the tailored SPPrL were analyzed by the participant before the interview. The interviews results are discussed jointly in the next section.

C. Case Studies Discussion

The interview first part concerned the software development processes, centered around the following topics: presence of a well-defined process in the company, process tailoring use, agile or planned process use and software artifacts.

It was found that only one of the five projects has a development process with well-defined activities and artifacts, with a planning phase where the process compliance team analyses the project to verify its adherence

(or its lack of adherence) to agile practices. This is carried out through the use of checklist that evaluates, among other things, the project size, projected duration, team size, definitions and architecture patterns.

The goal of the interview second part, about software quality, was to discover if the organization uses any quality model, if a defective artifact can delay the project or raise its cost and if, by selecting CMMI practices as proposed here, there were improvements in the software process. The answers about quality models were unanimous, no project use them. All the participants stressed the difficult to adequate the model to the project's reality. As for defective artifacts, some participants mentioned cases from their own organizations showing that they may indeed delay and make projects more expensive.

As for the CMMI practices selection by the experts, all found it beneficial, as the foreknowledge of the practices to be followed allows for a better planning of the artifacts that would allow these practices to be attained. They found it a simple way to use the CMMI, with an intuitive approach that facilitates process creation. Also, the automated activities generation also saves effort and time, by replacing the need for a deeper model analysis.

The third topic goal was to understand the importance of the software artifacts quality assessment, which teams found the quality plans more efficient and if the artifact quality assessment plans format was satisfactory. This topic results analysis show that the proposed plans may be used by both large and small teams, with the adequate metrics varying according to the team and the project. One participant felt that the plans may be more important for large and distributed development teams, as the importance of documentation tends to grow, as well as the need for better artifacts.

All experts said that the proposed quality assessment plans allow for an artifact's assessment. They found the plans well-organized and easy to understand, and appreciated the plans clear separation of CMMI data, RUP data and artifact assessment.

IV. CONCLUSIONS AND FUTURE WORK

The benefits of developing quality software products are diverse, widespread and well known. However, the importance of evaluating the quality of these products goes beyond commercial or security issues, because it aims to provide qualitative and quantitative results on the quality of the software produced. In addition, provide the necessary feedback for the improvement of the software processes. But to be effective, these results must be understandable, trustworthy, and in keeping with the environment surrounding evaluations.

This work showed a framework for quality assessment of artifacts created or changed by activities forming a tailoring software process. For each process component, different activities may be selected, sharing a similar situational context and covering the desired quality practices to be used by the tailored process. These activities have artifacts, which in turn are associated to the quality plans defined here. The artifact assessment plan is elaborated taking into account the set of artifacts selected for the tailored process and reusing

instances of the quality metamodel. It should be noted that the generated quality plan serves as reference for the process engineers, who can, however, modify the plan if necessary. Besides that, the quality plans should evolve through time, along with the organization's maturity.

The approach validation was carried out using case studies. The participants agreed that the proposed approach to assess the software development generated artifacts is valid and relevant.

Future work includes the use of quality plans in real projects by monitoring quality throughout the project. To address one of the limitations observed, namely the use of activities found in planned processes, we also suggest the association of the quality practices to other groups of activities, such as the ones found in agile practices and methods. So it would be possible to create quality assessment plans with agile methods metrics, such as progress and productivity.

ACKNOWLEDGMENT

We thank the Fapergs (Fundação de Amparo à Pesquisa do Rio Grande do Sul) and the Brazilian Army for the financial support through the SIS-ASTROS Project (813782/2014), developed in the context of the PEE-ASTROS 2020.

Abstract—In last few years, to solve the problem of code completion, using a language model such as LSTM to learn code token sequences is the state-of-art method. However, tokens in source code are more repetitive than words in natural languages. For example, once a variable is declared in a program, it may be used many times. Other elements such as generic types in templates also occur repeatedly. It is important to capture token repetition of code. For example, if usage patterns of variables are not captured, there is little chance for a model trained on one project to predict the name of an unseen variable in another project correctly. Capturing token repetition of source code is challenging because not only the repeated token but also the place at where the repetition should happen must be both decided at the same time. Hence, we propose a novel deep neural model named *REP* to capture the general token repetition of source code. The repetitions of code tokens are modeled as edges connecting between repeated tokens on a graph. The *REP* model is essentially a deep neural graph generation model. The experiments indicate that the proposed model outperforms state-of-arts in code completion.

Index Terms—language model, code completion, code recommendation, code token repetition, deep neural graph generation

I. INTRODUCTION

In the past few years, language models have attracted the attentions of researchers and achieved a great progress in natural language processing tasks, such as machine translation [1] and text generation [2]. A statistical language model is a probability distribution over sequences of linguistic units such as characters or words. With the rapid growth of open-source code and the high-speed development of artificial intelligence, applying natural language processing techniques to source code has become a research direction. The problem of code completion is difficult and attracts a lot of attentions of researchers in the field of software engineering. Based on the already written code, the system of code completion can recommend the suitable code automatically for software developers to improve the efficiency of software development. Different from code synthesis based on natural languages [3], [4] which requires an explicit intention of code described

in natural languages, code completion is aimed at mining and learning the hidden intention of code to recommend suitable code automatically. Due to the predictability [5] of source code, taking source code as natural languages to build language models (n-gram, RNN or LSTM) to suggest code has made great progress in the field of code completion [6]–[11]. Among the previous works, deep learning models such as RNN or LSTM have been proved to be effective. In more subdivided fields of code completion, API usage pattern learning also attracts attention of a large amount of researchers [12], [13]. There are many differences between natural languages and source code. Source code is more regular than natural languages. There exist elements which may occur more than once in one fragment of source code, for example, variables or generic types in templates. Thus, taking source code as natural languages directly is not enough.

Based on the observation that elements of source code are highly repetitive, a new direction has been opened to capture the token repetition of source code to improve the performance of code completion. When predicting code, if an variable is unseen before, there is little chance to predict that variable correctly. If the usage pattern of an variable has been learned, the place at where the variable will be occurred next time can be decided. Then at next time, the name of that unseen variable can be predicted correctly by copying the name of that previously existed variable at the right place. Other elements such as templates also have the property of token repetition. For example, in Java languages, it is a common scenario to get the element from *ArrayList<T>* and the following code: *ArrayList<T> arr = ...initialization...; T t = arr.get(0);* is common in many programs. Note that T could be the name of any class. In a new project, if some strange class name such as *UnseenStrange* is in placed of T and *ArrayList<T>* becomes *ArrayList<UnseenStrange>*, through learning the repetitive patterns of source code, the right code: *UnseenStrange t = arr.get(0);* can be generated.

It is difficult to learn the token repetition of source code. There are two main challenges. The first challenge is that when predicting next token, we need to judge whether the next token

should be the repetition of some previously existed token. The second challenge is that if the next token is decided to be the repetition of some previously existed token, we need to decide which previously existed token should be repeated. If a program is huge and contains a large amount of tokens, it is hard to decide which token should be repeated. To address the two challenges, we propose a novel *REP* model to learn the token repetition of source code. The source code is parsed into a token sequence. This token sequence can be viewed as a linear graph as every token has an hidden incoming edge from its previous token. If two tokens in a token sequence are same, an edge is added between the repeated tokens. Then, a complex graph can be generated based on a token sequence. The extra added edge indicates the repetition of tokens. The task of *REP* model is to learn the edge connection on the generated graph. The experiments show that the proposed model outperforms state-of-art baselines. In summary, the contributions of this paper include:

- 1) A novel *REP* model is proposed to capture the general token repetition of source code;
- 2) Evaluations on four data sets (total 29.15MB) indicate that the proposed model outperforms the state-of-arts.

II. RELATED WORK

Models for code completion. The statistical language models have been widely used in capturing patterns of source code to solve the problem of code completion. In [5], source code was parsed into lexical tokens and the n-gram model was applied directly to suggest the next lexical token. In [14], a large scale experiments was conducted by using n-gram model and a visualization tool was provided to inspect the performance of the language model for the task of code completion. In SLAMC [6], based on basic n-gram model, associating code lexical tokens with roles, data types and topics was one way to improve the prediction accuracy. Cacheca [7] improved n-gram model by caching the recently encountered tokens in local files to improve the performance of basic n-gram model. Decision tree learning was applied to code suggestion, based on this, a decision tree model which integrates the basic n-gram [10] was proposed for source code. The work [15] abstracted source code into DSL and kept sampling and validating on that specially designed DSL until the good code suggestion was obtained. Deep learning techniques such as RNN, LSTM were applied to code generation model [8] [9] [11] to achieve a higher prediction accuracy. The work in [11] confirmed that LSTM significantly outperforms other models for doing token-level code suggestion. Given large amount of unstructured code, deep language models such as LSTM or its variants are the state-of-art solutions to the problem of code completion. All works described above are trying to solve the general code completion problem in which every token of code should be predicted and completed based on the context in a fixed or changeable length. There are also a lot of works paying attention to the API completion problem. Common sequences of API calls were captured with per-object n-grams in [12]. In [13], API usages was trained on graphs. Naive-Bayes was

integrated into n-gram model to suggest API patterns. The migrations of API are studied in [16]. The completion of API full qualified name is studied in [17].

Models for code synthesis. Another important research field to use language models is code synthesis. In recent years, translating text description into source code have achieved a great success. Seq2Seq [18], Seq2Tree [19] and Tree2Tree [20] models are proposed to handle the problem of code synthesis. The models for code synthesis are all based on the framework of neural machine translation. There are two modules named encoding module and decoding module in the framework of neural machine translation models. The encoding module encodes source sentences (trees) into fixed size vector. The decoding module decodes the fixed size vector generated by encoding module into sequences or trees. As discussed in [21], intuitively, Seq2Tree takes grammar of code into consideration but is still based on the framework of Seq2Seq. Although there are big differences between neural code translation and code completion, the aim of the decoding module in code synthesis is same as that of the language model. Both the aims are to generate the suitable code. So it is fair to compare our model with the decoding module in code synthesis model. Traditional decoding module of neural machine translation model uses standard LSTM directly, so there is no need to compare. But the recently proposed tree decoding module in Seq2Tree or Tree2Tree models deserves to be investigated for the code completion task. The decoding module in Tree2Tree model in most recent work [22] are extracted and compared with our *REP* model. There exists repetitiveness in the synthesized code. Our *REP* model could be taken as the decoding module for all code synthesis models directly. We will further investigate the performance of taking *REP* model as the decoding module in code synthesis tasks in the future work. On top of general code synthesis problems, API synthesis is also studied in [3], [4]. In the research fields of natural language processing, text summarization [23] is an important problem which is related to synthesis. One application of text summarization is to automatically generate the title of an article based on the content of that article. In source code processing, there is a similar problem: how to generate the name of a function according to the content of that function. This problem of function name generation has been addressed by extreme summarization of source code based on deep neural attention network in [24].

Models for code classification. For the problem of code classification or the problem of identifying code similarity, TreeNN [25], [26], TreeCNN [27], EQNET [28] or GNN (Graph Neural Network) [29] have been proposed. There exists huge differences between code classification problems and the code generation problems.

Models for robustness. To make the language model more robust, instead of improving the model structure directly, another research direction is to use different sampling schedules [30] or to generate adversarial examples [31] based on the training data to improve the robustness of the model.

Models for capturing token repetition of code. By com-

paring the related works mentioned all above, as far as we know, the *REP* model is the first deep neural model based on graph to capture the general token repetition of source code to help improve the solution to the problem of token-level code completion. The newly proposed model is also the first model to address problems of learning usage patterns of variables, templates and cloned code when doing code completion.

III. PROBLEM FORMULATION

Traditional language model processes tokens (words) one by one. The processing is based on a linear chain to handle each token in a token sequence. The data (token sequence) can be converted to the directed acyclic graph (DAG). Each node in the graph has only one incoming edge from its corresponding previous node. Such edge indicates the order of occurrence of tokens in a token sequence and we give that kind of edge a name *CommonEdge*. For example, if $token_n$ has one incoming edge from $token_{n-1}$, then $token_n$ should occur instantly after $token_{n-1}$. Then any token sequence could be represented by a simple graph. Follow this idea, to represent the repetition of tokens, we add an edge named *RepetitionEdge* between the repeated two tokens. For example, in a token sequence, if $token_m$ is same as $token_n$ where $m < n$, the special designed directed edge *RepetitionEdge* is added from $token_m$ to $token_n$. To see whether a token $token_n$ is repeated or not in a token sequence is just to see whether there is an edge linked to token $token_n$ from some previously existed token. Then, the problem of learning the general token repetition of source code reduces to the problem of learning the edge connection in a graph. The problem of code generation (code completion) reduces to the graph generation problem. In traditional language modelling, the edges between tokens do not need to be explicitly modeled. In our setting, the patterns of edge connections between tokens need to be explicitly modeled and learned. An example is shown in Figure 1. The

Fig. 1: Graph for Code and its Token Repetition

circle in Figure 1 represents the token. The edges marked as solid arrow (*CommonEdge*) show the order in which tokens are processed in a token sequence. The repeated tokens are connected by dashed arrow (*RepetitionEdge*). The *REP* model is still based on the framework of language model and can be taken as a complement to the language model. Tokens in a token sequence are predicted one by one. For each token, *REP* model additionally judge whether the currently predicted token should be the repetition of some previously existed token. As the language model may predict wrong content (wrong variable names or wrong templates), *REP* model could help correct the prediction through mixing the patterns of code repetitiveness together. In this setting, the *REP* model is designed to predict correctly the incoming *RepetitionEdge* of each token.

Fig. 2: Complex Graph for Code and its Token Repetition

Note that, one token may have more than one incoming edge if there exist two or more previous tokens with same content as current token in a token sequence. This complex situation is shown in Figure 2. Among all incoming edges (*RepetitionEdge*), if one edge could be predicted correctly, the prediction about the token repetition is right. So it is absolutely unnecessary to predict correctly all edges of kind *RepetitionEdge*. Learning to predict correctly one among all edges of kind *RepetitionEdge* is enough. To make the learning procedure easier, we could retain and learn only one incoming *RepetitionEdge*. In fact, considering only one of the all possible edges of *RepetitionEdge* not only meets the needs about deciding the token repetition but also makes the whole problem easier. Therefore, only the nearest two repeated tokens are connected by an edge (*RepetitionEdge*). Formally, for n th token $token_n$, only the k th token $token_k$ connects to $token_n$ where k is determined by

$$k = \max\{ i \mid token_i == token_n, i < n \} \quad (1)$$

The simplified graph corresponding to the graph in Figure 2 is shown in Figure 3. In Figure 3, only the edges connecting between the nearest two repeated tokens are retained. By removing unnecessary edges, now, every node has at most one incoming *RepetitionEdge* making the problem concise. When predicting next token, the whole problem of learning token repetition of source code is further divided into two sub-problems: 1. deciding whether there is a *RepetitionEdge* connected to next token; 2. if it is determined that there must be a *RepetitionEdge* connected to the next token, deciding which token is the source token of that *RepetitionEdge* (the next token should be same as the source token, in another word, the source token is the token to be repeated). In addition

Fig. 3: Simplified Graph for Code and its Token Repetition

to the basic language model, learning the repetitiveness of source code (learning extra edge connections between tokens) can extract features of token repetition of source code to recommend code. The ability to learn token repetition can help us identify the usage patterns of variables, templates or cloned code. Details will be described in next section.

Fig. 4: Overall Architecture

IV. PROPOSED METHOD

Given the token sequences parsed from source code, our goal is to learn the general repetitiveness of tokens of source code to improve the performance of existing state-of-art language model. To accomplish this task, we design a novel *REP* model to learn the repetitiveness of source code tokens. Figure 4 demonstrates the overall architecture of our model. The basic part of *REP* model is the LSTM model. The LSTM model in *REP* generates the hidden feature vector (cell, h) for each token. When predicting the edge connection for $token_n$, the Edge Recognizer takes the hidden feature vector (cell, h) of $token_n$ and the hidden feature vector (cell, h) of each previously existed token to compute the probability for each possible incoming edge of $token_n$. The higher the probability, the more likely the edge should be added to the graph. For $token_n$, any edge of kind *RepetitionEdge* connecting from one of the previous tokens to $token_n$ is the candidate incoming *RepetitionEdge* of $token_n$. All possible candidate incoming edges (*RepetitionEdge*) of $token_n$ consist of edges of kind *RepetitionEdge* connecting from all the previous tokens to $token_n$. For example, for $token_3$, all candidate edges consists of two edges: 1. *RepetitionEdge* connecting from $token_1$ to $token_3$; 2. *RepetitionEdge* connecting from $token_2$ to $token_3$. The number of candidate edges (*RepetitionEdge*) is $n - 1$ for $token_n$. The Decision Maker is aimed at deciding whether the most likely edge predicted by Edge Recognizer should be really added or not. If the Decision Maker decides that there should be no edges (*RepetitionEdge*) connecting to the token being predicted, in this situation, the token predicted by the algorithm of the traditional language model will be taken as the final prediction result. If the Decision Maker decides that the next code token should be the one previously existed, in this situation, the source node (token) of the most likely edge will be thought to repeat at the position currently being predicted. So the token of the source of the recognized most likely edge will be taken as the final prediction result. To learn the general repetitiveness of source code tokens, when predicting a token, we need to take all previously existed tokens into consideration to decide whether or not one of the previously existed tokens should be repeated. The task becomes more and more challenging as the quantity of already predicted tokens becomes larger and larger. Traditional methods such as n-gram can only take limited quantity of tokens into consideration. There is little chance for those methods to discover the repetition of two tokens due to large

amount of other tokens between them. Deep learning methods scale well to high dimensional domains and have strong representational power. With the introducing of the deep neural networks, learning the general repetitiveness over a long token sequence becomes possible. In this subsection, we introduce our *REP* model which is based on the deep neural network.

A. LSTM in REP Model

The *REP* model is based on the LSTM model. LSTM model is applied to generate the state (cell and h) for every token in a sequence. Formally, the state generated for predicting $token_n$ by LSTM is referred to as $state_n$ ($cell_n$ and h_n). In rest of this section, the symbol $state_i$ ($cell_i$, h_i) refers to the state generated for predicting i th token $token_i$ by the LSTM. Traditional language model based on LSTM model uses h_n to compute the probability distribution of all candidate tokens to select the most likely token for $token_n$. The LSTM and its usage in traditional language model are omitted in this section. Please refer to [32] for the details of the algorithm of the traditional language model about how to use h_n which is generated by LSTM to compute the most likely token when predicting $token_n$. When predicting the edge connection for $token_n$, $h_n, h_{n-1} \dots h_1$ are used for computing the probability distribution of all candidate incoming edges of $token_n$. Details are shown in the following section.

B. Edge Recognizer in REP Model

Edge Recognizer is responsible for computing the probability distribution of all candidate incoming edges. Formal definition is as follows. The edge connecting from $token_m$ to $token_n$ where $m < n$ is referred to as $edge_{(m,n)}$. In rest of this paper, $edge_{(x,y)}$ refers to the *RepetitionEdge* connecting from x th token $token_x$ to y th token $token_y$. The probability of $edge_{(m,n)}$ is computed by:

$$P(edge_{(m,n)}) = \frac{h_m^T W h_n}{Z} \quad (2)$$

In Equation 2, Z is the normalization factor computed by:

$$Z = \sum_{m=1}^{n-1} h_m^T W h_n \quad (3)$$

The h_m is in the $state_m$ ($cell_m$, h_m) generated for m th token by LSTM. The h_n is in the $state_n$ ($cell_n$, h_n) generated for n th token by LSTM. In rest of this section, h_i is in the $state_i$ ($cell_i$, h_i) generated for i th token by LSTM. In Equation 2 and

3, W is the model parameter, h_m^T is the transposition of h_m . The training and predicting are all based on the probability of each candidate *RepetitionEdge* computed by Equation 2.

Training of Edge Recognizer. Remember that, in the section of Problem Formulation, each code will be converted into a token sequence, if $token_n$ is the repetition of some previously existed token, there must be an incoming edge of kind *RepetitionEdge* connecting to $token_n$. The source of that edge is the nearest previous token which is same as $token_n$. For $token_n$, we use the symbol: $near_n$ to refer to the position of that nearest token which is same as $token_n$. In another word, what we mean is that the nearest token (same as $token_n$) is the $near_n$ th token in the token sequence ($token_{near_n}$). According to the position of the source and the target, the incoming *RepetitionEdge* connecting from $near_n$ th token to n th token is referred to as $edge_{(near_n, n)}$. For $token_n$, we define a symbol $e_n \in \{0, 1\}$ which indicates whether there is an incoming *RepetitionEdge* connecting to $token_n$. If e_n is 1, this indicates that there is an incoming *RepetitionEdge* for $token_n$. If e_n is 0, this indicates that there is no incoming *RepetitionEdge* for $token_n$. If there is an incoming *RepetitionEdge* for $token_n$ in training examples, the source (token) of that incoming *RepetitionEdge* is referred to as $token_{near_n}$ which is the $near_n$ th token in the token sequence. The symbol $near_n$ refers to the position of the previously existed token which is nearest to $token_n$ and is same as $token_n$. To learn the edge connections in training examples, we follow the framework of Maximum Likelihood Estimation approaches: the probabilities of actually existed edges of kind *RepetitionEdge* in training examples should be as high as possible. Thus, the probability of the incoming *RepetitionEdge*: $edge_{(near_n, n)}$ (if there is one) for $token_n$ in training examples should be as high as possible. This is equivalent to minimize the following loss function. If there is no incoming *RepetitionEdge* for $token_n$, then $near_n$, $edge_{(near_n, n)}$ and $P(edge_{(near_n, n)})$ will be default meaningless values. This form avoids the using of condition judgment such as if-else to judge whether the incoming edge is existed or not and takes advantage of the high performance of GPU. With the probability of each edge, the loss function could be defined as (assuming that the quantity of code nodes in a data set is N):

$$\mathcal{L}_{ER} = \sum_{n=1}^N -\log(P(edge_{(near_n, n)})) * e_n \quad (4)$$

The symbol e_n indicates whether $token_n$ has an incoming *RepetitionEdge*. If there is no incoming *RepetitionEdge*, e_n is 0 and the final loss will exclude the loss for non-existent edges. The training objective of Edge Recognizer is to minimize the loss function 4.

Usage of Edge Recognizer in Prediction Phase. The edges with highest probabilities computed by Equation 2 are most likely to be added to the graph. In another word, the source of the edge with high probability has a high chance to be repeated. When predicting $token_n$, for the candidate incoming

RepetitionEdge with the k th largest probability, we use the symbol: src_k to refer to the position of the source of that k th most likely edge. In another word, the source of the k th most likely *RepetitionEdge* when predicting $token_n$ is the src_k th token ($token_{src_k}$). If $k = 1$, we can offer another formal definition of src_1 when predicting $token_n$:

$$src_1 = \arg \max_i P(edge_{(i, n)}) \quad (5)$$

When predicting $token_n$, if Decision Maker (described in the following subsection) decides that the $token_n$ should be the repetition of some previously existed token and top-k candidates are needed, $token_{src_1}$ (the source token of the edge with highest probability), $token_{src_2}$ (the source token of the edge with the second highest probability), ... and $token_{src_k}$ (the source token of the edge with k th highest probability) will be taken as the final recommendation. The top-k accuracy is computed by judging whether the desired $token_n$ exists in the candidates: $token_{src_1}$, $token_{src_2}$, ... and $token_{src_k}$.

C. Decision Maker in REP Model

The task of Decision Maker is to decide whether the edge with the highest probability computed by Edge Recognizer should be really added to the graph or not. When predicting $token_n$, Decision Maker is to decide whether there should be an edge of kind *RepetitionEdge* connecting to $token_n$. In the phase of predicting, the available information about *RepetitionEdge* is the probability of each candidate *RepetitionEdge* computed by Edge Recognizer for $token_n$. The probability that $token_n$ has an incoming *RepetitionEdge* ($token_n$ is the repetition of some previously existed token) is computed by:

$$P(token_n \text{ is repeated}) = \frac{h_{src_1}^T V_1 h_n}{h_{src_1}^T V_1 h_n + h_{src_1}^T V_2 h_n} \quad (6)$$

In the above equation, h_{src_1} is the h in state (cell, h) generated for the token at the position src_1 (src_1 th token) and $h_{src_1}^T$ is the transposition of h_{src_1} . The src_1 is defined in Equation 5. V_1 and V_2 are model parameters.

Training of Decision Maker. If there is an incoming edge in training example for $token_n$, $P(token_n \text{ is repeated})$ defined in Equation 6 should be maximized. Otherwise, the value: $1 - P(token_n \text{ is repeated})$ should be maximized. This corresponds to minimize the following loss. The loss function of Decision Maker is defined as:

$$\mathcal{L}_{DM} = \sum_{n=1}^N (-\log(P(token_n \text{ is repeated}) * e_n - \log(1 - P(token_n \text{ is repeated})) * (1 - e_n))) \quad (7)$$

The training objective of Decision Maker is to minimize the loss function 7. The final loss $\mathcal{L} = \mathcal{L}_{ER} + \mathcal{L}_{DM}$. To minimize the final loss \mathcal{L} is equivalent to minimize \mathcal{L}_{ER} and \mathcal{L}_{DM} separately.

Usage of Decision Maker in Prediction Phase. When predicting $token_n$, if $P(token_n \text{ is repeated})$ is greater or equal to 0.5, the recommendation result generated by Edge

Recognizer (described in the previous subsection) should be taken as the final result. Otherwise, if $P(token_n \text{ is repeated})$ is less than 0.5, the prediction result generated by the algorithm [32] of the traditional language model will be taken as the final prediction result.

D. Advanced REP Model

In previous subsections, there is only one LSTM model described in *REP*. To improve the expressiveness of the *REP* model, we could use two LSTM models, one for computing probabilities of edges in *REP*, one for computing the prediction result of the standard language model. In another word, the LSTM used for computing the prediction result of standard language model is the LSTM isolated from the LSTM model described in *REP*. Also, the embeddings of tokens involved in those two LSTM models could be isolated. In conclusion, we use one LSTM model as the standard language model and use another LSTM model to compute the probabilities of edges in *REP*. By doing so, the parameters have doubled in size and the performance of the *REP* model could be further improved. Actually, the *REP* model used in experiments is the advanced version just described in this subsection.

V. IMPLEMENTATION

Source code [33] which contains all data sets and all implementations of all models mentioned in experiments has been public. The implementation of the model is based on the deep learning platform TensorFlow. Apart from the parameters of the LSTM used in *REP* model, the other parameters of *REP* model are W in equation 2 and V_1, V_2 in equation 6. Adam optimizer in TensorFlow is used to automatically decide learning rate and momentum in training phase. The gradient is clipped by global norm. Parameters about clipping norm are set to default values offered by TensorFlow. The representation size (alias as embedding size or feature size) for one token is 128. Once the embedding size for one token is decided, sizes of all other parameters which participate in the calculation with the embedding of tokens can be decided successively. All models keep training until the accuracy on validation set does not exceed the optimal value for 50 epochs. All the training examples are trained one by one. The models are running on the computer with the setting: Windows 10 64 bit OS, Intel i7-6850k CPU, 32G memory and one Geforce GTX 1080 Ti GPU. Every function in source code will be extracted and tested. The code completion system will start at the beginning of a function to try to complete each token of the function one by one. The accuracy is the average of the prediction accuracy of each token of each function in test set. To generate tokens for the source code, some works [5] parse the code into lexical units through splitting the code by white space or other predefined separators such as $+$, $($, $:$ or $;$. The implementation of such parser may vary greatly. Different separators in use lead to different token sequence of source code. Thus, to make the token generation for code unified, the token sequence is generated in the following steps. The code is parsed into the abstract syntax tree (AST) through Eclipse JDT

at first. Then, the AST is traversed in pre-order. The content of each encountered node is pushed back onto a sequence. Now, the token sequence has been generated. Token repetition learning is also based on the token sequence generated in this way. Generating token sequence based on AST could also make it fair to compare the sequential model such as LSTM with tree models such as Tree2Tree model as the contents to be predicted are same in this setting.

VI. EXPERIMENT

Without loss of generality, the most widely used programming language: Java is chosen to conduct experiments. Four data sets are provided for evaluations. For each data set, the source code in that data set is divided into training set, validation set and test set in the proportions 60%, 15%, 25%. Follow the one billion word benchmark [34], similarly, the 0.15% least frequently occurred code tokens in our training set, all unseen tokens in validation set and test set are marked as *UNK*.

Data Sets. Famous open-source projects are used in experiments. As there are small functions which contain only one or two statements in those projects, we do some filtering to the code. The filtering steps are as follows: 1. Give each Java file a score (to get the score, divide the number of all tokens in all functions in the java file by the number of all functions in that java file); 2. Sort Java files according to the score from large to small and extract the first 85% Java files to blend into a data set. Details are shown in Table I. The fourth column headed by *Vocabulary* in Table I means the total number of unique tokens on the data set. The symbol DS refers to data set. For example, the DS1 refers to data set 1. The original size of Apache Lucene is 98.8MB and is too huge, so only the core module and analysis-common module are extracted into the data set.

TABLE I: Data Sets

	From Project	Size	Vocabulary
DS1	Log4J	1.76MB	6455
DS2	Maven	3.25MB	10516
DS3	FindBugs (GitHub version)	8.54MB	27573
DS4	Lucene (core & analysis-common)	15.6MB	55244

Research Questions. To demonstrate the ability of the proposed model, one research question is answered:

RQ1: Could *REP* model achieves better prediction accuracy than other state-of-art methods under all the data sets?

To evaluate the performance of our model, the state-of-art baselines: LSTM and tree decoding module in Tree2Tree [22] are compared with the *REP* model. The tree decoding module in other Tree2Tree models [35] is just LSTM model with slightly changes (one LSTM for decoding content of node, one LSTM for decoding the tree structure of node) and is irrelevant to this research because we only care about predicting the content of node in this research. Table II shows the prediction accuracy of different models evaluated on the test set of each data set. The top-k accuracy (value is in percentage, % is omitted to save the space) is computed for evaluating

TABLE II: Evaluation Result

	LSTM						Tree2Tree						REP					
	top1	top3	top6	top10	mrr	enpy	top1	top3	top6	top10	mrr	enpy	top1	top3	top6	top10	mrr	enpy
DS1	45.4	59.3	63.7	66.3	0.53	6.7	34.7	54.3	61.5	64.7	0.45	5.9	48.6	63.0	68.1	70.9	0.57	2.8
DS2	48.0	60.7	65.2	67.7	0.55	6.8	36.7	54.4	59.8	63.0	0.46	5.8	52.6	66.3	71.2	73.8	0.60	3.3
DS3	34.5	49.2	55.2	58.6	0.43	7.7	31.8	50.0	56.4	59.2	0.39	6.9	44.7	59.9	66.3	69.9	0.53	5.8
DS4	48.9	63.7	69.8	73.3	0.57	3.6	40.0	58.0	65.1	69.3	0.50	4.0	53.9	69.1	75.3	78.6	0.62	1.7

the model performance. When predicting next node, we rank all candidate tokens according to probabilities (computed by model) from large to small. The token with higher probability has smaller rank. The token with the highest probability has rank 1. The value in column headed with *mrr* is the average of the reciprocal of rank of the token. This metric indicates the overall prediction performance of the model. The larger the *mrr*, the better the performance of the model. The *enpy* headed column shows the entropy (*log* value of the perplexity) of the model. The smaller the entropy, the better is the model.

As can be seen from the data, the *REP* model outperforms all other state-of-art models in all 4 data sets. Especially for the top-1 accuracy, *REP* model achieves averagely 17.2% improvement compared to LSTM, achieves averagely 39.7% improvement compared to Tree2Tree. From the result, we can conclude that capturing the token repetition of source code can improve existing LSTM model which has solved the problem of gradient vanishing and gradient exploding to capture the long term memory. Source code is diverse. After randomly checking files in test set and training set, we have discovered that there is little chance for the exact same code appears in both the training set and test set. As argued in [30], if some sub-sequences or patterns in the context are unseen in training data, the discrepancy between training and inference could cause the system fail to predict the right result. This problem is named as *exponential bias* and *REP* model could solve that problem to some extent.

The tree decoding module in Tree2Tree [22] performs worse than LSTM. From this experiment, tree decoding module in Tree2Tree is strongly dependent on the attention mechanism used in its encoding module. Without the cooperation from the encoding module, the performance of a single decoding module is worse than standard LSTM. The reason has been carefully analyzed. In Tree2Tree model [22], trees need to be converted into binary trees. Converting a general tree to a binary tree needs to add more nodes makes the prediction task more difficult. The decoding module decodes the binary tree in the way that the left child node and right child node of one node will be predicted at the same time. This decoding procedure indicates that the right child is predicted without the information of the left child and vice versa. In the meanwhile, LSTM model predicts one by one meaning that the right child is predicted with the information of the left child (according to pre-order traversal of tree). The less use of the context information causes the lower prediction accuracy of tree decoding module in Tree2Tree [22]. On the other hand, the less use of the context could reduce the impact of the unseen data in context. When encountering a large amount of unseen

data, Tree2Tree could gain good generalization ability. That is why Tree2Tree performs better than LSTM in entropy on the first three data sets. Even so, Tree2Tree still performs worse than *REP* in entropy. As can be seen from the entropy (*log* value of the perplexity), *REP* achieves nearly half the entropy compared to that of other models. This experimental result is dramatically encouraging. Thus, by taking all conditions into account, *REP* outperforms other models.

RQ2: In which scenarios can *REP* model achieve better results than other models and what features of scenarios bring *REP* model to the better performance?

In the investigation of the prediction result of the experiment, we discover that *REP* model is good at predicting unseen data especially for unseen variable names or unseen type names. In our setting, unseen token in validation set or test set will be replaced with UNK. Both LSTM model and Tree2Tree model perform badly in distinguishing between UNK and other tokens when the number of tokens is huge. In *REP* model, by recognizing the hidden relationships of token repetition, another point of view could be offered to us to decide which is the most likely token for the next. If the model can confirm that the next token should be the repetition of some previously existed token, we could take the previously existed token as the final prediction result no matter the previously existed token is UNK or other tokens. Note that, for a token sequence of which the length is often less than 1000, the number of the previously existed tokens is at most 1000. In this setting, the *REP* model only needs to distinguish between at most 1000 tokens to decide the token repetition. In the meanwhile, for large projects, the number of total tokens is often greater than 6000, which means that the standard LSTM-based language model needs to distinguish between at least 6000 tokens to decide which is the most likely token for the next. Obviously, the task of recognizing token repetition is much easier than the task of the standard LSTM-based language model. That is the one factor why *REP* model could perform better than standard LSTM-based language model.

Limitation and Future Work. In experiments, only four Java projects are used, more projects could make the results of experiments more solid. In all projects of different sizes, the proposed model has achieved better results than all other models, which can prove the effectiveness of the model to a certain extent. The proposed method is not limited to the Java language and can be extended to other languages such as Python and C++. The extra work needed to do is to design Python parser or C++ parser to parse the code into the corresponding token sequence. The proposed model could be applied to the generated token sequence. In the future,

the performance of the proposed model could be further investigated on different languages such as Python or C++. If the code corpus is large, there would be a lot of tokens. The existence of a large number of tokens can cause trouble to apply this technique to industrial scenarios. The techniques which are designed to minimize the number of tokens could be applied to further reduce the total tokens to improve the model performance.

VII. CONCLUSION

In this paper, a novel *REP* model is proposed to capture the general token repetition of source code to improve the prediction accuracy of standard language model. The experimental results on huge data sets confirm that capturing the general token repetition of source code by *REP* model successfully improves current methods and makes a step forward for the problem of code completion.

Abstract—In last few years, using a language model such as LSTM to train code token sequences is the state-of-art to get a code generation model. However, source code can be viewed not only as a token sequence but also as a syntax tree. Treating all source code tokens equally will lose valuable structural information. Recently, in code synthesis tasks, tree models such as Seq2Tree and Tree2Tree have been proposed to generate code and those models perform better than LSTM-based seq2seq methods. In those models, encoding model encodes user-provided information such as the description of the code, and decoding model decodes code based on the encoding results of user-provided information. When applying decoding model to decode code, current models pay little attention to the context of the already decoded code. According to experiments, using tree models to encode the already decoded code and predicting next code based on tree representations of the already decoded code can improve the decoding performance. Thus, in this paper, we propose a novel tree language model (TLM) which predicts code based on a novel tree encoding of the already decoded code (context). The experiments indicate that the proposed method outperforms state-of-arts in code completion.

Index Terms—code completion, tree language model, tree encoding of context

I. INTRODUCTION

Taking highly repetitive and predictable [1] source code as natural languages to build language models (n-gram, n-gram with Bayes or decision tree, RNN, LSTM) to suggest code fragments has made great progress [2]–[9]. However, sequential models does not explicitly model the tree structure. In the meanwhile, tree classification models such as TreeNN [10] and TBCNN [11] have more powerful ability in capturing the characteristics of trees. The works in [10] have confirmed that tree models perform better than sequential models in classification tasks. On the other hand, it is hard to adapt the code classification models as the code generation models. This paper addresses this challenging problem and demonstrates the special property of the proposed model.

In code synthesis models, encoding module is used for encoding the user-provided information, decoding module is used for decoding the desired code from the encoding of

the provided information. In decoding module, we creatively use encoding model to encode the already decoded code to improve the performance of the decoding model. A novel tree decoding model (tree language model) which consists of Encoding model and Decoding model is proposed. In the rest of this paper, the term encoding model refers to the model which is used for encoding the already decoded code (context) in decoding procedure, not the one used for encoding the provided information in code synthesis tasks. Encoding model is responsible for generating the representation for a tree or a sub-tree. Decoding model is designed to traverse the syntax tree to accumulate encoding of encountered sub-trees to predict the next code. We propose a novel encoding model based on two-dimensional LSTM to generate better representations for trees. The experiments indicate that the proposed model outperforms state-of-arts. In summary, the contributions of this paper include: 1) A framework is proposed to predict next code based on the accumulated representations of sub-trees in an AST. 2) A new encoding model based on two-dimensional LSTM is designed to generate representations for trees.

Related Work: The statistical n-gram language model has been widely used in capturing patterns of source code. The n-gram model was applied to lexical code tokens in [1]. In SLAMC [2], they improved n-gram by associating code tokens with topics. In cacheca [4], they improved n-gram with caching recently appeared tokens in local files to improve prediction performance. In [12], source code was abstracted into DSL and had been sampled and validated until the good code suggestion was obtained. Deep learning techniques such as RNN, LSTM were applied to code generation model [6] [8] [9] to achieve a higher prediction accuracy. Decision tree was applied to code suggestion relying on a hybrid language model presented by [7]. In [5], code was trained on graphs. Naive-Bayes was integrated into n-gram model to suggest API usages. Seq2Seq [13], Seq2Tree [14] models were proposed to translate text description into the abstract syntax tree (AST) to handle the problem of code synthesis. The work [15] used basic Seq2Seq model to synthesize the API usage patterns based on natural languages. The aims of language model and the decoding

module in code synthesis models are similar: to generate the most likely next code. Thus, we compare these methods in the experiments. In the problem of program translation, Tree2Tree [16] model is proposed.

II. TREE LANGUAGE MODEL

A. Preliminary

AST(Abstract Syntax Tree): Figure 1 shows an example of an expression and its corresponding AST. In this figure, the tree is placed horizontally: the root is on the left and the leaves are on the right. In rest of this paper, all trees are placed horizontally.

Fig. 1. an example of AST

Concepts on AST: For the abstract syntax tree of source code, some concepts need to be given.

- τ_n : the content (token) of node n is τ_n
- Sibling nodes: If two nodes have the same parent, they are siblings. For example, in Figure 1, node a and node b are sibling nodes, node $+$ and node $-$ are sibling nodes.
- Previous sibling node: If node m appears prior to node n and m and n are sibling nodes, m is called the previous sibling of n . For example, in Figure 1, node a is located above node b , so a is the previous sibling of b .
- Previous adjacent sibling node: If node m is the previous sibling of node n and m, n are adjacent, node m is called the previous adjacent sibling of node n . For example, in Figure 4, n is the previous adjacent sibling of o .
- Sibling trees: If roots of two sub-trees are siblings, these two sub-trees are called sibling trees. For example, in Figure 4, the sub-tree rooted at m and the sub-tree rooted at n are sibling trees, sub-tree rooted at node m and the sub-tree rooted at node o are sibling trees.
- Previous sibling tree: If the root of tree T_1 is the previous sibling of the root of tree T_2 , tree T_1 is the previous sibling tree of tree T_2 . For example, in Figure 4, the tree rooted at node m is the previous sibling tree of the tree rooted at node n .

LSTM: In this paper, the main logics of LSTM and two-dimensional LSTM (2DLSTM) will be expressed as two functions: LSTM and 2DLSTM. These two functions are shown in Figure 2. Function $\text{LSTM}(x, \text{cell}, h)$ takes three inputs while the function $\text{2DLSTM}(x, \text{cell}, h, \text{cell2}, h2)$ takes five inputs. The outputs for this two functions are same: $\text{cell}_{\text{new}}, h_{\text{new}}$. In this paper, parameter x is the embedding of node token

on abstract syntax tree of source code. In LSTM, cell, h pair is taken as accumulated information from one direction, and 2DLSTM receives accumulated information: $\text{cell}, h; \text{cell2}, h2$ from two directions. Please consult [17] for more information about LSTM and two-dimensional LSTM.

Algorithm LSTM(x, cell, h)	Algorithm 2DLSTM($x, \text{cell}, h, \text{cell2}, h2$)
Require: x, cell, h	Require: $x, \text{cell}, h, \text{cell2}, h2$
Ensure: $\text{cell}_{\text{new}}, h_{\text{new}}$	Ensure: $\text{cell}_{\text{new}}, h_{\text{new}}$
$i = \sigma(W_i \cdot [x, h] + b_i)$	$i = \sigma(W_i \cdot [x, h, h2] + b_i)$
$j = \tanh(W_j \cdot [x, h] + b_j)$	$j = \tanh(W_j \cdot [x, h, h2] + b_j)$
$f = \sigma(W_f \cdot [x, h] + b_f)$	$f1 = \sigma(W_{f1} \cdot [x, h, h2] + b_{f1})$
$o = \sigma(W_o \cdot [x, h] + b_o)$	$f2 = \sigma(W_{f2} \cdot [x, h, h2] + b_{f2})$
$\text{cell}_{\text{new}} = f * \text{cell} + i * j$	$o = \sigma(W_o \cdot [x, h, h2] + b_o)$
$h_{\text{new}} = o * \tanh(\text{cell}_{\text{new}})$	$\text{cell}_{\text{new}} = f1 * \text{cell} + f2 * \text{cell2} + i * j$
return $\text{cell}_{\text{new}}, h_{\text{new}}$	$h_{\text{new}} = o * \tanh(\text{cell}_{\text{new}})$
	return $\text{cell}_{\text{new}}, h_{\text{new}}$

Fig. 2. LSTM and two-dimensional LSTM

TreeNN: Given a tree T , TreeNN [10] generates vector representation of a tree. TreeNN is defined in Algorithm 1. In Algorithm 1, the symbols: c_1, c_2, \dots, c_k represent all k children of node n , $[\cdot, \cdot]$ is the vector concatenation operator, σ is the activation function such as \tanh .

Algorithm 1 TreeNN(node n)

Require: node n
Ensure: representation of tree rooted at node n
if n is a leaf **then**
 $h = \text{embedding of } \tau_n$
else
 $h = \sigma(W_{\tau_n} \cdot [\text{TreeNN}(c_1), \dots, \text{TreeNN}(c_k)])$
end if
return h

Additional Functions Other functions used are defined here.

- $\text{GetLastChildOfNode}(n)$: returns the last child of tree node n . If n does not have any child, function returns *null*. In Figure 1, node c is the last child of node $-$, $\text{GetLastChildOfNode}(-)$ returns c .
- $\text{GetPrevAdjacentSiblingOfNode}(n)$: returns previous adjacent sibling of node n , if n does not have a previous sibling (n is the first child of its parent), returns *null*. In Figure 1, node $+$ is the previous adjacent sibling of node $-$, then $\text{GetPrevAdjacentSiblingOfNode}(-)$ returns $+$.
- $\text{Parent}(n)$: returns the parent node of node n in AST.

B. Encoding model

Encoding model such as TreeNN generates the representation for a tree through visiting the tree in post-order traversal. Figure 3 gives an illustration of the execution flow of encoding model. We propose the novel encoding model based on two-dimensional LSTM: AccuredTreeGen model. AccuredTreeGen model is the one used in Decoding model of Tree Language Model. The aim of AccuredTreeGen(n) is to generate the representation for a set of trees: the tree T rooted at node n and all previous sibling trees of tree T . Unlike

Fig. 3. data flow of encoding

traditional tree encoding model which generates encoding for a tree, The AccuredTreeGen model generates encoding for a set of trees. Figure 4 illustrates the difference of trees

Fig. 4. An illustration of TreeNN and AccuredTreeGen

handled by TreeNN(n) and AccuredTreeGen(n). The black circles are nodes in trees to be processed. TreeNN(n) only handles the tree rooted at node n while AccuredTreeGen(n) extraly handles all previous sibling trees of the tree handled by TreeNN(n).

Algorithm 2 AccuredTreeGen(node n)

Require: node n
Ensure: representation of tree with previous sibling trees
if $n == null$ **then**
 return $cell_{zero}, h_{zero}$
end if
 $embed_{\tau_n} = \text{embedding of } \tau_n$
 $sibling_{prev} = \text{GetPrevAdjacentSiblingOfNode}(n)$
 $child_{last} = \text{GetLastChildOfNode}(n)$
 $cell, h = \text{AccuredTreeGen}(sibling_{prev})$
 $cell2, h2 = \text{AccuredTreeGen}(child_{last})$
 $cell_{new}, h_{new} = 2DLSTM(embed_{\tau_n}, cell, h, cell2, h2)$
return $cell_{new}, h_{new}$

The algorithm of AccuredTreeGen is defined in Algorithm 2. AccuredTreeGen is a recursive model. For a node n , apart from the embedding of node n , the result of AccuredTreeGen(n) depends on the result of AccuredTreeGen(previous adjacent sibling of n) and the result of AccuredTreeGen(last child of n). Recursively, For the last child: $child_{last}$ of node n , the result of AccuredTreeGen($child_{last}$) depends on the result of AccuredTreeGen(previous adjacent sibling of $child_{last}$) and the result of AccuredTreeGen(last child of $child_{last}$). Keep computing the dependency recursively, we will find

that the result of AccuredTreeGen(n) is the accumulated information of all nodes on a set of trees: tree T rooted at node n and all previous sibling trees of tree T . If node n is null, AccuredTreeGen(n) will return $cell_{zero}$ and h_{zero} which are fixed default zero values. This is also the termination for the recursive AccuredTreeGen model. The gates used in two-dimensional LSTM make the model less troubled by vanishing gradient problem than TreeNN.

C. Decoding model

Decoding model traverses from the root to the leaves on a tree in pre-order to predict the token of each node. Figure

Fig. 5. data flow of decoding

5 illustrates the execution flow of the Decoding model. The Decoding model contains two sub-models: DecodeFirstChild model and DecodeNextSibling model. When we are visiting node n in pre-order traversal, DecodeFirstChild(n) generates prediction information for predicting the first child of node n . DecodeNextSibling(n) generates prediction information for predicting the next sibling of node n . The information generated by DecodeFirstChild or DecodeNextSibling consists of two vectors ($cell, h$). Every node except the root is either the first child or the next sibling of some node. So each node except the root can receive the prediction information from its parent or its previous adjacent sibling. The root node receives the fixed default values. The function FetchPrediction(node n) is defined to get the prediction information generated for predicting node n . The definition is in Algorithm 3.

Algorithm 3 FetchPrediction(node n)

Require: node n
Ensure: ($cell, h$) for predicting node n
if n is root of AST **then**
 return $cell_{zero}, h_{zero}$
end if
 $parent_n = \text{Parent}(n)$
if n is the first child of $parent_n$ **then**
 $cell, h = \text{DecodeFirstChild}(parent_n)$
else
 $sibling_{prev} = \text{GetPrevAdjacentSiblingOfNode}(n)$
 $cell, h = \text{DecodeNextSibling}(sibling_{prev})$
end if
return $cell, h$

In Algorithm 3, if node n is the root of AST which means node n does not have parent or previous siblings, the default zero values: $cell_{zero}$ and h_{zero} are returned. If node n is the first child of node $parent_n$, DecodeFirstChild($parent_n$)

generates prediction information ($cell, h$) for predicting the content of node n , as shown in the *then* branch of the if-statement in Algorithm 3. If node n is not the first child of parent $parent_n$, in this case, node n must have previous adjacent sibling: $sibling_{prev}$, DecodeNextSibling($sibling_{prev}$) generates prediction information ($cell, h$) for n , as shown in the *else* branch of the if-statement in Algorithm 3. In summary, FetchPrediction(n) just fetches prediction information from the parent of n or the previous sibling of n according to the position of n in AST. Assume that n is the first child of $parent_n$, then, the information ($cell, h$) returned by FetchPrediction(n) is just the information ($cell, h$) returned by DecodeFirstChild($parent_n$). Note that the prediction ($cell, h$) for node n returned by FetchPrediction(n) can be taken as the accumulated information of nodes visited before n .

The algorithm of DecodeFirstChild model is defined in algorithm 4. The embedding of node n and the accumulated

Algorithm 4 DecodeFirstChild(node n)

Require: node n

Ensure: ($cell_{out}, h_{out}$) for first child of node n

$cell, h = \text{FetchPrediction}(n)$
 $embed_{\tau_n} = \text{embedding of } \tau_n$
 $cell_{out}, h_{out} = \text{LSTM}(embed_{\tau_n}, cell, h)$
return $cell_{out}, h_{out}$

information of nodes visited before n ($cell, h$ returned by FetchPrediction(n)) are fed into LSTM to predict the first child of node n . The FetchPrediction, DecodeFirstChild and DecodeNextSibling (described in the following) functions call each other and form a recursive neural model. To predict the sibling of a node n , the algorithm of DecodeNextSibling model is in Algorithm 5. If $child_{last}$ is the last child of node n , AccuredTreeGen($child_{last}$) generates the representation ($cell2, h2$) for a set of trees: tree $T_{lastchild}$ rooted at node $child_{last}$ and all previous sibling trees of tree $T_{lastchild}$. The nodes in tree $T_{lastchild}$ and all previous sibling trees of $T_{lastchild}$ constitute all the descendants of node n . The embedding of node n , the accumulated information of nodes visited before n ($cell, h$ returned by FetchPrediction(n)) and the representation ($cell2, h2$) for all descendants of node n are fed into two-dimensional LSTM to predict next sibling of node n . For a node n , DecodeForFirstChild(n)

Algorithm 5 DecodeNextSibling(node n)

Require: node n

Ensure: ($cell_{out}, h_{out}$) for next sibling of node n

$cell, h = \text{FetchPrediction}(n)$
 $child_{last} = \text{GetLastChildOfNode}(n)$
 $cell2, h2 = \text{AccuredTreeGen}(child_{last})$
 $embed_{\tau_n} = \text{embedding of } \tau_n$
 $cell_{out}, h_{out} = \text{2DLSTM}(embed_{\tau_n}, cell, h, cell2, h2)$
return $cell_{out}, h_{out}$

and DecodeForNextSibling(n) both use the embedding of node n . The difference between DecodeForFirstChild(n) and

DecodeForNextSibling(n) is whether or not to take all descendants of node n into consideration. When predicting the first child of node n , we do not need to take descendants of node n into consideration because no descendant of node n has been visited in pre-order traversal of AST. When predicting the sibling of node n , all descendants of this node have been visited (predicted) and we use AccuredTreeGen to explicitly encode the already visited (predicted) sub-trees. Given a tree, starting with the root of that tree, all nodes can be predicted by keeping inferring the first child of a node and the next sibling of a node. Figure 6 gives an illustration about the data flow of encoding model and decoding model to show how decoding model interacts with encoding model. In Figure 6, solid arrow means the data flow of encoding while dotted arrow means the data flow of decoding. In Figure 6, we use the content of a node to refer to that node. As shown in the figure, the nodes $()$, $>$ and $+$ are the first child of their parents. DecodeFirstChild model is used to generate prediction information for those nodes. To predict node $-$ which is the next sibling of node $+$, the embedding of token $+$, the prediction for node $+$ (the data flow is marked with dotted arrow), the representation for all descendants of node $+$ (the data flow is marked with solid arrow) will be fed into two-dimensional LSTM to generate a new $cell, h$.

Fig. 6. an example of decoding combined with encoding

Tree Language Model is also a generalized framework in which the encoding model can be replaced with existing tree classification models. Take TreeNN as an example. If we want to use TreeNN in Tree Language Model, DecodeNextSibling model should be replaced with DecodeNextSiblingUsingTreeNN model. The definition of DecodeNextSiblingUsing

Algorithm 6 DecodeNextSiblingUsingTreeNN(node n)

Require: node n

Ensure: ($cell_{out}, h_{out}$) for next sibling of node n

$cell, h = \text{FetchPrediction}(n)$
 $encoding_{tree} = \text{TreeNN}(n)$
 $cell_{out}, h_{out} = \text{LSTM}(encoding_{tree}, cell, h)$
return $cell_{out}, h_{out}$

ingTreeNN is in Algorithm 6. The difference between DecodeNextSibling and DecodeNextSiblingUsingTreeNN is that DecodeNextSiblingUsingTreeNN uses TreeNN to encode the root node n and all its descendants into one vector instead of taking apart them. LSTM instead of two-dimensional LSTM is applied. It is a pioneering work to adapt the tree classification model as a language model. Other tree models such as TBCNN and EQNET can be adapted in a similar way.

D. Predicting and Training

For every node n , the prediction result ($cell \in \mathbf{R}^d$, $h \in \mathbf{R}^d$) for node n returned by $\text{FetchPrediction}(n)$ is used to compute the probability distribution of all tokens. The Algorithm 7 is the definition of function Predict . In Algorithm 7, $W_1 \in \mathbf{R}^{t \times d}$ and $bias \in \mathbf{R}^t$ are model parameters, t represents the total number of unique tokens in data set, d is the length of the embedding vector for one token. The $probs$ is the probability distribution for all tokens. The top k elements with the highest probabilities will be the final complement result. Top- k accuracy is computed in the way that if the desired token appears in the top k recommended tokens, the prediction is right, otherwise, the prediction is wrong.

Algorithm 7 $\text{Predict}(\text{node } n)$

```

 $cell, h = \text{FetchPrediction}(n)$ 
 $logits = \tanh(W_1 \cdot h + bias)$ 
 $probs = \text{softmax}(logits)$ 
return  $probs$ 

```

For every node n , training is to maximize the probability of n . This is achieved by minimize the loss of node n which is computed by function ComputeLoss . The Algorithm 8 is the definition of function ComputeLoss . In Algorithm 8, the $probs$ is the probability distribution for all tokens returned by $\text{Predict}(n)$. The $probs[\tau_n]$ means choosing the probability of τ_n (the actual content of node n) from $probs$. The final

Algorithm 8 $\text{ComputeLoss}(\text{node } n)$

```

 $probs = \text{Predict}(n)$ 
 $loss = -\log(probs[\tau_n])$ 
return  $loss$ 

```

loss is the summation of loss computed by ComputeLoss for each node in each AST. The training of the whole model is to minimize the final loss.

III. IMPLEMENTATION

Source code [18] of all models along with all data sets has been public. The source code is parsed into AST through Eclipse JDT. The implementation is based on Deep learning platform: TensorFlow. The model parameters consists of parameters in LSTM, parameters in 2DLSTM and W_1, W_2 in Algorithm 7. Because TensorFlow does not offer the implementation of two-dimensional LSTM, the logic of two-dimensional LSTM is implemented by ourselves. The physical environment is the computer with Windows 10 64 bit OS, Intel i7-6850k CPU, 32G memory and one Geforce GTX 1080 Ti GPU. The learning rate and the momentum are automatically decided by Adam optimizer in TensorFlow. Global norm is used to clip the gradient. Examples are trained or tested one by one. The representation size (alias as embedding size or feature size) for one token is 128. We will keep training the model until the prediction accuracy on the validation set does not exceed the optimal value for 50 epochs.

IV. EXPERIMENT

Without loss of generality, one of the most widely used programming language Java is chosen to conduct experiments. Java projects with high number of stars on GitHub are extracted and filtered into different data sets. Source code in each data set is divided into training set, validation set and test set in the proportions 60%, 15%, 25%. Every function declared in Java files will be parsed into an abstract syntax tree and every tree node in AST will be predicted to compute the prediction accuracy. The tree will be flattened into a sequence to apply sequential models such as LSTM. The sequence is generated by traversing the tree in pre-order and appending the encountered node back to the sequence. We mark the 0.15% least frequently occurred code tokens in training set and all unseen tokens in validation set or test set as *UNK*.

Date Sets: Three data sets: Dataset A, Dataset B, Dataset C are collected to conduct experiments to examine the performance of models. Details are shown in the following Table. Dataset A consists of all java files in project *apache commons*

	From Projects	Size	Vocabulary
Dataset A	apache commons io	2.0MB	5807
Dataset B	google guava	7.7MB	7538
Dataset C	Activiti & ESPlorer & AbFab3D & JComicDownloader	8.2MB	39886

io on Github. The project *google guava* is a Java project marked with 26554 stars on Github. Dataset B consists of Java files whose size is larger than 8K Bytes in the main module of *google guava*. Dataset C are Java files whose size is larger than 40K bytes in projects *Activiti* (3909 stars), *JComicDownloader* (188 stars), *ESPlorer* (733 stars), and *AbFab3D* (59 stars). The evaluation results on Dataset C may truly reflect the ability of each model because abstract syntax trees from Dataset C are huge. The fourth column headed by *Vocabulary* in Table IV means the quantity of unique tokens (the content of node on AST) on the data set.

Evaluation: In this section, Tree Language Model using the newly proposed encoding model: AccuredTreeGen model (based on two-dimensional LSTM) is abbreviated into TLM. Tree language model using TreeNN as the encoding model is abbreviated into TLM-TNN. LSTM and the decoding module in Tree2Tree [16] are also included in the baselines. The top- k accuracy (value is in percentage, % is omitted to save the space) is computed on every node in tree and the final top- k accuracy is the average of top- k accuracy of all nodes in all trees. When predicting next node, the model computes the probabilities for all candidate tokens. If we rank all tokens according to probabilities from large to small. For example, the token with the highest probability ranks 1, the token with the second highest probability ranks 2. The value in column headed with *mrr* means the average of the reciprocal of the rank for each token in a data set. This metric indicts the overall prediction performance of the model. The larger the *mrr*, the better the model. The column headed with *enpy* shows the entropy (\log_2 value of the perplexity). The smaller the entropy, the better the model.

Table I is the evaluation result of different models on test set. On small data sets: DS1, TLM achieves 22.2%, 9.3% higher top-1 prediction accuracy than tree decoding module in Tree2Tree and LSTM. The performance of TLM and TLM-TNN is similar, for top-1 accuracy and mrr, TLM performs better. On large data set: DS2, Tree2Tree performs much worse than other three models. TLM performs the best in all measurements. As can be shown, if the models used for code synthesis are directly applied to code completion tasks, the performance is bad. The reason will be described later. On large data set DS3, TLM achieves 40.3%, 13.8% higher top-1 accuracy than tree decoding module in Tree2Tree and LSTM. The performance of TLM and TLM-TNN is similar, for top-1 accuracy, TLM performs better. For top-k accuracy, as k becomes larger, performances of all models tend to be closer to each other. For top-10 accuracy, performances of all models are close. This indicates that for the top-k accuracy, the smaller the k, the more effective is the top-k accuracy to illustrate performances of different models. As can be seen, both TLM and TLM-TNN performs better than the rest non-TLM models. This demonstrates the advantages of the newly proposed Tree Language Model framework which uses tree encodings to encode the context to help predict code. In future work, we may adopt other measurements to investigate different models. By considering all conditions, on all 3 data sets, Tree Language Model framework performs better than other models. TLM performs the best on top-1 accuracy.

TABLE I
PREDICTION ACCURACY ON TEST SET

		top-1	top-3	top-6	top-10	mrr	enpy
A	Tree2Tree	38.6	57.4	63.7	67.6	0.49	4.3

		top-1	top-3	top-6	top-10	mrr	enpy
	Tree2Tree	34.7	54.0	61.7	66.1	0.46	6.2
	TLM-TNN	46.2	60.5	65.9	68.0	0.53	5.8
	LSTM	42.9	57.9	63.8	67.1	0.51	5.9

The reason for better performance of Tree Language Model framework is adopting tree encoding model to capture the characteristics of encountered trees or sub-trees. In Tree2Tree, a tree must be converted to a binary tree. This step introduces extra nodes. The extra introduced nodes make predicting more difficult. When standing at a node, two LSTM models are used for predicting the left child node and right child node of that node separately at the same time. Predicting left without using information of right (vice versa) causes the performance declining. Current synthesis models pay much attention to predicting code based on user-provided information but pay little attention to predicting next code based on the already decoded code (context). This paper investigates this problem.

V. CONCLUSION

This paper proposed a novel tree language model consisting of decoding model and encoding model. Two-dimensional LSTM is adopted to deal with the structural characteristics of trees. The experiments demonstrate that tree language model (TLM) achieves better top-1 prediction accuracy on large data set compared to state-of-art models.

Abstract—Association Rules Mining (ARM) is one of the most important tasks of Data mining. The purpose of ARM is to discover relationships having an interest between attributes/patterns stored in very large databases. Nowadays several efficient algorithms have been developed by the researchers for the discovery of relevant Association Rules (ARs). These latter are responsible for decision making in several domains, such as medicine, finance, marketing and many other fields. In this paper, we propose a new algorithm based on exhaustive search to find relevant AR to make the decision and to predict the chance of occurring the Diabetes Mellitus (DM). We develop an algorithm to mine data in less time and less complexity without losing information. Finally, we test our approach using a real database to evaluate the efficiency of our algorithm compared to Apriori algorithm.

Index Terms—Association Rules, Fast Exhaustive Search Algorithm, Support, Confidence, Fitness

I. INTRODUCTION

The task of ARM was introduced for the first time by Agrawal et al., [1] to discover relationships among attributes in databases. From these association rules, several decisions will be taken. The formal notations of ARM were introduced by Agrawal et al., [1].

Let $I = I_1, I_2, \dots, I_m$ be a set of m different attributes, T be the transaction that comprises a set of items such that $T \subseteq I$, D be a database with different transactions T_s . An association rule is an insinuation in the form of $X \Rightarrow Y$, where $X, Y \subset I$ are sets of items termed itemsets, and $X \cap Y = \emptyset$. X is named antecedent, Y is called consequent. The rule means X implies Y .

ARM goes through two steps: The first one is to identify the frequent items using minimum support threshold s and the second one is to generate the relevant rules from these frequent items using minimum confidence threshold c . Since the database is large and users concern about only those frequently purchased items, usually thresholds of support and confidence are predefined by users to drop those rules that are not so interesting or useful. The two thresholds can be specified by the users [2]. Support of an association rule is defined as the percentage/fraction of records that contain $X \cap Y$ to the total number of records in the database [2].

$$\text{Support}(XY) = \frac{\text{Support count of } XY}{\text{Total number of transaction in } D} \quad (1)$$

Confidence of an association rule is defined as the percentage/fraction of the number of transactions that contain $X \cap Y$ to the total number of records that contain X , where if the percentage exceeds the threshold of confidence, an interesting association rule $X \Rightarrow Y$ can be generated [2].

$$\text{Confidence}(X|Y) = \frac{\text{Support}(XY)}{\text{Support}(X)} \quad (2)$$

The generation of all the frequent elements is a time consuming task when the number of items is large [3]. For this purpose we developed an algorithm generating association rules in a direct way by maximizing the support/confidence of the rules skipping the frequent itemset generation step. Our approach is then to treat the problem of ARM as a multi-objective optimization problem where the goal is to find ARs while optimizing a fitness function (described below) i.e., it is a function for evaluating rules [4], it shows if an association rule is a good solution or not.

The remainder of the paper is as follows : Section II introduces some previous work on ARM, section III explains problem and technical solutions, section IV describes the proposed algorithm, the different improvements and its performance, in section V experimental results are presented and finally, the paper is concluded in Section VI.

II. LITERATURE REVIEW

A large number of previous studies have been focused on the problem of ARM. Agrawal et al., [5] developed Apriori algorithm. It first generates the set of elements from the previous element sets, then, a pruning step was applied on these candidates. Finally, ARs are deduced from the frequent candidates generated in the first step. Apriori algorithm is easy to execute and very simple but suffers from inefficiencies: scanning the database frequently; generating a large number of candidate sets [6] and demanding huge data storage [7]. Zaki [8] developed Eclat algorithm for discovering the set of frequent attributes. Zaki represented the database with a vertical representation to avoid the repeated traverse of the database. He decomposed the original search space into smaller pieces which can be processed independently in main-memory, and proposed three new search strategies for enumerating the frequent itemsets such as bottom-up search, top-down search, and hybrid search.

Han et al., [9] introduced Frequent Pattern Growth (FP-Growth) algorithm. Han et al., used three techniques: The first one was to compress the base as much as possible developing an FP-tree to avoid scanning it several times, the second one was to adopt a pattern fragment growth method to avoid the costly generation of a large number of candidate sets, and finally used divide-and-conquer method to decompose the mining task and reduce the search space.

Uno et al., [10] proposed Linear time Closed item set Miner (LCM) algorithm. They constructed tree-shaped transversal routes composed of only frequent closed item sets. LCM algorithm founded all frequent closed item sets in polynomial time per item set, without storing previously obtained closed item sets in memory.

Yuan [6] proposed an improved Apriori algorithm as a remedial to the previous defects. Yuan used a new database mapping way, pruned more candidate elements and used overlap strategy to count support. The improved Apriori algorithm achieves excellent performance by reducing the time consumed in transaction scanning for the generation of candidate itemsets and by reducing the number of transaction to be scanned.

Sheng et al., [11] proposed a novel method by combining the Apriori algorithm and probabilistic graphical model. Sheng et al. avoided the disadvantage that whenever the frequent items are searched the whole data items have to be scanned cyclically. The effectiveness and feasibility of the proposed method in ARM has been proved.

Liu et al. [12] proposed a fast Apriori algorithm, called ECTPPI-Apriori, for processing large datasets. The algorithm uses a parallel mechanism in the ECPI tissue-like P system. The time complexity of ECTPPI-Apriori is improved to $O(t)$ compared to other parallel Apriori algorithms.

Fu et al. [13] have developed a parallelization algorithm based on the Hadoop framework and the Map Reduce model. The algorithm proved its efficiency in extracting frequent elements and generating ARs from large transactional databases.

III. MATERIAL AND METHODS

A. Data Collection

For experimental evaluation, a bench mark dataset has been selected as input data <https://www.kaggle.com/uciml/pima-indians-diabetes-database>. The studied population is PIMA Indian population near Phoenix, Arizona, it is known to be one of the communities with the highest percentage of diabetes in the world. Diabetes is a multifactorial disease where multiple rare genetic, environmental and even behavioral variants influence collectively the expression and the prevalence of traits and diseases [14]. That population has been under continuous study since 1965 by the National Institute of Diabetes and Digestive and Kidney Diseases [15]. The dataset is composed of 768 patients, and two classes. The variables are medical measurements of the patient plus age and pregnancy information. The classes are : *C0*, indicates *True Diabetic Test* (268) and *C1*, indicates *False Diabetic Test* (500) [16].

Among the factors, Diabetes Pedigree Function (*DPF*) was developed by Smith et al. [15], This function takes into consideration genetic factors inherited from ascendants.

$$DPF = \frac{\sum_i K_i(88 - ADM_i) + 20}{\sum_j K_j(ALC_j - 14) + 50} \quad (3)$$

- 1) i ranges over all relatives, who had developed diabetes by the subject's examination date;
- 2) j ranges over all relatives, who had not developed diabetes by the subject's examination date;
- 3) K_x is the percent of genes shared by the relative;
- 4) ADM_i is the age in years of relative, when diabetes was diagnosed;
- 5) ALC_j is the age in years of relative j at the last non-diabetic examination (prior to the subject's examination date);
- 6) The constants 88 and 14 represent, the maximum and minimum ages at which relatives of the subjects in this study have developed diabetes;
- 7) The constants 20 and 50 were chosen such that:
 - A subject with no relatives would have a *DPF* value slightly lower than average.
 - The *DPF* value would decrease relatively slowly as young relatives free of diabetes joined the database.
 - The *DPF* value would increase relatively quickly as known relatives developed diabetes.

Table I illustrates an excerpt of data representing medical measures and observations collected after studying a set of (768) patients. The first column contains an ordering number for the patients. The eight next columns represent measures for medical factor:

- Number of times pregnant : p ,
- Plasma Glucose Concentration at 2 Hours in an Oral Glucose Tolerance Test : g ,
- Diastolic Blood Pressure (mm Hg) : b ,
- Triceps Skin Fold Thickness (mm) : s ,
- 2-Hour Serum Insulin (U/h/ml) : i ,
- Body Mass Index ((Weight in kg)/(Weight in m)²) : B ,
- Diabetes Pedigree Function : d ,
- Age (years) : a .

The last column describes the fact whether the corresponding patient is actually sick (*C1*) or not (*C0*).

TABLE I: Medical Measures

	p	g	b	s	i	B	d	a	Out
1	0	100	70	26	50	30.8	0.597	21	<i>C0</i>
2	0	100	88	60	110	46.8	0.962	31	<i>C0</i>
3	0	101	62	0	0	21.9	0.336	25	<i>C0</i>
...
768	9	184	85	15	0	30	1.213	49	<i>C1</i>

B. Discretization of Numeric Attributes (Factors)

In our database, the range of each numeric attribute is very wide. To overcome this problem it was decided to turn numeric attributes into discrete ones. Table II illustrates an excerpt for

different distinguished ranges for each measured criterion. For example, measures for the criterion *Age* (last line) may range over $\{21, 24\}$ or $\{25, 30\}$ (in fact also over $\{31, 40\}$, $\{41, 55\}$ or $\{56, -\}$ which are not represented in the excerpt).

When an interval ends with $-$, then it admits no upper bound. An interval suffixed by $*$ is the one to be picked up by default when the measured value does not fit into any interval.

The database in Table I can then be discretized by replacing each measured value for a given criterion by the identifier of the interval it fits into. The result is illustrated in Table III.

TABLE II: Medical Measures Ranges

C	R1	R2	...	R6
p	{0, 2}	{3, 6}	...	
g	{0, 89.1}	{89.2, 107.1}	...	{165.2, -}
b	{0, 0}*	{1, 76.1}	...	{98.2, -}
...
a	{21, 24}*	{25, 30}	...	

We note that the factor 10 has been chosen to obtain distinct interval ids. This is true in our example because for all factor, the number of intervals never exceeds 9. In the general case, this factor can be chosen as the closest power of 10 to the maximum number of intervals for factor to ensure interval's id uniqueness.

Uniqueness is needed here to obtain different items representing different factor ranges. This may be useful when considering sets of such items in the algorithms we present in this paper.

TABLE III: Discretized Medical Measures

	p	g	b	s	i	B	d	a	Out
1	11	22	32	43	52	63	73	81	91
2	11	22	33	44	52	65	74	83	91
3	11	22	32	41	51	61	72	82	91
...
768	13	26	33	42	51	63	75	84	92

C. Problem Description

Given the representation in Table III of the patients' database it is interesting to analyze which combination of factor ranges implies the most sickness (or no sickness). We may consider combination taking into account all or only subsets of the factor. To represent a given combination of factor ranges and the associated desired outcome (sickness or not) we are using an *Association Rule*, defined below.

definition 1: Given A a set of integers and c an integer, we define the corresponding *Association Rule* (or simply *Rule*), γ , denoted by $A \Rightarrow c$. A is called the *antecedent* of γ (and denoted by $\mathcal{A}(\gamma)$) and c its *consequence* (and denoted by $\mathcal{C}(\gamma)$). The *size* of γ (denoted by $\mathcal{S}(\gamma)$) is the size of its antecedent: $|\mathcal{A}(\gamma)|$.

An association rule $\mathcal{A}(\gamma)$ represents the logical implication: "if items in A are all observed on medical measures for a patient then the outcome for that patient is c ".

definition 2: Given an association rule γ , a projection of γ is a rule γ' , such that $\mathcal{A}(\gamma')$ is a non-empty subset of $\mathcal{A}(\gamma)$. When γ' is a projection of γ we also say γ is an enrichment of γ' .

We note that the encoded database of Table III can be represented by a sequence (array or list) of association rules. Given definitions 1,2 we can now state the problem we propose to investigate.

problem 1: Given:

- a sequence of association rules $\mathcal{P} = [A_p \Rightarrow c_p]_{p \in I}$, with the same size d , called *population*,
- an objective function f mapping each projection of an association rule in \mathcal{P} to a real value in $[0, 1]$,
- and an integer s between 1 and d .

Compute all the projections of size s of associations rules in \mathcal{P} that maximizes the objective function f .

We propose to solve the Problem 1 for all possible sizes of association rules. As objective function we will use the so-called *fitness*, defined below.

definition 3: Given two strictly positive real values α and β , and a set \mathcal{P} of association rules, the *fitness* function (denoted *fit*) maps each projection γ of elements in \mathcal{P} to a positive real value $fit(\gamma)$ as described below:

$$fit(\gamma) = \frac{\alpha \times supp(\gamma) + \beta \times conf(\gamma)}{\alpha + \beta} \quad (4)$$

where :

- the *support* of γ denoted by $supp(\gamma)$ is $\frac{y(\gamma)}{\mathcal{P}}$,
- the *confidence* of γ denoted by $conf(\gamma)$ is $\frac{y(\gamma)}{x(\gamma)}$,
- $x(\gamma)$ is the number of enrichments of γ in \mathcal{P} ,
- and $y(\gamma)$ is the number of enrichments of γ in \mathcal{P} , having the same consequence as γ .

We note that for a given association rule γ , $supp(\gamma)$ measures the probability of occurrence of items in $\mathcal{A}(\gamma)$ together with consequence $\mathcal{C}(\gamma)$ in the population, while $conf(\gamma)$ measures the probability of occurrence of the consequence $\mathcal{C}(\gamma)$ having all items in $\mathcal{A}(\gamma)$ appearing in the rules of the population.

IV. FAST EXHAUSTIVE SEARCH FOR ASSOCIATION RULE MINING ALGORITHM (FES-ARM)

To solve Problem 1 we propose the following exhaustive search algorithm. We notice that Algorithm 2 may be called by Algorithm 1 many times for the same rule. This is due to the fact that different rules can have common projections. We note that running Algorithm 2 with a rule that already have been treated does not bring more results. The proposed enhancement consists of using a *setRulesDone* which will hold all the already analyzed rules, and recursion in Algorithm 2 will only be initiated for rules that are not in *RulesDone*. There is also a second improvement: It tackles a costly part of the treatment : the computation of the fitness function itself. We propose to keep track for all computed fitnesses for all analyzed rules. This is efficient since fitness is likely to be computed many times for the same rule.

A. FES-ARM Algorithm

To solve Problem 1 we propose the following FES-ARM algorithm.

- 1) Compute all projections of rules in the population and keep only those having maximum fitness.
- 2) Projections of a given rule γ , are recursively computed by removing at each recursion step only one item from $\mathcal{A}(\gamma)$.

Algorithm 1: MAIN FES-ARM Algorithm

Input: \mathcal{P} and c
Output: $OptRules$, $OptFits$ and $RulesDone$

```

1 Initialize  $OptRules$  with  $\emptyset$  and  $OptFits$  with 0.0 for all rule sizes;
2 for  $\gamma \in \mathcal{P}$  do
3   SOLVE_FOR_RULE( $\gamma$ ,  $c$ ,  $OptRules$ ,  $OptFits$ ,  $RulesDone$ );
4 end

```

Algorithm 2: SOLVE_FOR_RULE

Input: γ , c , $OptRules$, $OptFits$ and $RulesDone$
Output: $OptRules$, $OptFits$

```

1 if  $\gamma \notin RulesDone$  then
2    $RulesDone.add(\gamma)$ ;
3    $CurrentFitness \leftarrow fit(\gamma)$ ;
4   if  $CurrentFitness > OptFits.get(\mathcal{S}(\gamma))$  then
5      $OptFits.put(\mathcal{S}(\gamma), CurrentFitness)$ ;
6      $OptRules.put(\mathcal{S}(\gamma), \emptyset)$ ;
7      $OptRules.get(\mathcal{S}(\gamma)).add(\gamma)$ ;
8   end
9   else
10    if  $CurrentFitness = OptFits.get(\mathcal{S}(\gamma))$  then
11       $OptRules.get(\mathcal{S}(\gamma)).add(\gamma)$ ;
12    end
13  end
14  if  $\mathcal{S}(\gamma) > 1$  then
15    for  $item \in \mathcal{A}(\gamma)$  do
16       $\mathcal{A}(\gamma') \leftarrow \mathcal{A}(\gamma) \setminus \{item\}$ ;
17       $\mathcal{C}(\gamma') \leftarrow c$ ;
18      SOLVE_FOR_RULE( $\gamma'$ ,  $c$ ,  $OptRules$ ,  $OptFits$ ,  $RulesDone$ );
19    end
20  end
21 end

```

Algorithm 1 takes as input the population \mathcal{P} , the considered consequence c and returns a mapping $OptRules : i \rightarrow \Gamma_i$ associating to each possible rule size i the set of rules realizing maximum fitness and a mapping $OptFits : i \rightarrow f_i$ associating to each possible rule size the actual maximum fitness. It uses a set $RulesDone$ that will contain all analyzed rules (for optimization purpose).

We note that Algorithm 1, solves several instances of Problem 1 at a time, i.e., for all rules sizes.

B. Complexity

Complexity of Algorithm 1 (using Algorithm 2) will obviously depend on concrete used implementations of mappings and sets data structure.

We propose to use Java *HashMap* (resp. *HashSet*) to implement mappings (resp. sets). These classes offer constant-time complexity for regular operations: add, remove and membership test (\in).

This means that all instructions in Algorithm 2 (the recursive call being omitted) are constant-time complexity, except for line 3 where a fitness is computed. Computing the fitness of a rule γ means running through the hole population of rules and testing whether $\mathcal{A}(\gamma)$ is a subset of the antecedent of the population member. Testing that a set A is a subset of another set B runs in $O(\min(|A|, |B|))$. This means computing the fitness of γ is $O(\mathcal{S}(\gamma) \times \overline{\mathcal{P}})$.

Algorithm 2 will be called for all projections of all rules in the initial population \mathcal{P} . There may be redundancy in those generated projections, since two rules can share projections. We note that the if test in line 1 of Algorithm 2 will be executed for all generated projections, with redundancy, while all the other instruction of this algorithm will be executed only once for each distinct generated projection. Each call to Algorithm 2 with rule γ and where the if test in line 1 will be positive, will cost $O(\mathcal{S}(\gamma))$.

Let N_{Γ}^s be the number of all computed projections of size s with redundancy and $N_{\Gamma,d}^s$ the number of all the latter projections without redundancy. We can safely infer that complexity of Algorithm 1 is

$$O\left(\sum_{s \in [1,d]} N_{\Gamma}^s + n \times \sum_{s \in [1,d]} N_{\Gamma,d}^s \times s\right)$$

We recall that d is the maximal rule size (in our example it is 8) and we note that $N_{\Gamma,d}^s$ and N_{Γ}^s are likely to be exponential in d and $\overline{\mathcal{P}}$ in the worst case.

C. Fitness Computation Enhancement

Computing the fitness for a given rule is a costly task. Indeed we explained in previous sections that it has $O(s \times n)$ complexity, where s is the rule's size and n the population size. We propose to reduce the fitness computation complexity using the following enhancements:

- 1) Provided that we already have computed a mapping $TransactionsByItems$, that sends every item $item$ to the set of the transactions (rules in \mathcal{P}) $\Gamma(item)$ where this item appears. We can compute then compute:

$$x(\gamma) = \bigcap_{item \in \mathcal{A}(\gamma)} TransactionsByItems(item) \quad (5)$$

If we extend the definition of *TransactionsByItems* to the consequences, we can also compute, for a given sequence c :

$$xy(\gamma) = \bigcap_{item \in \mathcal{A}(\gamma) \cup \{c\}} TransactionsByItems(item) \quad (6)$$

Since the complexity of computing the intersection of two sets A and B runs in $O(\min(\overline{A}, \overline{B}))$. We can infer that the complexity of computing every intersection is $O(s \times \min_{item \in \mathcal{A}(\gamma) \cup \{c\}} (TransactionsByItems(item)))$ and that reduces drastically the fitness computation (time) complexity. We note that pre-computing the mapping *TransactionsByItems* does not introduce too much cost, since it can be done while parsing rules from the database file.

- 2) We can also keep track of all computed fitnesses so far, using a mapping *ComputedFitnesses* that sends each already analyzed rule to its fitness value.

V. EXPERIMENTAL RESULTS

We propose in this section to discuss results obtained when applying the algorithm presented in this paper compared to Apriori Algorithm. We used databases containing 768, 7680 and 76800 entries, with antecedents of size 8 and 2 consequences, and executed 10 times.

- N: Number of iterations.
- C: The considered consequence.
- A.E.T : Average Execution Time

All times are measured in milliseconds (*ms*) except when a different unit is explicitly specified.

TABLE IV: Comparative table of Average Execution Time (A.E.T) provided by our Algorithm and Apriori Algorithm

n	C	A.E.T Apriori	A.E.T FES-ARM
768	91	667035	2120
	92	852392	2766
7680	91	> 48h	12855
	92		13342
76800	91		145355
	92		143346

Discussion: In this work we introduce an efficient algorithm to identify relevant ARs. Our experimental evaluation shows that complexity goes from exponential complexity $O(2^n)$ to polynomial complexity $O(\sum_{s \in [1,d]} N_{\Gamma}^s + n \times \sum_{s \in [1,d]} N_{\Gamma,d}^s \times s)$ in comparison with Apriori Algorithm (worst case) and in response time (mentioned in table IV). Compared to Apriori Algorithm, our approach proved the same efficiency in quality of generated rules with maximizing the fitness function, proving that we have not lost the quality of information as well even with the increased size of the database. These results are due to three improvements. The first one consists of using a *setRulesDone* which will hold all the already analyzed rules, to avoid analyzing the same rule several times (We propose mining specific to general).

The second one is computing the fitness of each transaction by pre-computing the mapping *TransactionsByItems* while parsing rules from the database file. The third one (It takes a costly part of the treatment) consists of keeping track for all computed fitnesses for all analyzed rules. This was efficient since fitness was likely to be computed many times for the same rule.

VI. CONCLUSION

This paper presents a new Fast Exhaustive Search algorithm FES-ARM for discovering efficient ARs to predict the chance of occurring the Diabetes Mellitus (DM). The proposed algorithm produces in a correct way relevant association rules (The same rules produced by Apriori algorithm) while optimizing the average execution time in the worst case to 314,64%. FES-ARM is tested on real databases containing 768, 7680 and 76800 entries, with antecedents of size 8 and 2 consequences, and executed 10 times. The complexity of FES-ARM Algorithm is improved from $O(2^n)$ to $O(\sum_{s \in [1,d]} N_{\Gamma}^s + n \times \sum_{s \in [1,d]} N_{\Gamma,d}^s \times s)$ in comparison with Apriori Algorithm. Our ambition for the future works, dealing with large transactional databases, is to develop new metaheuristics approaches to solve association rules mining as a combinatorial optimization problem.

Abstract—Through software analytics, raw data with low value originates information that is valuable and able to provide insights, enabling the support of claims that would otherwise not be possible to verify. The software development ecosystem has plenty of sources that can help understanding the quality of processes and products but, to reach that goal, it is necessary to collect and store the data. This paper describes an infrastructure to allow the collection, storage and analysis of data from software repositories. The scope of the research is an industrial case study, which encompasses several specificities: tools and work methodology. The current solution is able to collect information from the continuous delivery & deployment pipeline, which includes data sources such as the source code repository (SVN), the static analysis tool (SonarQube), the continuous integration server (from Jenkins jobs) and the continuous testing tool (an in-house tool called Cerberus). Future work also includes the implementation of components that will allow the collection of unstructured data from the bug-tracking system and incident management tool. As stated in the literature, correlating the history of issues and incidents will allow the team to address, or at least identify, areas of improvement.

Index Terms—CI/CD Pipeline, Mining Software Repositories, Machine Learning, Software Analytics, Software Quality

I. INTRODUCTION

Software Analytics as a means to predict or gather information about software development activities is an engaging research field that aims to provide insights and solutions, not only for the technical topics, but also for organizational issues. In general, one's aspiration is to guide teams to enhance the quality of the products being developed and processes being executed ([1], [2], [3], [4]). In the scope of software development, the ability to perform change impact analysis is especially relevant since team members will be able to receive direct feedback from their work and at the same time forecast or identify support for other tasks such as test-case selection and prioritization [5].

Mining Software Repositories (MSR) is among the new techniques used to perform change impact analysis [6]; this technique makes use of historical data available in software repositories, such as issue tracking systems and source code repositories. Menzies and Zimmermann write about the common vision shared in the literature [4]: “data from software

projects contains useful information that can be found by data-mining algorithms”. As such, commit messages and bug-reports are examples of artifacts from which knowledge related to change impacts can be extracted. For instance, Ying *et al.* [7] claim that a developer may benefit from patterns in the history change of a system while performing maintenance tasks. Therefore, well-known applications scope include recommendation systems, and effort and defects predictors for software development. New fields of research include: detectors for unexpected or bug-prone code, indicators for developer's mood by applying sentiment analysis to comments, and explorers for complex spaces. As for data science in the industry, what was seen in the past as cutting-edge research is now part of daily operations of IT companies [4], [8].

With the current shift concerning automated delivery and deployment, and when moving from manual and bureaucratic processes to almost full automation, all those tools pose as data sources. Nowadays, delivery and deployment are continuous practices supported by tools [9], and the capture of events is more straightforward. In addition to mine source repositories and bug tracker systems, the spectrum of sources may include: code review tools [10], Continuous Integration/Continuous Delivery (CI/CD) tools or automated tools for continuous testing. Even though there are principles and practices transversal to companies that implement continuous practices, a company's specific characteristics influence how these practices are implemented [11], including the business domain, the type of product being developed, or the impact on the customers (e.g., some companies report that frequent releases may lead to an increase on customer churn rate).

In order to gain visibility of all the events generated by continuous practices it is necessary to implement an infrastructure to support the data collection and storage. This paper reports on a real case study, implemented for the IT department of La Redoute¹, which is an *e-commerce* company. The infrastructure presented aims to collect data from several data sources available in the continuous pipeline: source code repository, static analysis tool, CI/CD server and continuous testing tool. The paper is the continuation of previous work

[12]; it described the ongoing research and motivation to apply machine learning techniques to improve the quality of processes and products developed in La Redoute's IT department. A particularity of the architecture presented in this paper is that it is emerging during the digital transformation of the company, i.e., new projects moving to micro-services cloud-based architecture, in opposition to monolithic solutions implemented in the past. The infrastructure being developed is also supported by this new technological stack which includes components such as Kafka², Kubernetes³, Elasticsearch, Logstash and Kibana (from the Elastic stack⁴). Considering some the advantages of software analytics and MSR, this infrastructure will support the team's need to anticipate issues ("Is this commit considered problematic?") and to understand the best and worst practices in place, both technical and social ("Do people on my team need training?").

The rest of paper is organised as follows: Section II overviews relevant literature; Section III describes the main requirements and the architecture being implemented, and finally, IV concludes this paper while identifying future directions.

II. RELATED WORK

This section overviews literature that takes advantage of repositories mining in order to find patterns and to extract knowledge about the aspects influencing the software development and evolution.

Ball *et al.* [13] proposed a framework to delve into the relationships between several components of the software development process: requirements, technological stack, software development and the development's team organizational characteristics. In the scope of C++ case studies, the authors derived a VCS-related metric: connection strength determined with basis on how probable it is that two classes are modified together. Additionally, Ball *et al.* highlighted the existence of valuable contextual information that could be leveraged to understand how a component evolved from one release to another; examples include code modified, date and time of modification, and the author. The assumption is that automated analysis can also be applied to contextual data.

Hipikat tool [14] was conceived by Čubranić and Murphy as a means to aid newcomers to an open-source project, which don't have the same support net when compared to traditional *in-house* teams. The authors use the concept of *implicit group memory* that infers links between archived artifacts produced in the source repository, issue-tracking systems, communication channels and online documentation. The *implicit group memory* is then used to recommend artifacts, from the archives, possibly relevant to the task assigned to the newcomer.

Zimmermann *et al.* [15] present the tool ROSE – a plugin for Eclipse IDE⁵ – that guides the programmer. An association rule mining algorithm was employed to mine the *version*

histories providing the developer means to: i) "suggest and predict likely changes"; ii) "prevent errors due to incomplete changes"; and iii) "detect coupling undetectable by program analysis". As the tool is based on the files' version history, it is possible to observe another type of coupling that is not code-based: coupling between items that are not applications or programs.

Canfora and Cerulo [16] proposed a method to infer the list of impacted source files that will be impacted by a change request. The method makes use of information from the source repository and the changes requests (Bugzilla⁶) and via information retrieval algorithms, the technique makes the link between the new change request and the historical revisions impacted by similar requests. The evaluation of the method was implemented in four open source projects, and the positive results range from 30% to 78%. The prediction of the effort required to test is another possible application pointed by the authors that will help both developers and project managers.

Ren *et al.* developed Chianti [17], a tool to support change impact analysis of Java programs, integrated in the context of Eclipse IDE. For this tool in particular, regression and unit tests, and corresponding executions, are the artefacts of interest, i.e., the tool reports on how tests' behaviour are influenced by changes. For each change on a test's behaviour, the tool also determines the "affecting changes".

Ying *et al.* [7] developed an approach that relies on data mining techniques to identify patterns on the change history of the base code; specifically, the approach searches for patterns among the changes observed on the set of files that commonly change together. Based on their approach, the authors report that history change patterns support recommendation systems that indicate additional code that should be modified when a developer is doing a modification of the source code. This work is aligned with work done by Zimmermann *et al.* [15] even if applying different algorithms.

Zanjani, Swartzendruber and Kagdi [6] also presented an approach called *InComIA* to understand the change impacts of an incoming request. They aim for connections between historical data, provided in task management applications (Mylyn⁷), and histories and contextual information available in commits (via source code repositories). A *corpus* of source code entities – methods and files – was created by applying several techniques: information retrieval, machine learning and source code analysis. For an incoming request, its text is used to query the *corpus* and as a result, the tool returns a list of the most prone to change entities.

TARMAQ is an algorithm developed by Rolfsnes *et al.* [5] for mining *evolutionary coupling* (a driver for change impact analysis); it was empirically validated on six projects – 2 industrial and 4 open source – and the authors claim better results when compared with ROSE tool [15], as it worked better for heterogeneous systems. *Evolutionary coupling* aims to understand how systems evolved during their lifecycle,

²<https://kafka.apache.org/documentation/>

³<https://kubernetes.io/>

⁴<https://www.elastic.co/>

⁵<https://www.eclipse.org/ide/>

⁶<https://www.bugzilla.org/>

⁷<https://www.eclipse.org/mylyn/>

the goal is to pick data that changed “together” and mine the connections between the entities that were modified. The authors focused at connections between files, although several granularity levels would be possible (methods or variables).

Chatley et Jones [18] presented a tool called *Diggit* which is able to generate code review comments in an automated fashion; the authors used historical changes from a Git repository, using a mining algorithm to pinpoint directions on eventual changes. The tool was integrated in a development team inside an industrial case study, and the authors also reflected on the impacts of adapting an academic research into the real world to be used by developers. The authors pinpoint potential both for commercial and open-source projects (which may include a higher number of developers and number of commits during the time). Motivation for their work encompasses not only the assurance of commits’ quality but also the support to improve developers’ competences.

Following a different perspective, Mens and Goeminne [19] studied the social component applied on the open-source community: work methodologies, cooperation, communication and information sharing. The main motivation was to understand how communities impact the evolution of a software product, some of the events that were analysed by authors are also true for industrial case studies, examples, departure of a key developer or the handover of a project to another team.

Murgia *et al.* [20] also adopted a more social approach by mining issue reports to gather emotional information about the software development. The authors focused on the issue tracking system of Apache Software Foundation⁸ and were able to observe emotions such as sadness, joy and gratitude, through a human observation of the reports. The motivation for analysing this type of information is on the fact that the lack of happiness or safety may lead developers to fall behind. Moreover, to support the importance of context in the quality, Bird *et al.* [21] report about the impacts of organizational aspects, which are seen as strong indicators of quality, refuting that geographically teams are producing worst products. Menzies and Zimmermann [4] also agree that social factors are promising quality predictors.

Another level of repositories mining is to mine repositories of repositories (RoRs). For instance, Sowe *et al.* [22] studied the types of projects being developed in the open source community, for that purpose the authors used metadata available in the RoRs FLOSSmole⁹.

Our research addresses a industrial case study, i.e., the scope include projects developed by an IT department composed by almost 110 people from Development and Operations. The underlying motivation for the implementation of the infrastructure described in this document is to have means to support and improve products, processes and competences. Even though there are a few studies reporting about industrial case studies, the majority of the aforementioned research focuses on open-source case studies. Nevertheless, those are a representative

sample of complex projects both in the technical and social perspectives.

III. ARCHITECTURE

A. Continuous Delivery & Deployment Pipeline

Figure 1 depicts a general view of the delivery & deployment pipeline implemented by the IT team; it is supported mainly by Jenkins¹⁰, integrated with the other tools so as to allow the build, static analysis, deploy and testing of the components being delivered and deployed.

The pipeline is triggered immediately upon a commit on the version control system, SVN¹¹. Jenkins listens for modifications on the code repository and initiates the build of the component after each new commit. In the same job instance, after the build, the component is submitted to SonarQube¹², which, in turn, executes the static analysis (reports about technical debt, test coverage, complexity) and enforces quality rules that should be respected. If the build and quality rules are valid, the project is deployed in a first non-production environment QA – *Quality Assurance*, so that developers can perform their first tests in a machine other than theirs. A successful deployment triggers a functional test campaign, ensuring non-regression, implemented through an *in-house* tool named Cerberus [23]. The global output of the test campaign – OK or KO – is used to decide if the component should be installed in the following environments in the pipeline. After QA, the team can move their components to the next environments – UAT and PROD. UAT or *User Acceptance Tests* is a pre-production environment allowing to perform more tests in a confined environment. After the deploy of a component in the UAT environment, the corresponding automated test campaigns will be triggered as well. For Production, it is also possible to execute automated tests.

B. Architecture

Altogether, the proposed architecture (Figure 2) collects structured data about: the commits, the Jenkins jobs status for build, deployment and test campaigns; SonarQube measurements and the summary for test campaigns executions.

As mentioned in the Introduction, the architecture described in this paper is implemented in a Kubernetes cluster, which is an “open-source system for automating deployment, scaling, and management of containerized applications”. This type of infrastructure eliminates most of the manual work required to set up and modify an infrastructure, in opposition to traditional Virtual Machines. Thence, if necessary, a new resource for data collection, treatment or analysis can be easily set up and integrated in the infrastructure.

The entry or starting point of the data collection process is the Kafka component – identified as “Data pipeline”. Kafka is a distributed streaming platform that allows, among other features, to implement the streaming of data pipelines in real-time. For this specific architecture, the jobs in the Jenkins

⁸<https://www.apache.org/>

⁹<https://flossmole.org/>

¹⁰<https://jenkins.io/>

¹¹<https://subversion.apache.org/>

¹²<https://www.sonarqube.org/>

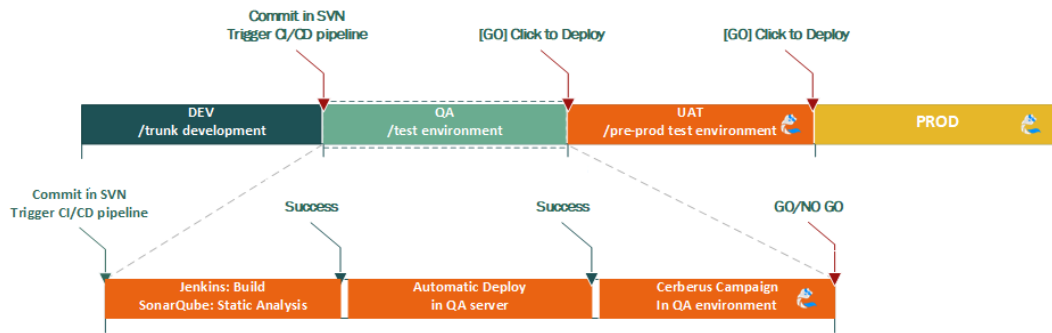

Fig. 1. Overview of development pipeline supported by Jenkins, SVN, SonarQube and Cerberus.

pipeline send data to a specific Kafka topic called “jenkins”. A *topic* defines a stream that holds specific types of events or messages. An advantage is that any consumer can pick a message or event in a topic and treat it according to their specific use case. The potential of streaming the events triggered in the continuous pipeline is huge, for instance, the “jenkins” topic is also supporting some release engineering tasks, since the team is able to extract statistics about the team’s velocity and the time necessary to reach production environments.

In this architecture, the consumer of the “jenkins” topic is referred as “Data filter”, which is a Logstash service that reads the messages and extract the meaningful data for this research. Logstash is an *Extract, Transform, and Load (ETL)* component. The “Data filter” will parse and load the useful data into a component implemented in Java, which in turn is responsible for correlating the data received with metrics from: i) the code quality analysis and ii) the result of the functional test campaign. This step will promote the construction of a complete data set that will serve the purpose of the system. The data will then be stored inside a special component, the “Data Repository”, which is an Elasticsearch engine that stores data as JSON documents. Elasticsearch allows quick searches and integrates very well with other technologies simplifying both data analysis and visualization tasks.

The second half of the architecture (“Decision Making Process”), represents the components that can consume data from the “Data repository”. It is expected to use Machine Learning techniques to predict the severity level of the events happening in the continuous pipeline. For that purpose, a first TensorFlow¹³ component is being implemented in the Kubernetes cluster. Additionally, it is important to provide means to visualize the data, and for that purpose we expect to implement useful dashboards. To begin, Kibana is also available in the cluster, facilitating the access and visualization of the data available in “Data Repository”.

With basis on this architecture, the next step is to implement all the processes and components that will analyse the data

and provide valuable insights to users, either developers or managers. For that purpose, future work will need to ensure some basic requirements [24] [18]:

- *Short execution times*: if the analysis takes too long, developers will feel tempted to abort it and to move on.
- *Short number of false positives*: a high number of false positives may lead to the abandonment of the framework.

C. Other data sources

Other data sources included in the “Data repository”, but that are currently being manually loaded include:

- *Developers experience*: the different developer categories are used as input. Developer’s data needs to be managed carefully to avoid exposing personal details. Future work may include information about the managers and team organization in order to understand the organizational impacts.
- *Impact of the project*: currently being loaded from an excel file; however, there is an ongoing project to implement a database repository which will ease the management of this type of information. Also, it is necessary to ensure that the owners of each software component share accurate information about the impacts and severity for the business.

A next step for this architecture includes the development of specific connectors to gather non-structured data from: i) Mantis – the bug tracking system for non-production issues; ii) *iTop* – system used to report issues detected in PROD environment; and iii) logs – any type of execution logs.

D. Early Observations

Even though is to soon to comment on the data collected and the insights that are possible to infer, it is interesting to report a curious observation. Linear regression was applied to two variables: i) the result of the Jenkins build job, and ii) the time of the day that a commit was done. An unexpected high number of build jobs, which are triggered by the commit, failed in the hour after the lunch break. A possible research

¹³<https://www.tensorflow.org/>

Fig. 2. Architecture to collect data from the CI/CD pipeline.

direction: What are the impacts of interrupting the “thinking flow” of a developer?

IV. CONCLUSIONS AND FUTURE DIRECTIONS

Even though software analytics opens several possibilities for “discovering, verifying, and monitoring the factors that affect software development”, there are several underlying issues [4]. The following paragraphs describe how those issues relate to the work described in this paper.

Even though the described architecture is prepared to collect data from several sources in the pipeline, there are factors that are not visible in those components nor collected in an automated manner. For that purpose, two surveys were conducted to obtain information that is not available in the tools used, but that is more related to the social component and team’s characteristics. This type of activity is time-consuming, but the surveys results are expected to uncover not only the points of improvement, but also the good practices implemented by the company.

The context may be another issue, as it may differ among projects, even when handled by the same team. Currently, we are restricting the research scope to new projects that have a high-level of readiness to integrate a micro-services architecture. Nevertheless, the legacy code, which is distributed across a panoply of projects using different technological stacks, represents a big part of the scope, and it may hinder bad practices that are propagated and need to be addressed by the team. This is a topic that needs to be monitored closely in order to understand how can we transfer the knowledge acquired from a project – that fits the standards of the new architecture – to a legacy project.

A frequent goal of this type of research, which focuses on the software development data, is to have actionable insights, i.e., how can we use the information available to take some real and concrete actions. This work is expected to provide information that can help teams reduce the overhead of manual tasks, raise automatic alerts in case of need, and also identify

potential needs in terms of training. These actionable actions will impact the continuous practices and drive business value, as an increase on the quality of processes and products is foreseen.

Abstract—In the multi-disciplinary *production systems engineering* (PSE) process, software engineers depend on requirements and design rationales coming from product and production process planning, summarized as *product/ion* knowledge. Unfortunately, the engineering artifacts coming from product/ion planning often represent important product/ion knowledge incompletely and not well integrated, leading to risks regarding software engineering quality. In this paper, we report on a case study at a large industrial PSE organization, investigating *Technical Debt* (TD) effects, items, and causes in PSE process documentation and configuration management according to the VDI guideline 3695 Part 2. We focus on requirements for and issues in the representation of product/ion knowledge in the engineering data provided to software engineers. Based on data elicited from PSE domain experts, we model TD concepts based on the *Quality Function Deployment* method as foundation for TD analysis and risk management. The initial validation with domain experts revealed how software engineers could benefit from improved product/ion knowledge modeling as foundation for better understanding the rationale of engineering design decisions.

Keywords—Multi-Disciplinary Production Systems Engineering, Product/ion Knowledge, Product-Process-Resource (PPR) Model, Process Management, Technical Debt

I. INTRODUCTION

In *production systems engineering* (PSE) organizations, many different engineering disciplines work together, such as basic system and process planners, detailed automation engineers and production optimizers, for fulfilling customer requirements towards the *Industrie 4.0* vision [1] regarding, for example, production system throughput and quality. In a typical PSE process, the domain experts work in parallel in discipline-specific workgroups that exchange engineering artifacts for iterative improvement. For making informed design decisions, industrial automation and software engineers depend on the high quality of input artifacts that contain software requirements as well as results and rationale of system design decisions [4][5].

Unfortunately, the quality of *software engineering* (SE) results, such as software code governing the transportation system of a production plant, is subject to risks due to the missing or incorrect representation of product/ion knowledge, i.e., knowledge on characteristics of the product, produced by the plant or characteristics of the industrial production process and their relationships to characteristics of the production system [13].

An example for such a relation is a *fragile product* that imposes limitations on the maximal acceleration during the transport between production system components. If a software engineer sets the transport speed high to maximize the system throughput, the product quality may suffer, leading to the costly redesign of the overall system. Limited awareness of domain experts on the knowledge requirements of partner roles in the project may lead to insufficient descriptions of relevant engineering data and knowledge. Risks from decisions based on insufficient and often incomplete information or from unplanned effort due to unreliable communication between basic and detailed planners could be better managed with adequate knowledge representations of product/ion knowledge throughout the process. Kathrein *et al.* point in [13] out that *engineering organizations* (EOs), as defined in the VDI 3695 [28], tend to focus on discipline-specific outcomes rather than on the collaboration of domain experts. The domain experts suffer from low quality of collaboration artifacts, but do not, in general, have the knowledge or the budget to improve the collaboration process.

In this paper, we investigate *Technical Debt* (TD) in the representation of product/ion knowledge in engineering artifacts exchanged between PSE workgroups as foundation for analyzing and managing risks from TD effects, items, and causes in a PSE organization. An example for TD is a missing or incomplete engineering process description, which makes it hard to manage projects across several domains and work groups. In this paper we adapt the definition of TD by Li *et al.* [16] according to engineering artifacts and the collaboration process: *TD are violations in engineering artifacts compared to best practices of engineering process documentation and configuration for collaborative workgroups in the PSE domain*. Main goal is to identify TD throughout the engineering process, for better PSE process management, in particular, SE risks.

We report on results from a case study at a large industrial PSE organization on TD regarding process documentation according to the PSE domain VDI Guideline 3695 Part 2 [28] concerning the *procedure model for project activities and configuration management in an engineering organization*. We focus on eliciting requirements for and in the representation of product/ion knowledge supporting software engineers in their decision-making process. In the case study, we identified TD items, where one TD item is a unit bearing quality risk [16], on insufficient description of engineering process and information in the data exchange process and insufficient representation of product/ion knowledge. Based on collected data samples, we relate TD concepts to each other and investigate their relationships

DOI reference number: 10.18293/SEKE2019-037

based on the *Quality Function Deployment (QFD)* [19] method. The *QFD* method allows analyzing and prioritizing customer requirements together with solution options. We use the *QFD* method for analyzing TD repayment options [19], e.g., which TD items should be addressed to reduce system design cost. Better understanding TD relationships is the foundation for advanced analyses of TD risks and TD repayment options.

The remainder of this paper is structured as follows: Section II summarizes related work on PSE, on knowledge representation in PSE, and on concepts of TD in PSE knowledge. Section III introduces the research questions and approach. Section IV reports case study findings regarding TD effects, items, and causes, and relates these TD concepts in a preliminary *QFD* style model. Section V discusses results and limitations of the research. Section VI concludes and provides an outlook on future research.

II. RELATED WORK

This section summarizes related work on *production systems engineering (PSE)*, on knowledge representation in PSE, and on concepts of technical debt in PSE knowledge.

A. Production Systems Engineering (PSE)

The engineering of production systems is a multi-disciplinary task involving various disciplines, such as mechanical, electrical, and software engineering [3]. The disciplines conduct a network of engineering activities where engineering decisions are taken and engineering data are created by engineers. The engineers use appropriate input data and engineering tools optimized for the discipline. One role, the automation engineering designs and implements the hardware and software of the production system control, a main software engineering task in PSE [27].

Within PSE, the importance of digital models is increasing. New activities related to the development and use of life cycle crossing digital shadows of complete production systems and their components are envisioned to enable the *Industrie 4.0* vision [17]. These models shall contain all relevant data and knowledge on production systems aspects. This includes the description of the involved production system components, the production processes they execute, and the product resulting from the production process. Schleipen *et al.* [24] calls this *PPR knowledge* and Kathrein *et al.* [13] use the term *production knowledge*. In this paper, we build on the *PPR* concept to identify shortcomings regarding knowledge representation that introduce risks to SE activities.

B. Knowledge Representation in PSE

Engineering knowledge is a specific kind of knowledge, oriented towards the production of artifacts, and, as such, requires knowledge modeling and representation approaches that differ from other types of knowledge, such as taxonomical knowledge characteristic for the life sciences domain [25]. Ontologies are

information artefacts that have been used extensively to explicitly represent such engineering knowledge. This is for example investigated by Ekaputra *et al.* [7] highlighting different ontology-based data integration strategies, possible objectives an engineering organization has, as well as data source types used.

Sabou *et al.* [23] provide an overview of such ontologies and classify them in terms of the aspects of the PPR process that they cover. For example, OntoCAPE¹ [20] is an ontology for supporting *computer-aided process engineering (CAPE)* focusing on describing production process information. The *Semantic Sensor Network (SSN)*² ontology, developed at W3C³, is well suited to describe process states and their observability, as well as resource states. The *Automation Ontology (AO)* captures knowledge about industrial plants and their automation systems to support engineering simulation models [21]. AO concerns mechatronic concepts to support simulation model design and integration.

The explicit modeling of PSE knowledge is characterized by the need to address recurring modeling needs specific for this domain, including: Modeling *Part-whole relations*. Legat *et al.* [14] observe that containment hierarchies are a well-accepted and frequently occurring organizational paradigm from modeling part-whole relations in (mechatronic) engineering settings. Modeling *connections between components*. Legat *et al.* [14] observe that *interface-based composition* describes the capabilities expected from an interface to enable reasoning tasks about the correctness of a system's structure.

The modeling of recurring knowledge structures can be well addressed by the reuse of *Ontology Design Patterns (ODPs)* that model best practices applicable to typical conceptualization scenarios [10]. Indeed, ODPs exist to support the conceptual modeling of (variations) of the engineering-specific modeling scenarios mentioned above. For example, modeling *Part-whole* relations can be achieved by reusing the *PartOf* ODP⁴, which allows modeling part-whole relations in a transitive fashion. The *Componency* ODP⁵ is a specialization of the *PartOf* ODP for modeling *part-whole* relations distinguishing between direct and indirect (i.e., transitively-assessed) parts of an object. While there are several approaches for knowledge representation in PSE they are often not used and lead thus to TD, which is addressed in this paper.

C. Technical Debt in PSE Knowledge

Avgeriou *et al.* [2] compare *Technical Debt (TD)* to friction in mechanical devices, requiring increasingly more energy to achieve the same results as parts deteriorate. This is also true for *software engineering (SE)*, as short-term gains create friction over the lifetime of a software-intensive system that require extra effort and cost to address or to repay. To deal with TD, Avgeriou *et al.* [2] propose to analyze TD repayment options and to investigate TD from different viewpoints. TD in a system consists of TD items that are measurable in an SE artifact. Li *et al.* [16] identify ten different TD types, with effects ranging from

⁵ Componency ODP: <http://ontologydesignpatterns.org/wiki/Submissions:Componency>

inconveniences to crippling whole software systems, making future maintenance costly [2]. Martini *et al.* [18] point out that large SE companies invest a quarter of the development time in managing TD to continue providing their SE functions.

Dong and Vogel-Heuser [6] draw a comparison, based on results from two case studies, between TD in PSE and in SE, as similar effects, such as short-term cost savings or lack of experience, occur in both domains. Causes of TD manifest in various dimensions, for example mechanical, electrical, or software engineering [6]. As process improvement and data exchange processes are success-critical processes in *engineering organizations* (EOs), they identify crucial TD in design and architecture, knowledge distribution and documentation [6].

Martini *et al.* [18] show how architectural TD accumulates during development in a project until reaching a crisis point that makes refactoring inevitable, increasing business value as the short-term sins are repaid adequately. Case studies by Biffel *et al.* [4][5] and Kathrein *et al.* [12][13] investigated engineering processes of EOs with a focus on the structure of collaborations between workgroups [13] and how data is exchanged [4][5]. These works represent building blocks for this paper, as they define a coherent context with basic concepts needed for TD investigations. The research highlights multiple use cases with different levels of TD, and points out missing *product/ion-aware* (PPR) knowledge as a limitation.

III. RESEARCH QUESTIONS AND APPROACH

This section introduces the research questions (RQs) following the *design science* method [29], and presents an illustrating use case to investigate TD in the representation of product/ion knowledge. Similarly, as in [26], we investigate TD as a form of software engineering risks, with effects and possible causes.

RQ1: What risks to software engineering results and activities are related to technical debt in the representation of product/ion knowledge in engineering artifacts exchanged between workgroups in production systems engineering? From the high-level RQ1, we derive the following sub-RQs.

RQ1a: What are effects of TD related to software engineering risks in PSE? We identify TD effects in the PSE process in interviews with domain experts. These TD effects can be defined as process management issues, i.e., deviations from the planned engineering process, and the process executed by individual domain experts. The identification of TD effects allows highlighting risks known to SE, but not to domain experts in PSE.

RQ1b: What are TD items regarding the VDI Guideline 3695 Part 2 in engineering artifacts exchanged between workgroups in PSE? The VDI Guideline 3695 Part 2 [28] provides valuable insights in describing engineering organizations (EOs) and potential improvement steps. The guideline provides a set of best practices that should be followed in an EO and allows analyses similar to code reviews in SE. Therefore, we define TD items in the PSE process by comparing selected target states in the VDI 3695 to the *as-is engineering process*.

RQ1c: What are causes regarding elicited TD items? As foundation for managing TD, we elicit in the case study candidate TD causes in the engineering organization. TD causes

strengthen the deviation between the as-is and VDI 3695 defined process and are important to address TD items and SE risks.

RQ2: How do TD concepts in the data exchange process relate to each other? After identifying TD concepts, we model their relationships as foundation for analyzing the impact of TD causes on TD items and effects, with a focus on SE concepts.

RQ2a: How do TD effects and TD items relate to each other? Main outcome of this RQ is a table based on the *QFD* method [19], developed with quality managers, who are responsible for defining an ideal PSE process across all involved disciplines and for possible improvement steps. The *QFD* method facilitates prioritizing relationships between TD effects and TD items that are relevant to reduce SE risks.

RQ2b: How do TD items and causes relate to each other? There are many and diverse TD cause candidates that can have different impacts on TD items. This RQ investigates most relevant TD causes to influence the TD items and effects. Main outcome is a table depicting relationships of TD causes and items based on the *QFD* method [19], created with quality managers.

To answer the RQs, we followed a case study design [22] by adhering to the following case study plan. [*Objective*] Exploring an existing engineering process [*Case*] in a large PSE organization. [*Theory*] Following the design science cycle according to Wieringa [29] in a holistic case study, [*Goal*] we identify common concepts at collaboration interfaces between PSE workgroups, and identify information bottlenecks regarding TD effects. [*Method*] Through seven semi-structured interviews (in a funnel approach) [22], [*Selection*] we elicit representative data from domain experts and investigate TD effects, items, and causes.

According to the design science cycle [29], this paper focuses on workshops and interviews regarding TD effects, causes, items, and the types and strengths of the relationships between the TD concepts. We discuss likely causes for the TD items found. Based on Matook and Indulska [19], we adapt the *QFD* method to focus in this paper on two dimensions of the *QFD House of Quality* (see Section V). In cooperation with quality managers, responsible for improving the PSE process, we design tables based on the *QFD* method [19] for investigating TD cause candidates. Finally, we present a conceptual evaluation, discussing presented repayment options to address SE-relevant TD in the multi-disciplinary engineering process.

Kathrein *et al.* [12][13] elicited the illustrating use case in Fig. 1 for *data exchange in the PSE process*. In this paper, the use case frames the election of TD concepts in the case study. In the beginning, the *system planner* (SP) receives product specifications from the customer (1) and aims at providing a competitive offer and at deriving specific knowledge on the production system for later use. This process is similar to software architecture design [14]. Output of this step (lilac arrow) are resource documents regarding the plant layout, calculations, and assembly sequences, delivered to the *process planner* (PP) (2).

Upon receiving the artifacts, the *PP* investigates these artifacts with a common schema that domain experts have developed over decades. For example, the first column always is the module identifier followed by the module name and a reference to an existing CAD drawing if possible. Main goal is to derive

The *production optimizer (PO)* receives all basic plans and tries to minimize the cycle times of the plant. However, this work requires different product/ion knowledge aspects and may cause many calls back to the *SP* and *PP* (5). The *PO* collaborates with the *automation engineer (AE)* (6), who is responsible for *PLC software engineering* tasks. From basic plans (4), the *AE* derives specific PLC software code. Goal of the *AE* is to trace design decisions as foundation for making informed design variations, such as the parameterization of the software and systems that execute production processes, e.g., the speed and acceleration of transport processes. In the next section we investigate this case study regarding TD effects, items and causes.

This section reports on findings from the case study regarding TD effects, items, and causes, and relates these TD concepts in a preliminary QFD model for the case study context.

TD effects. Regarding the use case, data exchange process, the following TD effects came up frequently in workshop sessions.

TD-E2 Data quality risks in engineering artifacts. Low quality of engineering artifacts may limit the production system capabilities and reduce reuse opportunities of system components.

Similar TD concepts in SE are missing documentation of interfaces, code, and implementation details.

Definition. The VDI Guideline 3695 Part 2 [28], configuration management, defines the target state A as “... *there are discipline-specific procedures for configuration identification, configuration monitoring, [...] Within a discipline, all employees follow common guidelines.*” However, in the case study, domain experts found artifacts not to be managed, but simply to evolve over time according to engineering personnel experience, without specific consideration for dependencies between engineering artifacts in different disciplines, which poses risks for SE activities that depend on consistent and complete inputs (see Fig. 1).

Measurement. There is no formal description of engineering artifacts and data, including dependencies between engineering disciplines, such as product, process, and system design. There is no configuration history for backtracking design decisions.

Relationships to effects. See Table I, in Section IV.C. TD symptoms include high effort and risk for propagating changes to systems design across disciplines, in particular for SE, when receiving inputs from several engineering disciplines.

Relationships to causes. See Table II, in Section IV.C.

Product/ion (PPR) knowledge representation insufficient (TD3PPR) (in exchanged engineering data). *Motivation.* Domain experts in production process design have product/ion (PPR) knowledge that would be, in many cases, important to engineers in later stages of PSE and optimization, in particular, for SE activities. However, the process designer tends to provide her engineering partners with hard-coded production system parameters rather than PPR knowledge as there is no dedicated tool or modeling language to allow the effective and efficient representation of PPR knowledge. Short-term benefit for the process designer is saving effort for modeling the PPR knowledge. Similar TD concept in SE would be missing information on non-functional requirements for a software system.

Definition. The VDI Guideline 3695 Part 2 [28], configuration management, defines the target state D as “*system-assisted cross-discipline*” configuration management to enable “*consistency check [...] at an early stage*”. However, without sufficient PPR knowledge representation, consistency checks between production process design and production system design are difficult, error-prone, and take considerable expert effort.

Measurement. The engineering data model misses representations for expressing PPR knowledge and rationale to trace design decisions, such as production system temperature settings to the welding temperature and force of a metal joining process.

Relationships to effects. See Table I, in Section IV.C. TD symptoms include in SE activities considerable costs of errors from changes and effort for preventing defects after changes.

Relationships to causes. See Table II, in Section IV.C. In the case study context, main cause candidates include workgroup-specific optimization of the engineering organization and insufficient means to express PPR knowledge.

C. Case Study results on TD cause candidates (RQ1c)

Cause candidates linked to context in the engineering organization, often for economic and historic reasons in the EO.

A1. Workgroup-related profit centers lead to the local optimization of workgroups with limited concerns for the optimization of projects across workgroups, often at the expense of SE.

A2. Engineering habit trained by discipline-specific education leads to engineers focusing on good results in their workgroup. Engineers are, in general, not aware about work tasks, dependencies, and problems in other workgroups, unless a partner asks them for an improvement.

A3. Unclear responsibilities of domain experts in data exchange process lead to ad-hoc procedures and data definitions.

A4. Limited collaboration effort across work groups without a dedicated role for coordinating the work across workgroups.

Cause candidates from engineering process description

B1. Engineering process modelled as an artifact-based workflow, not as a data-related workflow makes it hard to describe dependencies between SE and other disciplines, such as consistency rules that relate to the data model, not to artifacts.

B2. Engineering process defined, but not useful. There is a workflow definition for a process. However, the definition may be abstract and lack important description of content dependencies, such as relationships between the product and resource design, tainting the usefulness of the definition.

B3. Engineering process defined, but not operational. There is a process description. However, missing technical foundations, such as adequate process description concepts or tool support, make it hard or impossible to conduct the process.

B4. Engineering process defined, but not known to stakeholders. There is a process description somewhere in a manual. However, the relevant actors in the project are not aware of the process description for their daily work.

Cause candidates linked to information description

C1. Description of complex dependencies required due to a large number of disciplines (often 15 or more) in a PSE project. Complex descriptions of processes and artifacts and their dependencies in an *engineering organization* (EO) lead to a very complex network (consider Fig. 1, scaled up).

C2. Industry-dependent information description. The description of information depends on the industry and has to be adapted accordingly. There is no general standard that could be applied directly. There is no general EO model as the industry domains require a variety of EO structures and behavior

C3. Tool-driven process without product/ion (PPR) information description. Often, the process is defined based on a specific tool chain. Therefore, the functional and data export capabilities of the tool determine the exchanged information. The process is not aware of PPR as the discipline-specific tools only know the PPR knowledge that is relevant within the discipline.

D. TD effect and item relationships (RQ2a)

Following an adaptation of the *QFD* method according to Matook and Indulska [19], we create a *House of Quality (HoQ)*. Our *HoQ* provides insights into the relationships between TD effects and items horizontally (representing customer requirements in the original *HoQ*) and TD items and causes in the vertical axis (representing engineering requirements). For these two *QFD* dimensions, we design two tables expressing likely correlations and relationships. We elicited and aggregated likely relationships from a workshop with domain experts in the exploratory case study context [12][13]. As relationship types differ, we indicate the following types and strengths. *DS* indicates a *direct* and *strong* relationship (the stronger the item, the stronger the effect). *DW* indicates a *direct weak* relationship (a stronger item correlates moderately to a stronger effect), and *IW* expresses an *indirect weak* relationship (stronger cause leads to a lower TD item). *No* indicates that the TD item is not related to an effect, such as (*TD1Proc*) -> (*II. Data Quality Risk*).

RQ2a. Table I presents the relationships between TD effects (see Section IV.A) and TD items (see Section IV.B), similar to the *HoQ* analysis [19] matrix, TD effects horizontally and TD items in the vertical axis. The relationships are of the form TD item relates to TD effect, (*TD item*) -> (*TD effect*), expressing how a TD item relates to an effect.

Table I. Relationships between TD effects and TD items.

TD Effect/ TD Item	TD-E1 High Effort	TD-E2 Data Quality Risk	TD-E3 Economic Failure
TD1Proc	DS	No	DS
TD2Inf	DS	DS	DW
TD3PPR	DS	DW	DW

Legend: Relationships: DS: direct strong; DW: direct weak.

In Table I, all three TD items, relate strongly to the TD effect *TD-E1 High Effort* for SE. This is due to unclear descriptions of the process and information as well as missing product/ion knowledge, which all lead to high effort for tracing design decisions. An insufficient information description relates strongly to high risks in data quality, as artifacts are not built on common concepts or data models and thus lack any formal description. Missing product/ion knowledge is also related to the second TD effect (*TD-E2*), however not so strongly. All three TD items have a relation to the *TD-E3 Economic Failure*, as missing information in the engineering process leads to high rework and communication overheads.

E. TD item and cause relationships (RQ2b)

Table II represents the relationship between TD items (see Section IV.B) and TD cause candidates (see Section IV.C), (TD cause) -> (TD item). Cause candidates coming from the context of the EO (A1 – A4), and from the engineering process description (B1 – B4) have a strong direct relationship to the engineering process description (*TD1Proc*). For example, unclear relationships and descriptions which are not useful, make it very hard to describe the engineering process sufficiently to facilitate collaboration and coordination across multiple workgroups.

All three cause groups A, B, and C relate to the insufficient description of the engineering data exchange model (*TD2Inf*). Note the *inverse relationships* of a stronger focus on engineering

habits (intra process improvements) and descriptions of the engineering process as artifacts. This does not directly impact the TD item.

Table II. Relationships between TD items and TD causes.

TD Item -> TD Cause (see Sect. IV.C)	TD1 Proc	TD2 Inf	TD3 PPR
A1.Profit Center	DW	DS	DS
A2.Engineering Habits	DW	IW	DS
A3.Unclear responsibility	DS	DW	DS
A4.Limited collaboration	DW	DS	DS
B1.Eng. Proc. descr. as artifact	No	IW	DS
B2. Eng. Proc. descr. not useful	DS	DW	No
B3. Eng. Proc. not operational	DS	DW	No
B4. Eng. Proc. unknown	DS	No	No
C1.Inform. description. complex	DS	DW	No
C2. Inf. desc. Industry. depend.	No	DS	DW
C3.Tools w/o PPR	No	DW	DS

Legend: DS: direct strong; DW: direct weak; IW: indirect weak.

Insufficient descriptions of the engineering process make it impossible to successfully represent product/ion-aware knowledge (*causes Ax*) -> (*TD3PPR*). Causes regarding the information and data exchange description do not impact product/ion knowledge representations, as a major precondition for knowledge representation is the clarification of (a) the responsibility for each part of product/ion knowledge and (b) a suitable represented approach throughout an engineering process.

F. Preliminary validation in the exploratory case study

Throughout the domain expert interviews, we collected representative data samples from engineering artifacts. We derived tables I and II from analyzing these artifacts. As the tables present vital pieces of information regarding possible correlations, we initially elicited the relationships from domain experts. We discussed the relationship candidates in detail with quality managers, who are responsible for improving the engineering process and are knowledgeable in the overall process and work group habits, including SE. We resolved divergences between the views of the domain experts and the quality managers in a common discussion. Overall, the domain experts and quality managers found the preliminary TD concepts and analysis method useful and usable for identifying and addressing high-priority TD effects, items, and causes regarding SE activities.

V. DISCUSSION

This paper investigates risks for *software engineering* (SE) in activities related to the engineering process in a PSE organization (*RQ1*) and possible relationship between certain risks (*RQ2*). In this context, risks are TD effects for SE that occur in a PSE context with measurable probability and costs. To deal with these risks, da Luz *et al.* [26] presented a management tool for analyzing causes and effects. Similar to our work, Luz *et al.* [26] propose an approach to identify risks through selection, description and analyzation. However, the presented approach generalizes risks in a late phase, whereas we focus on organization specific TD effects and investigate these. In the exploratory case study context, SE activities depend on the requirements and design rationale from early engineering phases and often have to deal with locally optimizing workgroups, low awareness on collaboration processes, and missing understanding of requirements between work groups.

For software engineers, the *high effort* comes from risks regarding rework efforts due to frequent and late changes coming from earlier phases. As software engineers highly depend on weakly documented design decisions from early phases, a repayment option for TD is better knowledge representation of product/ion knowledge throughout the engineering process. The *low data exchange quality* impacts software engineers, who are made responsible for low quality system output, even if they write high quality code, but based on weakly communicated early design decisions. TD repayment for reducing the SE risk should focus on improving the documentation and communication of design decisions that are directly related to high-quality SE results. Finally, issues regarding unplanned efforts for reworks in the software design due to low system quality decisions may exceed the budget available to SE, leading to local *economic failure*.

The VDI Guideline 3695 Part 2 [28] was used to investigate TD items (*RQ1b*). This guideline can be seen similar to best practices for SE code development, and our analysis is equivalent to a code review. An *unclear engineering process description* makes it hard for software engineers to reliably configure production systems, as input from several disciplines may be contradicting. The missing collaboration in PSE forces software engineers to take the risky decision on which inputs to consider or ignore. Further, the *information description is not sufficient*. This makes it unclear for software engineers where to look for reliable information, as data syntax and semantics may change frequently, making it hard to validate input data and to automate the data exchange process. Software engineers thus often work based on risky assumptions. Finally, *missing product/ion aware knowledge* makes it hard in SE to take informed decisions for adapting the software system design if the preferred system design option is not feasible.

In *RQ1c*, we investigated possible causes regarding elicited TD items. Causes linked to the *context of production systems engineering* cannot be directly influenced by SE actors, but require the insight of PSE managers. We discussed the preliminary results at the case study EO with quality managers, who found the analysis useful for considering and prioritizing improvement options. Cause candidates linked to the *engineering process description* clearly motivate the need for better means of PPR knowledge representation as a foundation for process descriptions, considering conceptual, language, and usability aspects. This is similar to the need for proper software architecture descriptions identified by Guessi *et al.* [11]. The last group we identified are cause candidates linked to the *information description*. For example, it is challenging to combine methods for data integration [7] with domain-specific standards, such as *AutomationML* [7] or ontologies [23].

A *repayment option* to address TD items related to weak collaboration of workgroups is a new role, the *data curator*, similarly as presented in [9]. This role would be responsible for consolidating a common data exchange model and describe the engineering process adequately. This new role should needs to understand the requirements and limitations of the involved workgroups, in particular SE activities. As TD effects, items and causes are related to each other, we used the *Quality Function Deployment* [19] method to investigate relationships between TD effects, items and causes (*RQ2*).

In *RQ2a* we investigated how TD effects and TD items relate to each other. The *TD-E1 High Effort* is strongly and directly connected to all three TD items. This is obvious as reworks are often needed to compensate missing descriptions or information bottlenecks where especially software engineers are affected. Interesting is, that the *TD-E2 Data Quality Risk* is only weakly connected to PPR knowledge representation, even though this is an important information exchange concept. For SE this means that design decisions from early phases do not impact the code development so much as the overall information description, this could be for example the selection of an easily changeable component in the user interface.

RQ2b investigated how TD items and causes are related. Nearly all causes regarding the information description strongly impact the process description. This clearly motivates the need for better knowledge representation approaches, as the current engineering process is either not described, or the description is not useful or unknown to domain experts. As there are currently no tools that support the expression of PPR knowledge, software engineers could address this open issue to improve product/ion-aware knowledge representation and further allow a backflow of SE knowledge into early engineering phases as foundation for designing better reusable system parts.

Limitations. The research of this paper followed a case study in an engineering organization. However, the case study focused on only one company, which may not be representative for all EOs in general. While the domain experts in the study were very knowledgeable, their number was limited due to resource limitations of the available experts besides their daily business obligations. We found that the engineering process description may highly depend on the context, domain, and organization, thus future case studies should consider these variation points. While the domain experts found the preliminary list of TD effects, items, and causes, and their relationships useful for reflecting on TD repayment options in the case study context, these results require validation and discussion on comparable context for strengthening the external validity of the results.

VI. CONCLUSION AND FUTURE WORK

In engineering organizations, software engineers join the PSE process in a late phase and are concerned with detailing SE aspects of the software-intensive system. However, software engineers often only receive poorly described design decisions in form of engineering artifacts making it hard for them to derive adequate new (software) engineering knowledge or tracing the earlier design decisions. These shortcomings lead to risks regarding the SE quality and impact the project effort negatively, endangering project success. In this paper, we reported on a case study at a large industrial engineering organization with the focus of investigating technical debt (TD) effects, items, and causes as risks for software engineers. Results highlight that TD can slow down engineering organizations, making it hard to manage processes where multiple domains are involved. Main insight for addressing the found challenges is the introduction of a new role, the *data curator*, to facilitate the collaboration across workgroups. The results highlight requirements for the representation of product/ion knowledge in the engineering data provided to software engineers. Engineering data is heterogeneous and there are no guidelines for basic planners, leading to a large

number of individual and local data models, and making the data exchange hard to manage, often resulting in extra effort to maintain high software quality.

The relations between TD effects, items, and causes highlighted the need for better representations for product/ion knowledge as inadequate context and artifact descriptions lead to high efforts, in particular, for software engineers, and might result in economic project failure. The research findings provide domain experts, such as project managers or software engineers with insights into the engineering process. The presented model serves as a foundation for better understanding the rationale of engineering design decisions. This leads to better SE code due to (a) better understanding of design decisions, (b) more explicit representation of system limits that relate to product characteristics, and (c) better knowledge representation for tool support.

Future work. The results of the exploratory case study should be validated with empirical data from comparable engineering companies. We focused in this paper on product/ion-aware exchange of engineering artifacts. Future research should investigate the impact of knowledge representation options on selected SE. Finally, the more comprehensive representation of integrated PSE knowledge requires improved information security. The comprehensive and well-integrated knowledge is a prime target for attackers regarding corporate espionage and regarding the intentional change of artifacts for reducing the quality of the production system or the production process. Thus, future work should investigate security auditing aspects that consider the issues and repayment options identified in this paper.

Abstract—Feature model is an important model for capturing domain requirements and managing commonality and variability. However, the traditional feature modeling method is insufficient in expressing the variability requirements, which is easy to cause ambiguity and fails to describe the features in detail. In view of these shortcomings, this paper gives a unified definition of features, feature attributes and feature relationships, proposes configuration vector and variant constraint to enrich variability expression capabilities, and establishes an enhanced feature meta-model for software product lines. This feature model can help domain analysts effectively organize the variable domain requirements. In addition, the commonality of the domain expressed by the feature model is the basis for the development of highly reusable core assets. We propose that heuristic strategies automatically identify and extract core feature to obtain domain commonality. Finally, we take the chronic obstructive pulmonary disease home care product line as an example to demonstrate our proposed method.

Index Terms—feature modeling; software product line; core feature; commonality analyze

I. INTRODUCTION AND MOTIVATION

Software product line engineering is a paradigm for large-scale development of software applications [1]. The general idea is to plan and design reusable components for reuse before developing the system, and to manage the common and variable parts of the components [2]. As part of Feature-Oriented Domain Analysis(FODA) [3], feature model(FM) has proven to be an effective way to describe product line commonality and variability.

The Chronic Obstructive Pulmonary Diseases(COPD) Home Care System is a product line we are developing. The purpose of this application is to manage and monitor the stable COPD patients in home or community. It is designed to provide patients with environment monitoring, signs monitoring, doctor consultation, health education, acute exacerbation warnings and behavioral interventions. We have used FM to perform requirement analysis and domain analysis. Fig.1 uses the basic feature model(BFM) to demonstrate part of the features of the *signs monitoring* in the system.

Traditional feature modeling methods do not separate the perspectives of different stakeholders. The product line of

COPD home care involves services provided to users, domain knowledge related to COPD, various data monitoring devices and complex implementation technologies. If stakeholders share the same feature model view, they will not be able to effectively focus the perspective. Though extended-feature model [4]–[8] enrich the expression of variability from different perspectives, there is no agreement on the definition of modeling elements, especially two kinds of configuration information: mandatory and optional. This can lead to inadequate expression of variability and even semantic conflicts. Therefore, the traditional feature modeling methods are difficult to effectively satisfy the domain analysis requirements of our product line.

In addition, the COPD home care product line is a customizable application for individualized patients. The patient's use scenario and the patient's condition will bring more variability to the system. In the early stage of development, accurately extraction of core requirements in established domain model is required so that we can distinguish between common and variable requirements and build the basic platform based on core requirements in the subsequent development to speed up the time to market.

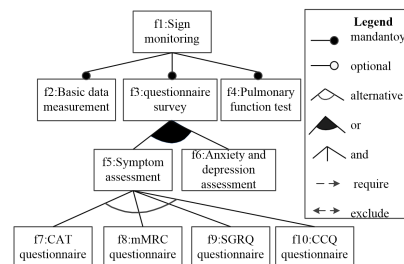

Fig. 1. Example of basic feature model.

In response to the above questions, this paper made the following contributions:

- Introduce an enhanced feature model meta-model. We classify features to form different levels of abstraction, propose configuration attribute vectors to resolve semantic conflicts and enrich the expression of model variability.

Foundation Items: The Science and Technology Department Project of Hunan China(2018TP2033)

DOI reference number: 10.18293/SEKE2019-110

- Based on our meta-model, a core feature extraction heuristic strategy is proposed. The purpose is to automatically analyze the commonality of product families on a consistent feature model.

The rest of this paper is organized as follows. Sect.II describes the related work. Sect.III introduces the meta-model modeling elements. Sect.IV describes the core feature extraction method. We use a practical case to verify our ideas in Sect.V. And we conclude our work in Sect.VI.

II. RELATED WORK

[7] introduced Forfamel, a rigorous conceptual model foundation that combines multiple feature modeling methods. A cardinality-based feature model(CFM) formally defined in [4]. CFM adds the concept of feature cloning, using feature-cardinality to represent the number of cloned features. Group-cardinality in CFM is used to express configuration constraint of variants in variation points. [3] considered that different features can be refined into the same feature, and proposed the concept of pseudo-feature. [6] classified feature into capability feature, operational environment feature, domain technical feature, and implementation technical feature. The FM was divided into four levels corresponding to feature classification which mapped to implementation domain.

Some works have been devoted to extracting core features. The concept of core feature proposed in [8]. [9] transformed feature model into binary constraint logic, automatically analyzed all valid product through the CSP solver and obtained the core features. [10] proposed an algorithm traverses BDD by backtracking method to determine the core features and dead features. Although the algorithm was very efficient, converting the feature model to BDD was time consuming and reached an exponential level.

III. THE ELEMENTS AND RELATIONS OF META-MODEL

Fig. 2 shows our meta-model. We will introduce the terms and concepts necessary to understand the meta-model.

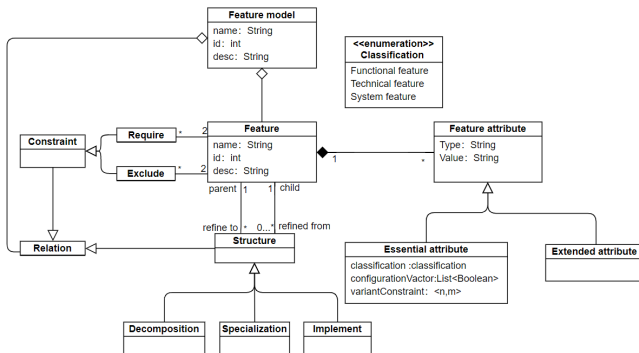

Fig. 2. Enhanced feature model meta-model.

A. Feature and Feature Attribute

Definition 1(Feature): A Feature f consist of a set of logically relevant software requirements that provide each stakeholder with the ability to satisfy specific business demand. A feature is defined as a 4-tuple: $f=(N,D,A,R)$, where: $N(\neq \phi)$ is the feature name to uniquely identify a feature. D is an explanation for the feature. A is a set of feature attributes, which describes the context information of the feature in a FM. R represents the relationship between the features.

We extend and represent the existing modeling elements with feature attributes. Feature attributes are divided into two categories:essential attribute and extended attribute. They are defined by a 2-tuple: $A=(T,V)$, where T is a set of attribute types for the feature, V is the value of the corresponding attribute type. Attribute of a feature can be expressed as: $f_A.type = value$. There are four types of feature attribute. $T:=\{Classification, Configuration, VariantConstraint, Extension\}$

Classification attribute. We classify feature into functional feature(FF), technical feature(TF) and system feature(SF).

- *Functional feature(FF)* is used to describe the services provided by the system, which can be clearly expressed and visible to users and is a specific behavior of the system.
- *Technical feature(TF)* is used to describe the technologies that implement functional features or non-functional indicators. Such features are not visible to the user, but developers are more concerned with these.
- *System feature(SF)* is used to describe the hardware resources, implementation environment of the system to facilitate communication between hardware and software engineers.

This categorization allows developers to refine different abstract level as they perform domain analysis and helps to separate the perspectives of different stakeholders. The expression $f_A.classification$ can be used to represent the classification attribute of feature f .

Configuration attribute. We attach optional and mandatory configuration information to the feature through feature attributes. Some domain feature modeling methods differ in their understanding of mandatory and optional feature. [5], [11], [12] gave an absolute definition of the mandatory feature, who considered that the mandatory features were the features appearing in all products in a product line, not related to its parent. However, [6], [7] interpreted it relatively, and considered that the mandatory feature must be selected when its parent feature was selected in the configuration process. We recognize and adopt the relative interpretation of the mandatory and optional, and introduces *core feature* to represent the absolute interpretation of mandatory feature. There are two drawbacks in the absolute definition of configuration attribute.

- It loses feature parent-child relationship contextual information.
- In the case that a feature has multi-parent features, the absolute definition is impossible to express the semantics

that child-feature's configuration attributes is different relative to different parent.

As shown in Fig.3(The specific features are represented by symbols.), feature $f1$ and $f2$ can be implemented by $f4$. The $f4$ is optional for $f1$ and mandatory for $f2$. When a feature have multi-parents, absolute interpretation of mandatory feature will cause ambiguous semantic. According to the definition of relativity in this paper, the configuration attribute of a feature may be different for different parent features, it is necessary to record these additional information which may change.

Fig. 3. Semantic conflict under absolute definition of configuration information.

Definition 2(Configuration vector): If the number of parent of a feature f is m and its parents are $(p1, p2, \dots, pm)$ from left to right in the feature diagram. Then C is a 1-dimensional vector of m components. $C := (bool_{p1}, bool_{p2}, \dots, bool_{pi}, \dots, bool_{pm})$

The component of vector C is boolean type, and $bool_{pi} = 1$ denotes that f is a mandatory feature relative to the i -th parent feature, otherwise it is an optional feature. We use $f_A.config = C$ to represent configuration attribute.

Variant constraint. This attribute represents the configuration constraint for all optional child-feature under a parent during configuration process. Similar to the group-cardinality in CFM. Fig.4 shows the feature *symptoms assessment*. In global initiative of COPD[13], we use $f2$ to evaluate the symptoms, and a comprehensive assessment is recommended using feature $f2$, $f3$ or $f4$ as supplement. Therefore, when selecting $f2$, at least one must be selected in $f3$, $f4$ and $f5$.

Definition 3(Variant constraint): $\langle n, m \rangle$ is an interval. The n is the lower bound and m is the upper bound. Let $k \geq 0$ be the number of optional child-features that satisfy $0 \leq n \leq m \leq k$. Variant constraint attributes of feature f indicate that if the feature is selected in configuration process, n to m optional features should be selected besides mandatory child-features. We use $f_A.variant = \langle n, m \rangle$ to represent configuration attribute.

Fig. 4. Example of variant constraint.

Extension attribute. This attribute is a feature extended attribute whose type is defined by the domain analyst. Such as adding the binding time and binding status of the feature.

B. Feature Relationships

Features form feature model with certain relationships. R is a set of feature relations and $R = R_{struct} \cup R_{constraint}$. $R_{struct} \subseteq f \times f$ represents the parent-child relationship of the feature. If feature $f1$ and $f2$ satisfy $(f1, f2) \subseteq R_{struct}$, then $f2$ is the parent of $f1$, and $f1$ is the child of $f2$. We extend three types of relations over structure relation, $R_{struct} = R_{decomposition} \cup R_{specialization} \cup R_{implement}$.

$R_{decomposition}$ describes the whole-part relationship between parent and child features. In Fig.1, $f1$ is decomposed into $f2$, $f3$, and $f4$.

$R_{specialization}$ represents that a feature can be specialized from different dimensions or aspects into more specific child-features. Child-features have the characteristics of parent, similar to inheritance in object-oriented, and they have special characteristics on the basis of inheritance. In fig.1, $f5$ is specialized into $f7$, $f8$, $f9$, $f10$.

$R_{implement}$ represents the technical implement or hardware support of the low-level features to the high-level features.

$R_{constraint} \subseteq f \times f$ represents the constraint between the same classification attribute features and $R_{constraint} = R_{req} \cup R_{excl}$. If $(f1, f2) \subseteq R_{req}$ indicates that $f1$ requires $f2$. If $f1$ is selected during configuration, then $f2$ also needs to be selected. This relationship is transitive. $(f1, f2) \subseteq R_{excl}$ indicates that $f1, f2$ cannot be bound at the same time, which is symmetry.

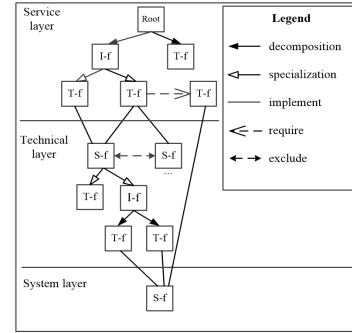

Fig. 5. Example of feature model structure.

Three classifications of features form three abstract levels of feature models. Fig.5 shows the basic structure of our FM diagram, where *root* is root of FM, *I-f* is the intermediate feature, *T-f* is the terminal feature, and *S-f* is the starting feature of the technical layer and the system layer. The above-mentioned structure relationships provide domain analysts with a way to construct a feature model. From root, the features are continuously refined through $R_{decomposition}$ and $R_{specialization}$. Then consider which technical features or system features are required to implement the service feature *T-f*. At this point, the technical feature or system feature is the *S-f* of the hierarchy, and then it can be considered whether these features can continue to be refined. By continuously iterating through this process, a FM diagram can be obtained. The relationship between $R_{decomposition}$ and $R_{specialization}$

makes the feature form the parent-child relationship of tree structure in the same layer, $R_{implement}$ connects T - f and S - f , thus connecting different abstract levels of FM, which becomes directed acyclic graph(DAG).

IV. ANALYSIS OF COMMONALITY

A. Core Feature Extraction Strategy

Definition 1(Core feature): Core feature is the feature that appear in all products which reflects the commonality of FM. If there are n valid products in the product line. Then core feature f_c are satisfied: $f_c \in \bigcap_{i=1}^n p_i$. Following rules are proposed to identify core feature:

Rule 1 The root feature in FM must be the core feature. Because the root appear in all products.

Rule 2 If there is a path starting from a core feature, and all the features on this path are mandatory for its parent, then these features are core feature. We call the core feature on this path directly accessible core features(DACF).

Rule 3 If there is a path starting from a core feature, and all the features on this path are linked by R_{req} , then these features are core feature. We call it the required transfer core feature(RTCF).

Rule 4 Indirectly accessible core features(IACF) that are easily overlooked.

Only extracting DACF and DTCF will result in incomplete core feature set. Fig.6 shows a special example (This figure is intended to make the example more intuitive, not the representation of our method.). Assume $f_1, f_{11}, f_{12}, f_{13}, f_{14}$ as FF , f_2 as TF . Feature f_{11}, f_{12} and f_{13} are all implemented by f_2 . Feature f_1 is the core feature, f_{11}, f_{12} and f_{14} are optional, f_{13} is mandatory, and the $f_{2A}.conf = (1, 1, 0)$. According to rule 2, only f_{13} is a core feature. However, because of $f_{1A}.variant = \langle 2, 2 \rangle$, one of the feature combination $\{f_{11}, f_{14}\}, \{f_{12}, f_{14}\}$ or $\{f_{11}, f_{12}\}$ must be selected. Therefore, f_{11} and f_{12} must be selected in the configuration process and f_2 is a mandatory feature for f_{11} and f_{12} . Then, f_2 which must be selected should be the core feature and it is IACF.

In more in-depth view, the main reason for the occurrence of IACF is that the variant constraints of core features make one of their optional child-features selected in the configuration process. It is precisely that these optional child-features have a common child and this child corresponded to these optional child-features is mandatory. Then this child that we called IACF must be selected. Therefore, a feature is IACF determined by its parents and its parents of the parents.

Fig. 6. Example of IACF.

We divide the structure in Fig.6 into three layers from top to bottom. When the following conditions are satisfied, the feature located in third layer must be the core feature.

Theory 1 The feature in first layer is a core feature.

Theory 2 The feature in the second layer is the optional child of the feature in the first layer, and these features all have the same child-feature, which is located in the third layer.

Theory 3 The feature located on the third layer is a mandatory feature relative to the features of the second layer.

Theory 4 Variant constraints of the feature on first layer make the feature on second layer must be selected.

Algorithm 1 get DACF set

Input: S_f

Output: S_{DACF}

```

1: function GETDACF( $S_f$ )
2:    $S_{DACF} \leftarrow \phi$ ;  $queue \leftarrow \phi$ ;  $wasIn \leftarrow \phi$ ;  $f_t \leftarrow \phi$ 
3:   for each  $f \in S_f$  do
4:      $queue.clear()$ ;  $wasIn.clear()$ 
5:      $queue.add(f)$ ;  $wasIn.add(f)$ 
6:     while  $queue \neq \phi$  do
7:        $f_t \leftarrow queue.poll()$ 
8:       if  $f_t \notin S_{cf}$  then
9:          $S_{DACF} \leftarrow f_t$ 
10:      end if
11:      for each  $f_c \in f_t.child$  do
12:        if  $f_c \notin wasIn$  &  $f_c.conf = (f_t, 1)$  &
            $f_c \notin S_{cf}$  then
13:           $wasIn \leftarrow f_c$ ;  $queue \leftarrow f_c$ ;
14:        end if
15:      end for
16:    end while
17:  end for
18:  return  $S_{DACF}$ 
19: end function

```

Next, we introduce the algorithms to extract DACF, DTCF and IRCF, then extract the core features completely.

B. Data Structures

We use the following data structures:

```

Feature{
  name:String
  child:list<Feature>
  parent:list<Feature>
  conf:map<Feature,Boolean>
  var:int[2]{n,m}
  req:list<Feature>
}

```

Where: *name* identifies a feature, *child* is the features child set, *parent* is the features parent set, *conf* is configuration attribute, *var* is variant constraint, *req* is required features.

C. Algorithm

Algorithm 1 gives a process of extracting DACF. The input is a core feature set S_f and output is S_{DACF} . S_{cf} is a

Algorithm 2 get RTCF set

Input: S_f
Output: S_{RTCF}

```
1: function GETRTCFSET( $S_f$ )
2:    $S_{RTCF} \leftarrow \phi$ 
3:   for each  $f \in S_f$  do
4:     GETRTCF( $f$ )
5:   end for
6:   return  $S_{RTCF}$ 
7: end function
8: function GETRTCF( $f$ )
9:   if  $f.req = \phi$  then
10:    return
11:   end if
12:   for each  $f_r \in f.req$  do
13:     if  $f_r \in S_{cf}$  then
14:       continue
15:     end if
16:      $S_{RTCF} \leftarrow f_r; \text{GETRTCF}(f_r)$ 
17:   end for
18: end function
```

global collection that holds all core features. The algorithm utilizes the breadth-first traversal of the graph, and sequentially searches for the mandatory child-features path starting from the feature f in the S_f . If f has multiple parents which are core features, as long as f is a mandatory feature relative to one of these parents, f is the core feature (line 12). Because of the mandatory path is formed.

Algorithm 2 gives the process of extracting the RTCF. Similarly, a core feature set is used as input, and the required transfer path starting from feature f in S_f is searched recursively, and all the features in the path are output. If a required feature of f is already the core feature, we ignore this feature to avoid repeated access (line 13-15).

Algorithm 3 gives the process of extracting IACF. As mentioned above, IACF must be a multi-parent features f_{mp} . So we take the multi-parent features set S_{mp} as input. The S_{mp} can be obtained by traversing the feature model once time (similar to algorithm 1), which is not discussed here. The feature f_{mp} is that IRCF determined by the attributes and structure of its parent-feature set S_p and its parents of parents feature set S_{pp} . These features must satisfy the above four conditions. Firstly, the parent relationship is used to find the f_p which needs to satisfy **Theory2** and **Theory3** (lines 8-12). The f_p that satisfies the condition is stored in the S_p . In this set, we search for all f_p 's parent-feature f_{pp} which is core feature to satisfy **Theory1**, and store the valid f_{pp} in S_{pp} (lines 13-19). To satisfy **Theory4**, traverse the S_{pp} to get the number of all optional child-features N_{aoc} of f_{pp} , the number of child-features $N_{ocisp} \in S_p$, and the variant constraint value $[n, m]$ (lines 20-27). If $n \geq N_{aoc} - N_{ocisp} + 1$, it indicates that f_p must be selected in the S_p . Therefore f is the core feature.

Algorithm 4 introduces the main flow of extracting core feature set. The root feature is used as an input and output is

Algorithm 3 get IACF Set

Input: S_{mp}
Output: S_{IACF}

```
1: function GETIACF( $S_{mp}$ )
2:    $S_{IACF} \leftarrow \phi$ 
3:   for each  $f \in S_{mp}$  do
4:      $S_p \leftarrow \phi; S_{pp} \leftarrow \phi$ 
5:     if  $f \in S_{cf}$  then
6:       continue
7:     end if
8:     for each  $f_p \in f.parent$  do

core feature set S_{cf} . When the core features are acquired each time using the above three algorithms, the newly discovered core features may cause other features associated with them to be transformed into core features. For example, a new core feature's mandatory child-feature or required feature is also the core feature. Therefore, we reuse the three algorithms to continuously synchronize the new core features to the S_{cf} until there are no new core feature. The set S_{temp} is used to temporarily store the core features acquired by a certain algorithm and use it as input to other algorithms. The set S_{mp} stores multi-parent features. In the inner loop, we alternately use algorithms 1 and 2 to obtain core features until there are no new ones (lines 4-17). In the outer loop, we judge whether there are new IACF in the multi-parent features. If new core features appear, it is necessary to go through the inner loop. If it does not appear, it means that the core feature set has been

27: end function
```

obtained completely.

V. CASE STUDY

We applied the above FM to the COPD home care system. As shown in Fig.7, it is part of the FM diagram of our product line, which takes the core feature *sign monitoring* as the root feature and covers the examples above. We use feature attributes and feature relations to describe the whole model, and apply the algorithm to extract the core features of the examples. According to the algorithm, $\{f1, f2, f3, f4, f9, f11, f19\}$ is the DACF. $\{f14\}$ is the RTCF, and $\{f15\}$ is the IACF. The final domain model has 336 features, including 264 service features, 64 technical features, 8 hardware features and 47 constraints. We implement the core feature extraction method, and the FM is transformed into a file representation in XML format. After applying the algorithm, 101 core features are obtained, and the proportion of core features to total features is 30.05%. Among the core features, 91 are DACF, 8 are RTCF, and 2 are IACF.

VI. CONCLUDE

In this paper, an enhanced feature meta-model is proposed to solve the ambiguous semantics, enrich the expressive ability of variable requirements, and provide a hierarchical way to

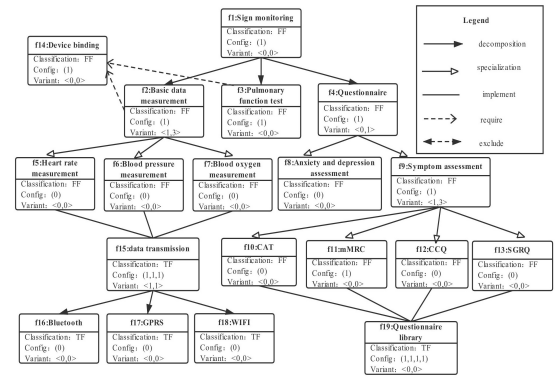

Fig. 7. Feature model fragment of COPD home care system.

construct feature model. Then, a heuristic strategy is proposed to identify and extract the core feature set on the meta-model. We implemented and applied this method to the product line of COPD family care system. The next step is to implement a visualization tool for our modelling method.

SSLDoc: Automatically Diagnosing Incorrect SSL API Usages in C Programs

Zuxing Gu, Jiecheng Wu, Chi Li, Min Zhou, Ming Gu
School of Software Engineering, Tsinghua University, Beijing, China, 100084

Abstract—Secure Sockets Layer (SSL) and Transport Layer Security (TLS) protocols provide a reliable communication channel between applications over the Internet. Implementations of these protocols (e.g., OpenSSL and GnuTLS) publish well-format documentation and examples online to guide the usage of SSL/TLS APIs. However, incorrect usages have caused many severe vulnerabilities (e.g., privilege escalation, denial of service, man-in-the-middle attack, etc.) in recent years. In this paper, we introduce SSLDoc to diagnose incorrect SSL API usages in real-world C programs automatically. The key insight behind SSLDoc is a constraint-directed static analysis technique powered by domain-specific usage patterns that we learn from real-world vulnerabilities and bug-fix-related patches. We have instantiated SSLDoc for OpenSSL APIs and applied it to large-scale open-source programs. SSLDoc found 45 previously unknown security-sensitive bugs in OpenSSL implementation and applications in Ubuntu. We created and submitted issues for all of them. Up to now, 35 have been confirmed by the corresponding development communities and 27 have been fixed in master branch.

Index Terms—SSL, API usage validation, static analysis, bug detection

I. INTRODUCTION

Secure Socket Layer (SSL) and Transport Layer Security (TLS) are the most widely deployed protocols in security-sensitive software. They provide a confidential and authentic end-to-end communication mechanism against an active, man-in-the-middle attacker. The details of these protocols are complicated and involves many steps to set up and validate certificate authority [1], [2]. Therefore, client programs usually rely on SSL libraries such as OpenSSL [3] and GnuTLS [4], which encapsulate the internal details and diverse kinds of cryptography algorithms into APIs with well-format documentation and examples. However, correct usage of SSL APIs is required to satisfy certain constraints, such as call conditions or call orders. Violations of these constraints will lead to software bugs and more critically, can have severe security implications. For example, missing error status code validation of SSL APIs will cause a denial of service by remote attackers (CVE-2016-2182 [5]), and broken SSL certificate validation will result in man-in-the-middle attacks [6]. A recent study show that SSL certificate validation is completely broken in many security-critical applications and libraries [7].

Many different tools, techniques and methodologies have been proposed to address the above problems. Clark et al. [8] present a comprehensive survey of SSL issues to enhance the certificate infrastructure used in practice. Brubaker et al. [9]

systematically test the correctness of the certificate validation logic in SSL/TLS implementations. However, they focus on SSL implementation and require considerable manual efforts to prepare a test environment.

To automatically detect incorrect usages of SSL APIs in client programs, static analysis has long prevailed as one of the most promising techniques [10]. For example, He et al. [11] design and implement SSLINT, a scalable static analysis tool to match a program dependence graph with a handcrafted, precise signature modeling the correct logic usage of SSL APIs. Although SSLINT is capable of detecting incorrect usages in practice, it is hard to apply to APIs without predefined signatures and produces many false positives and false negatives due to imprecise static analysis (e.g., flow-insensitive and context-insensitive). Yun et al. [12] present APISan for incorrect API usages of causal relation and semantic relation on arguments with security implications by leveraging the strength of static analysis (such as control dependency analysis) and code mining (such as frequent sub-itemsets mining algorithm). It provides accurate detection and can be applied to scale real-world system programs. However, a challenge for such tools is insufficient data to train models, which is particularly severe for SSL APIs in client programs.

In this paper, we aim at augmenting current detection capability of incorrect SSL API usage for large-scale C programs. The key insight is a constraint-directed static analysis technique powered by domain-specific usage patterns. To understand the root causes of incorrect usages of SSL APIs, we begin with a preliminary investigation of real-world vulnerabilities to summarize generic incorrect usage patterns. Leveraging this knowledge, we design and implement SSLDoc, a static analysis detector employing under-constrained symbolic execution [13] to generate abstract symbolic traces with rich semantics and detect incorrect usages. In this way, SSLDoc can precisely conduct a flow-, control- and context-sensitive analysis inter-procedurally (i.e., capable of capturing temporal sequencing of API calls, path constraints, and data flows between parameters and return values in or across procedures).

To evaluate SSLDoc in practice, we instantiated it with OpenSSL APIs and applied it to more than half million lines of source code, including OpenSSL implementation and 15 applications in Ubuntu. The result shows that SSLDoc discovers 45 previously unknown security-sensitive incorrect SSL API usages. We reported our findings to developers and received 35 confirmations, out of which 27 have been fixed in multiple branches. Moreover, we share the lessons

learned from bug detecting, issue reporting and discussions with developers.

In summary, our paper makes the following contributions:

- We design and implement SSLDoc, a static analysis tool to augment current detection capability of incorrect SSL API usage for large-scale C programs.
- We instantiate SSLDoc with OpenSSL APIs and apply it to real-world programs. It discovers 45 previously unknown incorrect SSL API usages, out of which 35 have been confirmed by developers.
- We share the lessons learned from bug detecting, issue reporting and discussions with developers in practice. We hope our findings can motivate more researcher to combat incorrect SSL API usages.

The rest of this paper is organized as follows. Section II provides motivating examples of our work. Section III presents the design of SSLDoc, followed by an evaluation in Section IV. We share the lessons learned in Section V and discuss related work in Section VI and conclude in Section VII.

II. MOTIVATING EXAMPLE

Instead of implementing SSL themselves, Client programs usually rely on APIs of SSL libraries such as OpenSSL and GnuTLS as well as higher-level data-transport libraries such as Curl [14]. While APIs encapsulate the details, they also expose rich semantic constraints. Violations of these constraints, in turn, lead to serious security problems.

To better understand incorrect SSL API usage patterns and how developers fix them in practice, we manually studied four years’ (from 2013 to 2017) CVE entries related to API usage bugs in National Vulnerability Database¹. They are extracted through approximate keywords matching (e.g., “OpenSSL API usage” and “incorrect SSL usage”) and contain concrete patches to fix the bugs. We investigate both the CVE description messages and patches, and identify two generic incorrect usage patterns as shown in Figure 1:

- **Certificate Validation.** SSL libraries encapsulate the core functionality of protocols and export APIs to utilize the implementation. However, the client needs to validate all kinds of certificates in applications. Missing validations might allow attackers to cause a denial of service or man-in-the-middle via an invalid one. Figure 1a shows an example of such vulnerabilities reported in CVE-2015-0288 [15]. Function `X509_get_pubkey()`² attempts to decode the public key for `x`. If an error occurs, it will return NULL. In function `X509_to_X509_REQ()`, the return value `pktmp` is used without checking the error code, which results in a NULL Pointer Dereference bug. Beyond null pointer checking, SSL libraries use various error protocols in practice (e.g., 0 or negative for errors in OpenSSL, but -1 to -403 in GnuTLS).
- **Causal Function Calling** SSL libraries allocate memory resources for cryptography algorithm computing, which

```

16    }
17    EVP_CIPHER_CTX_cleanup(&ctx);
18    [...]

```

(b) Incorrect usage for missing releasing resource reported in CVE-2014-3567 [16].

Fig. 1: Motivating examples of incorrect SSL API usages.

should release after their lifecycle by invoking a causal function calling. Violations of such causal relation (i.e., a-b pattern) will cause a denial of service (memory consumption) via an intentionally crafted input by remote attackers. For example, `EVP_CIPHER_CTX_cleanup()`³ clears all information from a cipher context `ctx` and free up any allocated memory associated with it. However, missing invoking it along the error handling path of `tls_decrypt_ticket()` will be exploited by a crafted session ticket that triggers an integrity-check failure as shown in Figure 1b.

Detection of the above bugs is not trivial. It requires a wide spectrum of semantics instead of simply syntactic matching. For example, function invocation of `X509_get_pubkey()` at Line 16 in Figure 1a is correct, because `check_suite_b()` validates the first parameter to ensure that `pkey` is not NULL. To filter out such instance, it

³https://www.openssl.org/docs/man1.0.2/crypto/EVP_CIPHER_CTX_cleanup.html

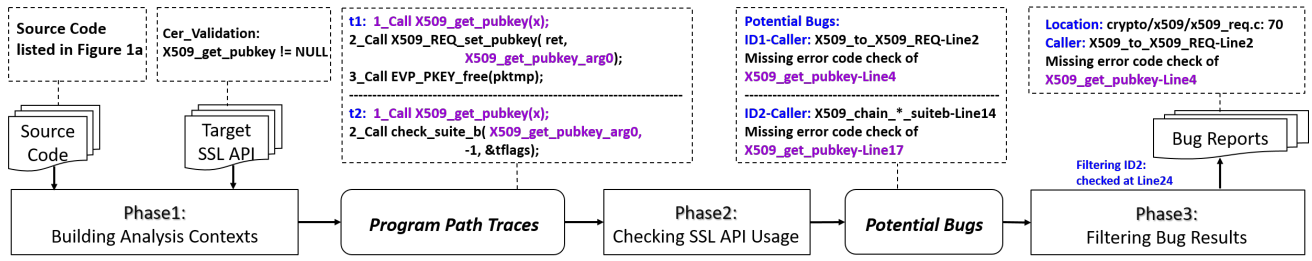

Fig. 2: Overview of SSLDoc's workflow.

demands a flow- and context-sensitive semantic analysis inter-procedurally. Moreover, path-sensitive analysis also should be taken into consideration to check memory leak along different error handling paths (e.g., Line 14 and 17 in Figure 1b).

III. APPROACH

In this section, we introduce SSLDoc, a static analysis tool to augment current SSL API usage detection capability for large-scale C programs. We first present a brief overview of our approach with an example of Figure 1a and elaborate each step of bug detection in the following parts.

As shown in Figure 2, SSLDoc takes the source code and target APIs as input and generates bug reports with concrete locations and reasons as output. Bug detection consists of three basic steps. (1) In **Phase-1**, the analysis context is built by constructing the control flow graph and creating *program path traces* for each target API by employing under-constrained symbolic execution. In this example, two traces, t_1 and t_2 , are generated, as shown in the box above **Program Path Traces**. In this way, SSLDoc can successfully capture the usage context of `X509_get_pubkey()`, `EVP_PKEY_free()` and those in between. (2) In **Phase-2**, SSLDoc employs the *traces* to detect violations of API usages as potential bugs. For example, two API-misuse instances of `X509_get_pubkey()` are found for missing certificate validations labeled as *Potential Bugs*. (3) In **Phase-3**, SSLDoc improves the detection precision by leveraging inter-procedural semantics and usage statistics. Then, the second misuse is filtered out for the check conducted in the `X509_to_X509_REQ()` at Line-24. We discuss the details of our approach as follow.

A. Building Analysis Contexts

SSLDoc performs symbolic execution to generate program path traces that capture rich semantic information for each

target API. In Figure 3, we illustrate the workflow for building analysis context, which consists of three steps. First, SSLDoc parses the source code and builds a control flow graph (CFG). Then, for each target API f , we select analysis entries as target API call sites by labeling the callers C , which invokes f . Next, for each caller $c \in C$, symbolic execution is employed to generate a series of program path traces T with rich semantics of usages of f while traversing the CFG.

We use \mathbb{N}, \mathbb{Z} to denote the set of non-negative and all integers, respectively. In Figure 4, we formally describe the structure of program path traces computed by SSLDoc, where $id \in \mathbb{N}, n \in \mathbb{N}, z \in \mathbb{Z}$ and ap is short for Accesspath [17] to represent memory locations in the form of regular expressions. Each trace t consists of a sequence of actions a^+ with a value map V . In particular, **Assume** action is used to capture path-sensitive semantics. All the actions are labeled while traversing CFG to support flow-sensitive analysis. V records the semantics from a symbolic variable sv to a concrete value cv . A symbolic variable is defined by an action labeled by id and the index n . For example, $id_f_arg_i$ denotes the i^{th} parameter of f called in the id^{th} action. In this way, we can capture the invocation context semantics. We use f_arg_0 to represent the return value of f and arg_0 for the symbolic variable returned by the caller c of f in **Return** action. Therefore, our program path trace is capable of capturing the flow-, context- and path-sensitive semantics.

In Figure 5, We illustrate three traces of the example code listed in Figure 1a. t_1 and t_3 are original code snippets, and t_2 is with the bug-fix patch. All traces start from the action calling `X_509_get_pubkey()`. Then, t_1 directly passes the return value `1_X509_get_pubkey_arg_0` into `X509_REQ_set_pubkey()` without certificate validation. By contrast, t_2 validates the return value immediately. Even though t_3 passes it into `check_suite_b()` without valida-

      2 _Call X509_REQ_set_pubkey(_, 1_X509_get_pubkey_arg_0);
t2 : 1 _Call X509_get_pubkey(_);
      2 _Assume(1_X509_get_pubkey_arg_0 != NULL);
      3 _Call X509_REQ_set_pubkey(_, 1_X509_get_pubkey_arg_0);
t3 : 1 _Call X509_get_pubkey(_);
      2 _Call check_suite_b(1_X509_get_pubkey_arg_0, _, _);
      2 _Assume(1_X509_get_pubkey_arg_0 != NULL);

```

Fig. 5: Program path traces of the code in Figure 1a, where we use “_” to represent values irrelevant.

tion, `check_suite_b()` checks the first parameter at Line 24 in Figure 1a.

Similar to the traditional analysis, the key challenge of building such path traces in large and complex programs is to overcome the path-explosion problem. We make two design decisions to achieve scalability without sacrificing substantial accuracy. (1) Limiting inter-procedural analysis. SSLDoc performs symbolic execution intre-procedurally for each caller c of the target API f at most two depth (i.e. we track c and callees of c). We refine the bug detection results by a filtering phase with the deeper inter-procedural semantics presented in Section III-C. (2) Unrolling loops. SSLDoc unrolls each loop only once to reduce the number of paths explored. While this restriction can limit the accuracy of the semantic computation, it does not noticeably affect the accuracy of SSL API bug detection for only a small number of usages related to loop variables.

B. Checking API misuses

In the checking phase, SSLDoc employs target APIs and the program path traces T to detect bugs. To configure usage pattern of SSL APIs, we provide each target f with a usage pattern type $f.\mathcal{T}$, which can be certificate validation with a predicate \mathcal{P} (e.g., `X509_get_pubkey != NULL`) and causal function calling with a usage pattern \mathcal{C} (e.g., `EVP_CIPHER_CTX_init(arg1) → EVP_CIPHER_CTX_cleanup(arg1)`, where `arg1` labels the target memory object). We illustrate our detecting algorithm in Algorithm 1. First, we extract all the target functions into $APISet$. For each API f , we detect API-misuse bugs along the traces T' that invoke f . Then, for each trace t in T' , we validate whether the usage pattern in $f.\mathcal{T}$ are satisfied along t . If a path fails, SSLDoc labels the call site of f along this t as a potential bug. To check the satisfaction of certificate validation along t , we compute the satisfiability of \mathcal{P} . That is, whether there is an **Assume** action to ensure \mathcal{P} . For usage pattern \mathcal{C} , we match with **Call** actions, which satisfy the target memory object constraint. If any of the constraints fail to match, SSLDoc reports a bug. For example, t_1 in Figure 5 fails to ensure the certificate validation `X509_get_pubkey != NULL`, which may result in a null pointer dereference bug.

C. Filtering Bug Reports

To achieve the scalability required to support real-world programs, we employ a limiting inter-procedural strategy to ad-

Algorithm 1 Algorithm for checking incorrect SSL API usage

Input: program path traces T , target APIs \mathbb{F}
Output: bug report R

```

1:  $R \leftarrow \emptyset$ 
2:  $APISet \leftarrow \text{extractTargetAPISet}(\mathbb{F})$ 
3: for each API  $f \in APISet$  do
4:    $T' \leftarrow \text{extractPathTraces}(f, T)$ 
5:   for each trace  $t \in T'$  do
6:      $result \leftarrow \text{satisfy}(t, f.\mathcal{T})$ 
7:     if ( $\neg result$ ) then
8:        $R \leftarrow \text{addBug}(t, f)$ 
9:     end if
10:  end for
11: end for
12: return  $R$ 

```

dress the path-explosion problem. The strategy generates false positives when a usage cross more than two functions. However, developers dislike using tools with low precision [18]. Therefore, we apply deeper inter-procedural semantics and rank the final results according to usage statistics.

First, we conduct semantic-based filtering. We attempt to infer semantics across functions. For the missing validation of certificate x , we further check the functions which directly receive x as a parameter. If these functions contain sanity check against x , we filter it out. For causal function calling pattern as $a \rightarrow b$, if the target memory object of a is directly assigned to the parameter of the caller c of a or returned by c , we check whether callers \mathbb{C} of c invoke b . We filter out the cases that contain function invocation of b .

Then, we conduct a usage-based ranking. Basically, we compute the number of correct/incorrect usage traces respectively, ranks bug reports in decreasing order of their likelihood of being bugs as $\mathcal{H}(f) = \frac{\# \text{of correct usage traces of } f}{\# \text{of incorrect uage traces of } f}$. The highest likelihood value indicates that more correct usages occur and the violations are less. Therefore, the violations are highly buggy. Note that, we use the trace number instead of call site number, because of the observation that many bugs occur along path-branches with different context semantics. However, we have to specially treat when $\mathcal{H}(f)$ is 0, because it indicates that all the usages are buggy. The preliminary experiment results show that it frequently occurs in small programs which invoke SSL APIs only once or twice.

D. Implementation

SSLDoc is built in Java language. We preprocess the source code into LLVM-IR 3.9⁴, which provides a typed, static single assignment (SSA) and well-suited low-level language. Then, we parse the LLVM-IR by javacpp⁵ and construct an extended control flow graph, which classifies the edges into control edges for semantic computation and summary edges to provide a mechanism to support large-scale programs. We have integrated part of OpenSSL APIs with SSLDoc and provide an interface to extend our analysis in a human-readable format named Yaml⁶.

⁵<https://github.com/bytedeco/javacpp>

⁶<http://yaml.org/>

IV. EVALUATION

In this section, we describe our results from incorrect SSL API usage detection on large-scale open-source programs using SSLDoc. We begin by providing the experimental setup. Then we present the security-sensitive bugs we found and concluding with lessons we learned.

a) *Experimental Setup:* We applied SSLDoc to find incorrect SSL API usages in OpenSSL implementation as well as applications using OpenSSL library in Ubuntu 16.04. Target applications are selected by search dependence attributes using package management command line “apt-cache rdepends libssl1.0.0”. In total, we found more than 1200 packages using this library and selected 15 packages which are open-source on Github and ongoing development. For all the 16 programs, we detect incorrect usages in the latest stable versions. Then, we use GNU cflow⁸ to extract target SSL APIs invoked in the applications and create usage pattern mentioned in Section II according to the user manual of OpenSSL⁹. In total, 136 different SSL APIs are integrated with SSLDoc. We ran SSLDoc on Ubuntu 16.04 LTS (64-bit) with a Core i5- 4590@3.30 GHz Intel processor and 16 GB memory.

b) *Result:* Overall, SSLDoc detected 45 previously unknown security-sensitive incorrect SSL API usages as listed in Table I. We tried our best to understand the context and created issues for all the bugs to the developers of each program. Up to now, 32 of the new bugs have been confirmed by the developers and 27 have been fixed in the master branch.

For example, in Figure 6 we present a bug caused by incorrect validation of connect status in dma, a small Mail Transport Agent, which is fixed at 12 hours after we submitted the bug report with bug description and explanation of bug traces. Function `SSL_connect()` initiates the SSL handshake with a server. It returns 0 and negative integers to indicate SSL handshake is not successful. However, the status validation in `dma/crypto.c` only checked against negative integers, which may cause a man-in-the-middle attack leading to leakage of user credentials and emails messages.

V. DISCUSSION

While investigating the bug reports generated by SSLDoc, we find several intricate bugs and gain useful experience in the bug reporting process with open-source developers. We share our following experience. **(1) Incorrect SSL API usages are not corner cases.** In total, we find 45 previously unknown incorrect usages. However, OpenSSL library has provided well-format documentation and examples to guide correct usages. These bugs may result from the lack of a bug information sharing mechanism and the lack of API usage constraints among client software developers. We believe that bug fixing is an essential activity during the entire life cycle of software development. Automatic bug-finding tools,

⁹<https://www.openssl.org/docs/manmaster/man3/>

such as SSLDoc, with large-scale analysis capability can be integrated into the development cycle. In addition, SSLDoc can be customized to incrementally address this problem.

(2) Accelerating manual auditing. SSL API usages usually have similar behavior patterns. For example, many types of vulnerabilities result from insufficient validation of input or missing certificate validations. However, discovering all the missing checks by human is tedious and time-consuming. Automatic tools can efficiently accelerate the manual auditing with differences extracted as good usages and bad usages. For example, two of the API misuses were fixed within 12 hours after we created the issues with possible fixing patches, as shown in Figure 6. **(3) Intentional choices.** We also find that many incorrect usages are not mistakes but intentional choices. Many error status code checks of return values are ignored by developers. During the bug reporting process with the OpenSSL developers, we learned that they intentionally ignore some error code checks for performance considerations or due to the lack of an error handling mechanism in C¹⁰.

VI. RELATED WORK

A few works in the past have analyzed application vulnerabilities due to improper usage of SSL/TLS. Georgiev et al. [7] employ dynamic analysis to conduct MITM attacks and demonstrate that SSL certificate validation is completely broken due to badly designed APIs of SSL implementations. Later, Clark et al. [8] present a comprehensive survey of SSL security and Brubaker et al. [9] apply Frankencerts, a smart fuzzer to test SSL/TLS certificate validation code in implementation. He et al. [11] develop SSLINT, a scalable, automated, static analysis system for detecting incorrect certificate validation vulnerabilities in client programs with pre-defined API signatures. To automatically infer usage pattern, Yun et al. [12] present APISan to infer correct API usages from source code without manual effort and detect various properties with security implications. Moreover, generic bug detection approaches also can be applied to SSL/TLS API usage, such as static analysis approaches [19], [20] and testing [21]. SSLDoc specifically targets SSL API usages in C programs and complements these works. In addition, our work can be easily extended to other domains.

VII. CONCLUSION

Client programs rely on APIs of libraries implementing SSL/TLS protocols to ensure reliable communications. Incorrect usage of such APIs will cause security-sensitive problems, even severe vulnerabilities. In this paper, we present SSLDoc, a static analysis detector to automatically diagnose incorrect usages of SSL APIs in C programs. We instantiate SSLDoc with APIs of OpenSSL and apply it to large-scale programs. We find 45 previously unknown bugs in OpenSSL implementation and 15 applications in Ubuntu which use SSL APIs, out of which 27 have been fixed. We share the lessons learned from bug detection and discussions with developers to

motivate more researchers and practitioners to combat incorrect SSL API usages.

Abstract—Automated program repair (APR) has great potential to reduce the effort and time-consumption in software maintenance and becomes a hot topic in software engineering recently with many approaches being proposed. Multi-location program repair has always been a challenge in this field since its complexity in logic and structure. While some approaches do not claim to have the features for solving multi-location bugs, they generate correct patches for these defects in practice. In this paper, we first make an observation on multi-location bugs in Defects4J and divide them into two categories (i.e., *similar* and *relevant multi-location bugs*) based on the repair actions in their patches. We then summarize the situation of multi-location bugs in Defects4J fixed by current tools. We analyze the twenty-two patches generated by current tools and propose two feasible strategies for fixing multi-location bugs, illustrating them through two detailed case studies. At last, preliminary results prove the feasibility of our methods with the repair of two bugs that have never been fixed before. By learning from successful experience in the past, this paper points out possible ways ahead for multi-location program repair.

Keywords—automated program repair; multi-location bugs; case studies

I. INTRODUCTION

Over the years, researchers develop various *Automated Program Repair* (APR) techniques aiming at reducing the onerous burden of fixing bugs. Generally, these automated repair tools can be classified into two categories, i.e., search-based methodology (e.g., GenProg [1] and RSRepair [2]) and semantics-based methodology (e.g., S3 [3] and Angelix [4]). Search-based repair method (also known as generate-and-validate methodology) generate patch candidates by searching within a predefined fault space determined by Fault Location (FL) techniques and then validate these candidates against the provided test-suite. Semantics-based repair methodology, on the contrary, utilizes semantic information generated by symbolic execution and constraint solving to synthesize patches. These state-of-the-art APR tools make great achievements on single-edit program repair.

Multi-location program repair, which refers to fixing multi-location bugs whose human-written patches contain multiple chunks [4, 5], has become a challenge since the rise of APR due to its complexity. Some recent empirical studies have shown the importance of multi-location repair: The study by Sobreira et al. [5] shows that more than 60% of the bugs in Defects4J [6], a well-known dataset containing 395 real bugs collected from six open-source Java projects, need fixing in multiple points and Zhong and Su [7] draw the conclusion that

programmers make at least two repair actions in total to fix more than 70% of bugs. So far, only Angelix and S3 have been reported to possess special features designed for multi-location bugs by capturing the dependence among multiple program locations. However, as the authors stated in [3], semantic-based repair exclusively modifies expressions in conditions or on the right-hand side of assignments, leading to its not so satisfactory performance. Thus, it is an emerging trend for solving multi-location bugs.

While some tools do not claim that they have the abilities to fix multi-location bugs, they generate correct patches for these bugs when being evaluated. For example, the patch in Listing 1 modifies the types of two variables in different locations and it is a typical multi-location defect. Recently, a tool named ACS [8] has reported to fix this bug successfully. This phenomenon motivates our study. In this paper, we analyze why these patches are generated and how they fix the bugs, aiming to provide practical guidance for future research by learning the experience. We first conduct an empirical study on the multi-location bugs in Defects4J and classify them into two categories according to repair actions in their patches. We then investigate the statistics of multi-location bugs from Defects4J that are successfully fixed by the current tools. We analyze the twenty-two patches for multi-location bugs generated by current tools and propose two suggestions for solving this kind of bugs, illustrating them through two detailed case studies. Preliminary results show the practicalities of our suggestions with the repair of two out of eight multi-location bugs in Defects4J that have never been fixed before. Our methods are successful by micro-adjustment of our suggestions with existing tools.

II. EMPIRICAL OBSERVATION

Two patches for multi-location bugs in Defects4J, Lang#35 and Chart#5, are shown in Listings 1 and 2, respectively. We divide multi-location bugs in this dataset into two categories by analyzing the repair actions in the two instances.

In Listing 1, developer changes two statements at different places into a same oracle-throwing statement. Modifications at each edit point share similar actions in syntax and thus this bug is classified into syntax similar multi-location bugs category (*similar multi-location bugs* for short). In this category, the similar modification we talk about may spread over both a single line of statement (Time#3) and a chunk of codes (Chart#14). Such cases are abundant in Defects4J, such as Time#3 where several similar *if* conditional statements are added, Math#49 where an object instantiation is modified in many functions from a same class, Closure#4 where a conditio-

```

- type = Object.class;
3295 + throw new IllegalArgumentException();
- .....
- return (T[]) new Object[] { null };
3574 + throw new IllegalArgumentException();

```

Listing 1. The patch of Lang#35

```

541 if (x == null) {
542     throw new IllegalArgumentException("Null 'x' argument.");
543 }
544 if (this.allowDuplicateXValues) {
545     add(x, y);
546     return null;
547 }
548
549 // if we get to here, we know that duplicate X values are not permitted
550 XYDataItem overwritten = null;
551 int index = indexOf(x);
552 if (index >= 0 && !this.allowDuplicateXValues) {
553     if (index >= 0) {
554         XYDataItem existing = (XYDataItem) this.data.get(index);
555         overwritten = (XYDataItem) existing.clone();

```

Listing 2. The patch of Chart#5

nal expression is modified similarly at two places, etc. Among the 244 multi-location patches in our dataset, this category has 70 instances, occupying 28.69% of the total amount. A small part of these cases (23/70) share exactly the same operations at each edit point, such as Chart#14, adding the same conditional block in four edit points.

The fixing shown in Listing 2 is different. It involves the addition of an *if* conditional statement and corresponding operations from lines 544-547 and the modification of the content of an *if* conditional statement in line 552. These modifications are compact and have great logical correlation in the program structure and we name this type semantic relevant multi-location bugs (**relevant multi-location bugs** for short). The criterion is from Abstract Syntax Tree (AST) level: *if the node under one modification appears in other modified places in this patch or the modified places are sub-nodes of a common node*, then the bug belongs to this type. Another example is the patch of Mockito#2 where developer first uses *Method Definition Addition* repair action from lines 30-34¹ and then operates *Method Call Addition* in line 11. This type is more popular in our dataset, holding 67.62% (165/244) of the total amount. This result is consistent with our perception that modifications performed at multiple locations aiming at solving a bug should have logical correlations, in most cases.

A small proportion of the dataset which contains 9 patches like Time#2 and Mockito#11 shows differences from the above two conditions: modifications at different places in these patches are neither similar nor logical related. We have not proposed any method for this kind of situation in this paper due to its peculiarity.

Note that the classification is based on the features of modifications at different places and it can provide guidance for repairing. *Similar* type bugs have no logical correlation at each location and thus we may fix these places one by one, however, *relevant* type bugs possess logical correlations at each location and it may affect other places when operating in one place. That is why *relevant* type bugs are more difficult to repair and it is proved through the results which we will show in the next section: more *similar multi-location bugs* have been fixed than *relevant multi-location bugs*. Also note that when counting the number of each category, we use a **relevant first** strategy which means if a patch contains both similar and relevant edits, it belongs to the latter. For example, in Math#74, two similar loop chunks are added but there is another modification about the loops, making this patch belong to relevant bug. The reason for this strategy is that if both kinds of

¹ Due to space limitation, some code snippets are not shown. Please check them in <https://github.com/program-repair/defects4j-dissection>.

TABLE I. STATISTICAL RESULTS

Bug ID	T	PM	S	jGP	jK	N	A	ssF	J	HDR	SF
C5	R					✓

M99	S						✓				
Similar	11	-	5	-	-	-	6	-	-	1	-
Relevant	9	-	3	-	-	1	3	2	-	1	-
Total	20	-	8	-	-	1	9	2	-	2	-

Column “T” means the type of this bug and R refers to *relevant* type while S refers to *similar* type. “✓” denotes this bug is successfully fixed by the tool. “Similar” and “Relevant” denote the numbers of different types of bugs fixed by each tool and “Total” denotes the total number of bugs fixed by each tool. It is marked with “-” if the tool cannot fix any bug.

operations are needed for fixing a bug, then the difficulty degree is near to repairing a *relevant* bug.

III. SITUATION STATISTICS

In this section, we investigate how the contemporary APR tools would handle the multi-location bugs. We select ten tools which have been evaluated on this dataset: ProbabilisticModel (PM) [9], SimFix (S) [10], jGenProg (jGP) [11], jKali (jK) [11], Nopol (N) [12], ACS (A), ssFix (ssF) [13], JAID (J) [14], HDRRepair (HDR) [15], and SketchFix (SF) [16]. Note that we adopt the experimental results for jGenProg, jKali, and Nopol reported by Martinez et al. [11] and the results of other approaches come from the corresponding research papers. The results are illustrated in Table I where each tool is represented by its acronym.

Generally speaking, 22 valid patches are generated and 20 multi-location bugs are successfully fixed including 11 *similar* type and 9 *relevant* type, among which M35 and M79 are fixed by two tools. There are only five tools being able to fix these bugs (i.e., SimFix, Nopol, ACS, ssFix, and HDRRepair) among which SimFix and ACS repair the most bugs with 8 and 9, respectively. Nopol and ssFix repair 1 and 2 bugs respectively and they can only fix *relevant multi-location bugs* at this moment. HDRRepair fixes one bug for each type.

IV. LESSONS LEARNED AND SUGGESTIONS

In this section, we propose two suggestions learned from successful experience and illustrate them through two detailed case studies.

A. Case Study 1: Patch of Lang#35 Generated by ACS

We list the patch of Lang#35 generated by ACS in Fig. 1. Another modification chunk performed at line 3578 is the same as the code in the figure. ACS is especially designed for synthesizing conditional expressions containing two steps: variable selection and predicate selection. It uses a method named *Oracle-Throwing* to avoid the crash, thus, it can generate patch as shown. However, why it is able to generate two modification chunks still needs further explanation. Note that Lang#35 is a *similar multi-location bug* which means the two modification points have no correlation in program structure. Thus, there may be multiple test cases aiming at testing different places in the program and they all fail. We find that the test suite for this project contains two failing test cases and when executing, ACS uses a *fitness function* which enables it to continue fixing if the repair actions that have been performed reduce the number of failing test cases (ACS does not introduce this feature in its paper, we get this information after connecting with the authors). Previous studies such as GenProg and HDRepair use fitness functions to guide the selection process of candidate patches while ACS exploits the deduction of failing test cases for solving buggy points one by one, bringing a new idea for *similar multi-location bugs*. The main challenge for applying this strategy is the precondition: the test suite must have enough failing test cases to expose the defects and thus we must strengthen the test suite. Test case purification [17], which means recovering the execution of omitted assertions, has the ability to generate more practical test cases and enhance the performance of test suite. EvoSuite is a commonly used tool for automated test suite generation and empirically, it can increase code coverage up to 63% [18]. Thus, if we first purify the test suite and add test cases, leading to an enhanced test suite, and then use this fitness function to repair, we may be able to solve more multi-location bugs. This strategy is suitable for our study subject, Defects4J, since all the projects in this benchmark are open source projects and the original test suites are manually created which means they may not cover all the entities in the code.

```
3300 //ACS's patch begin
3301 + if (element == null){throw new IllegalArgumentException();}
3302 //ACS's patch end
```

Fig. 1. Patch of Lang#35 generated by ACS

```
- // append the value to the list...
+ if (this.autoSort) {
+   if (overwritten!=null) {
+     this.data.add(-index - 1, new XYDataItem(x, y));
```

Fig. 2. Patch of Chart#5 generated by Nopol

program skips this conditional branch and goes to line 566 directly and thus the wrong expression in line 548 does not cause the error in line 564 which means the error is avoided. This strategy is to some extent like **fault tolerance** technique [19] and it is the same principle with ACS not producing human-written patch like Listing 1. We further study the reason for modifying line 563.

Recently, **Error Propagation Chain (EPC)**, which refers to a sequence of statements between program defect and program failure statement, is proposed by Guo et al. [20] to improve the efficiency of fault localization. We check their experiment results and find that line 563 is in this chain. That indicates a new direction for fixing *relevant multi-location bugs*: since modifications at each edit point possess correlation in logic and it is hard for current technologies to fix at each point, we can find out the closest intersection to the buggy points in the EPCs and utilize SMT solver to find a patch which avoids the error. It is possible to generate a patch as long as an intersection can be found no matter how many buggy points the program possesses. All we need to do is selecting out the top-k suspicious statements, calculating their EPCs, and searching for patches at the intersections preferentially. Note that two situations of *relevant multi-location bugs* have been introduced in Section II. If two AST nodes have dependency relations, one statement will appear in another's EPC; if two nodes are both under a common node, then there will be an intersection in their EPCs.

Suggestion 1: For *similar multi-location bugs*, use a suitable fitness function for guiding the repair process combined with strengthened test suite.

Suggestion 2: For *relevant multi-location bugs*, find out the intersection of several EPCs and search for modifications at that point.

B. Case Study 2: Patch of Chart#5 Generated by Nopol

The patch of Chart#5 generated by Nopol is shown in Fig. 2. Unlike the human-written patch shown in Listing 2 modifying two code chunks, this patch only modifies a conditional statement to repair this bug. The modification point is at line 563, just under the buggy point. Nopol is a semantic-based program repair tool utilizing angelic values and a Satisfiability Modulo Theory (SMT) solver for synthesizing conditional expressions. The conditional expression it generates really avoids the error. The variable *overwritten* is defined with *null* in line 546 and its value can only be modified if the condition in line 548 is met. When the condition in line 548 is not met, *overwritten* keeps the value *null* and the program goes to the conditional branch in line 563 where the condition is not satisfied, either, after being modified. Then the

V. EMERGING RESULTS

In this section, we introduce our preliminary experimental results. We first randomly selected four *similar multi-location bugs* whose test cases are not yet capable for exposing all the defects and used SimFix, the latest tool with the same fitness function as ACS contains, to perform the fixing using the strategy of Suggestion 1. We then randomly selected four *relevant multi-location bugs*, each of whose EPC is less than ten lines (due to the time limitation), added EPCs information into their bug locations as we introduced in Suggestion 2, and utilized Nopol for synthesizing patches. All the selected bugs have never been repaired and the results are shown in Table II.

We manually examine the generated patches and consider a patch correct if it is the same or semantically equivalent to human-written one. The results show that our strategies repair two bugs by applying our suggestions with two current tools.

TABLE II. PRELIMINARY RESULTS

Bug ID	SimFix + S1				Nopol + S2			
	M46	M49	L62	T3	M95	CL8	CL50	L22
Fixed?		✓				✓		

Test case purification focuses on recovering the execution of omitted assertions and thus is sometimes useless for strengthening the test suite. For example, in Math#49, the test case *OpenMapRealVector* fails for its first function invocation which leads to an *InvocationTargetException* and thus the following function invocations cannot be executed, being the reason for SimFix not fixing this bug. In our experiment, we added the test cases generated by Evosuite into test suite, successfully exposed the two defects, and at last fixed this bug. The generated patch is the same as the standard one provided by Defects4J. We performed the same operation to the other three *similar* type bugs but SimFix failed to generate patches for them for mainly two reasons. For Lang#62 and Time#3, the reason is SimFix finds for fix ingredients in the original projects but there is no similar code in the source files, indicating that we may combine source files with existing open source projects to enlarge the space for searching for fix ingredients in the future. While for Math#46, the reason is the code snippet is so large (10 lines) that it considers the donor with a return statement the same as human-written patch as not similar. However, after we adjusted the code snippet size to a finer-grained value (2 lines), it still neglected the snippet which contains fix ingredient, which indicates that the similarities for identifying donor code snippets need to be improved.

In Closure#8, the edit point in human-written patch is line 202 in class *CollapseVariableDeclarations*. We calculated the intersections of the EPCs of top-100 ranked suspicious statements and perform synthesis on these points. Finally, Nopol generated a patch which adds an if-conditional statement to avoid the error under the another class. We performed the same operations to the other three *relevant* type bugs but they failed because of not finding angelic value at the interpoints (Lang#22) and not synthesizing a patch (Math#95 and Closure#50), corresponding to two of five limitations (*No angelic value found* and *Timeout in SMT*) the authors discussed in their paper, which means the repair ability of Nopol needs to be improved.

By making some micro-adjustments of our suggestions with current tools, we fixed two multi-location bugs. The failed cases are due to the weaknesses of current tools according to our analysis, indicating the potential of our suggestions to fix more bugs when combined with more powerful tools.

VI. CONCLUSION

In this paper, we divided multi-location bugs in Defects4J into two categories according to the repair actions in their patches, summarized the situation of these bugs fixed by current tools, and learned the successful experience as well as put forward two suggestions for future research (one for each type). Guided by our suggestions, we successfully fixed two multi-location bugs in Defects4J which have never been repaired before. To our best knowledge, we are the first to propose strategies by analyzing patches generated by current tools, bringing new idea for APR techniques as well as pointing out possible ways for multi-location program repair.

Abstract

Many software analysis methods have come to rely on machine learning approaches. Code segmentation - the process of decomposing source code into meaningful blocks - can augment these methods by featurizing code, reducing noise, and limiting the problem space. Traditionally, code segmentation has been done using syntactic cues; current approaches do not intentionally capture logical content. We develop a novel deep learning approach to generate logical code segments regardless of the language or syntactic correctness of the code. Due to the lack of logically segmented source code, we introduce a unique data set construction technique to approximate ground truth for logically segmented code. Logical code segmentation can improve tasks such as automatically commenting code, detecting software vulnerabilities, repairing bugs, labeling code functionality, and synthesizing new code.

1 INTRODUCTION

With the proliferation of open-source development practices and code sharing services, such as GitHub and Bitbucket, large bodies of source code are increasingly available to developers. There are a number of ways in which these code corpora could assist with the software development process; of particular interest is the application of machine learning to software engineering practices. Recent literature has utilized machine learning with source code at scale, developing tools to generate comments [7], detect software vulnerabilities [11], repair bugs [4], label functionality [2], and synthesize new code [6]. Code segmentation - the process of decomposing source code into meaningful blocks - can augment these methods, for instance, by determining what portions of a file are functionally similar,

identifying where to generate automatic comments, and locating useful sub-function boundaries for bug detection.

Current approaches to segmentation do not intentionally capture logical content that could improve its usefulness to the aforementioned problems. Traditionally, code segmentation has been done at a syntactic level. This means that language-specific syntax, such as the closing curly brace of a class or function, is the indicator for a segment. Although this method is conceptually simple, the resulting segments do not intentionally take into account semantic information. Syntactic structures in natural language, such as sentences and paragraphs, are generally also indicators of semantic separation. In other words, two different paragraphs likely capture two logically separate ideas, and it is simple to delineate them by splitting at the end of each paragraph. Locating logical segments in source code, however, is a non-trivial task. Syntactic structures, such as a for-loop followed by an if-statement, are not particularly indicative of semantic changes in the code. Determining if the for-loop and if-statement are working to achieve the same logical task is a more difficult problem than the paragraph delineation analogue. Logical code segmentation captures arbitrary combinations of syntactic structures in a single segment.

Logical code segmentation has a multitude of uses, including: improving code search tools by returning relevant segments of code instead of entire files or functions, recommending locations to add comments, classifying the functionality of source code by reducing the problem space from entire files/projects to concentrated blocks of code, or using the segments as features for a model that attempts to determine the modularity or complexity of a given code file. Logical segments are able to featurize code, reduce noise, and limit a problem space to certain types of segments.

In this work, we develop a novel code segmentation method to generate logical segments in a language-agnostic fashion. Although language specificity may help model code by allowing options such as language-specific tokens and abstract syntax trees, it adds a non-trivial burden to operationalizing tools. Language specific approaches require

training many models, each with their own parsers, training sets, and hyperparameters. Our language-agnostic approach is able to avoid those extra steps, improving the generalizability, availability, and ease-of-use of the results. Because there is no data set of source code that is conveniently split into logical segments, we first establish a unique data set construction process using Stack Overflow¹ (SO). Human curation is critical to determining logical segments, and Stack Overflow provides that at a vast scale.

We build on prior work in natural language processing, training a bidirectional long short-term memory (LSTM) neural network to split source code into logical segments. Since this is the first work to perform this segmentation in the source code domain, we provide baseline models and multiple deep neural networks for comparison. We validate the results on six programming languages to display the language agnosticism of the method. Lastly, we qualitatively discuss the model’s results on real source code documents to provide insight on performance in the desired domain.

Our main contributions are as follows:

- A novel data set construction method that utilizes crowd-sourced data to approximate logical segments.
- First work, to our knowledge, to perform logical code segmentation regardless of syntactical correctness or programming language.
- Baseline models for the logical segmentation problem, demonstrating the relative effectiveness of our language-agnostic, deep neural network on six different programming languages.

2 RELATED WORK

The literature on source code segmentation is relatively sparse, with existing work offering syntax-specific solutions and requiring language specificity. Ning, Engberts, and Kozaczynski develop a code browser that allows users to select useful, reusable segments by analyzing the control flow and data flow in the abstract syntax trees (ASTs) of COBOL programs [9]. More recently, Wang, Pollock, and Vijay-Shanker attempt to locate logical segments by developing rules that look for specific syntactical patterns [12]. Wang et al. generate an AST for a given Java method, apply rules that analyze the data flow and syntactic structures, and then add line breaks around the resulting segments to enhance the readability of the method. Although these methods provide sophisticated analysis and rules, they are inextricably linked to the language that they operate on, and thus will not transfer to other languages.

In this work, we deviate from the practice of using ASTs as the foundation for our analysis. By treating source code

as a body of text akin to an NLP problem, we avoid any programming-language-specific challenges posed by other methods. Text segmentation has been researched more thoroughly than the source code analogue, with methods ranging from LDA [10], to semantic relatedness graphs [3], to deep learning approaches [1]. Of particular note is the use of bidirectional LSTMs to identify the breaks between segments of Wikipedia articles [8]. An LSTM is a recurrent neural network that processes sequential information [5]. Although we use the bidirectional LSTM as the primary framework of our model, we make several changes to adapt to the source code domain. We use a character embedding instead of the commonly used word embedding: due to the vast number of possible unique identifiers in source code, optimizing an embedding for each token is infeasible. Additionally, we require an evaluation metric specifically based on our data generation method to represent how well the model recognizes segments the method creates.

3 DATA SET GENERATION

We model code segmentation as a classification problem, where given a sequence of characters, we must predict whether a character denotes the beginning of a new code segment. In order to generate training data suited to the task, we use Stack Overflow, a forum where users can ask questions, receive answers, and post code snippets on a wide range of computer programming topics. Because the posters are focused on answering a specific question, the code snippets are generally geared towards a single logical task. Fig. 1 shows an example response on Stack Overflow containing blocks the user has marked as code. We pull code snippets by searching for posts tagged with six different programming languages: C, C++, Java, Python, Javascript, and C#.

One problem with the data, however, is that the distribution of the number of lines per code snippet is heavily skewed. Fig. 2 shows that the majority of code snippets are only a few lines long. Using the entire data set could bias the model to predict segments every few lines because the model will have seen so many short code snippets, which is unlikely to be the case in real source code files. Using only very long snippets, however, would not leave much training data. Thus, we heuristically filter out all code snippets that are less than four lines long using the elbow method.

After filtering, we generate segments by concatenating snippets with a newline character, thereby marking the beginning of a new segment. We refer to these as “dividing newlines.” It is important to note that not all newlines mark a new segment because a single code snippet may contain many newlines. After this process is complete, the result is essentially a giant block of concatenated code snippets. To obtain individual data points, we iterate through the block

¹<https://stackoverflow.com>

Figure 1. Example Stack Overflow post showing code snippets.

Figure 2. Graph depicting the heavily skewed snippet length distribution on Stack Overflow.

of snippets and generate data points using three methods: bag of characters, uncentered, and centered, shown in Fig. 3.

In the bag of characters method, one data point is created by taking 7 lines from the block of snippets and counting the characters to create a “bag of characters” for each line. These bags of characters are then concatenated together to create a single training sample. If the middle newline (the fourth of seven) is a dividing newline, then the label for this data point is a 1. Otherwise, the label is a 0. This process is repeated by sliding the 7 line window forward by 1 line. We track the counts of 256 unique characters, corresponding to all the ASCII characters, with an average of about 29 characters per line.

In the uncentered method, we create a data point by selecting all the characters in a 100-character window. In this

process, we assign one label for each character in the window, meaning one data point has 100 characters and 100 labels. If the character is a dividing newline, the corresponding label is a 1. This process is repeated by sliding the window by 100 characters. It is important to note that there is no guarantee a data point in this method will contain a dividing newline (or any newline at all). Even when the data point does contain a dividing newline, there is no guarantee that it will occur in the center of the input.

In the centered method, we create a data point by locating a newline and taking a window of 50 characters before and after that newline, for a total of 101 characters. If that newline is a dividing newline, then the label for this data point is a 1. Otherwise, the label is a 0. This process is repeated by centering the window on the next occurring newline. Whilst iterating through the block of snippets, any window that does not have a newline in the center will be ignored. It is important to note that other newlines, including dividing newlines, may occur in the window; however, the label is assigned based only on the center newline.

4 METHODOLOGY

We experiment with three models: a logistic regression model (to serve as a baseline), and two neural network architectures that utilize bidirectional LSTM layers. Every model is trained on seven training sets. Six of the training sets correspond to the different languages: C, C++, Java, Python, Javascript, and C#. The last training set combines all of the languages in order to evaluate language agnosticism.

The logistic regression model utilizes the bag of characters data format for training. Each bag of characters, corresponding to one line of code, contains counts for 256 unique characters. The model takes seven bags of characters, for a total input size of 1,792. The output is a value from 0 to 1, representing the probability that the bag of characters corresponding to the fourth line (the middle line out of 7) contains a dividing newline (recall the labeling scheme from section 3).

The first neural network architecture uses the uncentered data format for training. This model has an input layer of length 100, one for each character in an uncentered data point. Each character is passed through a 20-dimensional character embedding, which converts a character to a 20-dimensional, real-valued vector. These embeddings are passed to a bidirectional LSTM layer of size 256. A bidirectional LSTM allows for past and future information to be used together, whereas a standard LSTM only considers past information. If a human were to segment source code, they would likely look ahead and use future information to piece together their decisions. The sequential information that the bidirectional LSTM learns is condensed using three

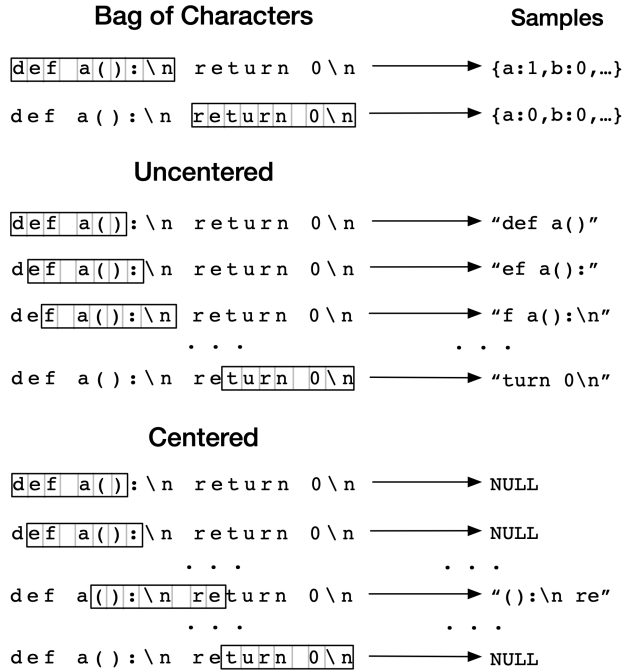

Figure 3. The three data generation methods operating on the same piece of code. The window sizes are shortened for visual clarity. In the bag of characters method, each sample is the concatenation of seven bags of characters corresponding to seven consecutive lines. In the uncentered method, each sample is simply all the characters in the window. In the centered method, each sample is all the characters in a window where the middle character of the window is a newline. If a window in the centered method does not contain a newline in the center, no sample (“NULL”) is generated.

time-distributed dense layers, sizes 150, 75, and 1, respectively. Since the layers are time distributed, the last layer has 100 total outputs (one for each time step). Each output is the probability that the character at that time step indicates the beginning of a new logical segment. The uncentered data format has 1 label for each character, so the 100 outputs and 100 labels are used to compute the loss. We use a batch size of 128, a dropout strength of 0.2 between each layer for regularization, and binary cross entropy as our loss function.

The second neural network architecture uses the centered data format for training. In terms of model structure, it is nearly identical to the uncentered model except that the input size is 101 characters and that it has one additional layer. The last layer of the centered model is a dense layer that maps the 100 time distributed outputs (last layer of the uncentered model) to a single output. Because the centered data format guarantees a newline at the center of the input sequence, only a single output is required from the centered

model. That single output and the label for the center newline are used to compute the loss.

4.1 Evaluation

Due to our data generation method, only a newline character can denote the beginning of a new code segment. As a result, we specifically measure the newline accuracy of our models. This distinction is critical because the logistic regression and centered models predict only on newlines, while the uncentered model outputs a prediction for every character, which would skew accuracy. The newline accuracy metric is the percentage of newlines that are classified correctly as either a dividing newline or non-dividing newline.

We split the collection of code snippets into train/validation/test sets of 80% / 10% / 10%. The training process is stopped when the model does not improve after 20 epochs.

5 RESULTS

In total, we train 21 different models: 18 single-language models and 3 multi-language models. For each of the three architectures (logistic regression, uncentered LSTM, centered LSTM), we train a model on each language individually, as well as a model on all the languages simultaneously. Table 1 displays the newline accuracies for each model/language pairing.

The logistic regression models perform the worst, but are still significantly better than predicting a non-dividing newline every time (non-dividing newlines are the most common). This is an expected result because the logistic regression models do not take into account character interactions like the more complex models. The neural network models show a significant improvement in performance over the logistic regression baselines.

Although the single-language models generally perform slightly better than their multi-language counterparts, the difference in newline accuracy is relatively small. This is a very positive result because the multi-language models are able to discern logical segments across languages with little to no performance hit.

Another interesting comparison is the difference in performance between the uncentered and centered models. In the single-language category, the uncentered models outperform the centered models across the board. On the other hand, in the multi-language category, the centered models are usually more effective. One possible reason for this is the difference in code context between uncentered and centered data points. In the uncentered data format, it is possible for a data point to contain no newlines whatsoever. This may help the model understand the difference

Table 1. Newline Accuracies of Each Model

Model	Language					
	<i>C</i>	<i>C++</i>	<i>Java</i>	<i>Python</i>	<i>Javascript</i>	<i>C#</i>
Single-Language Logistic Regression	95.26	95.2	95.6	91.61	94.53	95.63
Single-Language Uncentered LSTM	98.8	98.76	98.96	99.17	99.2	99.3
Single-Language Centered LSTM	97.35	98.35	98.84	97.82	98.79	98.87
Multi-Language Logistic Regression	94.76	94.81	95.1	90.76	93.48	95.09
Multi-Language Uncentered LSTM	98.33	98.56	98.75	97.98	98.65	98.86
Multi-Language Centered LSTM	98.5	98.62	98.82	97.83	98.73	98.95
Percent Non-Dividing Newlines	92.06	92.12	92.35	91.10	92.02	92.12

Table 1. Newline accuracy test results for every model and language. “Single-Language” models are trained and tested on one language at a time. “Multi-Language” models are trained on every language simultaneously and then tested on each language separately. “Percent Non-Dividing Newlines” is the newline accuracy if a model were to always predict non-dividing for every newline.

in context when a newline is actually present. In the multi-language scenario, however, snippets with no newlines may have a fundamentally different pattern for each language in the data set, which may significantly complicate what the model needs to learn. The centered multi-language models only need to learn the differences between languages as it pertains to the context around a newline, reducing the cost of learning on multi-language data. Given enough data and time, it may be possible that the multi-language models would be able to utilize the uncentered snippets more effectively.

One other noteworthy observation is the impact of similarity across languages. In the multi-language scenario, Python is the most syntactically distinct language and consistently performs the worst. It is feasible that the models are able to transfer knowledge across languages, so similar languages may benefit from each other’s data. The differences in results between languages may also speak to the quality of Stack Overflow snippets for those languages. It is possible that different programming languages attract different questions, topics, and code snippet qualities on Stack Overflow, which would ultimately influence the model’s performance.

5.1 Testing on Source Code

In order to better understand the utility of these models, Fig. 4 and 5 showcase examples of the single-language deep learning model running on a Python source file.

In Fig. 4, the model is able to recognize when the functionality of the code changes from defining a Keras model to loading the weights and compiling the model. Fig. 5 shows how the model is able to differentiate between a string operation in a for-loop and a new task of opening and writing

```
bimodel.add(TimeDistributed(Dense(75, activation = 'relu'))
bimodel.add(Dropout(.2))
bimodel.add(TimeDistributed(Dense(1, activation = 'sigmoid'))

filename = "/home/jdormuth/reversecrowd/trials/small-snippets/weights-
improvement-09-0.0030.hdf5"
bimodel.load_weights(filename)
bimodel.compile(loss = 'binary_crossentropy', optimizer='adam')
```

Figure 4. The model recognizes that compiling and loading the weights of a Keras model is a different task from defining the layers of the model. The dashed line is the model’s prediction of the segment location.

```
for x in range(len(divisions)-1,-1,-1):
    raw_code = replace_str_index(raw_code,divisions[x])
-----
text_file = open("source-code-test.txt", "w")
text_file.write(raw_code)
text_file.close()
```

Figure 5. The model distinguishes between string operations and writing to a file. The dashed line is the model’s prediction of the segment location.

to a text file.

6 CHALLENGES AND LIMITATIONS

One of the biggest challenges is the lack of ground truth logical segments. Because the Stack Overflow code snippets are simply concatenated together, the resulting data is not necessarily representative of real code. It is possible that two snippets concatenated together do not result in syntactically correct code. There is also no guarantee of standard formatting practices that one would expect to see in formal software projects.

Additionally, the data generation method assumes that a

code snippet represents a logical chunk of code. Although this is usually the case, there is no way to guarantee that all code snippets are segmented logically. It is possible that an individual snippet contains multiple logical tasks. It is also possible that two randomly selected snippets perform similar tasks; this introduces noise to the data set because they will still be labeled with a dividing newline.

One possible way to address these challenges is to use in-line comments in source code files as logical division points. There is intended meaning behind the placement of comments in source code files, whereas the concatenation of Stack Overflow code snippets is randomized. This method could better reflect the properties of source code.

7 CONCLUSIONS AND FUTURE WORK

We present a novel method to perform logical segmentation of source code. Using crowd-sourced data from Stack Overflow, we create a unique data set construction technique to approximate logical segments in source code. Drawing from the NLP domain, we develop deep neural network models utilizing bidirectional LSTMs that can predict on source code regardless of language or syntactical correctness. Lastly, we provide baselines and an appropriate metric to evaluate the performance of our models with regard to our data set construction.

Although our method is the first success in language-agnostic logical code segmentation, there are a variety of potential architectural and parameter improvements. We could incorporate an attention mechanism into the LSTM, allowing the model to learn more specific features in the source code. Another avenue could be adjusting model parameters such as window size, network depth, and loss functions. For example, the loss function of the segmentation models could be modified to incorporate the error term of another task that uses segments as input. Finally, input representations that are larger than character-scale may improve the models without significant increases in model complexity; word or token embeddings in addition to the character embedding may be able to achieve this.

Abstract—Image generation based on the generative adversarial network (GAN) has been widely used in the field of computer vision. It helps generate images similar to the given data by learning their distribution. However, in many tasks, training on small datasets of scenes may lead to mode collapse, such that the generated images are often blurred and almost the same. To solve this problem, we propose a generative adversarial network with transfer learning for mode collapse called TL-GAN. Owing to the size of the training dataset, we introduce transfer learning (VGG pre-training network) to extract more useful features from the underlying pixels and add them to the discriminator, which can be used to calculate the distance between samples, and to provide the discriminator with a new training target. The discriminator thus learns the best features that can distinguish between real data and generated data using the proposed model. This also enhances the learning capability of the generator, which learn further about the distribution of real data. Meanwhile, generator can produce new images more realistic. The results of experiments show that the TL-GAN can guarantee the diversity of samples. A qualitative comparison with several prevalent methods confirmed its effectiveness.

Index Terms—Image generation, Generative Adversarial Network, Mode collapse, Transfer learning, VGG pre-training network

I. INTRODUCTION

Most advanced deep neural network algorithms can learn highly complex problems and patterns [1]–[5], and their capabilities are impressive. However, humans can do far more than these algorithms on image recognition and speech recognition tasks, and it had appeared unlikely that such task could be automated. However, GANs [6]–[8] have made this possible.

Generative Adversarial Network (GAN) is an unsupervised method [9] that is among the most successful computer vision

algorithms. It has been extensively researched and developed, especially in the context of image generation [10]–[13]. GAN was proposed by Ian Goodfellow in 2014, and consists of two parts: a generator network G and a discriminator network D . The generator network generates samples by learning the distribution of real data. Its training objectives include maximizing the probability of error. The goal of the generator is to deceive the discriminator by generating images from random noise that are similar to real data, and the discriminator attempts to learn the differences between the generated samples and real ones.

Many applications of the GAN have been proposed [8], [14], [15]. For example, the iGAN contains two kinds of guidance information [8]: to paste the high-definition texture in the original image on the shape of the given object in it by using light field information in a different space. The texture on the paste is iterated until the resulting image appears realistic. Like the iGAN, the GP-GAN copies and pastes images directly [14], better integrates them into the original images and performs blending. However, it is a supervised training model. In the process of learning to blend, there is a supervised goal and a supervised loss function. CycleGAN allows two domains to transform each others images [15]. Traditional GAN features one-way generation while CycleGAN involves mutual generation. It is called a cycle because its network is ring-like. The input to CycleGAN is a pair of images.

Despite its wide application, it has many problems, such as training instability, gradient disappearance, mode collapse and so on. It is an important failure mode. Specifically, model collapse is called the most critical failure mode in GAN networks. Generators may reproduce exactly the same image, called pattern crash. Generally speaking, real world data distribution is highly complex and multimodal. The probability distribution described by the data has several "peaks" with different sub-groups of samples. The generator folds into a very narrow distribution, and the generated samples are no

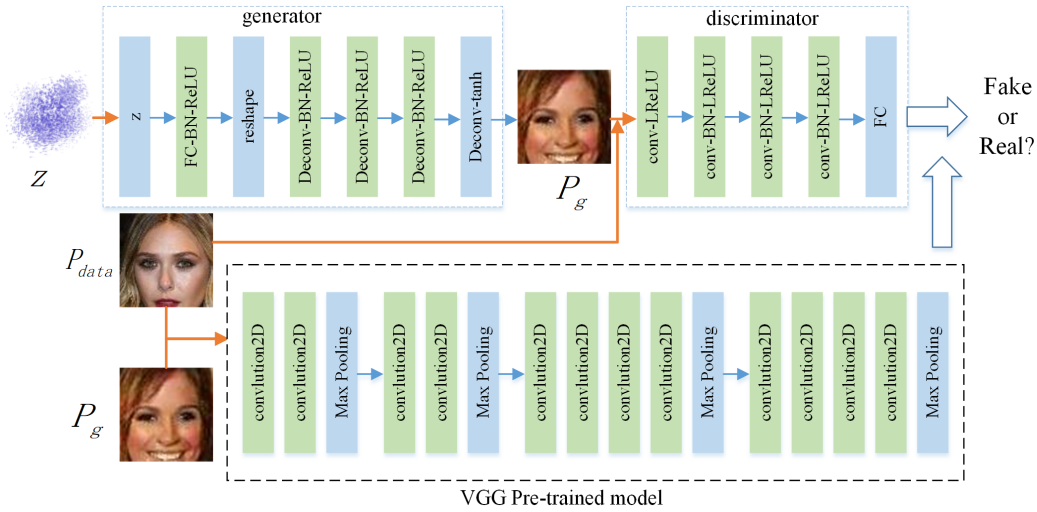

Fig. 1. Model architecture. z denotes random variables from a uniform or a Gaussian distribution, and P_g denotes fake images generated by the generator network. P_{data} represents real data, and conv and deconv denote the convolutional and the deconvolutional layers, respectively. FC denotes a fully connected layer.

longer changed. This obviously violates GAN's essence. For example, for face generation, we want to train a GAN that can generate face images. Generators need to learn hundreds of thousands or even millions of faces. However, if there are only tens of thousands of training data sets, the generator may collapse, resulting in poor diversity in the generated samples, which limits the usefulness of learning in GAN.

To solve the problem of mode collapse on small datasets in the GAN, we propose in this paper generative adversarial networks with transfer learning for mode collapse (TL-GAN). We introduce transfer learning (VGG pre-trained model) to extract useful features from the underlying pixels in images and add them to the discriminator. These features can be used to calculate the distance between samples and provide the discriminator with a new training target. This also enhances the learning capability of the generator, which can then learn more about the distribution of real data. Instead of encouraging samples generated by each generator to approach a single maximum likelihood, generator collapse is avoided. The overall performance of these samples are closer to the real image, and a suitable distance between different samples in the space can be ensured.

II. RELATED WORK

Although it is widely used, there are problems with the GAN, such as difficulty in training, mode collapse, and a lack of diversity in the generated samples. Several variants of the GAN have been proposed to solve these problems [10]–[13].

DCGAN: Since it was proposed in 2015, the DCGAN has been widely used in many applications, and significantly improves the stability of the training of the GAN and the quality of its results [10]. However, this only solves the problem temporarily and does not resolve difficulties in train-

ing. Furthermore, it is not easy to train D and G to reach equilibrium.

LSGAN: Proposed in 2016, the LSGAN uses the least-squares loss function instead of the loss function of the GAN to alleviate instability in its training and the lack of diversity that leads to poor image quality [11]. However, the LSGAN also has drawbacks. Its excessive penalty for outliers may lead to a reduction in the diversity of sample generation. It is likely to yield a simple imitation with minor modifications to the real data.

WGAN: The WGAN, developed in 2017, improves GAN in term of the loss function [12]. It removes sigmoid from the last layer of the discriminator, and forcibly truncates the updated weights to a certain range to meet the conditions of Lipschitz continuity. However, clipping the weight parameters blindly to guarantee stable training can lead to low-quality and low-resolution images.

WGAN-GP: The WGAN-GP, developed in 2017, is an improvement over the WGAN [13], specifically its continuity constraints. The contribution of WGAN-GP is that a technique to restrict Lipschitz continuity-the gradient penalty is proposed to solve the problem of mode collapse with a vanishing training gradient. While the WGAN-GP is an improvement over WGAN in some cases, it is not significantly superior to reliable GAN methods in terms of results. A number of researchers have attempted to solve problems in the GAN with mixed success.

III. GAN WITH TRANSFER LEARNING

A. Approach

In general, the GAN model uses a large number of training datasets, of the order of hundreds of thousands of images (CelebA, LSUN) [11], [16]. In such cases, the generated samples are diverse and high quality and conform to the

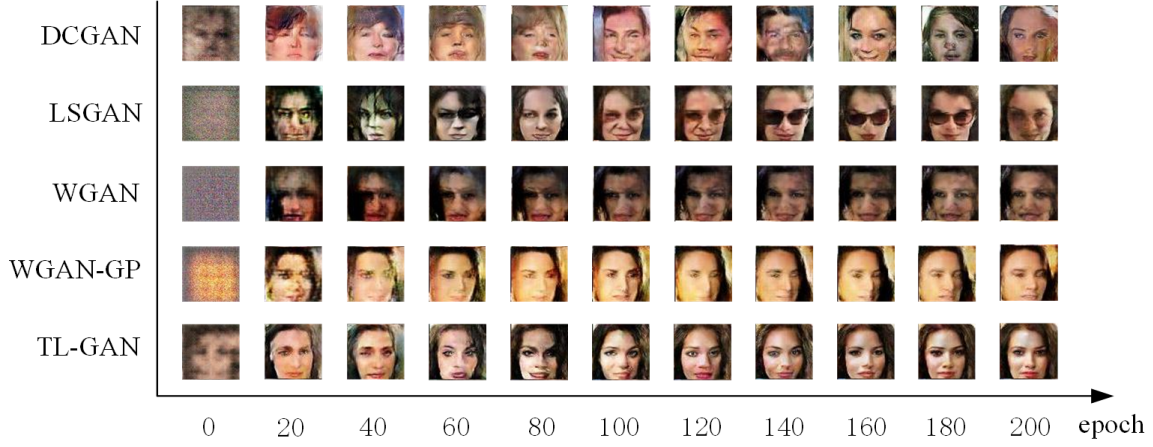

Fig. 2. Comparison of the DCGAN, LSGAN, WGAN, and WGAN-GP with our method for different epochs of a single sample on the CelebA dataset.

distribution of real data. However, in the case of a small training dataset, the generator network can learn only a few useful features such that the generated images look very fuzzy or even lead to mode collapse. To solve this problem, we introduce transfer learning that can transfer the influence of our knowledge on the visual perception of image generation tasks using a transmission parameter [17], [18]. The GAN with a model pre-trained on millions of image datasets using ImageNet outperforms a zero-trained depth model on the same small dataset. We use the trained VGG pre-trained model on real and generated images.

B. Model Architecture

Our network structure is shown in Figure 1. It comprises the generator network G , discriminator network D , and a VGG pre-trained model. The target of G captures the potential distribution of real data samples I_{data} , in addition to generating new data samples I_g . It starts with a random vector z as input to the generator network followed by a fully connected layer and subsequently employs a high-dimensional tensor with 512 feature maps. Note that we use the batch normalization layer for each deconvolutional layer, and the activation function makes use of the rectifier linear unit (ReLU) except in the last deconvolution layer. D is a dual classifier and determines whether the input to it is from the real data I_{data} or generated samples I_g . The discriminator network also makes use of multiple convolutions and uses the LeakyReLU as an activation function. At the end of the convolution, the tensor is stretched into a vector, which uses a fully connected layer. Our model employs a kernel of size 5×5 in both the generator and the discriminator. The VGG pre-trained model contains stacked convolution and coupled pooling layers. P_{data} and P_g are used as inputs to the VGG pre-trained model based on transfer learning to extract more high-level features. In the training process, the discriminator network aims to identify real and generated images, while the generator network attempts to make the generated samples more real with the aim of achieving the Nash equilibrium.

C. Loss function

1) *Adversarial loss*: Adversarial loss can maximize the probability of successfully determining whether a given image is from the training data or the generated samples. The goal of D is to separate images generated by G from real images. In this way, G and D constitute a min-max game. To better deceive the discriminator network such that it generates perceptually realistic images, we formally denote by D the adversarial loss of the discriminator network and by G that of the generator network. We define the adversarial losses of \mathcal{L}_d and \mathcal{L}_g as follows, respectively:

$$\mathcal{L}_d = E_{I_{data} \sim p_{data}(I_{data})} [D(I_{data})] + E_{I_g \sim p_g(I_g)} [1 - D(I_g)], \quad (1)$$

$$\mathcal{L}_g = E_{I_g \sim p_g(I_g)} [1 - D(I_g)], \quad (2)$$

where \mathcal{L}_g is the total loss of G , $D(\cdot)$ represents the output of the discriminator network, and $G(\cdot)$ is generated by G , which needs to learn real data distribution and produce more realistic images. When D cannot distinguish between real data and generated samples, the generator can better deceive the discriminator network. The final optimization of D is given by Eq. (3):

$$D^* = \mathcal{L}_d + \lambda \mathcal{L}_p, \quad (3)$$

where D^* is the total loss of D , and λ represents a constant.

2) *Perceptual loss*: We propose perceptual loss based on the VGG pre-training network to extract useful features from the underlying pixels and add some of them to the discriminator. These features are used to calculate the distance between samples and give the discriminator a new training target. It can thus solve the problem of blurred images and even mode collapse on small datasets. Moreover, the computational overhead of perception loss can be reduced by reusing the features

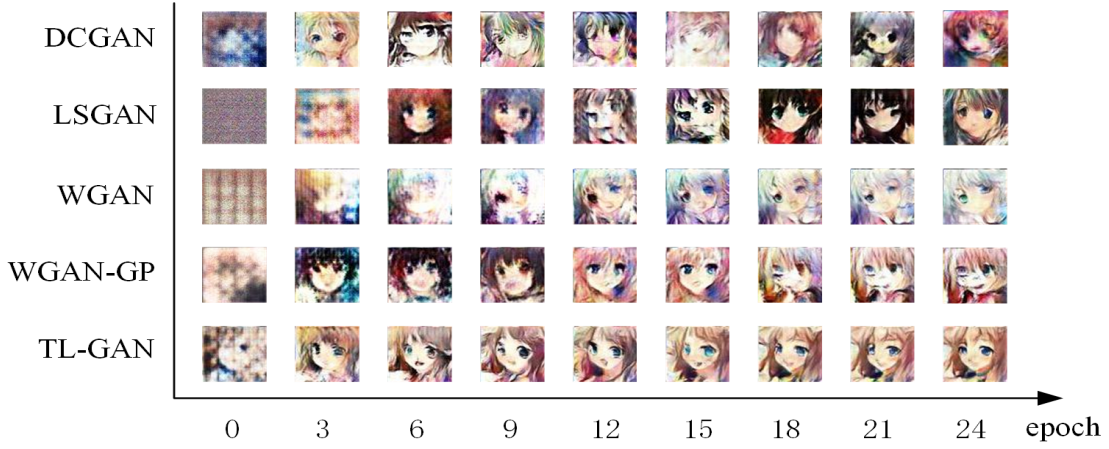

Fig. 3. Comparison of DCGAN, LSGAN, WGAN, and WGAN-GP, with our method for different epochs of a single sample on the Cartoon dataset.

extracted by the discriminator. To introduce the formula for perceptual loss, we define perceptual loss as:

$$\mathcal{L}_p = |V(I_{data}) - V(I_g)|, \quad (4)$$

where \mathcal{L}_p represents the perceptual loss, and $V(\cdot)$ represents the output of the VGG19 network.

IV. EXPERIMENTS

A. Details of Training

We used the CelebA and Cartoon datasets for training. In each training batch, we randomly selected 64 image patches as I_{data} patches, where each patch had a size of 64×64 . The random vector satisfied a uniform or a Gaussian distribution $P_z(z)$ as input to the generator network. To stabilize the network, the range of intensity of the input and output images was set to $[-1, 1]$.

TABLE I
STATISTICS OF THE DATASETS.

Datasets	Samples	Size
CelebA	10,590	64×64
Cartoon	51,223	64×64

The CelebA face dataset is an open dataset of the Chinese University of Hong Kong [16]. It contains 202,599 face images with 10,177 celebrity identities. For our experiment, we selected only part of the data as a small dataset for training, with 10,590 images. The Cartoon face dataset was downloaded from Konachan.net, a well-known animation gallery, with a total of 51,223 images. Our experiments directly used the Cartoon face dataset shared by HE [19].

Our experiments were implemented in Python on the TensorFlow framework using an NVIDIA Tesla M40 GPU to accelerate training, using an SGD at a learning rate of 0.001 for all layers to analyze model performance. The momentum parameter was set to 0.3, weight decay to 0.0001, and 64 was set as the cardinality of each patch of training. All weights

were truncated for a positive distribution and the standard deviation was 0.02. All convolutional layers were followed by leaky rectified linear units (LReLU) with a slope of 0.2. Training the CelebA and the Cartoon datasets took 4 and 3 hours, respectively.

B. Comparisons and Analysis

To verify the effectiveness of the proposed model, we compared it with state-of-the-art methods, including the DCGAN [10], LSGAN [11], WGAN [12], and WGAN-GP [13]. It is worth pointing out that there are no quantitative indicators to refer to in previous papers because the generated synthetic data have no corresponding real data reference. There was no clear measure to assess the results of image generation tasks. Inspired by [10]–[13], we used the final generated images for comparison. Our experiments contained two parts. In the first, we analyzed the effectiveness of our method on two small datasets. We analyzed changes in a single sample in the training process, and we studied the final visual effects. In the second part, we considered the stability of training in several methods.

1) *Evaluation of Visual Results: CelebA* We trained our model for 200 epochs on the CelebA dataset. For a fair comparison, we list the generated samples for the same steps in each epoch using several methods (see Figure 2). In the final epoch, we observed that the DCGAN [10], LSGAN [11], WGAN [12], and WGAN-GP [13] produced poor results on a single sample. Because the dataset was small and training time limited, the DCGAN experienced mode collapse. It generated images of faces of females and males alternately. The training process of the LSGAN was very unstable. It first generated the images of a face not wearing glasses, then one with glasses, and again one without glasses. The WGAN and WGAN-GP generated blurry images of faces because of slow convergence. On the contrary, TL-GAN generated clear images of faces from random noise in a single sample.

Cartoon We trained our model for 24 epochs on Cartoon dataset. We list the generated samples in the same steps in

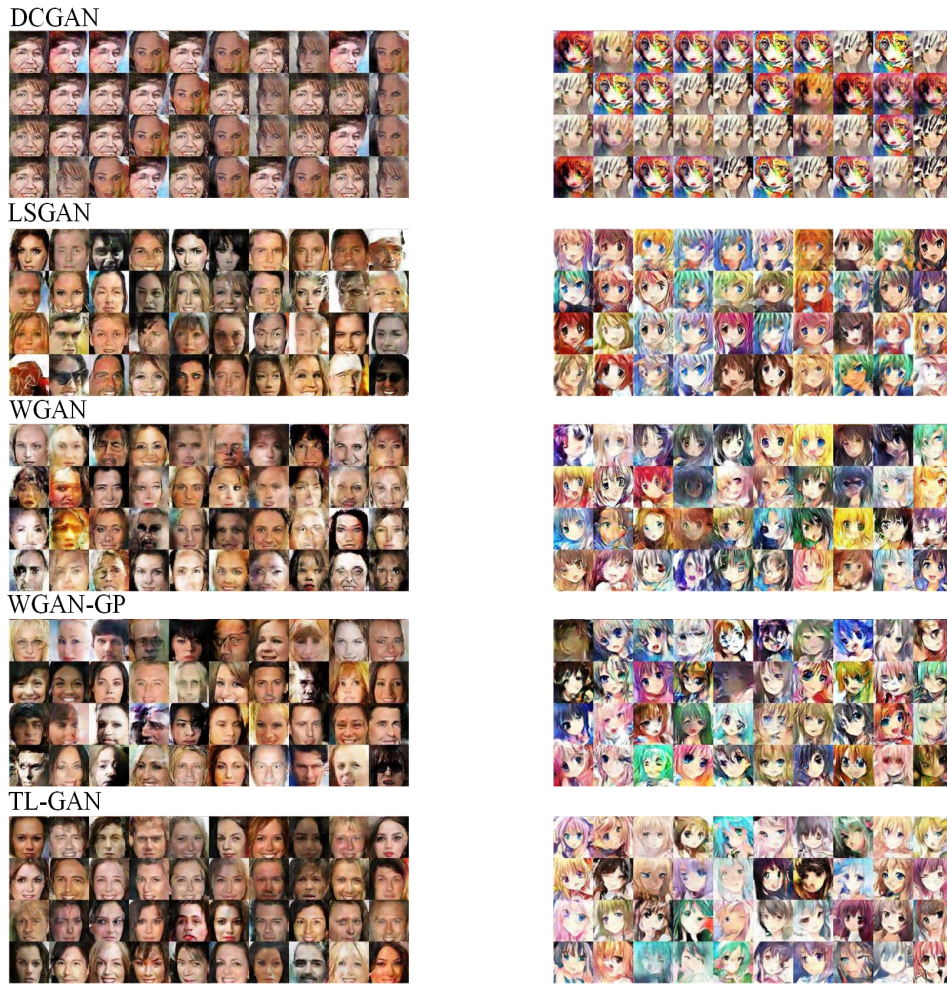

Fig. 4. Visual comparison of all samples on training dataset: CelebA dataset on the left and Cartoon dataset on the right.

each epoch from several methods. From Figure 3 it is clear that the samples generated by our method showed a steady increment in quality, and produced a perceptually realistic image. However, the phenomenon of mode collapse appeared in some other methods (DCGAN and LSGAN). We also found that all other methods except the WGAN were unstable, their generated samples did not follow a fixed trend in the generation of shapes of face images, and they constantly changed in the training process. The DCGAN and LSGAN yielded images of faces of different cartoon characters in the training process, and two types of such images were generated in training by the WGAN-GP.

Samples of the CelebA and Cartoon datasets that were used are shown in Figure 4. The DCGAN on CelebA exhibited mode collapse, and it lacked sample diversity, and thus many generated samples were almost identical. LSGAN experienced a moderate mode collapse, and some of the images of faces generated by it look very odd. The WGAN trained very slowly on the CelebA dataset and its resulting images were very blurred. A slight mode collapse was observed in the WGAN on the Cartoon dataset. For example, the images of some faces

were unusual and hairy body parts had unnatural details. Its results were better than those of the DCGAN and LSGAN, but the overall effect was unsatisfactory. The WGAN-GP also went through a slight mode collapse on the CelebA and Cartoon face datasets. The images of faces generated by it were vague and had strange details. The TL-GAN solved the mode collapse problem on the small datasets and guaranteed sample diversity. Moreover, the generator network quickly produced the images. It yielded quality images of faces.

2) *Comparison of convergence*: Loss convergence on the Cartoon dataset is shown in Figure 5. Loss of the DCGAN in the generator network increased, probably owing to the mode collapse caused by a too small dataset. The discriminator loss of the DCGAN also oscillated, and it could not differentiate real from the generated samples accurately. The loss of the generator and discriminator networks oscillated during the training of the LSGAN, which experienced a moderate mode collapse. Its convergence was also slow. The loss of the WGAN in the generator and discriminator networks tended to be normal, but was slower than that in our method and resulted in unclear samples generated after training. Gradient

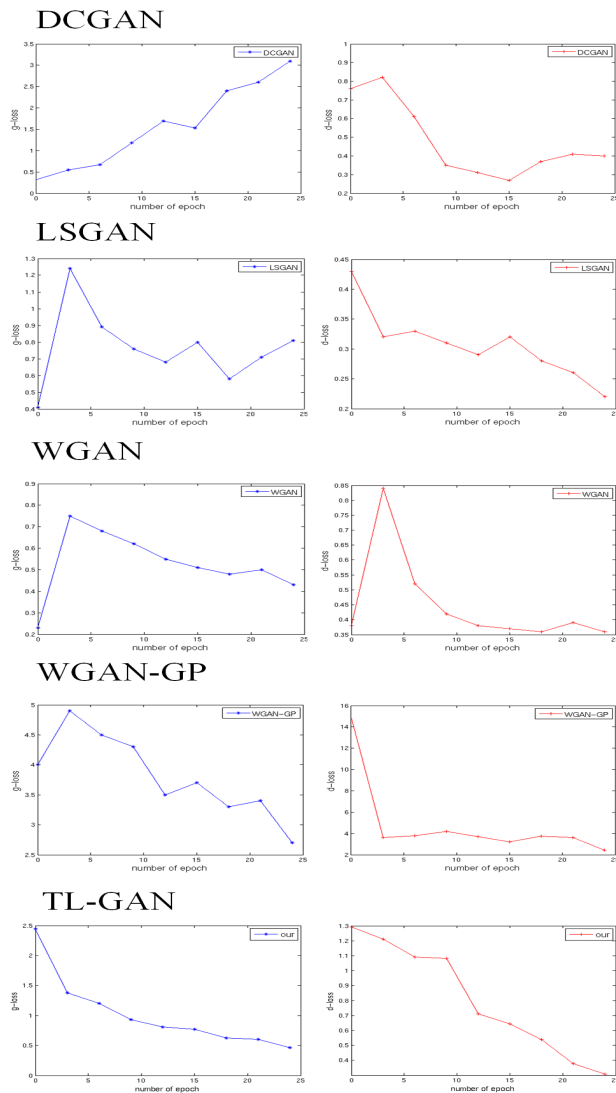

Fig. 5. Loss convergence in training on the Cartoon dataset. The generator is shown at the top and the discriminator at the bottom.

penalty was introduced in the WGAN-GP, and increased the losses of the generator and discriminator networks at first. As training progressed, the losses decreased. But after training, the results were still not good, and the generated samples were thus insufficiently clear. The results on even the Cartoon dataset were unstable, as a single sample constantly changed and there was no fixed shape to the images generated. The TL-GAN converged more quickly and was more stable than the other methods. It also produced more perceptually realistic images.

V. CONCLUSION

In this paper, we highlighted the problem of mode collapse on small image datasets and proposed generative adversarial networks with transfer learning for mode collapse (TL-GAN). Experimental results show that our method substantially outperforms state-of-the-art approaches, and samples generated

by it were close to real images. It can also ensure sample diversity. Compared with the other methods, the loss convergence of our model was fast and stable. In the future, we will continue to study how to use smaller data sets, such as thousands of images. Whether there will be collapse and good stability in our model.

Abstract

Broadly used and applied in many domains, Hidden Markov Models are a well established formalism, both in computer science and statistics. Among other reasons, they owe their popularity to a fast fitting method, *i.e.*, the Baum-Welch algorithm, allowing to adjust models to a variety of input data. Using expectation and maximization phases, BW assures an increase to the model likelihood at every iteration. Yet, to initialize the sequence of expectation-maximization (EM) steps, it is a standard procedure to start the BW algorithm from randomly generated values. We propose a, simple and fast, deterministic pre-fitting approach which derives the BW's initial values directly from the input data.

1 Introduction

Due to their relative simplicity and power to represent complex systems, Hidden Markov Models (HMMs) are one of the most widely used stochastic formalism for time series [31]. HMMs owe their flexibility and their ease of application to a well-developed methodological framework, including a model fitting algorithm. The so-called Baum-Welch algorithm (BW) can be considered a special case of the Expectation-Maximization (EM) algorithm (Section 2). In essence, it derives the maximum likelihood estimates for the parameters of a given model, *i.e.*, the best fit for the input data in the sense that the probability to observe the data given the model parameters is maximal. This is achieved by an iterative procedure guaranteed to increase the value of the likelihood at each iteration and such procedure finds a local maximum; therefore, offering a model solution even when the likelihood is untraceable or too costly to maximize directly. However, as well as EM algorithms in general, BW tends to be sensitive to its input parameters [6][9].

Several extensions have been suggested to overcome the flaws of EM [9][18][13][29]. They are based on combinations of algorithms and techniques such as classification, randomization or more complex stochastic additions. Others,

focused on improving the BW, have different approaches performing changes within the algorithm, which can also deal with possible convergence problems [4][26][16] [20].

Several extensions have been suggested to overcome the flaws of EM [9][18][13][29]. They are based on combinations of algorithms and techniques such as classification, randomization or more complex stochastic additions. Others, focused on improving the BW, have different approaches performing changes within the algorithm, which can also deal with possible convergence problems [4][26][16] [20].

Our solution focuses on the initialization only. It keeps the BW's structure and adds a pre-fitting deterministic step, which by avoiding bad initial parameters tends to obtain higher likelihood values in the first iteration, thus reducing the number of iterations needed to find a local maximum, which leads to a fast model fitting (Section 3). Although the difference is minimal, the possibility of deriving the initial values directly from the input data can be interesting for applying these models into different scenarios.

Since an HMM is usually used having serial data as its input [31], the idea is to use a deterministic discretization technique for time series prior to the actual model fitting. From this approximate description of the original observations, we then derive initial parameters which are fed into BW. These parameters are, in general, reasonably close to a local maximum. Thus, the combination of the parameter's selection step, in combination with the BW algorithm, is more likely to reduce the number of iterations to maximize the parameters, therefore leading to a local maximum likelihood faster than the most traditional approach, which is using random numbers to initialize the parameters.

Our approach is based on a Piecewise Aggregate Approximation (PAA) technique, which is used in the algorithm (Figure 1, Piecewise Expectation). The use of PAA with EM, Piecewise Aggregation EM (PAEM), has advantages regarding fitting speed and practicality due to its simpler set of parameters.

[—]*DOI reference number: 10.18293/SEKE2019-185

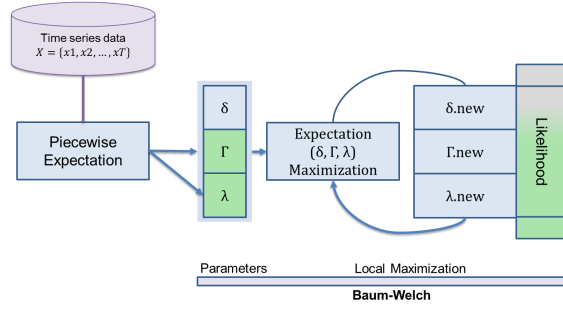

Figure 1: PAEM, schematic representation

Finally, we performed experiments and measures to compare the traditional use of BW against PAEM (Section 5). The main contribution of our approach is to reduce the time needed to fit HMM models. However, this is performed with a pre-fitting without modifying the original algorithm, which is a different approach than the others (Section 2.1). This pre-fitting can also be seamlessly used on time series data, reducing the modeling time.

2 Baum-Welch

The Baum-Welch algorithm (BW) is a version of EM algorithm for HMMs [5]. The goal is to estimate the parameters of an HMM given an input data [31], in the statistics literature, commonly described as observations. This goal implies that unlike a manual fitting approach, the initial distribution δ , the transition probability matrix Γ and the emission probabilities λ , are not estimated by the modeler observations but, automatically, by the model itself.

The BW algorithm works iteratively by successive maximizing local approximations of the likelihood function. It is guaranteed to maximize the likelihood at each iteration. EM alternates between two steps. The E-step computes the conditional expectation of the hidden states given the observations and the model current parameters, Γ , δ and λ . These computations are based on the complete data log-likelihood, which is basically the natural logarithm of the likelihood function to avoid the underflow problem [14]. In the M-step, the expectations are maximized according to its parameters.

2.1 Variants and derivations There are several variants and extension for the standard EM algorithm, also described as Generic EM (GEM). This section concisely shows an extensive literature review for the EM variants and derivations. We briefly classify the GEM-based algorithm, in order to establish their relations and differences compared to our approach.

We can globally classify these variants into deterministic and stochastic versions. Among the deterministic versions, Classification EM (CEM) [9], Accelerated EM (AEM) [18], Aitken's acceleration (AA)[13], [25], Expectation

tation Conditional Maximization (ECM)[29], ECM Either (ECME) [23], Space-Alternating Generalized EM (SAGE) [15], Parameter-Expanded EM (PX-EM) [24].

The stochastic versions include Stochastic EM (SEM) [8], Stochastic Approximation type EM (SAEM) [8], Data Augmentation algorithm (DA) [27] and Monte Carlo EM (MCEM) [30]. Although many of them are focused on Gaussian mixture models, all these variants have slightly different approaches to solving slightly different problems. A common problem is the EM step sensitiveness to the initial parameters [6]. Bad initial parameters will lead to more EM steps (iterations), which are necessary to find the local maximum likelihood.

All these GEM-based algorithms have in common the use of an iterative MLE or Recursive MLE (RMLE). However, not all fitting algorithms are based on the MLE. Some are based on Minimum Model Divergence (MMD) and Minimum Prediction Error (MPE), which can be extended to Recursive Prediction Error (RPE) as a general recursive stochastic algorithm [3]. MMD, in few words, can be described as a combination of MLE and the minimization of parameter's divergence using entropy measures. Also, Minimum Prediction Error (MPE) which consists of measuring an HMM error output prediction and provide an updated estimation for the HMM parameters [11]. Among the algorithms, using MPE we can emphasize Collings *et al.*, [11] and LeGland and Mevel [21]. Using MMD we can emphasize Garg and Warmuth [17].

Despite the uses of MMD and MPE, we focus on the classic MLE, which is commonly used for HMMs. So far, works based on MLE are the following: [4][26][16][20][7]. However, our approach does not intend to create an entirely new algorithm nor improve it within itself. Instead, we perform a pre-fitting to avoid the BW sensitiveness, an approach used by some EM variants. Also, we do not intend to create an optimal algorithm, but a better version of the traditional BW, which aims to be a practical option that does not suffer from the same flaws of a GEM, which as well as BW, is strongly dependent on its initial parameters [9]. Therefore, the convergence time is directly dependent on how good are these initial conditions.

3 PAEM

The efficiency of fitting HMMs can be improved by combining the EM algorithm with data mining techniques such as classification methods or the K-means algorithm [9][31]. These techniques are used to choose the initial parameters intelligently, thus reducing the impact of the EM/BW sensitiveness to them.

As showed in the Section 2.1, there are many algorithms which have been derived from the generic EM. However, they are based on different techniques and adapted for different situations. Here, we adapt and combine a Piecewise

Aggregation technique for time series to represent the original observations and perform a pre-fitting for the BW algorithm, calling this extension the Piecewise Aggregation EM (PAEM). PAEM profits from the simplicity of the PAA method and the dynamism of a SAX [22] inspired method, which can be applied for different kinds of distributions concerning time series. These characteristics allow us to derive meaningful initial parameters by a fast approximation of the data, avoiding failing on dimensionality problems, such as a fail to converge, which can be given by higher dimensions; or imprecise representations, which can be lead by a strong dimensionality reduction.

PAEM's initial approximation enhances the initial parameters Γ and λ , making them close to the global maximum, which leads to a faster fitting compared to the traditional random initialization. This is due to the need of a single initialization to maximize the parameters and to a first better fitting, which reduces the sensitiveness effect and tend do avoid EM iterations. Fig. 1 illustrates the general idea: a pre-fitting in a phase called piecewise expectation prior to the traditional BW. Two of three parameters are previously updated, Γ and λ , which together with the steady state, stored in δ , tends to lead to a first better likelihood. The piecewise expectation cost is $\vartheta(T)$, which is lower than forward-backward procedures $\vartheta(N^2T)$, briefly described in the previous section. Therefore, once a pre-fitting saves one iteration, the final computational cost should be lower.

3.1 Piecewise Expectation Piecewise Aggregate Approximation (PAA) is a technique to reduce data dimensionality through discretization. It has been widely applied in the context of time series analysis. Despite being simple and intuitive, PAA has been shown to be as powerful as more sophisticated dimensionality reduction techniques such as Discrete Fourier Transform [1], Discrete Wavelet Transform [10], Singular Value Decomposition [19].

To perform dimensionality reduction, PAA creates a discrete version of the original TS in w blocks. These blocks are usually a division of the length of the TS. In our case, the faster mapping characteristic is especially attractive. Since we intend to reduce the total time necessary to fit a model, more robust approaches might be too costly for a pre-fitting procedure.

Given a time series S with length n , $PAA(S)$ is defined as a sequence $PAA(S) = \{\mu(B_1), \mu(B_2), \dots, \mu(B_w)\}$, where μ is the mean, w is the maximum number of blocks and B_i is a block in the index i , being $(1 \leq i \leq w)$. The mean of a block is given by the Equation 3.1. If the division n/w results in a float number, the result is truncated and another block is made of the remaining part of the series.

$$(3.1) \quad \mu(B_i) = \frac{w}{n} \sum_{j=\frac{n}{w}(i-1)+1}^{\frac{n}{w}i} S_j$$

Despite its simplicity, PAA is enough to start an appropriated representation of a given series. We use it as a mapping to set up variables and then calculate Γ through MLE. Other PAA advantage is that it has only one parameter and due to it being mainly used to reduce a time series dimensionality, it is not critical for our problem. Therefore, given a set of observations $X = (x_1, x_2, \dots, x_T)$, PAEM only needs one parameter, the model number of states n . It starts by getting a sequence of symbolic values ϕ , with range n , that better describes X . The total number of Blocks is equal to $w = T/m$. Thus, we identify the approximation sequence with $\phi = (\mu(B_1), \mu(B_2), \dots, \mu(B_w))$.

The number of states n defines the division of the values $\mu(B_i)$. This generates the λ values of the HMM. Thus, vector ϕ has a sequence of w elements composed by n symbols. For instance, in $\phi = \{1, 2, 3, 1, 2, 3, 2, 2\}$, $w = 8$ and $n = 3$. Now, we can extend the whole approximation process to a set of equations.

Vector ϕ is directly used to get the probabilities and set the transition probability matrix, Γ , which together with λ are the two necessary parameters for an HMM model since δ can be initiated *null* and then filled with the steady state. Due to this solution be directly related with PAA, we call this part of the algorithm, "Piecewise Expectation".

To generate Γ , we use the elements of $\phi^{(t)}$, $1 \leq t \leq w$ and $1 \leq i, j \leq n$. The non-normalized matrix Γ is filled by the cumulative sum of the probability to find an element $\phi_j^{(t)}$ just after an element $\phi_i^{(t)}$.

$$(3.2) \quad \Gamma_{(i,j)} = \sum_{t=2}^T P(\phi_j^{(t)} | \phi_i^{(t-1)})$$

Different than Γ , the elements of λ are directly extracted from the piecewise approximation procedure. The generated values are actually close to the BW's ones. This small distance between the pre-fitted and the pos-fitted value is constantly observed in our experiments.

4 Experiments and Results

Our experiments aim to measure and compare how fast the local maximum likelihood is achieved through BW and PAEM. In other words, to prove the efficiency of our algorithm in finding the best model fit. To do so, we used randomly generated and randomly chosen time series from Data Market [12]. We separated our tests in three steps. First, to compare the generated maximum likelihood from different initialization of BW against the PAEM approach. Second, to detect the number of necessary executions to achieve the global maximum likelihood; consequently, how long it takes to achieve the global maximum likelihood. Third, a direct measurement of the user for PAEM vs BW.

Our tests followed the hypothesis that a human operator begins with no knowledge about the dataset. In other words,

we consider no previous data mining or machine learning techniques have been performed. For the last two sets of test (Section 4.2 and 4.3), the BW initialization followed the standard strategy [9], it was performed through random normalized numbers to all parameters. We used 12 different time series for models ranging from 2 to 4 states. Regarding these 36 tests, for each BW execution, 50 different seeds were used. To avoid outliers, the best and the worst 5 were taken out. From these 40, we used the best, the worst and the average measurements to compare against PAEM.

4.1 Likelihood Prior to the user time and iteration tests, we compared the fitness of BW and PAEM with only one initialization. Since the Expectation-Maximization part is the same, if the BW parameters are not equiprobable they should reach the same likelihood. Otherwise, if BW is inferior, it means that not all randomized parameters are good as an input. If PAEM is inferior, it means that the pre-fitting fails. Table 1 shows this experiment with BW and PAEM, where * means that we used an equiprobable λ to initialize the BW. In fact, if the BW's parameters values are not equiprobable, it tends to converge to a maximum likelihood. The problem usually happens when an equiprobable λ or Γ is given as an input, which is trivial to avoid.

Table 1: Experimental model measurements using random numbers as parameter initialization.

Model	# states	mLLk	AIC	BIC
BW (Equip. λ)	2	1268.92	2547.84	2560.86
BW	2	635.32	1280.65	1293.67
PAEM	2	635.32	1280.65	1293.67
BW (Equip. λ)	3	1268.92	2559.84	2588.50
BW	3	510.22	1042.44	1071.09
PAEM	3	510.22	1042.44	1071.09
BW (Equip. λ)	4	1268.92	2575.84	2625.34
BW	4	471.82	981.65	1031.15
PAEM	4	471.82	981.65	1031.15

Although an equiprobable λ suggests a bad fitting, this is not true for all scenarios. Despite a tiny improvement, in some cases, an equiprobable λ retrieved a better likelihood. For the other datasets, a similar phenomenon occurred in some models with more than 3 states. This suggests that a simple condition to avoid an equiprobable parameter may not be a good solution.

Considering one decimal precision, PAEM reaches a better likelihood in 3 cases against 2 from the pure BW. Table 2 shows these cases. For all the 36 experiments, PAEM was better in 17 occurrences against 19 of the pure BW. However the difference in the vast majority of these cases lies in a nth decimal precision, which can be seen in Table 2, it represents a negligible probability.

4.2 Iterations As in the previous section, we started by checking our hypothesis through experiments using 50 dif-

Table 2: -Log-Likelihood comparison, cases where the difference exceeds a precision of one float point.

BW	PAEM	$\Delta\%$	
210.13	209.71	0.01%	favorable to PAEM
740.52	697.38	5.80%	favorable to PAEM
773.44	718.20	7.10%	favorable to PAEM
471.82	489.84	3.60%	favorable to BW
321.55	322.99	0.40%	favorable to BW

ferent seeds to BW, excluding the best and the worst 5. From the 40 remaining we collected the best, the average, and the worst case concerning the BW initialization and its number of iterations to reach a convergence. As PAEM generates the parameters through a deterministic technique, it only needs one initialization. Figure 2 shows the average scenario. The other scenarios have a similar behavior.

Figure 2: Average scenario for the required number of iterations to find a convergence. Experiments organized according to the models more favorable to BW (left) to the ones more favorable to PAEM (right).

In these pictures, we can clearly see PAEM requiring fewer iterations to find a convergence (right side), while just in a few cases, the random parameters outperformed PAEM (left side). Furthermore, these are retrieved from the experiments described in the Section 4.1, which shows an equivalent likelihood, between BW and PAEM, for 87% of the cases. Also, the far most significant scenario which PAEM performed poorly, loses with a difference of 3.6% (Table 2, BW=471.8).

Concerning all the results for the ordinary BW; 40 seeds for all the 12 series and the 2, 3, and 4 states model; the random values for BW got an average of 47.4 iterations against 25 from PAEM's. This shows a significant improvement for the initial parameters quality against the traditional random approach. Furthermore, in the vast majority of the tests, PAEM found a convergence with fewer iterations (Figure 2).

4.3 User Time Since both, BW and PAEM, tend to converge to the same likelihood and the cost to randomize values to BW is trivial, the real advantage of PAEM lies on a faster

convergence, which is given by fewer iterations derived by a better likelihood at the first iteration.

We performed time measurements to see how fast each procedure is in relation with BW. Although the running time is highly correlated with the number of EM iterations, a lower running time is the final goal, therefore, a more precise measure regarding the time actually used by BW and PAEM. In a standard machine, Intel i5, 2.3GHz, 8GB, a four states model had an average time of 0.34 seconds running with PAEM and 1.17 seconds running with BW. This difference is directly linked with the number of iterations. As described in the previous sections, in most cases, PAEM's pre-fitting tends to avoid at least one iteration of the forward-backward procedure, which costs $\vartheta(N^2T)$, which is more than PAA $\vartheta(T)$.

The user time spent, from both, had a strong correlation with their number of iterations. Specifically, BW had a correlation average of 93% and PAEM 76%. Which can be explained by the different seeds in BW and the lack of a precise control considering an ordinary machine running other applications. Also, PAEM's pre-fitting has a fixed running time for series with the same length, which has a different impact according to the series number of iterations necessary to find a convergence.

Now, considering the average scenario, we look for each of the 36 experiments. Thus, the radar showed by Figure 3, illustrates the total time spent in relation to the average scenario for each time series. From this figure, we can clearly see the time percentage difference from each technique and for each time series. This plot shows the overall better performance of PAEM, failing in just 6 cases, which are the time series 1, 10, 16, 21, 24, and 26. However, a difference in the case 26 is meaningless since the difference is 0.0004 in favor of BW.

Among these time series, a critical poor performance was achieved on the time series #1 and #10, which happens to be the shortest time series in the experiment. Considering BW and PAEM, respectively, for the first time series, considering an average case, it required 0.026 and 0.110 seconds. Time series X10, required, respectively, 0.025 and 0.064 seconds.

Considering larger models, we can verify that PAEM performed better, in average, for any number of states less or equal to 22. Further tests are required for larger models. Finally, we emphasize that, our code was extended from [31] and they do not have focus on performance. Therefore, the user time is far from optimal and the difference might be much less than the observed in our experiments.

5 Discussion

Through exhaustive tests, with different series, we found PAEM to be faster than BW with its traditional stochastic initialization. Its performance is due to, usually, fewer itera-

Figure 3: Radar chart showing the slowest process taking 100% of the time. An average scenario considering the user time.

tions in the EM procedure. In fact, as shown in Figure 2, in the vast majority of executions, the convergence is achieved using a fewer number of iterations than the pure BW. Furthermore, the time needed to the piecewise approximation is far smaller than one EM iteration.

However, it is important to emphasize the overall better performance and that PAEM does not aim to be an optimal solution. We focus on a simple alternative to the initial and usual randomization of parameters. Although there are other techniques that improve the original BW, PAEM lies in a simple initialization that is fast and easy to implement, making it a suitable alternative to performing HMM fitting. In fact, there are cases where authors related a faster solution using simpler MLEs [2]. Other techniques such as the Levenberg-Marquardt algorithm, can be used to maximize directly the likelihood, which can be faster than EM approaches [28].

For the future improvements, we shall focus on measuring the initial likelihood and the user time according to different kinds of data and distributions. PAEM is based on a simple Piecewise Aggregation technique. It may have a better global performance if a more advanced technique is used instead of Piecewise Aggregation. For this reason, we do not focus on measure the impact of w in its parameters. In a future work, we can focus on comparisons, such as the impact of different values of w and more robust techniques, like SAX [22] and its derivations. However, the time spent to pre-process the data must be lower than the original one. Otherwise, the overall performance might decrease. Another important test is to detect how efficient PAEM scales regarding models with a different number of states.

Abstract—Continuous software engineering (CSE) is an agile process that supports lightweight, flexible, and rapid software development. Decision-making is crucial for CSE, and developers need to know the decisions made and the related rationale to evolve the software. This knowledge is called decision knowledge. The management of decision knowledge in CSE environments remains unexplored. The agile manifesto suggests to value working software over comprehensive documentation as well as individuals and interactions over processes and tools. What does this mean for the documentation, exploitation, and sharing of decision knowledge? We report on results from an interview study with 24 practitioners from 17 companies on how decision knowledge is managed during CSE. The practitioners mainly capture decision knowledge in an informal way, for example, in natural language discussions. Wiki and issue tracking systems represent the preferred medium to preserve decision knowledge. Mentioned benefits are an improved decision-making process, accountability, knowledge sharing, and reuse. However, the exploitation of the captured decision knowledge remains partly unclear.

Index Terms—Decision knowledge, rationale, interview study, continuous software engineering, agile software development.

I. INTRODUCTION

Continuous software engineering (CSE) is an agile process that supports lightweight, flexible, and rapid software development [1]. This process is intertwined with ongoing issue-solving and decision-making. For example, developers make decisions regarding the software development process, existence and non-existence of software artifacts, or the software quality [2]. Developers need decision knowledge, i.e., knowledge about the decisions and their rationale, to evolve the software. Rationale covers the justification behind decisions.

CSE offers opportunities and bears challenges for the management of decision knowledge. The opportunities are that developers already document decision knowledge in documentation locations such as commit messages, issue comments, or pull requests during established development practices, e.g., when committing code changes. Thus, the documentation of decision knowledge during CSE is non-intrusive in comparison to using a separate tool. This might help to overcome the capture problem that is often mentioned in articles about decision management [3]. The challenges are that the documented decision knowledge might be hard to access and exploit for developers since it is distributed and might be not formalized. Further, decisions can rapidly be changed which might lead to an inconsistent and outdated documentation. It is unexplored how decision knowledge is managed during CSE in practice.

We conducted a semi-structured interview study with practitioners from 17 companies using CSE. We already reported on the state-of-the-practice of CSE in these companies [4], [5]. In this paper, we report on how the companies manage decision knowledge. We contribute insights on which types of decisions practitioners think are important to capture, how they capture decision knowledge, what benefits they see in capturing decision knowledge, how they share decision knowledge, and how they deal with change. These insights should help us to reach our overall goal to support software evolution with decision and usage knowledge in CSE [6], [7].

The remainder of this paper is structured as follows. In Section II, we present our research questions, the procedure of the interview study, and descriptive data of the interviewees. In Section III, we answer the research questions. Section IV discusses this work and Section V lists threats to validity. Section VI presents related work on decision knowledge management in practice. Section VII concludes the paper.

II. RESEARCH METHOD

In the following, we describe our research questions, the interview study, and data about the study participants.

A. Research Questions

We focus on four research questions, each refined by sub-questions that we asked the practitioners during the interviews.

RQ1: *Which decisions are captured, why, and how?* This research question investigates approaches to explicitly capture decisions and rationale during CSE within companies. Sub-questions are: Which types of decisions do practitioners capture? Where do practitioners capture the decisions, with which techniques and tools? Do practitioners link decisions and rationale to other software artifacts and if so, how? How do practitioners preserve the evolution history of decisions? When and how often do practitioners capture decisions? Why do practitioners capture decisions, i.e., what are the benefits and what do they do with the captured decisions?

RQ2: *Which important decisions are not captured by practitioners, why not?* This research question aims to find types of decisions that remain implicit and reasons why they are not captured. Sub-questions are: Which important decisions do practitioners not capture during CSE? Why do practitioners not capture these decisions? What would be the benefits if practitioners captured these decisions?

RQ3: *How do practitioners share decision knowledge?* We want to investigate how practitioners share decision knowledge during CSE, with these sub-questions: What are the knowledge sources from which practitioners retrieve necessary information for decisions that are not captured? How do practitioners share knowledge to avoid knowledge vaporization?

RQ4: *How do practitioners deal with changing decisions?* We aim to investigate on how practitioners deal with change, with the sub-question: How do practitioners identify parts of the system that are affected by new or changed decisions?

B. Interview Study

In the following, we summarize the realization of the interview study that is described in more detail in [4], [5].

1) *Procedure:* We performed a semi-structured interview study [8], which is a survey study and thus a means to perform a field study [9], [10]. We separated the study into a *design and planning*, *data collection*, and *data analysis* phase.

During the *design and planning* phase, we prepared a questionnaire. Its first part addresses the practitioners' background and working context. Furthermore, it contained interview questions as listed below the respective research question in Section II-A. The interviews also included research questions that are not addressed in this article (see [4], [5]). We contacted companies which to our knowledge apply CSE.

During the *data collection* phase, we conducted 20 interviews between April and September of 2017. The interviews were conducted either in person or via phone. The interviews took 70 minutes on average and were audio-recorded with the permission of the interviewees. We transcribed the audio recordings and sent the transcripts to the interviewees to correct misunderstandings. We guaranteed the anonymity of the practitioners by publishing only aggregated results.

In the *data analysis* phase, we analyzed the transcripts [11]. We utilized a *qualitative data analysis* software to apply two stages. During the first stage, we allocated answers to an interview question. Hereafter, we performed a fine-grained coding stage. To answer the interview questions concerning the types of decisions captured and not captured, we derived the codes from Kruchten's taxonomy [2]. This taxonomy distinguishes between existence decisions, non-existence decisions (bans), property decisions, and executive decisions. For the remaining interview questions, we identified emerging topics and coded the answers in terms of these topics. We analyzed the results quantitatively. In the case that two interviewees participated in an interview, we treated their answers as one subject.

2) *Participants:* During 20 interviews, we interviewed 24 practitioners from 17 companies. While seven of the companies provide consultancy services, ten companies develop software products. Based on their role description, we grouped the 24 practitioners into five categories: *CSE specialists* (5), e.g., a continuous deployment manager or a DevOps engineer, *developers* (6), *project managers* (6), *technical leaders* (6), and one *executive director*. On average, the practitioners have spent two years in the respective role, have an experience in IT projects of ten years, and participated in 19 IT projects.

III. RESULTS

We present results on the research questions introduced in Section II-A. Each subsection starts with a summary followed by a more detailed analysis of the research question.

A. Decisions Captured during CSE

In three interviews, the practitioners state that they do not capture decisions at all. In these cases, we skipped the interview questions for RQ1 and started with RQ2.

RQ1: *Which decisions are captured, why, and how?* Practitioners mainly capture executive and existence decisions regarding the software architecture and feature implementation. They mostly capture decisions in wiki and issue tracking systems in informal discussions and rely on techniques for establishing trace links and version control that come with these systems. Practitioners capture decisions as part of regular practices, such as code reviews and meetings. They mention improved decision-making, accountability, knowledge sharing, as well as reuse support as benefits. However, the exploitation of the decision knowledge is partly unclear.

1) *Types of Captured Decisions:* Twelve practitioners report that they capture *executive decisions*, i.e., decisions concerning the software development process, technologies, or applied tools. Such decisions impact the entire project or several projects. Similar to non-CSE environments, the executive decisions can be made by a steering committee. However, one practitioner highlights that CSE supports strongly that developers themselves are enabled to make high-level decisions. As examples, the practitioners mention to capture the decision to use a certain branching strategy or to do continuous delivery. One practitioner mentions to capture decisions on when they can consider a task as done, i.e., the definition of done, and on when a build can be deployed to the users. *Existence decisions* state that some elements will appear in the software [2]. Thirteen practitioners capture existence decisions concerning requirements, architecture, implementation, test cases, and bug reports. Six practitioners report that they capture decisions related to the elicitation, prioritization, and effort estimation of requirements for features. Eight practitioners mention that they capture architecture decisions and another nine mention that they capture decisions regarding the implementation of features, e.g., on why a class was created. *Non-existence decisions or bans* state that some elements will not appear in the software [2]. Five practitioners report to capture possible alternatives to solve a decision problem during their decision-making process. After evaluating the alternatives against criteria, they pick one alternative as the decision. The alternatives they discard are documented non-existence decisions. One practitioner reports to capture decisions regarding the prioritization of test cases and bug fixing activities based on risk assessment. *Property decisions* concern the quality of the system and can be guidelines, design rules, or constraints [2]. One practitioner provides the example that they captured the decision on how to deal with data inconsistency after they have replaced their relational database with a NoSQL database.

2) *Documentation Locations, Techniques, and Tools*: Practitioners use various documentation locations, techniques, and tools to capture decisions during CSE. Eight practitioners mention that they capture decisions in *external documents and tools* such as *Word* files, architecture design documents, or final project reports. Only one practitioner mentions to use an architecture management tool, which in their case is the *Enterprise Architect*. Thirteen practitioners report on using a *wiki system* such as *Confluence*. One practitioner mentions that they rely on template pages to capture decisions. Ten practitioners mention that they capture decisions in an *issue tracking and project management system*, such as *JIRA* or *Redmine*, as part of the issue description and its comments. One practitioner describes that they use a distinct discovery issue type to indicate that a decision needs to be made. Similarly, another practitioner mentions that they use a tag to mark those issues that contain an open decision. One practitioner highlights that in their opinion *pull requests* are the best place to capture decisions to implement features. They create feature branches for a requirement and create a pull request directly afterwards to discuss the feature implementation within the pull request. Another practitioner reports that they document decisions as part of the *code* in comments and in *code reviews*. Code reviews can be done in pull requests, issue comments, or using dedicated code review systems, such as *gerrit*. Three practitioners mention commit messages as a documentation location for decisions and another three mention informal communication systems, e. g., *chat tools* like *Slack*, and *emails*.

3) *Linked Artifacts*: None of the practitioners uses a particular technique to establish links between captured decision knowledge and software artifacts. However, practitioners mention techniques that come naturally with capturing decision knowledge in some documentation locations. For example, the practitioners report that the decisions captured in the issue tracking system can be traced to the respective issues such as user stories and also to artifacts that are linked to these issues, e. g., software components and code. In addition, they also mention that separate documents or wiki pages can be tagged; for instance, version numbers can enable traceability between decisions and software builds. Practitioners find it hard to keep the documentation of decisions and software artifacts in a consistent state. The practitioner using the architecture knowledge management tool criticizes that there are no links between the design models and the wiki system where they also capture decisions. They insert snapshots of the models into the wiki page, which they rate as highly unusable, especially when the models get changed. Another practitioner suggests to capture decisions as close to the code as possible.

4) *Evolution History of Decisions*: Similar to the linking of decision knowledge and artifacts, a preservation of the evolution history comes naturally in those *documentation locations that offer version control*, e. g., the issue tracking system. One practitioner describes that they have a technique to *mark a revised decision*; they link the revised decision with the new one rather than overwriting the revised decision. However, the practitioner admits that they never used the technique.

5) *Capturing Practices and Frequencies*: Six practitioners report that they mainly capture decisions *on demand*, e. g., when planning bigger updates. One practitioner states that they only capture a decision in case they need to discuss on it, i. e., for controversial issues. Seven practitioners mention that they capture decisions as part of *regular practices* such as code reviews, meeting, and retrospectives. The practitioner reporting about the tag to mark an open decision states that the product owner regularly filters for such tagged issues.

6) *Benefits and Exploitation*: Five practitioners mention that they document decisions since the documentation improves *decision-making*, i. e., leads to better decisions since the criteria become clearer. Eight practitioners state that they capture decisions and rationale for *accountability* reasons, e. g., as a proof on why a certain feature has been developed and to avoid misunderstandings in the future. One of them states to exploit captured decisions when recovering a former state of the software. Three practitioners state that they capture decisions for *knowledge sharing* purposes. Among them, one practitioner highlights that it is necessary to share the knowledge about where a new decision needs to be made, i. e., also to share issues. Two practitioners capture decisions in order to support *reuse* in the future to avoid duplicated work.

We asked the practitioners to rate the statement *The explicit capturing of decisions benefits our software development process* with one answer from a five point Likert scale. In thirteen interviews the practitioners rated this statement: one disagreed, three were neutral, and nine agreed (Figure 1). The practitioners who disagreed and were neutral emphasized that if the utilization of the captured knowledge was more clear, they would give a higher rating.

B. Decisions not Captured during CSE

Although some practitioners capture executive, existence, non-existence, and property decisions during CSE, others either a) do not capture the same type of decisions or b) provide other concrete examples for decisions that they do not capture.

RQ2: Which important decisions are not captured by practitioners, why not? Decisions regarding the CSE process, prioritization, alternatives that are not selected (non-existence decisions), and the underlying rationale stay implicit. Practitioners do not capture decision knowledge because they fear intrusiveness and inconsistency, miss clear use cases for exploitation as well as techniques and tools. They see a potential benefit in supporting software evolution through captured non-existence decisions and decisions for code.

1) *Types of Decisions not Captured*: Seven practitioners provide examples for *executive decisions* regarding the CSE process that they do not capture but that they think would be important to capture. They state that the decisions on the continuous integration and deployment pipeline and the respective stages, e. g., the develop, test, and production stages, stay implicit in the head of developers. In total, eleven practitioners mention that they do not capture certain *existence decisions*. Such decisions relate to features, software

The explicit capturing of decisions ...

Figure 1. The practitioners' attitude towards capturing decisions (above) and towards capturing decisions that they currently do not capture (below).

architecture, implementation, and tests. For example, a practitioner reports to document application programming interfaces between microservices using *Swagger* but does not capture decisions for the design of such interfaces and the underlying rationale. The practitioners report to capture the outcome value regarding the prioritization of requirements based on cost estimation, test cases based on risk estimation, and bug fixing activities. However, the rationale is not captured, especially if it comes to reprioritization. Two practitioners report that they do not capture configuration decisions, e.g., which compiler or framework versions they use. Three practitioners criticize that they do not capture the rationale behind decisions and that they do not capture decisions on why they did not pick a certain alternative for an issue, i.e., *non-existence decisions or bans* stay implicit. Two practitioners mention that they have a common understanding of certain *property decisions*, e.g., about the coding style, but that such decisions are not documented. One practitioner provides the example that they did not capture the decision whether to use either a synchronous or an asynchronous inter-service communication between microservices. The practitioner states that these kind of decisions are made very quickly and then get reused by others, but are neither discussed nor captured.

2) *Reasons why Decisions are not Captured*: Two practitioners report that the decisions on how to deploy the software used to be captured in external documents but are no longer captured since the deployment is now automated. However, they still keep the former documents to externalize this knowledge. Four practitioners see a problem in *rapid changing decisions* that lead to outdated decisions, i.e., to inconsistency between the captured decisions and their implementation. One practitioner associates the waterfall process with capturing decision knowledge. Five practitioners report that they *lack appropriate techniques or tools* to capture decisions and rationale. Three of them state that their *process is not mature enough* to involve decision management. Six practitioners do not capture decisions because they *lack techniques for an easy retrieval and exploitation* of the captured decisions. Eight practitioners fear the *overhead and the intrusiveness* of capturing decisions and rationale. They could not spend the effort and do not have enough time. One practitioner mentions that the cost-benefit-ratio would be too high if they captured more decisions than they currently do according to the 80/20 rule. However, the practitioners admit that the extra effort could be reduced by applying better capturing techniques.

3) *Potential Benefits if Captured*: As for the captured decisions, practitioners see potential benefits in establishing accountability, improving decision-making and knowledge sharing, as well as a support of reuse and maintenance activities. They also stress that capturing decisions and rationale would support continuous learning as part of the CSE process. Two practitioners see a potential benefit in retrieving decisions and rationale for code when evolving code. In their opinion, this could *ease the understanding of code*. Three practitioners state that it would be useful for them to know about alternatives for a decision and the rationale why they were not selected during software evolution. One practitioner mentions disaster recovery as an example why knowledge sharing and capturing decisions was important.

We asked the practitioners to rate the statement *The explicit capturing of decisions would benefit our software development process* regarding the decisions that they currently do not capture. Practitioners of eleven interviews rated this statement: three disagreed, one was neutral, and seven agreed (Figure 1).

C. Sharing of Decision Knowledge during CSE

We dedicated two interview questions to address this research question.

RQ3: How do practitioners share decision knowledge?

Practitioners strongly rely on face-to-face communication, i.e., colleagues' knowledge, to recover implicit decisions. To share knowledge equally they apply techniques such as pair programming and inviting all team members as reviewers to pull requests. However, they also try to recover implicit decisions using reverse engineering.

1) *Alternative Knowledge Sources*: Six practitioners state that they try to do *reverse engineering* to recover knowledge from code and issue tracking systems. Ten practitioners mention that they *ask colleagues*, which has the disadvantage that both the inquiring person and the respondent need to interrupt their current activity. One practitioner reports that they have an *emergency mobile phone* that is carried by one knowledgeable project member for a period of time; afterwards, it is passed to the next project member. Two practitioners report that it can be hard to *scan through many emails and pull requests* to recover a decision. Thus, this decision was somehow documented but hard to retrieve. Another practitioner enforces that decisions are hard to retrieve in communication channels using the slogan "if it happens in [chat tool], it did not happen".

2) *Avoidance of Knowledge Vaporization*: The practitioners try to avoid knowledge vaporization by sharing knowledge between project members. One practitioner states that in larger teams it is both necessary to share the knowledge within and across team boundaries. Knowledge management should address both the intra- and inter-team scope. Within teams, the practitioners try to share knowledge between all members as homogeneously as possible. They strongly rely on face-to-face communication. Further, one practitioner mentions that they always *invite all team members as reviewers for pull requests* and also do *pair programming* to distribute knowledge. One practitioner states that they encourage team members to always share their notes with others, e.g., by using a wiki system, instead of “writing diaries”. Two practitioners mention to have a dedicated process to onboard new project members. Generally, practitioners state that if a project member is about to leave the company, they would have a period of time during which this person tries to share and capture their knowledge.

D. Managing Changing Decisions during CSE

Overall, we received only few responses from practitioners regarding the management of changing decisions during CSE.

RQ4: *How do practitioners deal with changing decisions?*

Practitioners use cost and risk estimation as well as prioritization before integrating changing decisions. They depend on implicit knowledge and team communication to identify parts of the system affected by new or changed decisions. They rely on automated tests to detect side and ripple effects.

None of the practitioners report about a technique or tool to identify parts of the system that are affected by new or changed decisions. One practitioner reports about their *change management* process. For a change request, the project leader needs to decide whether the change will be integrated and—if so—the developers *estimate the cost* for the change, *define a priority*, and break it down into tasks. Other practitioners emphasize the importance of *automated tests* to detect side and ripple effects as well as *risk management*. One practitioner of a consulting company criticizes that workflows often do not scale when the project and the respective team sizes increase. Change impact analysis would be especially important for larger projects, however, it is not integrated since it had not been necessary at the beginning when the project was small.

IV. DISCUSSION

In the following, we discuss the results in terms of findings, problems, and our improvement ideas.

From the results of our interview study, we cannot make a clear statement of which decisions are captured and which decisions stay implicit, since some practitioners mentioned to capture decisions that others do not capture and vice versa. Yet, the answers towards RQ1 and RQ2 provide examples of decisions practitioners consider important to be captured and for which purposes. It is interesting that many practitioners find executive decisions regarding the CSE process important to be captured. Reasons might be that CSE involves a continuous

process improvement that comes with a continuous decision-making. The CSE process contains many defined workflows that developers need to decide on and for which they need to have a common understanding [1], [4].

Our findings confirm the challenges of CSE listed in Section I: In 19 interviews, the practitioners mention that their decision capturing method needs to be improved and that it is far from being perfect. Only in one interview, a practitioner in the role of a quality manager states that they are very focused to capture decisions. The degree of formalization of decision-making and documentation in practice seems to be rather low. During the interviews, only five practitioners mention to capture alternatives for a decision, i.e., non-existence decisions. However, Kruchten states that it is very important to capture non-existence decisions as they are not visible in the software artifacts and cannot be recovered using reverse engineering [2]. Also, the underlying rationale is not captured systematically. The practitioners argue to not capture decisions since the rapid change would make them outdated soon. Further, the practitioners state that the usage of too many tools for capturing decisions can be frustrating. As reasons they list a) redundancy, i.e., they need to document knowledge in more than one tool, which means twice the effort and might result in an inconsistent documentation, and b) a workflow interruption, i.e., they have to change their working context for documentation purposes, which means intrusiveness.

Although the practitioners confirm to document decision knowledge in typical documentation locations, e.g., the issue tracking system, the opportunities of CSE for an improved decision knowledge management are not yet exhausted. The practitioners stress that the utilization of the captured decision knowledge is not clear to them and that it is not exploited in a proper way. They also highlight that they have difficulties to find and retrieve the decisions—especially if captured in informal communication channels such as *Slack*. In summary, the capturing and exploitation of decision knowledge needs to be better integrated into the daily practices of developers.

We aim to provide solution proposals for these findings applicable for practitioners [12]. In [7] and [13], we describe ideas for a *continuous decision knowledge management (ConDec)* as part of CSE and in [14] we present a dashboard for knowledge visualization. The ConDec tool support¹ integrates with existing tools to minimize the intrusiveness of the decision knowledge management, e.g., with the issue tracking system. It provides many features for capturing and exploiting decision knowledge during CSE and supports knowledge sharing and changes. For example, ConDec enables the explicit, formal capture of decision knowledge in the description and comments of *JIRA* issues, commit messages, and code comments. It does not restrict the type of decisions, i.e., developers can capture executive, existence, non-existence, and property decisions. It enables developers to view decision knowledge in relation to software artifacts such as features and code. We evaluate the ConDec tool support in agile student courses [15].

V. THREATS TO VALIDITY

We conducted the interview study from a positivist philosophical stance, i.e., we try to draw conclusions on how practitioners manage decision knowledge during CSE from the interviews. We discuss the four criteria for validity as usually done for empirical research with a positivist stance [9], [8]. A more detailed discussion can be found in [4], [5].

Construct validity focuses on whether the theoretical constructs are measured and interpreted correctly. The practitioners might have interpreted the interview questions different to what we intended. To reveal misinterpretations, we allowed them to ask questions at any time and conducted two interviews with colleagues that we discussed afterwards. We used open-ended questions to elicit as much information as possible.

Internal validity concerns whether the results we draw really follow from the data, e.g., whether there are confounding factors that influence the results. The practitioners might have provided answers that do not fully reflect their daily work, since they knew that the results would be published. We guaranteed the full anonymity of interviewees and companies to address this. The interpretation of answers might be biased by the authors' *a priori* expectations, which we addressed by coding the transcriptions and discussing the codes.

External validity addresses the generalizability of the study results. We contacted companies that we already knew, which might result in a selection bias. It is mitigated by the fact that the authors are from two universities with different industrial contacts. Interviews are subjective, since they rely on the practitioners' statements. To reduce subjectivity, we conducted 20 interviews, to acquire a wider set of opinions.

Reliability validity concerns the study's dependency on specific researchers. After we carried out coding training and checked intercoder reliability, two authors individually coded different transcripts. We addressed this threat by discussing questions during coding. In addition, a third author of this paper supervised the interview analysis.

VI. RELATED WORK

Miesbauer and Weinreich collected 120 examples of decisions made in practice using an interview study [16]. Similar to our study, they classified these decisions according to Kruchten's taxonomy [2] and list documentation locations. They also found that the majority of the decisions were existence decisions and that property decisions were rarely mentioned. In contrast to our study, they found that practitioners did not mention non-existence decisions. They did not ask for practitioners' knowledge sharing and change management practices, but list influence factors for decision-making.

Similar to our work, Furtado *et al.* explore tools, processes, and benefits of knowledge management [17]. They found *Google Drive* and email lists applied most prevalent to capture knowledge and point out the value of the informal messaging service *Slack* to improve knowledge sharing. In contrast to our study, they did not focus on decision knowledge and their results are limited to one institution only.

VII. CONCLUSION

We reported on findings from an interview study on how practitioners manage decision knowledge in CSE environments. The practitioners mainly capture decision knowledge in an informal way, in wiki and issue tracking systems. The exploitation of the captured decision knowledge is partly unclear and needs to be improved. We develop techniques and tool support for a continuous decision knowledge management.

ACKNOWLEDGEMENTS

This work was supported by the DFG (German Research Foundation) under the Priority Programme SPP1593: Design For Future – Managed Software Evolution (CURES project). We thank the practitioners for sharing their insights.

Abstract—The use of biological signals to understand software development has become more popular in the last few years but poses new challenges with respect to the overall experimental settings. In this paper we present such challenges and the approach we took to overcome them. We illustrate our approach by evaluating two programming situations: pair programming and programming with music. The subjects involved in the experimentation are mostly students, however, in the largest case we involved graduate students coming from industry with at least three years of working experience. The results in general support the validity of this approach and encourage to go further in this research line. Moreover, as a byproduct, the analysis of pair programming confirms, from a biological perspective, early hypotheses that pair programming induces higher level of concentration.

Index Terms—Empirical methods, software experimentation

I. INTRODUCTION

Software is the result of the creating activity of software developers. It is clear that improving developers' working conditions might lead to improving the quality of created software the same as productivity of the employer. It is also should be said that working in an area full of distracting agents or activities will decrease the worker's performance. There are lots of different assumptions and myths on how to improve the software development process, but almost no one has an argued proof. Moreover, there is no a general way for evaluating a developer's physical and mental state. As a consequence the state of mind of developers play a major role in the quality and the productivity of the produced software systems. In the recent years, the research arena has become more aware of this fact and new studies have emerge, some of which also directly analyzing biological signals. However, the overall research field in this area is still in its infancy. This paper presents the early results and challenges of using a full EEG to understand the brain activity during coding, in research that started about two years ago [1]. Specifically, we are trying to evaluate empirically how different settings may induce different brainwaves, and from this, understand the mental states of developers in such different settings and thus devise the most suited for a variety of work tasks and conditions. In this prototypical phase, a wide approach has been taken in collecting and analyzing the data, considering "standard" working tasks, in essence preferring breadth over depth in the analysis [27].

Our intention is threefold:

- to perform a preliminary observational evaluation of the areas where phenomena could occur for a followup deeper evaluation;
- to gather a better understanding of the opportunities and the problems arising when collecting and analyzing developers data using EEG, in the hope of facilitating future research;
- to expand our research by supplying our initial results to researchers and research groups interested in replicating our findings.

We have considered two settings, primarily because they represented two situations already present in our working context:

- developing using pair programming (the largest part of the experiment);
- developing with music in the background (still considered, given the interest of the involved researchers).

Notice that we have decided to include in this paper also the small portion of collected data referring to programming with music, as it uses a different experimental protocol which adds a significant breadth at this initial investigation.

The subjects involved in our research belong primarily to two groups:

- graduate students with at least three years of working experience in the industry, who can be assimilated to professionals
- undergraduate students

The unique contribution of this work is that the results in general support the validity of this approach and encourage us to go further in this research line. Moreover, as a byproduct, the analysis of pair programming confirms, from a biological perspective, early hypotheses that pair programming induces higher level of concentration; this appears quite remarkable.

This paper is organized as follows. Section II presents the overall background of the paper. Section III outlines the approach taken to analyze the data and how the data was collected. Section IV details the analysis of the data that we have collected. Section V summarizes the early results that we have obtained so far. Section VI outlines the challenges that we have faced in this kind of empirical work to share it with

other researchers worldwide in the quest of identifying best practices. Section VII draws some conclusions.

TABLE I
SUMMARY OF THE EXPERIMENTS

Id	Situation	Subjects	N	Analysis
1	Pair programming	Graduate students with working experience	10	ERD
2	Pair programming	Undergraduate	3	Correlation
3	Programming with music	Undergraduate	2	ERD
4	Programming with music	Undergraduate	2	Correlation

II. BACKGROUND

As mentioned, there has been an increased interest in using biological signals to understand the mind of developers, in particular using three main kinds of devices:

- electroencephalogram (EEG),
- functional magnetic resonance imaging (fMRI),
- various bio-metric sensors.

a) Electroencephalogram: This is the technique we are considering. To our knowledge, so far a complete portable EEG device has been used in areas related to software engineering only in the study conducted by Lee et al. (2016) [16] on exploring how the mind of developers evolved from novice to experts in program comprehension tasks.

b) Functional magnetic resonance imaging: Functional magnetic resonance imaging (fMRI) provides indirect estimation of brain activity, measuring metabolic changes in blood flow and oxygen consumption as a result of increased underlying neural activity. This technique allows the detection of active regions of the brain [8]. As a result, fMRI is widely used to determine specific brain regions which are responsible for the certain mental activity. In order to learn about software developers' brain activity, researchers chose code review and code comprehension as the primary activities for which brain activity needs to be understood [8], [22], [23].

Siegmund et al. (2014) detected activation specific Broadmann-areas during code comprehension [22]. In their followup work (2017) they investigated the difference between bottom-up program comprehension and comprehension with semantic cues in terms of brain areas involved [23]. This study uses very accurate techniques to explore the work of the brain, the fMRI. Floyd et al. (2017) have performed a similar study applying fMRI to understand the mental activities surrounding program comprehension [9].

c) Ensemble of bio-metric sensors: An alternative approach has been to use an ensemble of bio-metric sensors like eye trackers for measuring pupil size and eye blinks, electroencephalography to determine brain activity, electrodermal activity sensors to detect skin-related activity, and heart-related sensors [10], [17], [29].

TABLE II
TECHNICAL CHARACTERISTICS OF THE MITSAR SMART-BCI EEG DEVICE

Options	Smart BCI EEG headset
EEG channels	24
Poly channel	1 for ECG
Reference	A1, A2, (A1+A2)/2, Cz, REF
Frequency band	0(DC) 70 Hz
Sampling rate	2000 Hz
Storage rate	250 Hz
Noise	1.2 μ V peak-to-peak
Input range	$\pm 300\mu$ V

This approach was applied in a series of investigations which will be described below. The main interest in these investigations was to obtain metrics that correlate with software developers performance. Züger and Fritz (2015) used interruptibility [29] while Müller and Fritz (2015) used positive and negative emotions of software developers [17] as metrics of progress in the change task. They processed the data from multiple bio-sensors and applied methods of supervised learning (Naive Bayes) to distinguish levels of these cognitive states [17], [29].

In these studies, monitoring the state of the mind in depth was limited because:

- the assessment of emotions was performed subjectively by the participants [17];
- a single channel EEG device was used, which may result in an error of up to 50% [21].

III. APPROACH TO DATA ANALYSIS

a) Infrastructure used: We used wireless 24 channel Mitsar SMART-BCI elastic cap for our experiment (details are in Table II). The placement of electrodes was according to the standard 10-20 scheme. Technical characteristics of the Mitsar Smart-BCI EEG device are presented in II. One of the very important steps of EEG recording is the preparation of the EEG cap. We used the canonical type of cleaning before the experiment which is cleaning with spirit. During the data recording, we also used conductive gel to provide a better connection between electrodes and scalp.

Since we use a multi-channel EEG device, the first step to undertake is to select the channels that are the core of the analysis. On the one hand, many channels provide a wide range of information from the whole scalp. On the other hand, this information can be redundant. Moreover, electrodes placed on different parts of the scalp are affected by different types of EEG artifacts, e.g. frontal electrodes are more likely to be affected by muscle and eye movements. During the experimental set up of the device, we found out that a signal from the frontal electrodes cannot be cleaned with EEG preprocessing techniques like Individual Component Analysis and manual filtering. We did not propose any other methods than these two for frontal electrodes since we found out for this particular experiment, central electrodes would

be enough for the analysis and result. Based on this fact we decided to analyze only central electrodes (F3, Fz, F4, C3, Cz, C4, P3, Pz, P4) since they provide proper quality data which can be used in further analysis.

The collected data have a lot of interference including:

- imperfection of EEG equipment;
- metal objects nearby;
- Wi-Fi and mobile network, mobile phones;
- artifacts from the person (e.g. blinking, jaw movements, sneeze);
- harsh background sounds;
- size of the cap.

Moreover, there are patterns to take into account, like the age, the gender, and other physiological characteristics of the subject.

Therefore, after the selection of the channels, we have performed a cleaning of the data with the following filters:

- **Amplitude filtering:** All data which was not in the range $[-200\mu V; +200\mu V]$ we considered as an artifact and removed from the signal. If the total share of noisy data in the channel was more than 20% we considered the channel as compromised and removed it from the dataset.
- **High and low pass filters:** The range of filter was picked according to the possible variance of individual alpha and theta waves and equaled to $[2Hz; 15Hz]$.
- A **notch filter** was used to remove the noise from AC lines.

b) *Processing of the EEG data:* As mentioned above, we decided to use only clean channels (data). The choice of clean channels was reasoned by EEG artifacts that are very hard to be recovered to the original data. Moreover, we use the following infrastructure:

- **Programming tools:** Anaconda 3 Python distribution, NumPy, and SciPy packs, MNE 0.16.1
- **Electrodes:** 'F3-Cz', 'Fz-Cz', 'F4-Cz', 'C3-Cz', 'C4-Cz', 'P3-Cz', 'Pz-Cz', 'P4-Cz' (depending on the setting)
- **Filtering:** Finite impulse response method, as provided by MNE library

Our approach is described in Algorithm 1, implemented, as mentioned using Python 3 with scipy and numpy libraries.

c) *Analysis of the EEG data:* The first step of analysing the data is an adjustment of alpha and theta waves ranges since they could be different for various ages. The variability of alpha waves in age-matched groups has been shown to have a normal distribution ($\mu = 10Hz$, $\sigma = 1Hz$) and exhibits tonic changes, increasing from childhood to adulthood, then declining according to the following formula [13]: $PeakAlphaFrequency = 11.95 - 0.053 \times Age$

We computed peak alpha frequency for each participant (or Individual Alpha Frequency - IAF) and used as the anchor point for calculating alpha sub-bands.

The importance of alpha sub-bands comes from the fact that they improve the accuracy of amplitude measures and more accurately reacts on functional differences of the different oscillators, i.e., functional groupings of neurons, which

Data: EEG measurements of participants

Result: ERD Distributions

for each measurement in Data **do**

IAF(individual α frequency) = $11.95 - 0.053 \cdot Age$;
 theta = [IAF - 6; IAF - 4];
 L1A = [IAF - 4; IAF - 2];
 L2A = [IAF - 2; IAF];
 UA = [IAF; IAF + 2];
 fft = FFT(measurment) erdall= (calibration
 (participant) - fft) / calibration(participant);

end

for each subband **do**

erd [subband] = mean(erdall [subband]);

end

Algorithm 1: ERD distribution calculating algorithm

contribute to alpha power. For instance, the phasic changes in the lower-1 alpha (L1A) and lower-2 alpha (L2A) sub-bands are considered to be as an indicator of task-related attentional demands including both components of attention - alertness and arousal [14]. On the other hand upper alpha (UA) changes correlates with semantic memory processing and synchronization in the theta band reflects episodic memory and the encoding of new information [14]. Concluding all above it can be said that our choice of features depended on the connection between the EEG feature and the cognitive processes that this feature can represent.

In our study we used these ranges of sub-bands:

- L1A range is [IAF - 4Hz ; IAF - 2Hz]
- L2A range is [IAF - 2Hz; IAF]
- UA range is [IAF ; IAF + 2Hz]
- Theta range is [IAF - 6Hz ; IAF - 4Hz]

Next step is counting the number of waves included in the corresponding interval. In this way, we can evaluate the brain activity at each time point.

The analysis is then centered in two main techniques:

- ERD,
- Correlations of brainwaves.

The **ERD** (Event-Related Desynchronization) is a measure of the level to which neurons no longer oscillate in synchrony as they become activated to process the given task [5]. Consequently, more task demanding work should cause bigger ERD difference between rest and programming periods. ERD is calculated as it is shown in the formula below:

$$ERD = \frac{(amplitude)_{rest} - (amplitude)_{programming}}{(amplitude)_{rest}} \times 100\%$$

The ERD is computed for 2000ms window of the signal via Fast Fourier Transformation (FFT). As a result, we obtain a time-series or distribution of ERD for each sub-band for each different programming activity. The name convention of the ERD time-series is presented in Table VI.

Intuitively calculating ERD is subtracting the values of the spectrum from calibration value and normalizing on the

calibration value. As a result we obtain a normalized spectrum of difference in which we find a mean value for the specific frequency ranges. We performed this procedure for each channel and calculated resulted distributions as the average among all channels. For example, we can have active spectrum only for alpha and theta waves as seen from Table III in case of pair programming. This implies that the result can vary and we can get active spectrum for other different waves based on different ERD value based on different types of experiment.

The analysis of the **correlation of brainwaves** identifies the relationships existing among theta and L1-alpha waves, L2-alpha and upper alpha waves. Strong correlations explain different mental activities and statuses.

For instance from all the data obtained from EEG, individual L1-alpha waves stands out as a measure that can be correlated with other brainwaves such as L2-alpha or upper alpha waves. For example, in our studies correlation between these waves in case of pair programming was slightly higher as compared to solo programming whereas this correlation was lower in the case of programming with music rather than without music. These examples from our study imply that correlation can differ affecting the results to be higher or lower depending on the type of experiments we are performing.

d) Experimental protocol: In all cases the students were divided in two groups: treatment and control, even if in one case the control group was very small; again, please remember that the goal of this study is to determine in practice the feasibility of the approach rather than performing sound and reliable observation for the situation under consideration. Each part of the experimentation was scheduled in a separate day and, given the initial availability of two EEG device, when two subjects were involved, they were analyzed together. The following is the detailed steps and here P1 indicates participant one and and P2 indicates participant two.

The steps for the analysis of pair programming have been:

- 1) Calibrating P1 and P2. The calibration part consists of two parts. First one is when subjects sit with closed eyes in front of the computer in a restful state and the second one is the same but with opened eyes. The steps are required to measure alpha and theta synchronizations during calm state.
- 2) Solo programming of P1 and P2 (60 minutes).
- 3) Break, rest period without hard mental activity (10 minutes).
- 4) Pair programming, P1 is on driver mode, P2 is a navigator (60 minutes).
- 5) Break, rest period without hard mental activity (10 minutes).
- 6) Pair programming, P1 is on navigator mode, P1 is a driver (60 minutes).

The steps for the analysis of the effect of music have been:

- 1) Calibration P1 (with and without music): First, the subject sits with the closed eyes in front of the computer in a calm state and for the second time with the same instructions but with opened eyes. As it was mentioned

before, these steps and instructions are necessary to determine the alpha and theta synchronization during the restful state.

- 2) P1 starts programming for the given task without music. (60 minutes)
- 3) Rest period without any types of hard mental activity. P1 is on calm state (break) for 10 minutes.
- 4) P1 starts programming for the given task and listening for a music (the music was chosen by P1 according to his personal preferences). (60 minutes)

e) Description of the collected data: As mentioned, the subjects involved in our research belong primarily to two groups:

- volunteer graduate students with at least three years of working experience in the industry, who can be assimilated to professionals,
- volunteer undergraduate students.

The graduate students were mostly recruited during the so-called “bootcamp,” a two weeks course preparing our students to of preparation to study. Such students are between 23 and 30 years of age and come directly from industry with at least 3 years of experience, so we can consider them almost as professional for the purpose of the generalizability of data.

The undergraduate students were mostly second year students participating at the data collection for curiosity and interest in neurosciences.

Excluding calibration data, the dataset contains 36 hours of recorded EEG data mostly for the analysis of pair programming (11 hours for driver, 11 for navigator and 12 for solo) and 2 hours for programming with music.

IV. ANALYSIS OF THE COLLECTED DATA

Pair programming (PP) is a technique of extreme programming and other agile methods where two developers work together on one workstation, one being the “driver,” who uses the keyboard and write the code, the other being the “navigator” who provides systematic guidance to the driver [12]. Pair programming was picked as a primary topic of the study since it may influence on software developer’s productivity and attention. There have been multiple studies on pair programming evidencing its pros and cons, the pros including: reducing a defect rate, improving the design, increasing productivity [6], and increased concentration of developers [25]. Music Programming is a common practice but, despite of this, rarely investigated: developers and programmers listen to music of their choice while coding.

Our experiment about Pair Programming involved 11 graduate students with ERD to analyse the data and 3 undergraduate students with correlation analysis; our experiment with Music Programming involved 2 undergraduate students and used correlation to analyse the data (Table I).

a) ERD: During the evaluation using ERD, we compare the ERD values in 3 working cases: solo, driver, and navigator. We check the difference between such values using the non-parametric Mann-Whitney test and we determine the significance of the difference. As mention, given the exploratory

goals of this paper we do not systematically track the significance of the result; in this case we use the significance level as an indication of a significant effect of the “treatment,” that is, working in pair or working with music.

Specifically, we consider ERD of theta waves, which desynchronizes (decreases) with the higher memory load, ERD of all alpha ranges (L1A, L2A, UA) synchronizes (increases) with a higher level of attention and semantic memory processing (in other words, the higher value of ERD in alpha band indicates higher attention and semantic memory processing during the given task for the given participant). Using this information we can calculate statistics of ERD distributions of the same sub-bands but from the different activities and compare them.

TABLE III
VALUES OF ERD IN THE FIRST EXPERIMENT

Sub-band	Highest value	Significance	Interpretation
L1A	Pair - navigator	Yes	Higher attention required
L2A	Pair - navigator	No	As above
UA	Not conclusive	No	Nothing
Theta	Solo	No	Usually opposite of L1A, so confirms the results

b) *Correlations*: Using correlations we compare Pearson’s correlation coefficients between the 3 cases of pair/solo programming (solo, pair/driver, and pair/navigator) and the 2 cases of programming with and without music. The brain-waves differ from each other while any kind of mental or physical activity is done by the object. As theta waves decrease with the higher memory load and all the alpha ranges (L1A, L2A, UA) increase with a higher level of attention and semantic memory processing, the correlation of this waves should differ over time. Using this information we can calculate the statistics of the correlation of the same sub-bands from the different activities and compare them. To perform a comparison of Correlation, we performed Pearson’s correlation coefficients (Tables IV and V).

V. RESULTS AND DISCUSSION

a) *Analysis with ERD*: In general, desynchronization in the lower alpha band reflects higher levels of attention [14]; for such band in the case pair programming we obtained the highest ERD for pair-navigator mode and equal values for

TABLE IV
CORRELATION ANALYSIS FOR PAIR PROGRAMMING

Participant	Theta and L1- α	L2-alpha and Upper α
1 (PP-Driver)	0.9	0.8
1 (PP-Navigator)	0.86	0.82
1 (Solo)	0.80	0.86
2 (PP-Driver)	0.799	0.9
2 (PP-Navigator)	0.81	0.85
2 (Solo)	0.84	0.87
3 (PP-Driver)	0.88	0.82
3 (PP-Navigator)	0.93	0.73
3 (Solo)	0.875	0.81

TABLE V
CORRELATION ANALYSIS FOR PROGRAMMING WITH MUSIC

Environment	Theta and L1-alpha	L2-alpha and Upper alpha
With music (Participant 1)	0.825	0.878
Without music (Participant 1)	0.875	0.815
With music (Participant 2)	0.827	0.91
Without music (Participant 2)	0.827	0.835

solo and pair-driver mode (Table III). It may mean that pair programming in navigator mode requires more attention, and this reflects the intuition that the navigator position requires evaluating and guiding the development, which in turn intuitively requires a significant effort of attention, also because the navigator is not involved in a physical contact with the keyboard. The analysis of UA was not conclusive.

According to Klimesch et. al. [14] synchronization in the theta band reflects episodic memory and the encoding of new information. For the theta region we obtained a highest value for solo programming, followed by the navigator, and finally the driver. Theta and alpha waves are supposed to be invariant, which roughly means when alpha increases, theta decreases, and vice versa. As a result, we have that higher desynchronization means lower synchronization. If we denote ERS as event-related synchronization we get the following relation: $ERS_{pair-driver} > ERS_{pair-navigator} > ERS_{solo}$.

Anyway, for now, it is difficult to interpret the meaning of difference in episodic memory working. However, the second part which states the theta band reflects the encoding of new information might be true in case of pair programming.

The analysis of ERD for programming with music did not evidence any specific patterns, perhaps also because of the limited dataset available.

b) *Analysis with correlations*: The analysis of the correlation for pair programming (Table IV) appears somehow to support the claims made with the analysis of ERD. Indeed, the very small dataset is not conclusive for practical reasons, still seeing a second experiment conducted with a different approach hinting at the same pattern as the first one, provides some observational confirmation of the statement that the navigator in pair programming has higher level of attention.

The analysis of the correlation with music (Table V) is again not conclusive, and again we can replicate the limits of the small dataset.

VI. CHALLENGES ENCOUNTERED

Since the goal of this paper is primarily to provide a reference for future experiences in using biological sensors to detect the states of minds of developers, it is important to underline the different challenges that emerged during the experimentations, so that future research can take suitable precautions to mitigate or even eliminate them:

- 1) As this was quite a new experiment in the field of computer science, there was a lack of other works and papers related to the field of computer science to structure our overall experimental setting, therefore it took a considerable effort to define a solid experimental protocol and in due course a significant amount of data got lost.
- 2) The EEG picked up a lot of muscle activity, clouding our data. So subjects had to stay as still as possible and blink as minimum as possible.
- 3) The device could not record from the subjects with the thick hair even with the addition of the gel.
- 4) The EEG experiment was highly influenced by environment noise, so a lot of filtering was done. Location of the experiment highly depends on the goal of the experiment, so it was difficult to find its perfect place.
- 5) Large number of subjects were required and a huge number of experiments were conducted for extraction of useful data and information from the device because the device had poor signal to noise ratio, therefore, this approach is quite effort intensive.
- 6) It took a long time to start the experiment because the device required a complex arrangement of many electrodes around the head with the use of different gels; moreover, also the setup of the computer software required some time.

VII. DISCUSSION AND CONCLUSION

As mentioned, the goal of our work is to provide a new contribution to people interested in performing analysis of software development using biological signals, thus discovering a whole new understanding of the state of mind of developers, who are the main resource in the production of software. To this end we have run four experiments, the largest of which involving 10 graduate students with at least three years of programming experience, so with a professional background similar to developers working in companies, thus providing higher credibility to our observational findings. We have run three additional very small experiments with undergraduate students. The subject of the first largest experiment and of a second small experiment was to analyze pair programming, while the other two small experiments focused on programming with music.

The first result that we have obtained is that, despite several possible challenges, some of which discussed in Section VI, the approach appears to work. For the largest experiment, anyway involving only 10 subjects, we did obtain some observational conclusions confirming previous evidence that pair programming increases the level of attention from a clear biological standpoint. We think that this result is remarkable.

For the case of programming with music, we have not been able to achieve any significant result. We are not discouraged by this – it is an effect of the significant amount of work required to run such experiment and we think that a larger experiment may lead to more conclusive statements.

We have also seen that as the time progresses, indeed, we have become more effective in collecting the required data, so there is an important learning phase that, while it cannot eliminate the significant amount of effort required by this approach, still can partially mitigate it. As a lateral comment, we have not identified any pattern in the data we have lost, so we assume that the results that we have obtained in the largest experiment related to pair programming does not suffer of it.

Moreover a growing number of experiments could be relevant in software relevant for safety critical situations, infrastructures, etc. [2]–[4], [7], [24], [28] or during learning phases [11], [18]. It would also be interesting to involve the open source community in sharing personal data [15], [19], [20], [26].

Summing up, based on all the results, our future work will be based on more focused experimentation on specific programming situations using larger datasets of students and then, indeed, trying to move our analysis to the industry. Also we will try to use not only central electrodes but also the frontal electrodes and for the evaluation, not only correlation and ERD but also other available techniques will be used, thus generating more accurate and comparable results. After applying different approaches for EEG data processing it was found that described correlation methods does not provide veridical outcomes for the further analysis so it should not be used for analyzing EEG data. The observed results might be used for identifying the most productive programming techniques. In the future researches we will test other conditions which may have an impact on developer's productivity.

Abstract—Because verification and validation are important activities in model driven engineering (MDE), verifying interfaces preservation is considered an interesting step to understand the evolution of data models by analyzing their interfaces. The interfaces defined on a data model can be used to define model evolution correctness using observational semantics. In this paper, we propose an approach that supports rigorous analysis, verification and validation of behavioral re-factoring. Our work addresses the problem of data model evolution in a formal modelling and verification setting. We focus on data conservation in the specific context of space engineering, where data models may involve thousands of concepts, relationships and each concept has a number of fields or attributes and each relationship has a number of properties.

Index Terms—data models evolution, data model transformation, data models comparison (Bi-simulation), graphs, labelled transition system (LTS)

I. INTRODUCTION

Because project stakeholders require an easy and safe (behaviour-preserving) technique to update model-based applications, several approaches based on formal methods have been proposed [1]–[3]. This work gave rise to several formal comparison approaches [4]–[6]. In this paper, we propose an approach that supports analysis of models behavior preservation after re-factoring. It consists in checking that the APIs (Application Programming Interfaces) of a source data model still hold on the target data model. To address the problem of data model evolution, we have identified three requirements.

Accessibility. Access to model concepts shall be preserved after model refactoring i.e. source model *getters*

or *setters* shall be preserved. Accessibility requirement becomes a path problem in a graph.

Cardinalities. The cardinalities defining the extensions of the relationships between source model concepts (specifying the allowed number or range of instances) shall be preserved after model refactoring.

Knowledge. In order to strengthen concepts evolution, a knowledge base can be associated to the refactoring process to define possible knowledge equivalences or relationships between model concepts. Ontologies are good candidates for such knowledge bases [7].

This paper deals with the *accessibility* requirement. It particularly focuses on the models produced in space engineering.

This paper is organized as follows. Section 2 overviews related work. The proposed approach to handle model evolution and data migration is presented in Section 3. Basic definitions are presented in Section 4. Section 5 summarizes our results, overviews our experiments and positions our approach with respect to the state of the art. Finally, section 6 concludes and provides future work.

II. RELATED WORK

The problem of model refactoring has been addressed by several authors with different perspectives.

Application Programming Interfaces (API). They offer operators to process model concepts by encapsulating modelling details. [8] proposed two categories of application interfaces: external and internal ones. External APIs are designed by library maintainers for clients usage while internal ones are used by the library

code itself. To automatically collect refactoring operations between two APIs versions, [8] uses the *Reffinder* tool, which identifies up to different 52 refactoring types between two API versions. The identified refactoring types are structural, only detectable by mechanical transformations. However, [9] observes that APIs breaking changes are not involved in refactorings. In this case, an application built with an older version of the component API, may fail under a new component API version. When the problem is visible, the application fails to compile or to link. Moreover, it may succeed to compile but its behaviour may be altered [10].

Refactoring. Refactoring-based migration tools are discussed in [11] where the research CatchUp tool is used to update applications. It uses refactorings descriptions to help application developers migrate their applications to a new version. It aims to update applications by recording and playing back the refactorings. Only few refactorings have full records and replay support. According to [10], refactoring at model level is inherently more challenging due to difficulties in assessing the potential impact on structural and behavioral features of the software system.

Data models comparison. Authors in [6] address the problem of user interface (UI) evolution. They focus on the user interface behaviour preservation and study the design process of a user interface resulting from the evolution of a former user interface due to the introduction of new devices and/or new interaction capabilities. Interface behaviors are described by labelled transition systems (LTS) and comparison is handled by bi-simulation of LTS. Furthermore, [4] describe how user interfaces equivalence, with respect to their interaction capabilities and appearance, can be measured. The UI divergences are highlighted, and the possibility of leaving these divergences out of the analysis is provided.

Our previous work [12] proposes an intrusive approach to manage model evolution based on structural differences. It results in a set of evolution operators from source to target models. Models are inspected to identify a set of differences and may produce false positives/false negatives.

In this paper, we propose a non-intrusive approach to handle model evolution. Instead of using a syntactical approach, we rely on API preservation. We consider that a data model evolution is correct if the source data model API is preserved in the target one. The approach is based on path access preservation and graph bi-simulation [13].

III. HANDLING MODEL EVOLUTION AND DATA MIGRATION: OUR APPROACH

In order to handle the semantic data changes involved in the development and exploitation of complex systems in a critical application domain like space engineering, we need to design a rigorous protocol to control the semantic model evolution and data migration.

The approach we propose to compare a source and a target data model relies on 4 steps. Each step manipulates graphs to handle modelling language's semantic evolution. Fig. 1 depicts the defined approach.

- **Step 1. Data models refactoring (interpretation).** It identifies, in each data model, the concepts altered by the evolution. Two input data models will be compared according to these shared identified concepts. According to the latter, both source and target data models are interpreted into a shared model. We use labelled directed graphs (LDG) as ground shared model. Two LDG are produced for source (LDG_s) and target (LDG_t).
- **Step 2. Data models projection.** For each LDG produced from Step 1, a set of labelled transition systems (LTS) with different initial states is produced.
- **Step 3. LTS comparison.** The obtained LTS for both source and target data models are compared using a simulation relationship. Each target LTS shall simulate the corresponding source LTS. When all the source LTS are simulated by the target ones, concept access path preservation is ensured.
- **Step 4. Data conservation.** If step 3 succeeds, source data instances conforming to source and target data models are migrated. The migration procedure is defined depending on the kind of established simulation relation of step 3: strong simulation (source data instances are reused) or weak simulation (source data instances are refactored using the API corresponding to the path identified by the simulation relation).

IV. FORMALISATION OF OUR APPROACH

For the *accessibility* requirement identified in section I, and according to step 1, we define *LDG* as the unified ground model in which data models are transposed.

A. A formal model for checking data model evolution

In the following, C , $attr$ and Bt denote the set of data model concepts (classes, entities, etc.) of attributes and of basic types (Boolean, Integer, etc.).

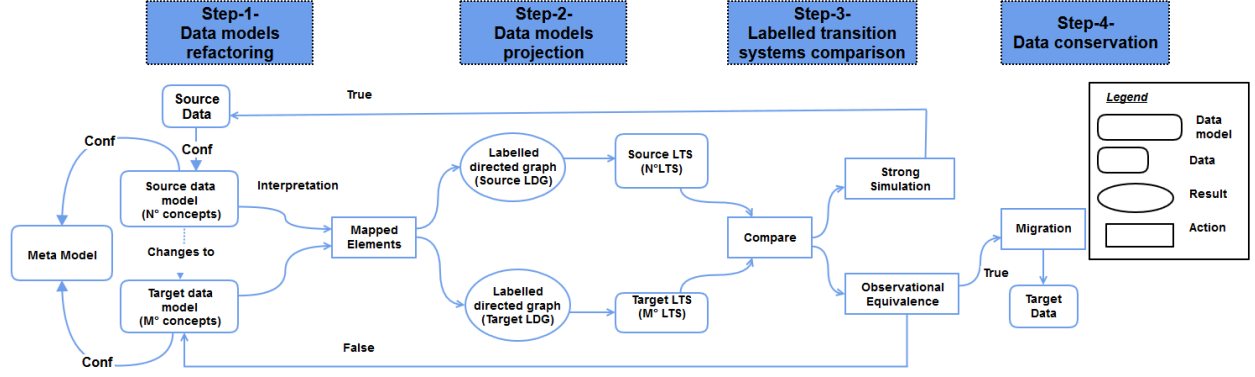

Fig. 1. A four steps based approach for data migration.

Definition 1: A Labelled Directed Graph $ldg \in LDG$ is a graph $ldg = (V, E)$ where

- $V = C \times \mathbb{P}(attr \times Bt)$ is a non-empty set of nodes. Each node represents a concept and its attributes.
- $E \subseteq V \times label \times V$ is a set of directed edges denoting the relations between the concepts.

For any $e = (v_s, l, v_t) \in E$, v_s and v_t represent the source and target node of edge e . Node $v = (c, \{(a_1, t_1), \dots, (a_n, t_n)\}) \in C \times \mathbb{P}(attr \times Bt)$ defines

- c as a concept (class, entity, relation, etc.), with
- $\{(a_1, t_1), \dots, (a_n, t_n)\}$ as a set of typed attributes.

We have considered (l) as a *label* $\subseteq \{isa, refs, haspart, partof, ref, cast, prop\}$ the set of relations for: inheritance *is_a*, aggregation *refs*, composition *haspart*, reflexive composition *partof*, references between concepts *ref*, casting *cast* and association property *prop*. Other relations may be studied for other analyzed data modelling language.

Definition 2: A labelled transition system lts is a structure $lts = (S, s_0, T, \rightarrow)$ where S is a finite number of states, $s_0 \in S$ is an initial state, T denotes a set of labels and $\rightarrow \subseteq S \times T \times S$ is a transition relation. The specific label $\tau \in T$ denotes empty label used to model internal actions, i.e., non observable actions in our approach. We note LTS as the set of lts and T^* as the set of all possible sequences built on labels of T [13].

LTS is the projection of graph LDG on each concept, i.e. each graph ldg has many lts with different initial states corresponding to different concepts.

Step1. Interpretation

Interpretation is the process that produces a graph $g \in LDG$ from a conceptual model $cm \in CM$ where CM is

a set of conceptual models like UML, Entity-Relation (ER), XIF¹.

We denote $CM \xrightarrow{Int} LDG$ and $g = Int(cm)$ the function that describes this process. Each concept (e.g. a class for UML diagrams, an entity for ER, an element for an XIF data model) resp. each concept relation (e.g. inheritance, class association, an entity relation) of cm is interpreted by a node resp. by an edge in the graph g .

Step2. Projection

Projection is the process that produces a set $LTS = \{lts_1, \dots, lts_n\}$ of $lts \subseteq LTS$ from a graph $ldg = (V, E) \in LDG$ where n corresponds to the number of nodes in g . We denote $LDG \xrightarrow{Proj} LTS$ and $LTS = Proj(g)$ the function that describes this process. The following transformation rules for projection define a lts .

Nodes of $V = C \times \mathbb{P}(attr \times Bt)$. For each node $v = (c, \{(a_1, t_1), \dots, (a_n, t_n)\}) \in C \times \mathbb{P}(attr \times Bt)$ in g ,

- the concept $c \in C$ defines a state $c \in S$
- each type $t_i \in Bt$ defines a state $t_i \in S$
- each attribute a_i defines a transition $(c, a_i, t_i) \in \rightarrow$

Edges of $E \subseteq V \times label \times V$. Each edge $e = (v_s, l, v_t) \in E$ where $v_s = (c_s, \{(a_{s1}, t_{s1}), \dots, (a_{sn}, t_{sn})\})$ and $v_t = (c_t, \{(a_{t1}, t_{t1}), \dots, (a_{tn}, t_{tn})\})$ defines a transition $(c_s, l, c_t) \in \rightarrow$.

Initial states for each lts . Finally, each node $v_i \in V$ of the graph $g = (V, E)$ defines the initial state of $lts_i \in \{lts_1, \dots, lts_n\}$.

The projection results in a set of labelled transition systems associated to any data model. Therefore, analysis techniques defined for labelled transition systems can be applied. In particular, our approach uses lts comparison

¹XIF Interchange Format (XIF): A standard in space engineering to define space data models [14].

techniques based on the definition of a simulation relationship.

lts as a model for APIs

An *api* in a set of *API* is made of operations op_i like *getters*, *setters*, *testers* etc. to respectively access, modify or query concepts or attributes of a data model. We note $api = \{op_1, \dots, op_m\} \in API$.

For a given $lts \in LTS$, we say that an $api \in API$ of a given concept c is valid if and only if for each operation $op_i \in api$ there exists a path, starting from the initial state corresponding to the concept c , which accesses each input and output concepts used by any $op_i \in api$. We say that lts satisfies the api API and note $lts \models_a api$.

This definition can be extended to the APIs of any concept in a graph $g = Int(cm)$ resulting from the interpretation of a conceptual model cm . We say that a set $Api \subseteq API$ of APIs defined on g is satisfied if and only if for each $api \in API$ there exists a $lts_i \in Proj(ldg)$ such that $lts_i \models_a api$. We note $g \models_g Api$.

Step 3. LTS comparison

Let g_s and g_t be two *ldg*. Let $lts_s \in Proj(g_s)$ and $lts_t \in Proj(g_t)$ be two *lts* with an initial state associated to the same concept c and api an API defined on the lts_s on the concept c .

We say that api is preserved on lts_t if and only if lts_t simulate lts_s (written as $lts_t \sim lts_s$). Informally, all the paths in lts_s are also paths in lts_t i.e. api is still satisfied in lts_t . Formally, we write

$$lts_t \models_a api \iff lts_t \sim lts_s \wedge lts_s \models_a api$$

Step4. Data conservation

Let g_s and g_t be two *ldg* and Api a set of API defined on g_s such that $g_s \models_g Api$. We say that a set Api of APIs is preserved on g_t if and only if for all $api \in Api$ such that $\exists lts_s \in proj(g_s) \wedge lts_s \models_a api$ there exists a $lts_t \in proj(g_t)$ such that $lts_t \sim lts_s \wedge lts_s \models_a api$. Formally, we write

$$\begin{aligned} g_t \models_g Api & \iff \\ \forall api \in Api, \exists lts_s \in proj(g_s), \exists lts_t \in Proj(g_t). & \\ \text{such that } lts_s \models_a api \wedge lts_t \sim lts_s & \end{aligned}$$

Definition 3: Finally, we say that a **conceptual model cm_t is a correct evolution of a conceptual model cm_s with respect to a set Api of APIs** if and only if

$$g_s = Int(cm_s) \models_g Api \implies g_t = Int(cm_t) \models_g Api$$

Once the conceptual model cm_t is proved to be a correct evolution of cm_s , instances can be migrated. The APIs of the source conceptual model are used to rebuild the instances in the target data model. Some of the produced instances may be partially valued in case cm_t is richer than the source data model.

B. Example

Below, we apply the defined methodology on the example of a conceptual UML class diagram depicted on Figure 2. The objective is to check if the class diagram on the right hand side of Figure 2 is a correct evolution of the one on the left hand side.

Fig. 2. An example of a data model evolution.

Step1. Interpretation

An example of evolution of an UML class diagram is given in Figure 2. The source and target data models are interpreted using the *Int* function leading to two *ldg*. The source data model contains three concepts A , B and C . Concept B and concept C inherit from concept A . Concept A has three attributes $a1$, $a2$ and $a3$. Concept C has one attribute $a4$ and concept B has one attribute $a5$. In the target data model, we decide to push-down the attribute $a3$ from concept A to both concepts B and C .

Step2. Projection

We project the source and target *ldg* to labelled transition systems. Since three nodes are identified at the *ldg* level, we obtain three *lts* for both source and target *ldg* as shown on Figure 3 for the model on the left hand side of Figure 2. The initial state of each *lts* is one of the three nodes of the associated *ldg*.

Step 3. LTS comparison

In this case study, strong equivalence is not ensured. However, each target *lts* weakly simulates the corresponding source *lts*. One may notice that the opposite does not hold.

Fig. 3. Projection of a *ldg* to a set of *lts*.

Step4. Data conservation

For data migration, we can assert that the obtained *ldg* and *lts* are conform to Definition 3. The functions of the APIs can be used for data migration.

V. CASE STUDIES

Our approach has been deployed in the space engineering domain. We have studied several case studies with complex data models. In this section, we review the case of the Microscope data model. The Microscope space mission aims at testing the universality of free fall, for the first time in space [15]. In the following, we consider an extract of the data model used to parameterize the telemetry processing and especially to combine two telemetries.

Step1. Interpretation

As shown in Figure 4, it was decided to refactor the data model by replacing two attributes by two composition relationships towards a new class, called *AbstractData*.

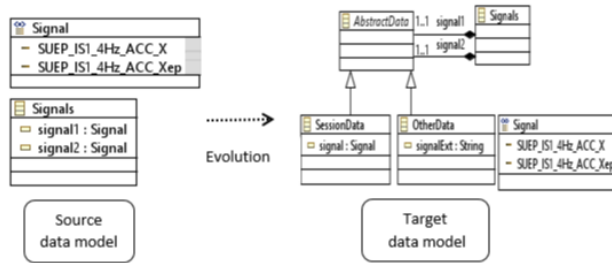

Fig. 4. An extract of a data model evolution in Microscope.

The original attributes *signal1* and *signal2* are factorized into a class *SessionData*, inheriting from *AbstractData* and owning a *signal* attribute of type *Signal*. This way, end-users can combine two telemetries with a known signal or not. Thus, we can identify the following evolutions:

- a new abstract class named *AbstractData* is added;

- two new classes named *SessionData*, *OtherData* inheriting from *AbstractData* are added;
- a new attribute named *signal* of type *Signal* is added to the class *SessionData*;
- a new attribute named *signalExt* of type *String* is added to the class *OtherData*;
- the types of *signal1* and *signal2* are changed from *Signal* to *AbstractData*.

As explained previously, the source and target data models are transformed into two LDG. In the source LDG, the class *Signals* become one concept. In the target LDG, three new concepts appear : *AbstractData*, *SessionData* and *OtherData*.

Step2. Projection

As shown in Figure 5, we project the source and target LDG to one source *lts* *lts_s* and one target *lts* *lts_t*.

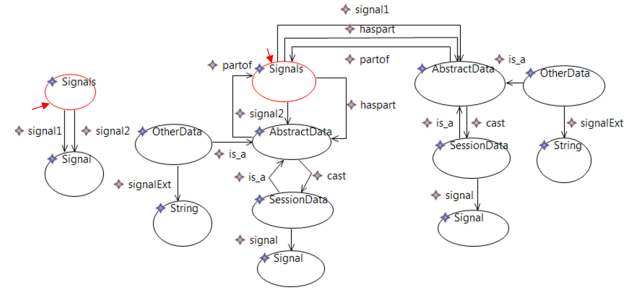

Fig. 5. An extract of the projection of the *ldg* to a set of *lts* in Microscope.

As the *Signals* concept is the only concept that exists in both sides, the initial state of each *lts* is *Signals*.

Step 3. LTS comparison.

As shown in Figure 5, from the initial state *Signals*, all the source transitions are feasible if we cast the target *signal1* and *signal2* to the concept *SessionData*:

$$signal1_{source} = ((SessionData)signal1_{target}).signal$$

$$signal2_{source} = ((SessionData)signal2_{target}).signal$$

Thus, *lts_t* simulates *lts_s* since the following weak simulation binary relationship $R = \{ \langle Signals, Signals \rangle \}$ exists. One may notice that the opposite is false because of the transition *signalExt*.

Step4. Data conservation

During the migration, the values of the old instances of the class *Signals* are preserved, through the creation of two new instances of the class *SessionData*, initialized with these values.

VI. CONCLUSION AND FUTURE WORK

Tool support: The use of the CADP² toolbox helps a lot. Our investigations proved that we have been able to get the diagnosis of the comparison results.

Using template transformations, we were able to transform the Microscope data models to an LDG, then to obtain an internal representation of labelled transition system in AUT (automaton) format. Finally, the simulation between the two automatons is checked, using observational equivalence relationship, thanks to the CADP BISIMULATOR module.

Results and Discussion: In this paper, we presented a semantic observational approach for treating data models evolution. The main interest of the proposed approach is the transposition of the information accessibility in a data model at a logical interface level into a path problem in a labelled directed graph. The approach proved capable to capture all evolutions of a data model into a single logical operator instead of a no-exhaustive list of evolution operators.

Finally, the proposed approach is generic, it is not defined for a single specific data modelling language. It applies to any data modelling language provided that an interpretation of each data model by a *ldg* (from which a set of *lts* is produced) is defined.

Concluding remarks: We believe that addressing the problem of model evolution based on model behavior is promising. Interfaces defined on data models are used to define model evolution correctness using observational semantics. They are also used to prove the existence or the non-existence of composite operators having the property to preserve information contained in original instances.

Relying on labelled transition systems has three potential advantages. First, the overall system is often easier to understand due to the formal and precise nature of the representation scheme. Secondly, the behavior of the system can be analyzed using labelled transition systems theory and associated techniques, which includes tools for analysis. Finally, techniques developed for the comparison of parallel programs can also be applied.

Future work: As a perspective of this approach, we expect to realize a comparative study between the proposed approach and the previous one by comparing traces found by a graph comparison algorithm to structural differences found previously in [12]. We also intend to extend our work to address the evolution of models in presence of cardinalities. Finally, integrating domain knowledge through the introduction of a domain

ontology helps in identifying semantic equivalence at concepts levels and thus address heterogeneous models evolution.

ACKNOWLEDGMENT

Authors would like to express their gratitude to Dr. Raquel Araujo OLIVEIRA for her comments and her constructive suggestions.

Documenting and Exploiting Software Feature Knowledge through Tags

Marcus Seiler

Barbara Paech

Institute for Computer Science, Heidelberg University, Germany

E-mail: {seiler|paech}@informatik.uni-heidelberg.de

Abstract

Knowledge about features and their relations to detailed requirements or code is important and useful for many software engineering activities such as for performing change impact analysis and tracking feature progress. Documenting feature knowledge is challenging, as companies document features and requirements in issue tracking systems (ITS) and work on code in integrated development environments (IDE). Managing feature knowledge over time is challenging, as features, requirements, and code continuously change. Also, managing the relationships through trace links is challenging, as creating links manually is too time-consuming, and recovering links retrospectively is too error-prone. We developed an approach and tool TAFT to document feature knowledge in ITS and IDE continuously. TAFT uses feature tags to indicate relations between feature descriptions, requirements, work items, and source code. Currently, TAFT comprises a dashboard to track the feature progress, a recommendation system to suggest feature tags for specifications, an inheritor to apply feature tags automatically, and capabilities to navigate in feature knowledge. The tool is integrated into the developers' work environments Jira and Eclipse. In this paper, we present details on the tool support for TAFT, and we report on the results of a case study, which indicates its acceptance.

1. Introduction

Nowadays, many software-developing companies use an issue tracking system (ITS) to support software engineering work [2]. ITS contain several software engineering artifacts like requirements, development tasks (work items), or bug reports. An integrated development environment (IDE) is typically used to work on code that implement artifacts from ITS. Within ITS, requirements are often formulated as requests to modify or to add a specific feature. Since information regarding features is spread across the two sources ITS and IDE, it is hard to document and maintain features

and their relations to code. Explicit knowledge about features and their relations to other artifacts, such as detailed requirements or code is not only useful for software evolution [14], but is also important for many software engineering activities including management tasks such as tracking the feature progress for release planning [9], and including development tasks, such as identifying affected artifacts when performing change impact analysis [11]. While the artifacts of feature knowledge are available in ITS and IDE, in practice their relationship is often managed implicitly or incompletely. This makes it difficult to exploit the feature knowledge for development and management tasks.

In previous work [19], we presented an interview study with practitioners on the use of tagging for feature knowledge and first ideas on a lightweight tagging approach to document feature knowledge. In this approach all artifacts relating to a feature are tagged with the feature. The experts from practice found our ideas beneficial. Documenting feature knowledge using tags seems easy at first glance. However, the experts indicated that providing suitable tags is not that easy and managing feature knowledge across different tools, and over time is a challenging task. The tag consistency over time is challenging, as the development of software systems is characterized by continuous change to features, requirements, and code [7]. In this paper, we present tool support to document, maintain, and exploit feature knowledge with tags in ITS and IDE consistently and efficiently. Currently, our tool support focuses on consistency across different tools and on efficiency to apply tags. The tool support comprises a dashboard to track the feature progress, a recommendation system to suggest feature tags for specifications, an inheritor to apply feature tags automatically, and capabilities to navigate in feature knowledge.

We conducted a case study with students in order to evaluate the acceptance of our approach and tool support according to the technology acceptance model (TAM) [6]. The results show that the students found our approach very useful for navigating to code parts during bug fixing. They rated our approach and tool support as easy to use and emphasized that the approach is intuitive to use. Also, they are motivated to use the approach and tool in future. The

students mentioned the following concerns: cumbersome initial set-up of the dashboard, missing support for viewing metrics from past sprints, and inaccurate recommendations.

The remaining paper is organized as follows: Section 2 introduces the terminology used throughout the paper and our *TAFT* approach. Section 3 describes the details on the tool support. Section 4 describes the case study with its research questions, hypotheses, and results. Section 5 discusses related work. Section 6 finally concludes this paper.

2. Background

This section briefly introduces the terms software features and feature knowledge. Then it describes our approach in more detail.

2.1. Software Features and Feature Knowledge

Various definitions of the term software feature exist in the literature [12, 4, 3]. We adopted the definition by Bosch [4] and define a feature in the context of this paper as a *functional or non-functional property of a software system*.

Different software engineering artifacts that are documented during specification and implementation relate to a feature. A feature description provides a general specification of the feature. Requirements refine the feature. Work items describe development tasks related to realizing the feature. Code implements (parts of) the feature. We therefore define feature knowledge as *knowledge comprising feature descriptions and all related software engineering artifacts such as requirements, work items, and code, as well as their relations*.

Figure 1 shows an example of feature knowledge from the studied project (cf. Section 4). As shown on the left hand side of Figure 1, a feature description was documented during specification and was refined by a requirement afterwards. The work item describes the implementation task for the requirement. Finally, the right hand side of Figure 1 shows the code implementing the functionality of the requirement.

2.2. The Feature Tagging Approach (*TAFT*)

The process of assigning keywords to artifacts is an effective approach to attach additional information to artifacts [20]. We developed a lightweight approach to manage feature knowledge across ITS and IDE [19]. Instead of creating traces between feature knowledge, feature knowledge is tagged with the same keyword. In particular, we use tags for feature descriptions, requirements, work items, and code. The *TAFT* approach works as follows: One tag for each feature of a software is used. The tag summarizes the feature in a short and concise manner. This tagging adheres to the following rules: First, a feature description is tagged with a feature tag if and only if it contains the description

of the feature. Second, a requirement is tagged with a feature tag if and only if the requirement refines the feature. Third, a work item is tagged with a feature tag if and only if the described task addresses specification, quality assurance, or implementation of the feature. Finally, source code is tagged with a feature tag if and only if the source code implements (parts of) the feature.

In the example given in Figure 1, the tag *Transportation* is used to summarize the described feature. The feature tag is applied to the feature description, the requirement, and the work item in Figure 1 as they relate to the feature *Transportation*. The second statement of the code listing in Figure 1 shows the feature tag, as the code implements parts of the feature *Transportation*.

Our approach is independent of the development method used. Thus, *TAFT* is applicable for projects using traditional methods such as waterfall, and for projects using a modern development method such as agile. Moreover, we do not make any assumptions about the cardinality of the relations between features and requirements or between features and code. Thus, it is possible to have requirements, work items, and code tagged with multiple features unlike in the example.

3. Tool Support for *TAFT*

We developed tool support for *TAFT* in Jira¹ and Eclipse², which are common tools for managing software development projects and for working on code, respectively.

Our tool supports the two stakeholders developer and project manager in capturing feature knowledge through labels in Jira and annotations in code. It also supports them in exploiting feature knowledge for development tasks and for management tasks, respectively. We annotate the code with tags instead of tagging commits, as commit messages often contain noise in terms of tangled changes. Tangled changes could result in wrong feature knowledge when tagging a commit [8, 13]. Moreover, code annotations help to understand the code [21] and the cost for creating and maintaining annotations in code is negligible [10]. We rely on Java annotations instead of comment annotations. Unlike comment annotations, Java annotations are language specific, but they retain in the compiled byte code. This is useful for exploiting feature knowledge in (legacy) software even if the source code is not available (anymore).

In the following, we describe the details of the main tool functionality: the feature navigator, the feature dashboard, the feature recommendation and the feature inheritance. The Eclipse plug-in *Feature Navigator* analyzes the source code of a project and scans the code for annotations to support developers. Figure 2b shows a screenshot of the

Feature: Integration of an API to retrieve data from public transportation such as stations and their departure schedules.	<pre>// Package, imports and further code omitted @Feature("Transportation") public class OpmvManager implements IOpmvManager { public void queryStation(String stationID) { Request request = new Request.Builder().url(new HttpUrl.Builder() .scheme("http").host("rnv.the-agent-factory.de") .addQueryParameter("stationID", stationID).build()); new OkHttpClient().newCall(request); } }</pre>
Requirement: As a user, I want to click on a station in order to view the departure schedule.	
Work item: Implement service function to retrieve the departure schedule of a station.	

Figure 1: Example of feature knowledge documented in specifications and in code

Feature Navigator. The *Feature Navigator* lists code files implementing a certain feature. The developer can search for features and code files and can directly navigate to a code file once s/he clicked the code in the *Feature Navigator*.

The Jira dashboard *Feature Dashboard* supports project managers in tracking the progress of features in a project. Figure 2a shows the *Feature Dashboard*. The *Feature Dashboard* scans the project for feature tags and displays various metrics, e.g., the number of features, the number of requirements (in this case user stories), and the number of code lines implementing a feature. The metrics are calculated based on the labels applied to issues and the annotations applied to code. The dashboard can be configured for a project and the shown metrics can be selected. Multiple instances of the dashboard are possible to have metrics for multiple projects.

Developers and project managers might not document or update feature knowledge regularly, if the effort is too high. As suggested by Robillard et al. [15], we use recommendation systems to reduce the effort for the tool users. The completion of labels when typing parts of a feature tag is a built-in function of Jira. We extended Eclipse’s code completion capabilities to complete annotations in code when typing parts of an annotation. Both, the label completion in Jira and the annotation completion in Eclipse represent simple recommendation systems. In addition, we developed a Jira plug-in to *recommend feature tags* for issues. Currently, we recommend existing feature tags based on the issue description using a multi-class Naive Bayes classifier. The feature tags are presented to the user together with the confidence score of the classifier. The user is then able to click on the feature tag to apply it to the actual issue. Figure 2c shows the recommended feature tags (Transportation, RouteFinding, Filter, Tweets) with their corresponding confidence scores on the right hand side of the Figure for a user story *Departure Schedule*. In this example, the best matching feature tag is *Transportation* with a confidence score of 74.71% and is shown at the first position of the list. It is up to the user whether to apply one of the recommended feature tags. The classifier is trained iteratively whenever a user applies one of the recommended feature tags. In addition, we provide a feature tag inheri-

tance plug-in for Jira to further reduce the effort to apply feature tags manually. The inheritance plug-in uses existing relations from Jira to automatically apply feature tags for issues in parent-child relations such as a user story consisting of several work items.

4. Evaluation of TAFT

We conducted a study with students in order to assess the acceptance of the *TAFT*. In the following, we describe the design of the case study and the applied research method in Section 4.1. Section 4.2 presents and discusses the results. Finally, Section 4.3 discusses threats to validity.

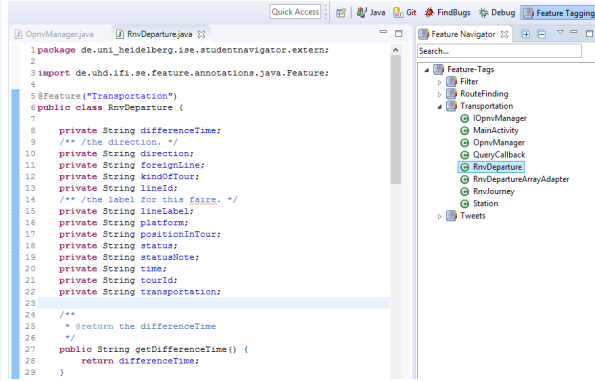

4.1. Case Study Design & Research Method

Study Context: The study was performed during a development project with six students over a period of six months. The project lasted from October 2017 to March 2018. The students developed an indoor navigation app for Android-based devices for a real customer. Primary users are (other) students who use the app to locate and navigate rooms where lectures take place. Also the app is able to retrieve information from public transportation allowing to display the departure schedule of a nearby station. The customer was a mobile development company. The development method was Scrum-like. In each sprint, one of the students acted as Scrum master and thus was responsible for development planning and communicating with the customer. The customer provided a high-level vision description of the app. The students derived features and refined them during development in agreement with the customer. They used Jira with epics to describe features and with user stories to refine features, and with work items to describe development tasks. The students used Git for Java source code and Eclipse as development environment. They applied our *TAFT* approach and used its tool support during the project. At the beginning of the project, the approach and the basic usage of the tool support were introduced. Also, the students were supported in the initial set-up of the tool support.

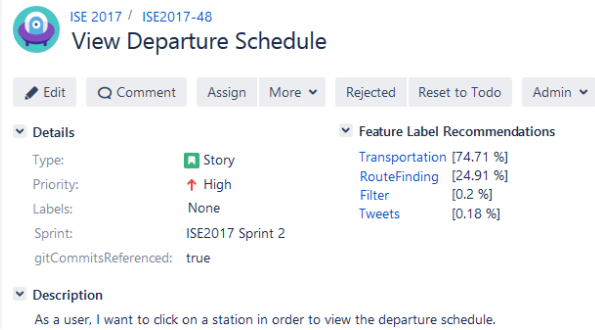

At the end, the project comprised five epics, 17 user stories, 74 work items, and 40 code files. According to our approach, the feature tags were applied to the user stories,

(a) Dashboard to track feature progress

(b) Navigator to find feature in code

(c) Recommendation to suggest feature

Figure 2: Tool support for the TAFT approach

the work items, and the code files. We conducted semi-structured interviews with the students to evaluate the acceptance. The questionnaire used during the interview contained open and closed questions.

Research Questions, Metrics, and Hypotheses: To evaluate the acceptance of our tool, we build upon the Technology Acceptance Model (TAM) by Davis et al. [6], which models the user acceptance of information technology. In our case, the information technology is the approach and the tool support. TAM uses the variables *perceived ease of use*, a *subjects' intention to use* and *perceived usefulness*. We raise the following research questions for acceptance evaluation:

RQ_1 How easy is it to use the approach and tool support?

RQ_2 How useful is the approach and tool support?

RQ_3 Do the students intend to use the approach and tool support in future?

Regarding the tool support, we are particularly interested in the recommendation and the dashboard. For usefulness, we are particularly interested in progress tracking and feature knowledge relations. We provided a questionnaire to

the students with questions corresponding to the research questions.

According to Davis et al. [6] point scales such as Likert scales can be used to measure the variables of TAM. We used a Likert scale with five scale points for asking the students to assess the approach and tool support. The answers to the Likert scale were mapped to an integer as follows: strongly disagree = 1, disagree = 2, neutral (neither agree nor disagree) = 3, agree = 4, and strongly agree = 5.

We use the students' assessments together with their rationale for the ratings as metric for RQ_1 , RQ_2 , and RQ_3 , respectively. Our hypothesis for acceptance is: We expect that the values for the TAM-variables are higher or equal to 3.5. Thus, we expect that most of the responses are in the range between neutral (with a slight tendency to agree) and strongly agree.

4.2. Results & Discussion

In the following, we use the answers to the open questions to provide the details for the assessments of the students.

The students stated that the approach is easy to use (RQ_1) as it is very intuitive to use. All students found it easy to apply feature tags to issues. A minority stated that applying feature tags in code is more complicated. The students needed more effort to equip some code files with feature tags, as these code files implemented multiple features. This is backed up by the numbers of the project. Each of the 17 issues had exactly one of the tags applied. Of the 40 code files, 37 had at least one of the tags applied. The majority (33 code files) contained one tag. One code file each contained two and three tags. Two code files contained four tags. Altogether, it seems easier to tag specifications instead of code files. The recommendation is rated easy to use and a little less useful compared to the usefulness to relate and track feature knowledge. Overall, the students stated that the recommendation works well and that the recommendation can help to prevent incorrect feature tags. However, the students did not use it very often (only for 14.04% of all issues). A minority reported that wrong recommendations for feature tags decrease the usefulness. One reason could be that the students were presented with all feature tags including those with low confidence values. Therefore, we need to study how recommendation usage can be improved.

Overall, the students found the approach useful (RQ_2). The use of the dashboard to track the progress was rated as easy and very useful. The students stated that the dashboard exactly provides the data needed to perform the tracking. However, they missed the functionality to view metrics for past sprints in the dashboard. Also, a minority perceived the initial set-up of the dashboard somewhat cumbersome.

The result for the intention (RQ_3) is rather poor compared to the other two variables. The rather low intention to use the dashboard could be due to the fact that this is mainly helpful for the project manager and the students do not see themselves as project managers in the short future. The students justified the assessment for the intention with the dependency on the project size. In smaller projects with a similar scope as this evaluation project, the students would rather not use the approach and the tools, as the application and maintenance of the tags creates overhead for developers and they can remember the feature knowledge by themselves. In very large projects, students indicated that there could be many feature tags that need to be managed. Therefore, they would apply the approach and tool support in those projects. Some students used the feature tags in code to locate code parts that might be affected by bugs. We plan to investigate whether improved support for locating code affected by bugs would raise the motivation for future usage.

Overall, our hypotheses hold and we conclude that our approach is feasible and accepted. We applied our approach in a new project, but it could be also applied to an existing project. The requirements and the code files of an ex-

isting project must be equipped with feature tags in retrospect to make our approach work. The effort for this re-documentation is considerable as the relations between all requirements and all code files have to be mapped to the features. However, it can be incrementally done during refactoring or other changes to features.

4.3. Threats to Validity

We discuss threats according to Runeson et al. [16].

Construct Validity: The construct validity was ensured through data source triangulation by using direct methods (semi-structured interviews with open and closed questionnaires) as well as indirect methods (review of data produced by tool logging). A possible threat is that researcher and interviewee might interpret the questions differently. The threat is mitigated by the format of face-to-face interviews, which enabled the interviewees to ask questions. Also, another researcher checked the questionnaire for applicability and understandability.

Internal Validity: The students knew that the researcher had developed the approach and its tool support. The threat was mitigated as the researcher appreciated both positive and negative feedback from the students. The motivation of the students to use the approach and its tool support might be influenced by worries about grades. However, the researcher was not involved in the final grading and the usage had no influence on the grades.

External Validity: The documented feature knowledge is specific to this development project and the size of the development project is limited. Moreover, we applied our approach for a new project only. Thus, the results for other projects can be different from the results reported in this study, and the findings cannot be generalized for developers working in industry. However, the project contained situations common to projects in industry, e.g., the elicitation of requirements by the participants, changing requirements due to changed customer needs, as well as communication problems across developers regarding their tasks.

Reliability: One researcher did the interviews and assessments to ensure consistency. Other researchers might interpret the results in another direction. The researcher documented the steps during design, data collection, and analysis. In addition, another researcher reviewed the design of the case study and the steps for analysis to increase reliability. This also ensures the reproducibility of the study.

5. Related Work

Our approach relates to traceability. *TAFT* provides a coarser-grained traceability as commonly used trace links, as the relations between requirements and code files are established on feature level. In [18], we compared the trace links resulting from tags with other approaches to create traceability links.

There are few approaches which also use tags to document and exploit feature knowledge. Mainly they are from the area of product lines where features are used to manage variability. Thus, they are more heavyweight than our approach. Savage et al. [17] present an Eclipse based tool for locating and tracing feature in code. The underlying approach is different from ours, as they do not directly tag code with its implementing features. Instead, a user manually relates code to feature using an annotation after feature location was performed. Similar to the metrics in our dashboard, they provide a view showing the distribution of features across the code. Ji et al. [10] present an approach to equip code with feature annotations. They simulated the development of a product line of cloned projects using the annotation approach. They found that maintaining such annotations in code is not costly, but useful for maintenance tasks. Andam et al. [1] and Burger et al. [5] both present a standalone tool for locating features in code. Both use comment annotations to document features in code and they use feature location techniques to annotate the code (semi-)automatically. Andam et al. [1] also provide a dashboard for viewing feature metrics. In contrast to ours, their dashboard targets at developers by providing more specialized metrics, e.g. nesting depths of annotations. As the tools focus on feature location, all of them provide capabilities to navigate in feature knowledge documented in code. None of the tools tag specifications nor do they provide recommendations or inheritance of tags.

6. Conclusion & Future Work

In this paper, we reported on the tool support of our *TAFT* approach and its acceptance in a case study with students. Overall, the results show that the approach and tool support are accepted.

In future work we would like to address the problems experienced by the students. To further ease the application of feature tags, we are also working on recommendations to suggest feature tags in code and on inheriting feature tags for code. In addition, we want to investigate how practitioners think about our tool, e.g., by performing interviews with practitioners.

Acknowledgement. We would like to thank all students for their effort in this study.

Abstract—Shared bicycle, as a green means of transportation, is very popular among people and it is an important way for many people to travel daily. In recent years, with the increasing scale and frequency of bike sharing system, the unbalanced use of shared bicycle has a great impact on the users' experience, which is one of the main problems faced by current system operators. Division of the traffic area can not only provide a new idea for solving the problem of unbalanced bike usage, but also provide a theoretical and practical basis for the planning, layout, construction, operation and scientific dispatching of shared bicycle system. However, there are few clear methods to study the partition method of shared dispatching area. To solve this problem, based on historical bicycle data, traffic station data, we analyze the rules of shared bicycle space-time characteristics and propose a method of dividing shared bicycle dispatching areas by combining K-medoids clustering, association rules and total demand constraint adjustment. We evaluate our approach on the New York City (NYC Citi Bike) bicycle sharing system and show the advantages of our approach for Large-scale station-level dispatching area optimization (beyond baseline approaches).

Keywords—scheduling area partition method; bike sharing system; rebalance; clustering; Total demand optimization

I. INTRODUCTION

Bicycle sharing system is widely used domestically and abroad. It provides great help to solve the problem of "last kilometer" and traffic jam. A user can rent (i.e. check-out) a bike at a station near their origin and return (i.e. check-in) it to a station close to their destination. A record is generated when a bicycle is borrowed/returned, including the location of the origin station, the location of the destination station, and the duration of the ride.

However, bicycle sharing system still faces challenges in bike rebalancing between stations. Essentially, bike usage is constrained by time and location, so the traffic in the whole city will be unbalanced. For example, some stations may have a lot of bicycles returning, but some stations may not have available bicycles for users. In order to solve this problem, Most studies directly predict bicycle demand during a future period in order to avoid unbalanced problems and dispatchers manually schedule ahead of time, but the accuracy is not high, and when the number of stations is large, dispatchers need to schedule each station manually, which increases the workload and difficulty of delivery personnel and makes it difficult to

achieve efficient and orderly scheduling. Thus, in order to reduce the workload and the difficulty of their jobs, therefore makes it difficult to achieve efficient and orderly scheduling. Thus, in order to reduce the workload and difficulty, we start with reducing the scale of the problem, which is to divide the whole traffic into different areas. The location, station-station trip frequencies as self-fluidity and the bike demands are taken into account, and the areas are adjusted by constraints to achieve the optimal results of the maximum balance within the areas. This not only reduces the workload and difficulty of dispatchers, but also experiments (see Chapter IV, Part C) show that the demand distribution of bike usage of cluster is more regular than that of station-level bike usage. Therefore, our proposed method lays a foundation for improving the accuracy of bike usage demand prediction in the future.

In these days, the scanning method and the clustering algorithm [1] are mainly used domestically and abroad to divide the vehicle scheduling area. Among them, the scanning method [2] is only applicable to the cases where the number of users is small and the distribution area is not large. Although the spatial clustering algorithm [3] applicable to the cases of a large number of customers and a large scheduling area, there is still a lack of criteria for reasonably allocating the weights of spatial and non-spatial attributes, or a lack of accurate methods to define the distance between feature attributes. If applied directly to dynamic scheduling of shared bicycle system, it may lead to large random errors.

Bike sharing system has a large number of stations and complex attributes, which makes it difficult to calibrate their attributes one by one. However, due to the self-fluidity of shared bicycle [4,5], there is a strong correlation between some stations. Therefore, if the association rules are used to collect stations with strong correlation and adopt K-medoids algorithm [6,7] and constraint adjustment for scheduling, it can effectively avoid large random errors.

Based on the above analysis, considering the actual bike demand of real-time dispatching of bike sharing system, we propose a scientific method for dividing the shared bicycle scheduling area by combining K-medoids clustering, association rules and restraint adjustment of total demand in the bike sharing system. In the first step of this method, K-medoids clustering is applied to the stations of bike sharing system. Then on the basis of the self-fluidity between stations and the transformation relationship between stations, the set of strong

association rules is screened out by using association rules. According to the constraints of the total demand in the areas, the total demand within the areas is optimized, and the regional division of dynamic dispatch of urban shared bicycle system is finally realized.

II. DESIGN OVERVIEW

We provide an overview of the symbols used in this paper (Table I) and problem definitions, as well as the description of design approach.

A. Basic Definitions

Definition 1: Station information. A station $S_i = (id, lon_i, lat_i)$ denotes station information, where id represents the unique identity of each station, lon_i is the longitude of the station, lat_i is the latitude of the station.

Definition 2: Trip. A Trip $T_r = (s_o, s_d, \tau_o, \tau_d)$ is a historical bike usage record, where s_o denotes the origin station, s_d is the destination station; τ_o and τ_d are the time when bike is checked out at s_o and checked in at s_d , respectively.

Definition 3: Demand of bicycles. In time t , given a set of Check-out of station S_i , $O_{S_i}(t) = \{O_{S_1}, O_{S_2}, \dots, O_{S_n}\}$ and check-in of station S_i , $I_{S_i}(t) = \{I_{S_1}, I_{S_2}, \dots, I_{S_n}\}$. We want to get the demand of each station $S_i.d(t) = I_{S_i}(t) - O_{S_i}(t)$.

Problem Definition: Scientific division of regions. Given a set of stations $S_i = \{S_1, S_2, \dots, S_n\}$, we want to cluster each station S_i to form $C_{1, i} = \{C_{1,1}, C_{1,2}, \dots, C_{1, k}\}$ clusters.

TABLE I. NOTATIONS

Notation	Description
N	Number of historical bike usage records
ρ	Coefficient of normal bike transaction records
n_b	Number of shared bikes
t	Days of data acquisition
λ	Coefficient of bike flow distribution
ω	Coefficient of on-frame mobile bike
$r_{i,j}$	Correlation coefficient from station i to station j
$n_{i,j}$	Number of bikes from station i to station j
n_i	Number of bikes flowing out from station i
S_i	The i^{th} station
T_r	A bike usage record
C_i	The i^{th} cluster
$O_{S_i}(t)$	Check-out of station S_i in time t
$I_{S_i}(t)$	Check-in of station S_i in time t

B. Design Methodology

Despite the time and location of the user's choice of borrowing is random, bikes are bound to be checked in at some station. Based on this simple observation, bike sharing system is decoupled in Figure 1 into two parts by analyzing the

mobility [8,9] of bikes and characteristics. Based on historical bike usage records, we first use statistical methods to analyze the spatial and temporal distribution characteristics of bikes. Then, considering the space-time distribution characteristics of shared bikes, we propose a scientific method for dividing dispatching areas (see chapter III). Finally, the experimental results of NYC Citi Bike System show the advantages of our method.

Figure 1. Components of a bike-sharing system

III. SCHEDULING AREA PARTITION ALGORITHMS

In this chapter, firstly, the spatial and temporal distribution characteristics of bike sharing system operation data are analyzed. The purpose is to grasp the operating regularity of the system, mine the trip patterns, obtain the macro operation rules of each station, and improve the quality of the dynamic scheduling of the bike sharing system. Then we put forward a scientific division method and show the specific steps of implementation through the above analysis. The goal of scientific partitioning is to transform the problem from a complex one (about 1,000 predictions per hour) to a simpler one, thereby reducing the complexity of the problem, making it easier to handle and helping to avoid over-fitting.

A. Spatiotemporal Analysis

Distribution Characteristics. As shown in Figure 2, from the macro-analysis [10] of the impact of month on the shared bicycle demand, it can be seen that there is a regular pattern of increasing demand from April to June. From June to September, the demand is stable but still in a high level. Selecting these months is conducive to dealing with the imbalance during the peak period. The figure on the right specifically shows the time distribution regular pattern of two different parameters, stations and time. It can be found that the early peak appears around 8 o'clock and the late peak appears around 5 o'clock.

Figure 2. Law of time distribution

Analysis of Spatial Distribution Characteristics. Spatial distribution [11] characteristics analysis is based on each station as the research object. It analyses the distribution regularity of the whole city and the stations to which the vehicles borrowed from the station are returned or the vehicles

returned to the station are borrowed from the station, and calculates the correlation between the stations. Station correlation refers to the flow correlation between two stations. We use the correlation coefficient to express their correlation. The larger the value, the more frequent the bicycle flows between the rental points, the greater the travel demand of users in this area. The formula can be expressed as follows.

$$r_{i,j} = n_{i,j} * n_i^{-1} \quad (1)$$

Through the analysis of the spatial distribution characteristics of the stations, the borrow-return flow relationship between the stations in the system is determined, which provides the data basis for clustering the dispatching areas.

B. Specific realization

Figure 3 presents the iterative procedure of the partitioning method which organically combines three factors (location, self-fluidity and bike usage demand) of the stations. Stations within the same circle represent a cluster. The algorithm repeats the following three steps in each iteration: Geo-clustering, Strong Association Rule generation and constraint adjustment.

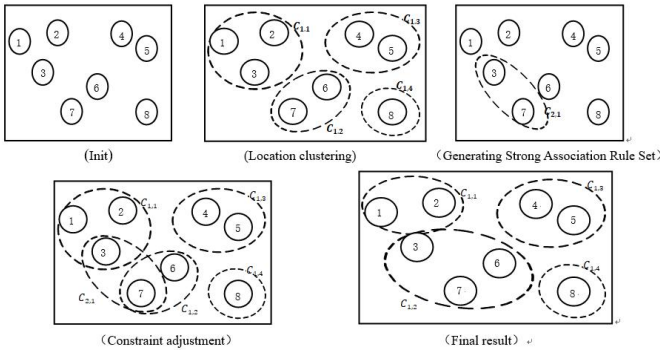

Figure 3. Partitioning method procedure

- **Location clustering.** According to the geographic location of each station, it is clustered into $K_1 = \{C_{1,k}\}_{k=1}^{k_1}$ by K-medoids method, this is the first time that location clustering is performed on all stations in the shared system”.
- **Strong Association Rule Set generation.** check-in/check-out between each station is calculated by the statistics of historical bike usage records, and the strong association rule set $\{C_{2,k}\}_{k=1}^{k_2}$ is screened by Aprior algorithm [12,13]. In this paper, we select 7:00-9:00 in the early peak period and 17:00-19:00 in the late peak period as the basis for screening strong association rule sets. In the process of preliminary classification of shared bicycle stations by association rules, the minimum support threshold Sup_{min} is very important, which determines the quality of clustering in the next step. If the value is too small, the correlation between the stations in the set is very weak, it will bring great errors to the later clustering to divide the

dispatching area. If the value is too large, some stations with correlation may be screened out. When the next clustering division is carried out, most stations with less correlation will be introduced, which will also lead to larger errors in the result of division. Since there is no general method to determine the minimum support threshold, which is usually set artificially according to specific conditions, this paper considers that in a bike sharing system, the minimum support threshold should be determined according to various factors, and the expression is as follows.

$$Sup_{min} = \frac{N * p}{t * \omega * n_b} * \lambda \quad (2)$$

A frequent itemset [14] is formed by selecting the records whose correlation coefficients are greater than those of the bike usage records. The relevant stations are put into the same set by using association rule algorithm. The stations in the set are the result of the users' free choice of the place to rent or return the bike when they travel. The principle of dividing the dispatching area is to excavate the travel rules of the users and balance the task of dispatching the vehicles. To improve scheduling efficiency, the correlation set meets the precondition of adjusting clustering in the next step.

- **Constraint adjustment.** The cluster $\{C_{2,k}\}_{k=1}^{k_2}$ obtained in step 2 and cluster $\{C_{1,k}\}_{k=1}^{k_1}$ obtained in step 1 are calculated as follows.

$$\{C_{2,k}\}_{k=1}^{k_2} \cap \{C_{1,k}\}_{k=1}^{k_1} \quad (3)$$

where $\{C_{1,k}\}_{k=1}^{k_1}, \{C_{2,k}\}_{k=1}^{k_2} \neq \emptyset$. If the result calculated by (3) is $C_i \{C_{1,k}\}_{k=1}^{k_1}$, it is the result of optimization, On the contrary, s_i in C_i is calculated in $\{C_{1,k}\}_{k=1}^{k_1}$ and $\{C_{2,k}\}_{k=1}^{k_2}$ as follows.

$$C_s(t) = \min \left| \sum_{i=1}^k s_i \cdot d(t) \right| \quad (4)$$

where the $C_s(t)$ value at $\{C_{1,k}\}_{k=1}^{k_1}$ is the smallest, then s_i is classified as $\{C_{1,k}\}_{k=1}^{k_1}$, and vice versa.

Until all the collection in the k_1 clusters: $\{C_{2,k}\}_{k=1}^{k_2}$ are processed.

C. Algorithm Complexity Analysis

Time complexity [15,16]. The time complexity of our proposed method is mainly composed of k-medoids clustering and searching for the minimum total demand. In k-medoids algorithm, each point needs to be enumerated and the sum of its distances to all other points is obtained, so the complexity is $O(n^2)$. In addition, the time complexity of seeking the

minimum total demand is $O(n^2)$. To sum up, the time complexity of the whole algorithm is $O(n^2 + n^2)$, i.e. $O(2n^2)$.

Spatial complexity[17]. The main memory overhead of the algorithm is the calculation of the cluster center and the total demand. The memory overhead can be effectively reduced by calculating the distance of a single data object at a time and the local demand in the morning and evening peak periods, which results in a spatial complexity of $O(n)$, so the spatial complexity of the whole algorithm is $O(n)$.

Algorithm 1: Partition Method Algorithm

Input: Station $\{S_i\}_{i=1}^n$, Trips $\{T_r\}_{r=1}^n$, iteration threshold K, parameters $K_1 > K_2$

Output: K_1 clusters $C_{1,1}, C_{1,2}, \dots, C_{1,k_1}$

```

1: Cluster  $\{S_i\}_{i=1}^n$  into  $K_1$  Clusters,  $C_{1,1}, C_{1,2}, \dots, C_{1,k_1}$  By K-medoids Based on locations;
2: Stations  $\{S_i\}_{i=1}^n$  into  $K_2$  Clusters,  $C_{2,1}, C_{2,2}, \dots, C_{2,k_2}$  By Aprior Algorithm;
3: Initialize  $k=1$ ;
4: While  $k < K$  Do
5:   for  $a=1:n$  Do
6:     for  $i=1:n$  Do
7:       If  $C_i = C_{2,a}\{S_i\}_{i=1}^n \cap C_{1,i}\{S_i\}_{i=1}^n \neq \emptyset$  and  $C_i \neq C_{2,a}\{S_i\}_{i=1}^n \neq C_{1,i}\{S_i\}_{i=1}^n$  Then
8:         Calculate  $C_i(t)$  in the set of  $C_{2,a}\{S_i\}_{i=1}^n$  and  $C_{1,i}\{S_i\}_{i=1}^n$  respectively for S in  $C_i$ ;
9:         If  $S_i \in C_{1,i}\{S_i\}_{i=1}^n$ ,  $\min(C_i(t))$  Then
10:           $S_i$  is classified as cluster  $C_{1,i}\{S_i\}_{i=1}^n$ ;
11:         Else  $S_i$  is classified as cluster  $C_{2,a}\{S_i\}_{i=1}^n$ ;
12:        $k=k+1$ ;
13: Return  $K_1$  clusters  $C_{1,1}, C_{1,2}, \dots, C_{1,k_1}$ 

```

Figure 4. An Algorithm of Partition Method

IV. EXPERIMENTS

In this section, we use our proposed method to construct a model for partitioning the scheduling area, and test our method on two data sets (station data and bike data [18]).

A. Data Collection

This paper uses two data sets, one is historical bike usage data set, the other is station data set. These data sets record data from April 1 to September 30, 2014. Through the statistical collation of the data set, the station information and the historical bike records are unified into bicycle data set, a total of 473,620 records were recorded. The detailed description below can be obtained in Table II.

TABLE II. DETAILS OF THE NEW YORK DATA COLLECTION IN 2014

Bike Data	#Stations	344
	#Bikes	6800
	#Records	5,359,995

B. Baseline & Metric

The method in our work to divide traffic dispatching areas is denoted as Partition Method (PM) by combining K-medoids clustering, association rules and total demand. In order to confirm the effectiveness of our algorithm, we carried out experiments to compare our method with the following baselines:

Bipartite Station Clustering(BSC)[19]. This method grouped individual stations into clusters according to their geographical locations and transition patterns. Finally, the whole traffic is divided into 23 groups.

Adaptive Capacity Constrained K-centers Clustering (CCKC)[20]. This method considers the distance between stations and the location of outliers, grouping outliers with other outliers, and setting up delivery personnel in outliers.

Metric. The metric we adopt to measure results are Sum Of The Squared Errors (SSE).

$$SSE = \sum_{i=1}^k \sum_{p \in C_i} |p - m_i|^2 \quad (5)$$

Where p is the sample point in C_i and m_i is the center of C_i .

C. Experimental result

Station-level partition method. Intuitively, the larger the number of clusters, the lower the prediction accuracy. When there is only one cluster, its usage demand is the whole traffic flow, which can be predicted accurately; when there are clusters, it means that each station forms a cluster, and the outflow/ inflow of the cluster fluctuates greatly, even if it can be predicted, but it is difficult to predict accurately. However, on the other hand, the number of clusters should not be too small, because if the cluster is too large, such as a cluster containing all stations, redistributing bicycles to the cluster cannot provide convenience for users. Therefore, we take the number of outliers as the baseline though many experiments, and finally the number of clusters is determined to be 23.

Similarly, we use another method to evaluate the effectiveness of our method. That's the elbow method SSE we talked about above. When the number of clusters K is less than the number of real clusters, the aggregation degree of each cluster will be greatly increased with the increase of K . When K reaches the real cluster number, the aggregation degree returns will be rapidly reduced with the increase of k , so the decrease of SSE will decrease sharply, and then become flat with the increase of K value. That is to say, the graph of the relationship between SSE and K is as follows: The shape of an elbow, and the K value corresponding to this elbow is the real clustering number of data. Obviously, As can be seen from Figure 5, when the SSE value is the smallest, the number of clusters K is still 23. Therefore, the effectiveness of our method is verified.

Figure 5. Evaluation of our method

Determination of Minimum Threshold. In addition, when we use Aprior algorithm to further filter the set of strong

association rules, the minimum support threshold will be involved. In the process of borrowing and returning, because some records of data set are abnormal transaction records generated by the manual bicycle dispatching operation of the station, the coefficient of normal bicycle transaction records is taken as $\rho=0.98$; when selecting data samples, there are about 6800 bicycles in the bike sharing system, but a considerable number of bicycles are in the Off-Shelf state during the peak period, that is to say, they do not participate. With the flow of shared bicycles, the coefficient $\omega=0.9$ of mobile bicycles on the rack is taken. when shared bicycles are moving at the station, according to the results of data analysis, bicycles leased from one s may be returned to other 3-5 stations besides their own, so the distribution coefficient of bicycle flow is taken as $\lambda=0.25$, according to formula (2), the minimum support threshold $Sup_{min}=0.1$ is obtained. The final result is obtained through the restraint adjustment of the total regional demand. (as shown in Figure 6.)

Figure 6. Clustering results

Performance comparison. In order to confirm the effectiveness of our model, we carried out experiments and compared our method with two baselines. CCKC (adaptive constrained central point clustering) and BSC (clustering based on K-means method according to the transformation relationship and geographical location between stations). The effectiveness and efficiency of the proposed PM are shown in Figure 7. It can be seen that for a given number of vehicles, we can concentrate on optimizing the stations and effectively find abnormal stations. With the increase of the number of vehicles scheduled, the number of outlier stations decreases rapidly. PM algorithm can help determine the minimum number of vehicles covering all target stations, or balance operation costs and the number of outlying stations.

Figure 7. Comparison of clustering efficiency

Clustering Analysis of Shared Bicycle Usage Distribution. Figure 8 shows the demand of shared bicycle in different time at station level and class level. It can be concluded that the trend of shared bicycle demand is more stable after using the zoning algorithm. This demonstrates the effectiveness of our proposed partition method, and also provides the possibility for improving the prediction accuracy of shared bicycle demand in the traffic field.

Figure 8. Station and cluster distribution

V. CONCLUSIONS

Based on the characteristics of complex relationship, large scale and large randomness among stations of bike sharing system, we consider the self-mobility of bikes among stations. We study urban bike sharing system with three algorithms: Association rules, K-medoids clustering and total demand restraint adjustment, and take New York City bike sharing system as an example to simulate and partition. This method takes into account the relationship between stations, the attributes of geographical location and the total demand for bicycles. Compared with CCKC and BSC methods, it is concluded that the number of outliers in this method is more stable and the value of SSE is the smallest. Furthermore, The area obtained by our algorithm is more stable than that of single station, which also shows that our method provides a theoretical basis for improving the accuracy of traffic flow prediction.

Abstract—The paper aims to create an intelligent model of data analysis in the registry of the secondary energy distribution network. With emphasis on the search for possible inconsistencies that can be only cadastral or really physical. For this, it uses some techniques of data mining giving focus for the detection of anomalies. This study used a private database containing information about the assets that make up the secondary energy distribution network, such as: poles, transformers, disconnectors, among others. The research was developed following all steps presented in the CRISP-DM methodology. To detect the anomalies, it was used algorithms Isolation Forest, DBSCAN and BIRCH. As a result, the three algorithms pointed to a set of specialty anomalies, validated by a specialist, however, Isolation forest was more accurate in the inference of the anomalies. From this study, distribution companies will be able to identify risky or financially problematic situations in advance.

I. INTRODUCTION

With the great volume of data coming from diverse sources and produced by different entities (citizens, applications, public institutions, among others), an urgent need was generated to treat this data in an automated way. Through the extraction of information and production of knowledge, applications can be created that directly reflect the improvement of services available to all citizens. In response to these needs, emerged Data Mining (DM) [1].

Data mining is a technology that has emerged from the intersection of three areas: statistics, artificial intelligence, and machine learning. It aims to extract useful knowledge (eg patterns) of complex and vast data. The techniques used for data mining are from different approaches and their applications depend on the nature of the data and the scenario of the problem [2].

There are six categories of widely accepted and implemented data mining techniques: classification, grouping, association, regression, summarization, and anomaly detection [3].

Anomaly detection techniques have been applied successfully in critical systems and result in better damage control and component failure prediction [4].

Therefore, the accomplishment of this work becomes significant as it seeks to contribute with studies for the detection

of anomalies, in addition to studies in the area of data mining in the energy sector.

II. APPROACHES BASED ON ANOMALIES DETECTION

A. Detection of Anomalies

With the increasing use of advanced database technologies developed over the last few decades, it is not difficult to efficiently store huge volumes of data and be able to retrieve them whenever necessary. While data storage is very valuable to an organization, most organizations are unable to extract relevant information in a timely manner for decision making. This situation has aroused recent interest in research in the area of data mining [7].

Detecting behavioral deviations in data can solve problems of identifying frauds, disturbances and irregularities in general. This works based on the identification of points placed outside reasonable limits, called anomalies [8].

An anomaly is an observation that presents a great distance from the others of the series sampled or that is inconsistent. The existence of anomalies typically implies the interpretation of the results of the statistical tests applied to the samples [9].

Several applications today require in-depth data analysis to filter sporadic values and ensure system reliability. Such techniques are especially useful for fraud detection, where malicious attempts often differ from most nominal cases and can therefore be prevented by identifying external data. These anomalies can be defined as observations that deviate sufficiently from most observations to consider that they were generated by a different process [10].

These observations are called anomalies when their number is significantly smaller than the proportion of nominal cases, usually less than 5% [10].

Various methods of learning machines are suitable for anomaly detection. However, supervised algorithms are more restricted than unsupervised methods because a set of labeled data needs to be provided. This requirement is particularly expensive when labeling must be performed by humans. Dealing with a fairly unbalanced class distribution, which is inherent in anomaly detection, can also affect the efficiency of supervised algorithms [11].

III. METHODOLOGY

One of the most popular methodologies to increase the success of data mining processes is the CRISP-DM (Cross-Industry Standard Process for Data Mining) [12]. The methodology defines a non-rigid six-phase sequence that allows the construction and implementation of a mining model to be used in a real environment, helping business decisions [13]. Therefore, the development of this work will follow the six phases of CRISP-DM.

A. Business Understanding

Electric power distribution networks are composed of high, medium and low voltage lines. These are, respectively, the sub-transmission networks, primary and secondary energy, where they concentrate different purposes. The secondary network of distribution, focus of analysis in this work, is that which supplies the common users and small building facilities, that is, the great mass of users of the distribution companies [5].

Every year, hundreds of people are hit by direct or indirect damages from clandestine electricity connections throughout Brazil. There are records of transformer overload that causes harm to the community and fires that are traced back to this type of crime [6].

B. Data Understanding

To obtain the partial results, it was necessary to integrate the bases provided by the company into a single table, containing all the information passed for analysis. After the integration, some necessary techniques were applied for the selection of the data that will compose the model.

The databases were integrated using one table as reference for joining the others. The table used as reference for the merge was the one referring to the poles that make up the secondary distribution network. At the end of this initial integration a table with 165 attributes and 2,249,159 records was obtained. It can be noted that this is a table with large horizontal dimension and possibly reducible. Some analyzes were carried out in order to obtain a possible reduction of dimensionality.

C. Data Preparation

Initially, a statistical analysis of the attributes was performed, which served to deepen the data. It was possible to verify the quantity, mean, standard deviation, minimum and maximum of each quantitative attribute.

An analysis was performed regarding the variance of the attributes, since attributes with low variance do not influence significantly in the models of machine learning. Soon after the first adopted strategy a reduction was achieved for 112 attributes.

Next, an analysis was performed on the correlation of the variables, where it was possible to observe that only 47 variables had some degree of correlation with some other one in question. Among the variables with some degree of correlation, few had a correlation with greater significance.

After the previous step was created a data dictionary that helped a little more in the understanding of the data. With

the data dictionary, it was made explicit that most attributes are categorical and discrete quantitative. With a deeper understanding of the data it was possible to perform a new dimensionality reduction for 96 attributes.

After consulting with a specialist in the area of electricity, some more attributes were removed, as it was clear to the expert that they would not add value to the model. At the end of this attribute selection step, the database was reduced to 52 attributes.

1) *Sub-databases*: It was necessary to create sub-databases, in which they were extracted from data from the main database, which contained 2,240,756 records and 52 attributes. The extraction of sub-bases was necessary because some of the algorithms used were not having good results with the complete base and also to obtain a better understanding about the influence of each equipment.

The sub-databases were extracted as follows: base only with the attributes of the poles, base only with poles that had some equipment connected to it, base with poles only with capacitor banks, base with poles only with fuses, base with the poles with only lightning rods, base with the poles only with disconnectors, base with the poles only with sectionalizers and a base with the poles only with transformers.

These sub-databases were important for a better understanding of the influence of each equipment in the general context of the problem.

D. Modeling

The modeling implementation will be performed using the Python platform, as it provides a variety of routines for statistical calculations (linear and nonlinear methods, statistical tests, grouping, simulations, anomaly detection, etc.) and is strongly recommended for modeling and analysis statistic.

E. Evaluation

The evaluation was carried out mainly by the specialist engineer of the electric sector. The three algorithms were confronted in their results, with the focus of a more robust validation regarding the performance of each of them.

F. Deployment

An application, for use by electrical industry experts, is still being developed. Upon completion of the development, the tool will be thoroughly tested in real production scenarios.

IV. RESULTS AND DISCUSSIONS

A. Isolation Forest

The implementation of Isolation Forest [14] that was used to obtain the results of this research came from the scikit-learn library [15]. The library provides the results on a scale between -1 and 1, with the closest results of -1 being characterized as possible anomalies. The values of the parameters that were configured in the execution of the algorithm are: max_sample = auto and contamination = 0,01.

Fig. 1. Histogram showing the result of the execution of the Isolation Forest to the database of poles that have some equipment.

In the graph of Figure 1, the possible anomalous points in the region between -0.15 and -0.10 can be found. The other points of the base were condensed to the right of the graph, indicating that they were points more difficult to isolate and therefore have a high probability of not being anomalies.

Fig. 2. Histogram showing the result of the execution of the Isolation Forest to the database of the poles that have capacitor banks.

In Figure 2, it is noted that the points received normality notes in distinct groups and not in a continuous block. The points with the highest anomalous characteristics were well isolated and closer to -0.10 or less.

Fig. 3. Histogram showing the result of the execution of the Isolation Forest to the database of the poles that have disconnectors.

In Figure 3, two isolated groups located to the left of the graph are evident. One of the groups of points is a little closer to the normal characteristics to the right of -0.10. The most extreme group and also with fewer points is that it appears to have more anomalous characteristics.

Fig. 4. Histogram showing the result of the execution of the Isolation Forest to the database of the poles that have sectionalizers.

In Figure 4, you may see a small group of possible anomalous points located to the left of the graph. The rest of the data were grouped in points closer to normal.

Fig. 5. Histogram showing the result of the execution of the Isolation Forest to the database of poles that have transformers.

In Figure 5, can be analyzed a very small group to the left, far from the rest of the points. This group has a great possibility of being anomalous points.

With emphasis on the enhancement of Isolation Forest [14] results, two other algorithms, DBSCAN [16] and BIRCH [17], were used. The three algorithms used are part of the Scikit-Learn [15] library. The algorithms DBSCAN [16] and BIRCH [17], had their results compared to the results of Isolation Forest [14], in order to provide greater certainty about the anomalies found.

B. Analysis of Anomalies

With the result of the execution of the Isolation Forest [14] algorithm, in the sub-databases, being supported by the specialist engineer and the algorithms DBSCAN [16] and BIRCH [17], several anomalies.

1) *Poles with Capacitor Banks*: In this sub-base anomalies were found by the algorithms and a specific one was validated by the specialist engineer. The capacitor bank, which the specialist validated, was the only one in the whole sample that had a different cell power than the others.

2) *Poles with Fuse Keys*: In the sub-base in question, an anomaly was found and validated by the specialist. Anomaly analysis demonstrated that the pole on which the fuse switch was located demonstrated a single supported stress within all samples.

3) *Poles with lightning rods*: The analysis of the sub-base of the poles with lightning, presented a single para-ray that was with the primary tension different from the others.

4) *Poles with Disconnectors*: Among the poles with disconnectors that presented anomalies, the one that stood out showed the highest rated current among all.

5) *Poles with Sectionalisers*: All the anomalous poles that contained sectionalizers presented the same nominal voltage, being the only one different in this aspect which demonstrated greater anomalous characteristics.

6) *Poles with Transformers*: Among the poles of this sub-base, two main anomalies were found, later validated. The first is that there are two poles with heights and the same construction materials, but with different efforts. And the next anomaly, comes from a single pole with a state different from the others.

V. CONCLUSION

This article focuses on a major challenge: the detection of anomalies in the registration of the secondary energy distribution network. It was concluded that this work was able to meet the challenge, after the identification of the anomalies by the algorithms and subsequent results of the dosages by a specialist engineer in the electrical sector.

The identified anomalies can be complex and difficult to understand we argue that anomaly detection approaches should support experts when analyzing anomalies along with the related alarms. It is shown how much information can be provided by the proposed rule based anomaly detection approach.

We assume that it is necessary to identify but also to understand anomalies to choose appropriate anomaly countermeasures. Future work will concentrate on expanding and evaluating the proposed approaches root cause analysis capabilities. For this, visualization and management tools will be created that enable to handle the provided information in an interactive manner.

Abstract — The labor market is becoming increasingly competitive, with new technologies and products being launched at all times. Companies that have the privilege of creating the products at the beginning of innovation can serve more customers and thus generate more profits. In this search for the market, companies are increasingly willing to please their customers, trying to understand what they seek. There are several concepts, ways, strategies, and technologies that help companies better understand what people are searching for, interfering with this market. These strategies include Future-oriented Technology Analysis (FTA) and others, such as Knowledge Management (KM), from which we focus on Technological and Participatory practices. These strategies are directly related bringing a fundamental advantage to the company that knows how to use these concepts effectively.

Keywords — Knowledge Management, Participatory Knowledge Management, Technological Knowledge Management, Future-oriented Technology Analysis.

I. INTRODUCTION

The last years have shown a growth in new ways of thinking through information technologies. With this growth, also increased the competition for the manufacture of products where companies are seeking to meet more and more the needs and expectations of their customers, leading to a race for innovation. All these transformations make companies do not know where, when and how to innovate to become more competitive ahead of their competitors.

A company needs to have a competitive intelligence to become more attractive to its consumers, knowing when to make deliver the right product at the right time. Therefore, innovating in management methods and processes is one of the main challenges of a market with fierce competition, a high degree of uncertainty and a great deal of information available.

As a possible solution to this problem, the prospection is introduced to increase the company's competitiveness, seeking to find new trends so that companies can know where they should invest. Future studies directly support decision-making at various levels in the society. The purpose is not to predict the future, but find desirable futures and ways to achieve them.

Future-oriented Technology Analysis (FTA) is an umbrella term for a wide range of activities that facilitate decision-making and coordinated action, especially in the formulation of science, technology and innovation policies. Understanding the changes in technologies is only a part of the understanding of the market; some other aspects can help the companies to gain their competitiveness. Among them, there are the

Technological Knowledge Management (TKM) that consists of numerous practices and use of new tools and the Participatory Knowledge Management (PKM), which involves the sharing of information through groups of people, social networks, and institutions. These strategies may be directly related, bringing advantages to the company that uses them effectively.

II. THEORETICAL FOUNDATION

A. Future-oriented technology analysis (FTA)

Drucker [1] states that it is not important to predict the future because it considers that it is uncertain and it is not possible to be sure of what is to happen. In contrast, Schwarz [2] argues that several managers can already understand the need to study the future for understanding what is needed.

A company must always be ahead of its competitors in technological innovations, being aware of the market's directions and prepared to face or take advantage of new technologies [3]. To make it happen, the FTA is introduced, and its importance is undeniable. However, FTA has many different concepts which are still being studied and deepened.

FTA can be defined as a set of methodologies to support decisions about emerging technologies, including their development and future impacts [4]. Therefore, several groups with different goals use a set of several approaches for the future that share some assumptions and differ in others. Their objective is to support decision-makers with analyses and new ideas to be prepared for the future [5].

B. Technological Knowledge Management (TKM)

Knowledge Management requires technologies to be done efficiently: they support strategies, processes, and methods that help to better disseminate and apply information within the enterprise. Several technologies that can help KM such as the implementation of intranets, data warehouses, data mining, decision support tools, video conferencing, groupware, electronic panels, online databases, expert systems, intelligent search agents and management of electronic documents.

TKM seeks to understand technological progress and its impacts, to enable institutions to deal with change and, above all, to integrate innovation into organizational strategy [6]. Currently, it is considered to have the most significant impact on the changes that are taking place within companies; however, although technology is widely recognized as being essential for competitiveness, technology management has been one of the most challenging activities among the attributions to managers [7]. Despite the advantages offered by

technologies, some challenges are faced by companies when trying to implement them, Betz [7] cites some such as: "the not invented here syndrome", the physical separation of the research laboratories of the responsible sector, the use of inadequate techniques of planning and technological monitoring, being able to result in a distorted vision about the future and the late use of new technologies, resulting in the loss of the market for competitors [7].

C. Participatory Knowledge Management (PKM)

PKM is the KM derived to participatory management, which is the set of organizational conditions and managerial behaviors that encourage the participation of all in the management process. Participatory management empowers the group members to make organizational decisions [8]. Involving of everyone means that, in the beginning, no person, at any hierarchical level, should be excluded from the participatory process, everyone is aware of the methods and approaches that are being implemented within the company.

A more knowledge-oriented view can be given by Valtolina et al. [9], where they define PKM as the use of methods, tools, and guidelines to mediate cooperation between user groups and IT professionals. PKM facilitate collaboration between users who have different types of knowledge, and each user is responsible for disseminating the information. In general, PKM can be summarized as the use of a group of people to generate and use knowledge on different topics.

III. USING TKM, PKM AND FTA IN DECISION-MAKING

A. FTA relation to PKM and TKM

Godet [10] argues that all those who intend to foresee the future (prophets, oracles, seers, sensitives, clairvoyants, and others) are impostors because the future does not exist, it is yet to be created and therefore it is not written anywhere. In fact, talking about technological prospecting regarding knowledge can be a bit tricky as the future is uncertain and can change at any time. So how can there be statements about such? FTA seeks to assist in decision-making by looking at a history of events that may have implications for future circumstances. Logically it is not yet possible to predict the future and to know for sure what will happen, but it is possible to look at the past and the present to raise hypotheses and assumptions about some events of the future.

The junction of the FTA and KM can be seen as information-based activities, to enable an organization to anticipate its competitors and anticipate the changes that may occur, and as a consequence take advantage of that condition to increase its competitive intelligence [11]. FTA has a long-term vision and a greater focus on technology, while competitive intelligence has a short-term view with a broader discussion.

Bell and Olick [12] reformulate the idea of knowledge of the future by arguing that it is possible to postulate and think to predict some possibilities. These postulates can be seen as sets of knowledge that have to do with the consequences of situations that can evolve into a possible future.

The FTA-KM relationship is relevant since the former tries to predict future events while the latter focuses on knowledge management within the company. If the next trends are

incorporated in the KM before they happen, they can be introduced as soon as possible in the company, bringing a competitive intelligence that aims at finding the risks and opportunities in the market early, to generate a competitive advantage. The combination of these two ideas can be seen in a very simplified way, as if FTA were to seek new knowledge and trends that can affect the market, and then enters the part of the KM that will analyze this information to manage new expertise within the company, trying to understand, store and use in the best possible way what was introduced.

As already explained, KM has some ramifications, such as TKM and PKM, and each of them relates to FTA differently, each with its particularities. The basis for the intermediation between the TKM and FTA starts at the information collection stage, which is then addressed to the treatment of them, and, finally, the systematization of the information. In other words, it is the analysis, interpretation, and production of knowledge so that, in the end, the dissemination of results is done. The TKM and PKM are interconnected and are two poles of different concepts of KM, the former more geared towards the use of technologies and the latter for the active participation of all in an interactive way.

One of the areas of FTA that can integrate more with TKM is the technical evaluation, which seeks to predict the consequences of the introduction of a specific technology in all the spheres with which it interacts. Looking at technology management, it aims at understanding the use of tools and their impacts to enable institutions to cope with change. By reading the two concepts, it is easy to see that there is a relationship between the two, where they can help each other. With these ideas in mind, prospecting can seek new technologies that can be supported by TKM, where the former finds new concepts that can be integrated into the organization while the latter tries to manage these concepts better, trying to find better ways to apply each one of the ideas more effectively. Overall, the first aid provided by TKM for knowledge management is the use of new technologies to facilitate the exchange of information between users, increasing data speeds, assisting in connecting people of different groups.

Jaspers et al. [13] state that in the TKM, the stakes are the ways of dealing with concrete facts, for example, sites, databases, publications, dissemination procedures, among others. In this concept, forecasting processes deal with a considerable mass of information and rely primarily on systems to obtain more real and comprehensive knowledge. In this part, new technologies can help in the efficient and faster dissemination of information that has been constructed through FTA methods. On the other hand, FTA may be able to find some relevant information about the use of possible technologies, which now need to be learned and implemented within the company.

When speaking in a group of people, the first thing that comes to mind is the PKM, which has more emphasis on social practices and interactions between individuals and groups that create, develop and use knowledge, approaching the idea of the social learning cycle, taking into account cultural factors, values, and opinions. PKM includes various means of exchange and communication, such as a face-to-face meeting.

Surveys are increasingly using the dynamics, effects of simultaneous effort/cooperation of groups and processes of dialogue to achieve new knowledge [13]. This is one of FTA main points of connection with PKM, the use, and application of information that is provided by groups of people to create new concepts within companies, linking people who are positioned in different groups.

As is the case in many other KM fields, future-oriented TKM concepts run the risk of being considered sufficient, neglecting the social side of PKM. However, a forecast is not only a process for collecting, analyzing and filtering data, and it also has a social dimension that is also very important: society needs to exchange ideas and develop visions for a collective future [13]. One of the challenges of PKM is how to efficiently use participants' knowledge and imagination to search for hypotheses for the future, by continually initiating and optimizing the interaction of information and people [13].

One of the areas of FTA that best fit with the PKM is the vision that guides the future by consensus, which uses as a base the opinions collected through the cognitive and intuitive process of a group of experts, and the PKM aims at using the mutual knowledge of a group of people. A link between these two concepts is easy to see, and the participation of groups can help create new ideas for the future.

B. Proposed Approach

As it was seen, PKM and TKM are directly related to FTA and bring several benefits to the company that correctly uses these techniques, but it is worth remembering that with these advantages they bring some harm. So, we need to know how to use them correctly. The main problems encountered were: the fear of using new technologies, the reluctance on the part of the professional to share their knowledge and the time of learning, depending on the technology presented. We seek to solve these problems creating a new concept junction model (PKM, TKM, and FTA), improving management agility, decision-making efficiency and the generation of competitive advantage.

The proposed model is presented in Fig. 1. The starting point for this methodology will be to look from the past to the present to develop a future forecast. In this method, two metrics are used: a projection based on existing data (looking at the past) and one based on queries and opinions (having something more focused on people and the present) so that, thus the future can be predicted. These two methods are being used to try to reduce the number of predicted errors and have both advantages and disadvantages. The first is a quantitative method and requires reliable and standardized historical bases, while the second is a qualitative method that presents problems with the limit of knowledge of specialists and interested people. With the two being used collaboratively, it is hoped that the problems cited will be minimized.

After the initial presentation of the methodology making use of FTA, some techniques are necessary for the forecasts to be made in the best way. Some are presented below.

- **Market monitoring:** used to predict possible trends, be it short, medium and long-term;
- **Interviews and brainstorming:** collecting participants' opinions;

- **Cross-impact analysis:** understanding the relationships of factors and trends found;
- **Roadmaps:** analysis of the technologies found;
- **Creation of scenarios:** considerations of plausible futures.

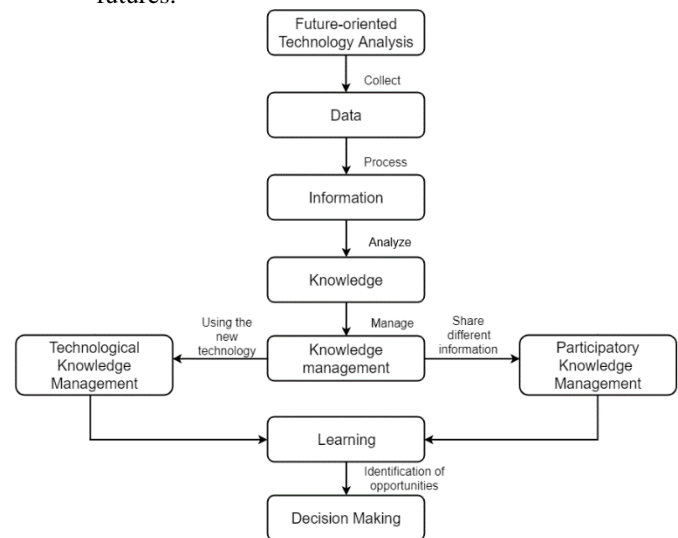

Fig. 1. Junction model with concepts of FTA, PKM, and TKM.

Five prospecting techniques have been presented, each of which has advantages and disadvantages. The use of trends offers predictive substances based on quantifiable parameters in the short term; however, at the same time, it requires historical data and thus vulnerable to change; the use of interviews and brainstorming can bring a large number of information depending on the way it is performed, yet, it is limited to the knowledge of the people who participated in the process; the analysis of cross-impacts is of great importance when a critical scenario is being developed, since it can understand the relationships between the information that has been found, but care must be taken not to obtain a biased and unreal result; the use of roadmaps seeks to implement and execute strategic maps in order to align the company's strategy with its technological capabilities, but care must also be taken in this part to avoid constructing something that cannot be accomplished; Finally, the creation of scenarios presents rich and complex portraits of possible futures, but it may bring something unattainable. Practitioners must observe which methodology best fit their context, and it is worth emphasizing that a combination of techniques is always well-seen, aiming at reducing the number of future errors. In this phase the first stage of the process ends, bringing with it the new technologies that have been recovered through prospecting. With this, many new and old data will be collected (loose data or random data without any analysis). After this collection, the data will be analyzed and thus transformed into information (organized data), and finally, this information will be converted into knowledge entering the context of the company.

With the knowledge in hand, steps in the KM. As said before, it works on the data that the company has, managing knowledge. In this approach, this management will be divided into two parts, the control of technological expertise and the participatory management of experience, each with its function. The former will try to understand the technical

culture that was brought by FTA so that they can be introduced into the company. At this stage, two problems that have already been described are added; the fear of using new technologies and the lengthy learning time depending on the technology presented. In order to solve these two problems, four different approaches will be used: the first step will be to make a conceptualization of the employees, if they seek to understand the benefits of the technologies will be easier to accept them, as a consequence, the person will also be more willing to learn to use it. Patience, therefore, is essential in this first moment, it is necessary to explain calmly and repeat the information several times, if necessary. This first point will help the employee to accept the technology. Then, a series of training is started which can be done on the person's machine, leaving the user with the highest possible tranquility. On the other hand, face-to-face training will also be carried out, where the person can take his most recurring questions to be clarified with specialized professionals in the field. In the third stage, the concept of pair programming will be used with another view, where some jobs with different levels of difficulty will be advised to various people who have done the training, always seeking to leave a more experienced person with a less skilled one. In the fourth and final phase, it will be suggested that people who have never performed a particular task can try, to be able to learn more about the work and, consequently, decrease the dependency of specialists in a specific area within the company. This last proposal would help the employees to create, in turn, a desire to seek new knowledge, because only then would they be able to deliver the task.

Once the TKM issues have been resolved, PKM is introduced so that people from many different knowledgeable areas can share their information in a unified way. The main idea is everyone would participate equally in this step, being able to collaborate with what they judge necessary, completely altering the organizational climate, where all employees would be like "leaders" having a self-management, stimulating, guiding and coordinating changes. This model is very flexible and aims at leveling the group, boosting participation and dismembering the traditional model. For this model to be deployed correctly, two points must be aligned within the company. The first one is the need for communication between the sectors to make information exchange possible. The second is that a friendly working environment is necessary, where everyone can be allowed to speak equally.

In the PKM stage, a new problem is presented, the reluctance on the part of the professional in sharing their knowledge. In the search for the solution of this problem, some ways of exchanging information will be presented. The first is to create an intranet so that employees can register what they find relevant. The second is to create a bank of ideas to encourage employees to adopt a creative attitude. Awards would be given to the ideas that were judged more pertinent, promoting a friendly competition among the participants. The last thought would be the creation of study groups within the company, where groups with specific themes would be created, each week a different group would talk about what they have learned over time, thus spreading the information in another way. The groups would be formed with a fixed time, so that people are always participating in different groups at all times,

sharing what they learned. This completes the stages of the search, analysis, knowledge generation and conceptualization. Learning in this scheme can be seen as an extension of the idea of experience, i.e., people will do with everything they have understood and learned. They know how to use the knowledge in the right way, identifying what is the best decision to make.

IV. FINAL REMARKS

The market is increasingly competitive with new creations. For a company to win its market, it must have an advantage over the others. In this quest for advantages, technological prospecting methods are being used so that it is possible to create visions of the future and thereby to know what are the new preferences and trends of this market. In this search for new technologies, FTA can benefit from several methods to try to predict the future, such as the use of road mapping, expert opinion, trend monitoring, among many others.

Once this new information has been retrieved and stored, it needs to be handled and managed for better use. At that time the part of the KM enters, seeking to manage this data the best way. For this to happen effectively, KM was branched out in two areas to PKM and TKM, each with its primary focus.

In this work, we presented a brief explanation about the aspects of FTA, TKM, and PKM, after the necessary reports have been made, a search on what has already been done to improve this area was carried out, and finally a new approach of utilization of these three concepts. As future work we intended to test it in an organization to confirm its viability.

I. INTRODUCTION

In the Software Engineering field, one has been observing an unceasing search for quantitative measures capable of assessing internal software attributes such as maintainability, reusability, agility, among others. The argument is that these characteristics, also known as architecturally significant requirements (ARS), when combined, determine the product quality [1], what in turn affects the development costs, particularly while under the software maintenance cycle.

A natural choice to study the association level among software components is through the usage of call graphs, where vertexes may represent software elements in a system, and the edges map their calls, giving shape to a complex network of relationships [2]. Such representation may be dynamic, indicating that it was captured during system execution, or static that on the contrary, analyzes the source code structure. Call graphs have proven its utility in many software development activities such as compiler optimization and program understanding [3].

Considering this scenario, the following research question emerge: "Which software attributes may be revealed through the application of common complex network analysis measures on call graphs?". We also intend to analyze the topological and basal properties of software in network theory field. In this work, we utilize the Hibernate library, a well-known Object/Relational Mapping (ORM) framework, widely employed in Java-based enterprise applications.

The rest of this paper is organized as follows: In section 2 we expose our methods and materials. In section 3 we discuss our results, and finally, in section 4 we conclude our work.

II. MATERIALS AND METHODS

This paper relied on the static call graph representation extracted from Hibernate library in its version 5.1.3¹. All the undertaken analysis presented here utilized the software Gephi² and the complex network analysis package named NetworkX³, for the Python language. We used the Gephi to

create the network's visual representations and to acquire its basal properties. Through of NetworkX library was performed data manipulations and the investigations in this study.

A. Call graph extraction

To extract the static call graph structure from Hibernate, we developed a tool named Call Graph Extractor (CGE⁴). This tool can read the bytecode of Java classes embedded into JavaArchive files (JAR files) with the goal of extracting the caller and the callee for all instructions of each class contained in the referred file. In other words, our software analyzes internal methods of a class, regardless of their visibility (public, private, static, and so on), creating a relationship table in an output file.

B. Graph modeling

In our method, for each extracted call, we create three vertexes: The caller method, the callee class, and the callee method. If the caller and callee classes are different, indicating an object transition, we link them with two edges observing the rule: $[(callerMethod, calleeClass), (calleeClass, calleeMethod)]$. If the caller and callee classes are equals, denoting an internal call, then the rule applied is different: $[(callerMethod, calleeClass), (callerMethod, calleeMethod)]$. It is worth noting that our representation cannot be considered bipartite due to the presence of edges linking same type vertexes, in our case, methods.

In order to constrain the graph representation to the library domain, we discarded the calls whose caller or callee instructions did not belong to the "org.hibernate" package, consequently removing any call to the native Java library. Following these procedures, we obtained a graph comprised of 27,556 vertexes and 57,919 edges.

III. RESULTS AND DISCUSSION

In this section we present the basal properties of Hibernate network analyzing its small-world, scale-free and community properties. Among the values for some of the main complex network measures are: average shortest path = 19.664; the average clustering coefficient = 0.194; the average shortest path

DOI reference number: 10.18293/SEKE2019-035

¹<http://www.hibernate.org>

²<https://gephi.org/users/download/>

³<https://networkx.github.io>

⁴<https://github.com/dfalci/callgraphextractor>

= 19.644; average degree = 2.02; network diameter = 62; modularity = 0.838 and the number of communities = 446.

In order to verify the existence of small world which is characterized by being a regular networks that can be highly clustered, like regular lattices, have small characteristic path lengths, like random graphs [4]. In our Hibernate network representation, we calculated the link creation probability p as shown by the equation 1, where l is the number of edges and n represents the number of vertexes. With the p value, we proceeded to the generation of a random network based the Erdős-Rényi model [5]. For the random network, we registered an average clustering coefficient $C = 0$ and an average shortest path $d = 3.479$. These values were obtained from the mean of the values obtained by five random networks. The value of C is derived from the very low value of p , which may produce random graphs with sparse connectivity, so sparse that may result in a disconnected graph, as it is the case. Through the comparison of the values obtained from Hibernate and random networks, reported in the equation 2. One may say that the Hibernate network presents small-world characteristics. Its clustering coefficient is much higher than the one of the random network, while the average shortest path in both networks is close, although the average shortest path obtained for Hibernate network is more than five times greater than the value achieved by the random network.

$$p = \frac{2l}{n(n-1)} = \frac{2(57,919)}{27,556(27,555)} = 0.0001525 \quad (1)$$

$$C_{Hibernate} \gg C_{Random} \quad \text{and} \quad d_{Hibernate} \approx d_{Random} \\ 0,194 \gg 0 \quad \text{and} \quad 19.664 \approx 3.479 \quad (2)$$

The Hibernate network degree distribution analysis suggests that it may be classified as a scale-free network. Scale-free indicates that the development of large networks is governed by robust self-organizing phenomena that go beyond the particulars of the individual systems [6]. It follows a power law distribution ($P(k) \sim k^{-\alpha}$) whose main characteristic is the existence of a few number of vertexes possessing a large number of connections while the vast majority of vertexes have a small number of links. The log-log plot reveal the angular coefficient $\alpha \approx 2.6$. One of the main properties of scale-free networks is its failure resistance. This definition though, must not be used in a software context, since a failure on the smallest software component may compromise the whole system. This finding is in compliance with previous studies [7], [8], [9].

The modularity analysis was based on the algorithm described by [10], known as Louvain method. The modularity value ($M = 0.838$) is close to the maximum possible value (I) which reveals a high network propensity to form communities. In fact, 446 communities were detected by this method, which results in an average value of 61.78 vertexes per class. The ten biggest classes, though, holds 47.45% of the total number of vertexes.

Rank	Betweenness	Degree	PageRank
1	org.hibernate.type.TypeFactory	org.hibernate.internal.CoreMessageLogger	org.hibernate.internal.util.StringHelper
2	org.hibernate.boot.cfgxml.spi.LoadedConfig	org.hibernate.internal.CoreMessageLogger.Slogger	org.hibernate.internal.CoreMessageLogger
3	org.hibernate.boot.MetadataSources	org.hibernate.engine.spi.SessionImplementor	org.hibernate.internal.CoreLogging

Figure 1. Top ranked software components

The Figure 1 shows the top 3 vertexes obtained from the analysis of the main complex network analysis measures when applied to Hibernate's call graph. Due to the lack of comparison ground for the task of describing the relevance of such software components, particularly over the Hibernate source code structure, we limited our analysis to present the top ranked software elements for each network measure.

IV. CONCLUSION

In this paper, we analyzed the properties of a widely employed Java-based software through its static call graphs. We investigated its topology that revealed a small-world and scale-free network, in compliance with the findings of [7], [9], [8]. Furthermore, we have identified that the network exhibits a strong propensity to form communities. Finally, we highlighted the top 3 software components for some of the main complex network analysis measures.

The tools developed in this work may benefit research in this field of study as it provides accessible means to create static call graphs for Java-based software. In future we plan to compare the traditional measures applied in software engineering domain with the ones obtained through the application of complex network analysis measures. We also plan to investigate the application of modularity as way of finding higher level software components and its respective relevance within system.

An Approach for Collecting Real Estate Development News

I. THE APPROACH

Fig. 1. The architecture of the proposed approach

Figure 1 presents the architecture of our approach to collect, classify and rank real estate development news from the Web. We highlight that the crawler component of our approach firstly uses a set of seed URLs to collect real estate development news, storing them in a business pages corpus, re-feeding itself from URLs contained in the collected pages. The crawling flow used by our approach is similar to a previous work reported in [1].

Second, the filter component extracts textual features, i.e., page title, page description, and page text, from the real estate development news corpus. For this, it filters valid pages by removing pages from invalid URLs, duplicated, empty, redirected and private pages. Then, it performs stop words removal, stemming, and removal of punctuation, accents and special characters in order to increase the quality of the textual features. Finally, it exploits a real estate development ontology to extract entities from the textual features.

Third, the ranking component uses supervised algorithms to learn a ranking model in order to provide an ordered list with the most relevant business opportunities extracted from the Web.

II. PRELIMINARY EXPERIMENTS AND RESULTS

To evaluate our approach, we run experiments to answer the following research questions: i) how effective is our approach to collect and filter real estate development news? ii) which textual features provide better filtering performance? The evaluation of the entity recognition and ranking strategies will be carried out in future work.

Particularly, we use a dataset composed of 419 real estate development news, reported in Table I, previously collected from the Web and labeled by experts to evaluate two different algorithms used to generate the filtering models: SVM (Support Vector Machine) with linear kernel and RF (Random Forest). Additionally, we use nine configurations for training and test sets, varying the training and test percentages from 90-10 to 10-90, we performed 5-fold cross-validation [2],

and we report effectiveness in terms of accuracy, i.e., the percentage of true positives for all positive predictions. Moreover, we evaluate four different sources of textual features extracted from the business pages: i) Title (TO); ii) Title (TD) + Description; iii) Title + Full Text (TF); iv) Title + Description + Full Text (ALL).

TABLE I

NUMBER OF REAL ESTATE DEVELOPMENT NEWS COLLECTED USING OUR APPROACH.

Processing Steps	# Remaining Pages
Crawler	1,493
Duplicate Removal	1,034
Invalid URLs Removal	564
Empty Removal	558
Redirected Removal	466
Private Removal	419

Table II shows the accuracy of each learning algorithm used to filter real estate development news with different features for each training and test configuration schema. From Table II we observe that the title-only feature is less effective than the others, since it contains few words that are related to the business context. Additionally, we observe that SVM mostly outperforms RF with accuracy from 92% to 100% depending on the number of instances used in training.

TABLE II

FILTERING REAL ESTATE DEVELOPMENT NEWS ACCURACY.

Config.	RF				SVM			
	TO	TD	TF	ALL	TO	TD	TF	ALL
90/10	0,70	1,00	0,90	0,93	0,80	0,96	0,96	1,00
80/20	0,65	0,96	0,83	0,90	0,73	0,96	0,98	0,98
70/30	0,64	0,90	0,93	0,86	0,71	0,89	0,97	0,92
60/40	0,68	0,81	0,88	0,95	0,73	0,91	0,97	0,91
50/50	0,71	0,86	0,87	0,90	0,75	0,95	0,87	0,93
40/60	0,70	0,82	0,77	0,83	0,73	0,87	0,86	0,92
30/70	0,72	0,72	0,71	0,88	0,71	0,86	0,93	0,91
20/80	0,71	0,52	0,72	0,92	0,72	0,75	0,90	0,90
10/90	0,72	0,71	0,71	0,78	0,73	0,79	0,87	0,92

Recalling our first and second research questions, these observations attest the effectiveness of our approach to collect and filter real estate development news. In addition, we show that our textual features provide impact positively in the filtering performance.

Abstract—The adoption of GraphQL is on the rise, many companies and institutes are adopting it due to its ease of use, ease of maintenance, and hide the complexity from the user. Such advantages come from using a unified global schema and mapping it to the underlying data sources. The semantic web community has already adopted a similar way to map different data resources (e.g., R2RML). We present a novel way of generating GraphQL server from R2RML mappings.

Index Terms—GraphQL, R2RML, Wrapper, Adapter

I. INTRODUCTION

Facebook developed GraphQL¹ as an alternative to REST and made it open source to be used by the public in 2015. A GraphQL server consists of multiple components: schema, resolvers, and data sources. The GraphQL schema is the exposed view - an interface that the user (the person who writes queries) can use to access the underlying data sources. GraphQL resolvers are written codes (in a programming language) to link fields in the data sources to the exposed schema. The data sources are the where the data are stored and can be retrieved from such as a Relation Database (e.g., MySQL).

R2RML [1], published in 2012 by the RDB2RDF W3C Working Group, is a W3C recommendations for transforming the content of relational databases into RDF datasets. It allows the users to specify rules of how this transformation being done, such as how the URIs be generated, or which columns to be used in the transformation rules.

II. MORPH-GRAPHQL

In [2] we introduce morph-GraphQL², that takes as its input R2RML mappings and generates the corresponding GraphQL server. GraphQL engine interprets queries written in GraphQL and use the corresponding resolvers to fetch the data from the data sources. This workflow is shown in Fig. 1. R2RML

will be the input to morph-GraphQL and it will output the corresponding GraphQL resolvers and schema. The schema, resolvers and the data source are the input to the GraphQL engine.

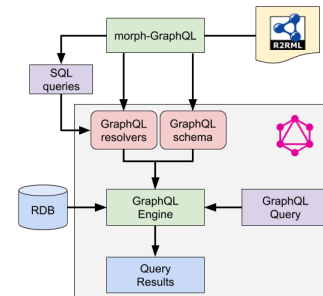

Fig. 1. Workflow of morph-GraphQL

In this demo we will show how we create R2RML mappings for the CSV files³ containing Star Wars data that is used as the example in the reference implementation⁴. Then we will use morph-GraphQL to generate GraphQL schema and resolvers from created mappings. Finally, we will evaluate some queries corresponding to the Star Wars example.
